3. The combined area of all Group F-1 fire areas on all floors, including any mezzanines, exceeds 24,000 square feet (2230 m²).
4. ~~A Group F-1 occupancy used for the manufacture of upholstered furniture or mattresses exceeds 2,500 square feet (232 m²).~~

903.2.7 Group M. An automatic sprinkler system shall be provided throughout buildings containing a Group M occupancy where one of the following conditions exists:

1. A Group M fire area exceeds 12,000 square feet (1115 m²).
2. A Group M fire area is located more than three stories above grade plane.
3. The combined area of all Group M fire areas on all floors, including any mezzanines, exceeds 24,000 square feet (2230 m²).
4. ~~A Group M occupancy used for the display and sale of upholstered furniture or mattresses exceeds 5,000 square feet (464 m²).~~

903.2.9 Group S-1. An automatic sprinkler system shall be provided throughout all buildings containing a Group S-1 occupancy where one of the following conditions exists:

1. A Group S-1 fire area exceeds 12,000 square feet (1115 m²).
2. A Group S-1 fire area is located more than three stories above grade plane.
3. The combined area of all Group S-1 fire areas on all floors, including any mezzanines, exceeds 24,000 square feet (2230 m²).
4. A Group S-1 fire area used for the storage of commercial trucks or buses where the fire area exceeds 5,000 square feet (464 m²).
5. ~~A Group S-1 occupancy used for the storage of upholstered furniture or mattresses exceeds 2,500 square feet (232 m²).~~

Reason: The original proponent offered no technical justification in the original proposal. The fire event that was used to support the original emotional proposal was located in a building that was 59,000 square feet in area. It was not provided with fire sprinklers. The code currently requires that this size building be provided with fire sprinklers. Previous legacy codes have also required fire sprinklers in this size building. This requirement is over-restrictive and should be removed from the code.

When the provisions were revised in the 2012 IFC, the revision was not tied to FIRE AREA, but instead was based on some area of the upholstered furniture and mattresses. It is not clear how the areas are measured. Is it the area of the space, display or building that requires the fire sprinklers? This vague language makes enforcement more difficult.

The second issue is that the provisions in these sections conflicts with provision in Section 3206.2 for high piled combustible storage (HPCS). It creates a loophole because the IFC high piled combustible storage provisions set an area threshold of 500 square feet when the height of mattress storage is > 6 feet in a public-accessible area. The provision for Group M occupancies for upholstered mattresses and furniture sets an occupancy area threshold of 5,000 square feet. The committee wasn't thinking about HPCS when they considered the proposal and it was further amended on the floor.

Finally, loss history has never been presented substantiating why upholstered furniture and mattresses warrant a different threshold for sprinkler protection.

Cost Impact: This will reduce the cost of construction.

903.2.5.2 (New) [IBC [F] 903.2.5.2] (New) 903.2.5.2.1 (New) [IBC [F] 903.2.5.2.1 (New)] 903.2.5.2.2 (New) [IBC [F] 903.2.5.2.2 (New)]

Proponent: Brad Emerick, Denver Fire Department representing the Fire Marshal's Association of Colorado (FMAC) and the Colorado Chapter of the ICC (CCICC) (brad.emerick@denvergov.org)

Add new text as follows:

903.2.5.2 (IBC [F] 903.2.5.2) Group H-3 Bulk storage of distilled spirits. Automatic Sprinkler system requirements for bulk storage of distilled spirits in wooden barrels and casks shall be in accordance with Sections 903.2.5.2.1 and 903.2.5.2.2.

903.2.5.2.1 (IBC [F] 903.2.5.2.1) Ceiling sprinklers. Distilled spirits stored in wooden barrels and casks in H-3 fire areas shall be protected with ceiling sprinklers in accordance with the requirements for relieving-style metal containers in NFPA 30 for the following storage configurations

1. Double-row racks with a load depth of no more than 3 barrels per row on each rack and 10 feet or less in height, or
2. Single-row racks with no more than 4 barrels per row, and 10 feet or less in height

903.2.5.2.2 (IBC [F] 903.2.5.2.2) Engineered systems. An approved engineered automatic sprinkler system design is required for bulk storage of distilled spirits stored in wooden barrels and casks in Group H-3 fire areas for any of the following storage configurations.

1. Storage in multi-row racks with three or more rows of racks
2. The number of barrels or casks per row exceeds that specified in Section 903.2.5.2.1.
3. Storage height Greater than 10 feet.

(Renumber subsequent sections)

Reason: There is confusion about the applicability of flammable liquid (Chapter 57) and hazardous materials (Chapter 50) provisions to distilled spirits because of the exceptions for distilled spirits and wines stored in wooden barrels and casks in IFC Chapters 50 and 57 (and NFPA 30). The issue arises because of the growing popularity of "boutique" or "craft" distillers locating their operations in urban areas. The proposed language clarifies bulk storage provisions for distilled spirits but does not alter the intent. The proposed language does not affect provisions applicable to use, nor those applicable to liquor storage in retail or wholesale establishments.

First, note distilled spirits are Class 1C and Class 1B flammable liquids. They are primarily comprised of ethyl alcohol (ethanol) and water with concentrations ranging from approximately 19% to 99%. The boiling point of pure ethanol is approximately 178°F so an ethanol mixture with water will boil between 178°F and 212°F. The closed cup flash point for a 19% concentration of ethanol in water is 100°F and for a 58% concentration is 73°F making the mixtures in this range Class 1C flammable liquids (these values are not adjusted for altitude). Ethanol concentrations in water between 58% and 99% are Class 1B flammable liquids.

Second, the Building Code establishes occupancy. If a quantity of a Class 1B or Class 1C flammable liquid exceeding the maximum allowable quantity (MAQ), the room in which it is located is an H3 Occupancy. Please remember this applies to bulk storage (casks, barrels, metal containers, etc. exceeding 1.3 gallon capacities) and not liquor stores and wholesale distributors for which there are several exceptions.

Third, H occupancies have to be sprinklered. The sprinklering requirements for flammable and combustible liquids are outside the scope of NFPA 13. NFPA 13 points to NFPA 30 (Flammable and Combustible Liquids Code) for detailed requirements. Ethanol stored in any container larger than those excepted for retail – other than wood – is addressed there.

This is not because wood is inherently safer than metal, plastic or glass – it is not. It was probably inserted in the legacy code(s) back when casks were stored in liquid storage warehouses separated by hundreds of feet from one another and urban distilleries weren't contemplated. It was probably held over today because there is not yet an established sprinkler criteria for the storage of Class 1C flammable liquids in wooden barrels and casks. THIS HOWEVER DOES NOT MEAN THESE ROOMS SHOULD BE EXEMPT FROM SPRINKLERING REQUIREMENTS!

Fourth, there is no established sprinkler criteria for flammable and combustible liquids stored in wood casks. The modification proposed to Section 903.2.5.2 provides a baseline sprinkler criteria for distilled spirit storage quantities over the Class 1C flammable liquid MAQ, up to 10 feet in height, 2 racks (flu space) with 3 barrels per row in each rack, or single rack with 4 barrels per row. An engineered sprinkler design is required for quantities over the MAQ stored in a manner that exceeds any of these parameters. The language allows the fire code official the latitude to accept published recommended industry practices in lieu of an engineered design or test.

Relieving-style containers are identified because the wooden barrels and casks will release their contents when exposed to fire as the metal bands expand and the staves separate. Metal is identified because plastic and glass are much more vulnerable than wood. Ten foot height is identified as this envelopes the maximum storage heights of wooden barrels and casks typically seen in craft distilleries and is well below the 25 foot storage height permitted in NFPA 30 for relieving-style metal containers.

Last, please note that except for establishing a baseline sprinkler design criteria, the applicable code requirements have not been changed.

Cost Impact: This change will not affect the cost of construction.

	Assembly:	ASF	AMF	DF

903.2.5.2-F-EMERICK

F128 – 13

903.2.9 (IBC [F] 903.2.9), 903.2.9.1 (IBC [F] 903.2.9.1), 903.2.10.1 (IBC [F] 903.2.10.1), 202

Proponent: Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azubiamia@yahoo.com)

Add new text as follows:

903.2.9 (IBC [F] 903.2.9) Group S-1. An automatic sprinkler system shall be provided throughout all buildings containing a Group S-1 occupancy where one of the following conditions exists:

1. A Group S-1 fire area exceeds 12,000 square feet (1115 m²).
2. A Group S-1 fire area is located more than three stories above grade plane.
3. The combined area of all Group S-1 fire areas on all floors, including any mezzanines, exceeds 24,000 square feet (2230 m²).
4. A Group S-1 fire area used for the storage of ~~commercial trucks or buses~~ commercial motor vehicles where the fire area exceeds 5,000 square feet (464 m²).
5. A Group S-1 occupancy used for the storage of upholstered furniture or mattresses exceeds 2,500 square feet (232 m²).

903.2.9.1 (IBC [F] 903.2.9.1) Repair garages. An automatic sprinkler system shall be provided throughout all buildings used as repair garages in accordance with Section 406.8 of the International Building Code, as shown:

1. Buildings having two or more stories above grade plane, including basements, with a fire area containing a repair garage exceeding 10,000 square feet (929 m²).
2. Buildings no more than one story above grade plane, with a fire area containing a repair garage exceeding 12,000 square feet (1115 m²).
3. Buildings with repair garages servicing vehicles parked in basements.
4. A Group S-1 fire area used for the repair of ~~commercial trucks or buses~~ commercial motor vehicles where the fire area exceeds 5,000 square feet (464 m²).

903.2.10.1 (IBC [F] 903.2.10.1) Commercial parking garages. An automatic sprinkler system shall be provided throughout buildings used for storage of ~~commercial trucks or buses~~ commercial motor vehicles where the fire area exceeds 5,000 square feet (464 m²).

Add new definition as follows:

SECTION 202 GENERAL DEFINITIONS

COMMERCIAL MOTOR VEHICLE. A motor vehicle used to transport passengers or property where the motor vehicle:

1. Has a gross vehicle weight rating of 10,000 pounds or more; or
2. Is designed to transport 16 or more passengers, including the driver.

Reason: The current text is not clear on what constitutes a "commercial" truck or bus. The intent of this proposal is that sprinklers should be installed based on the size of the vehicle. A definition of a commercial motor vehicle is needed. These criteria are from the DOT regulations 49CFR390.5, and correlate with IBC Section 1607.7. (See S70-09/10, AMPC1.)

The fuel load is significantly increased with these larger vehicles. Large commercial vehicles typically have an increased quantity of fuel in the vehicle fuel tanks. The vehicles may have larger amounts of upholstered interior furnishings. Large commercial vehicles may be storing or transporting additional combustibles on-board which also increases the fuel load and fire duration.

Cost Impact: The code change will not increase the cost of construction.

	Assembly:	ASF	AMF	DF

903.2.9-F-ZUBIA-FCAC

F129 – 13

903.2.11.1 (IBC [F] 903.2.11.1)

Proponent: Paul Armstrong, P.E., CBO, City of El Monte representing the ICC Orange Empire Chapter Code Committee (paul@jaspacific.com)

Revise as follows:

903.2.11.1 (IBC [F] 903.2.11.1) Stories without openings. An automatic sprinkler system shall be installed throughout all stories, including basements, of all buildings where the floor area exceeds 1,500 square feet (139.4 m2) and where there is not provided at least one of the following types of exterior wall openings:

1. Openings below grade that lead directly to ground level by an exterior stairway complying with Section 1009 or an outside ramp complying with Section 1010. ~~Openings~~ Each opening shall be at least 20 square feet in area and shall be located in each 50 linear feet (15 240 mm), or fraction thereof, of exterior wall in the story on at least one side. The required openings shall be distributed such that the lineal distance between adjacent openings does not exceed 50 feet (15 240 mm).
2. Openings entirely above the adjoining ground level totaling at least 20 square feet (1.86 m2) in each 50 linear feet (15 240 mm), or fraction thereof, of exterior wall in the story on at least one side. The required openings shall be distributed such that the lineal distance between adjacent openings does not exceed 50 feet (15 240 mm). The height of the bottom of the clear opening shall not exceed 44 inches (1118 mm) measured from the floor.

Reason: Item 1 does not have a minimum area requirement for openings in exterior walls to allow for an exemption from the installation of a sprinkler system. These openings are intended to be used by Fire Department personnel during emergency response operations. This revision uses the area requirement found in Item 2 and is consistent with the IBC commentary on this topic.

Cost Impact: The code change proposal will not increase the cost of construction.

903.2.11.1-F-ARMSTRONG

F130 – 13

903.2.11.1.3 (IBC [F] 903.2.11.1.3)

Proponent: Joanne T. McCaughan, Code Specialist, Washington State Building Code Council, representing Washington State (joanne.mccaughan@des.wa.gov)

Revise as follows:

903.2.11.1.3 (IBC [F] 903.2.11.1.3) Basements. Where any portion of a basement is located more than 75 feet (22 860 mm) from openings required by Section 903.2.11.1, or where new walls, partitions or other similar obstructions are installed that ~~restrict the application of water from hose streams~~ increase the exit access travel distance to more than 75 feet, the basement shall be equipped throughout with an approved automatic sprinkler system.

Reason: The enforcement of determining obstructions that can restrict the application of water from hose streams leaves too much room for judgment and will result in inconsistent application of this provision; this concern was echoed in the ICC manual, Significant Changes to the IFC/2012 Edition (p.65).

This proposal provides code language and distances that are consistent with this provision of the code by utilizing the exit access travel distance to establish the threshold that would trigger the requirement for fire sprinklers in a basement. This provision works for both new construction and tenant improvements to an existing basement.

The life safety concern is that a basement could be initially constructed with no walls or partitions, which would make the exit distance easy to obtain. As new walls or partitions are constructed, the exit distance is reviewed again to ensure that it does not trigger fire sprinklers.

This approach removes the judgment of the current wording and provides a more reasonable and enforceable provision. Washington State is adopting this language as a statewide amendment to the 2012 IFC.

Cost Impact: The code change proposal will not increase the cost of construction. For initial construction, the cost of construction will not be affected. However, if revisions to floor plans result in exit access travel distances that exceed 75 feet in an existing basement, costs could potentially increase.

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

903.2.11.1.3-F-MCCAUGHAN

F131 – 13

903.2.11.3 (IBC [F] 903.2.11.3)

Proponent: Brad Emerick, Denver Fire Department representing the Fire Marshal's Association of Colorado (FMAC) and the Colorado Chapter of the ICC (CCICC) (brad.emerick@denvergov.org)

Revise as follows:

903.2.11.3 (IBC [F] 903.2.11.3) Buildings 55 feet or more in height. An automatic sprinkler system in accordance with Section 903.3.1.1 shall be installed throughout buildings with a floor level having an occupant load of 30 or more that is located 55 feet (16 764 mm) or more above the lowest level of fire department vehicle access.

Exceptions:

1. Airport control towers.
2. Open parking structures.
3. Occupancies in Group F-2.

Reason: This proposal revises the language to specify a NFPA 13 sprinkler system is required in buildings meeting the height criteria. The proposed change only affects residential buildings on sloping sites where the lowest level of fire department vehicle access is significantly below grade plane. It has no other effect on sprinkler requirements related to the height of a building, namely IBC Section 540.2 which permits NFPA 13R sprinkler systems in residential buildings up to 60 feet in height – measured to the roof from grade plane (vs. lowest level of FD vehicle access).

If the lowest level of fire department vehicle access is at grade plane or on the high-elevation side of a sloping site, and the building height with respect to grade plane is 60 feet, then the highest occupied floor will be 10+ feet below this at a height of 50 feet or less – but below “55 feet to the highest occupied floor” in either case. Per IBC Section 540.2, a 13R sprinkler system is still permitted.

On a sloping site, where the lowest level of fire department vehicle access is on the low-elevation side of the site, firefighters are presented a building face taller in stories and feet than the nominal height of the building. If this face is tall enough that the highest occupied floor is 55 feet above them, the additional protection afforded by an NFPA 13 sprinkler system- especially with combustible construction – is warranted.

Cost Impact: This change will not affect the cost of construction.

F131-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

903.2.11.3-F-EMERICK

F132 – 13

903.2.11.3 (IBC [F] 903.2.11.3)

Proponent: Eric R. Rosenbaum, Hughes Associates, Inc. representing the Air Traffic Control Tower Fire Life Safety Task Group (erosenbaum@haifire.com)

Revise as follows:

903.2.11.3 (IBC [F] 903.2.11.3) Buildings 55 feet or more in height. An *automatic sprinkler system* shall be installed throughout buildings with a floor level having an *occupant load* of 30 or more that is located 55 feet (16 764 mm) or more above the lowest level of fire department vehicle access.

Exceptions:

1. ~~Airport control towers.~~
2. ~~1.~~ Open parking structures.
3. ~~2.~~ Occupancies in Group F-2.

Reason: The proposed change reflects changes accepted in Section 412.3 of the IBC regarding air traffic control towers. The accepted change in the IBC requires an automatic sprinkler system in all air traffic control towers with an occupiable floor 35 ft or more above the lowest level of fire department vehicle access. This accepted change is more restrictive than current IFC requirements and could cause confusion if left in the IFC. A copy of the accepted change is as follows:

412.3 Airport traffic control towers. The provisions of Sections 412.3.1 through 412.3.11 shall apply to airport traffic control towers occupied only for the following uses:

1. Airport traffic control cab.
2. Electrical and mechanical equipment rooms.
3. Airport terminal radar and electronics rooms.
4. Office spaces incidental to the tower operation.
5. Lounges for employees, including sanitary facilities.

412.3.1 Type of construction. Airport traffic control towers shall be constructed to comply with the height limitations of Table 412.3.2.

TABLE 412.3.2 HEIGHT LIMITATIONS FOR AIRPORT TRAFFIC CONTROL TOWERS	
TYPE OF CONSTRUCTION	HEIGHT ^a (feet)
IA	Unlimited
IB	240
IIA	100
IIB	85
IIIA	65

a. Height to be measured from grade plane to cab floor

412.3.2 Stairway Stairways in Airport traffic control towers shall conform to the requirements of Section 1009. Such *stairways* shall be a smokeproof enclosure in accordance with Section 909.20. The stair pressurization alternative in accordance with Section 909.20.5 shall be permitted to be used. *Stairways* shall not be required to extend to the roof as specified in Section 1009.11.

412.3.3 Exit access. From observation levels, airport traffic control towers shall be permitted to have a single means of exit access for a distance of travel not exceeding 100 ft (30 m). This means of egress shall be permitted to include exit access utilizing an unenclosed stair at the observation level.

412.3.4 Single means of egress. Not less than one *exit stairway* shall be permitted for airport traffic controls towers of any height provided that the *occupant load* per floor is not greater than 15 and the area per floor does not exceed 1,500 square feet (140 m²).

412.3.4.1 Arrangement of single means of egress. Airport traffic control towers permitted a single exit and located above another building shall be provided with one of the following:

1. Exit enclosure separated from the other building with no door openings to or from the other building
2. Exit enclosure leading directly to an exit enclosure serving the other building, with walls and door separating the exit enclosures from each other, and another door allowing access to the top floor of the building that provides access to a second exit serving that floor.

412.3.4.2 Interior Finish. Airport traffic control towers permitted a single exit in accordance with Section 412.3.4 shall be restricted to interior wall and ceiling finishes of Class A or Class B.

412.3.5 Automatic fire detection systems. Airport traffic control towers shall be provided with an automatic fire detection system installed in accordance with Section 907.2.

412.3.6 Automatic sprinkler system. Airport traffic control towers shall be equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1.

412.3.7 Standby power. A standby power system that conforms to Chapter 27 shall be provided in airport traffic control towers more than 65 feet (19 812 mm) in height. Power shall be provided to the following equipment:

1. Pressurization equipment, mechanical equipment and lighting.
2. Elevator operating equipment.
3. Fire alarm and smoke detection systems.

412.3.8 Elevator Protection. Wires or cables that provide normal and standby power, control signals, communication with the car, lighting, heating, air conditioning, ventilation and fire-detecting systems to elevators shall be protected by construction having a minimum 1-hour *fire resistance rating* or shall be circuit integrity cable having a minimum 1-hour *fire-resistance rating*.

412.3.9 Accessibility. Airport traffic control towers need not be *accessible* as specified in the provisions of Chapter 11.

Cost Impact: This code change will increase the cost of construction from the current code requirements in some instances; however, reflects current building practices of the FAA.

	Assembly:	ASF	AMF	DF

903.2.11.3-F-ROSENBAUM

F133 – 13

903.3.1.1 (IBC [F] 903.3.1.1), 903.3.1.1.2 (New) [IBC [F] 903.3.1.1.2]

Proponent: Marshall Klein, International Code Consultants, representing Multi Housing Council

Revise as follows:

903.3.1.1 (IBC [F] 903.3.1.1) NFPA 13 sprinkler systems. Where the provisions of this code require that a building or portion thereof be equipped throughout with an automatic sprinkler system in accordance with this section, sprinklers shall be installed throughout in accordance with NFPA 13 except as provided in Sections 903.3.1.1.1 and 903.3.1.1.2.

903.3.1.1.2 (IBC [F] 903.3.1.1.2) Bathrooms. In Group R occupancies, other than Group R residential care facilities, sprinklers shall not be required in bathrooms that do not exceed 55 square feet in area and are located within individual dwelling units or sleeping units, provided that walls and ceilings, including the walls and ceilings behind any shower enclosure or tub, are of noncombustible or limited-combustible materials with a 15-minute thermal barrier rating.

Reason: This change is necessary to reinstate an exception that has been in existence since 1976 but was nevertheless deleted from the 2013 edition of NFPA 13 with no technical justification. Because the 2015 I-codes will reference the 2013 edition of NFPA 13, it is necessary and appropriate for the IBC and IFC to reverse NFPA's unsupported action on this issue.

Although reinstating the small bathroom exception will have a limited impact on new construction because many bathrooms exceed the 55 sq. ft. area limit in the exception to accommodate wheelchair access, the more important consequence will be removing an unnecessary cost increase for building owners who choose to retrofit existing properties with small bathrooms that were built before it was common to provide wheelchair access. Codes and standards should not erect any unnecessary barriers to retrofitting sprinklers into existing properties, such as existing high-rise buildings.

Background: In the 1976 edition of the Life Safety Code, to encourage cost effective fire protection systems for apartment buildings, NFPA 101 Section 11-3.8.3.4.1 provided an exception to permit bathrooms that did not exceed 55 sq. ft within individual dwelling units to omit sprinklers when the apartment building was sprinklered in accordance with NFPA 13. The basis of the 55 sq. ft. area is that this area accommodates a "typical" small bathroom that contains a standard tub, a toilet and a sink...nothing more. This exception was later duplicated from NFPA 101 into the 1991 edition of NFPA 13 with the understanding that the next edition of NFPA 101 (1994) could delete the exception since NFPA 13 would have it covered. NFPA 101-1994 then, as planned, deleted the exception.

The situation remained "status quo" until the cycle that produced the 2010 edition of NFPA 13. A proposal to delete the bathroom exception for apartments was initially rejected by the NFPA 13 Committee during the ROP process (Code Proposal 13-202 Log #79) with the Committee Statement for rejection as "No technical data was provided supporting this change". During the ROC process, a public comment (Comment 13-141 Log #235) was submitted by the National Fire Sprinkler Association (NFSA), and the NFPA 13 Committee reversed itself by accepting the Comment, even though no new technical information had been provided. Nevertheless, the NFPA membership rejected this revision at NFPA's annual conference, and the 2010 edition of NFPA 13 retained the exception.

During the 2013 edition cycle for NFPA 13, the issue was raised again, and this time, still with no technical justification, NFPA accepted the change. As a result, NFPA 13-2013 (Section 8.15.8.1.1) only allows omission of sprinklers from in bathrooms in hotels and motels, not apartments.

The history of apartment unit bathroom fires is statistically minimal. According to the recent NFPA Home Structure Fire Report, January 2009, Table 9B, "Reported Apartment Structure Fires by Area of Origin 2003-2006 Annual Averages", out of 113,000 fires/year, only 1600 (1%) are in bathrooms. Given that we have more than 35 years of experience with the bathroom sprinkler exception being in place (since it was put into NFPA 101 in 1976), one would certainly expect anecdotal or statistical experience to indicate the existence of a problem, if there were one. On the contrary, apartments have consistently rank at the top of the list with respect to sprinkler reliability and performance statistics, and no statistical (or other) evidence was presented to or by the NFPA 13 committee to justify deletion of the bathroom sprinkler exception for apartments.

Cost Impact: The code change proposal will not increase the cost of construction.

F133-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

903.3.1.1-F-KLEIN

F134 – 13

903.3.1.2 (IBC [F] 903.3.1.2)

Proponent: Brad Emerick, Denver Fire Department representing the Fire Marshal's Association of Colorado (FMAC) and the Colorado Chapter of the ICC (CCICC) (brad.emerick@denvergov.org)

Add new text as follows:

903.3.1.2 (IBC [F] 903.3.1.2) NFPA 13R sprinkler systems. *Automatic sprinkler systems* in Group R occupancies up to and including four stories and 60 feet in height above grade plane shall be permitted to be installed throughout in accordance with NFPA 13R.

Reason: There has been confusion as to where you measure the four story limitation for NFPA 13R sprinkler systems. This proposal clarifies the intent of NFPA 13R limitations by using the correct language for building height and correlating with the NFPA 13R committee.

There is a breakpoint in the codes for building heights between 30 feet above the lowest level of fire department access and four stories. This is the point where stair enclosures have to be 2-hour rated, where at least one stair is required to extend to the roof, when standpipes are required, where emergency escape and rescue windows are no longer required, etc. This height correlates with the upper limit at which fire departments can conduct operations using ground ladders. Hand-carried ladders can typically only reach 30 to 40 feet above the grade from where they're set. A higher degree of safety has historically been required in buildings taller than this because an offensive attack will include – maybe exclusively – internal operations.

In residential buildings, this is also the threshold where sprinkler systems are required to be more robust; i.e., where NFPA 13 systems are required.

With the relaxation in requirements for residential pedestal buildings leading to the consolidation of combustible framing (and the contents) in the highest stories, it makes no sense to also relax the sprinklering requirements for that portion of the building. More stories means more time required for search and rescue. Combustible construction – especially if the attics and interstitial floor/ceiling spaces are not protected, means less time is provided.

Cost Impact: This change will not affect the cost of construction.

	Assembly:	ASF	AMF	DF

903.3.1.2-F-EMERICK

F135 – 13

903.3.1.2 (IBC [F] 903.3.1.2)

Proponent: Tim Pate, City and County of Broomfield, CO, representing Colorado Chapter Code Change Committee

Revise as follows:

903.3.1.2 (IBC [F] 903.3.1.2) NFPA 13R sprinkler systems. Automatic sprinkler systems in Group R occupancies up to and including four stories in height above grade plane shall be permitted to be installed throughout in accordance with NFPA 13R.

Exception: The number of stories of Group R occupancies constructed in accordance with Section 510.2 and 510.4 of the International Building Code shall be measured from the horizontal assembly creating separate buildings.

Reason: There has been confusion as to where you measure the four story limitation for NFPA 13R sprinkler systems. This proposal clarifies the intent of NFPA 13R limitations by using the correct language for building height and addressing the use of these systems in podium buildings.

Cost Impact: This change will not affect the cost of construction.

F135-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

903.3.1.2-F-PATE

F136 – 13

903.3.1.2.1 (IBC [F] 903.3.1.2.1)

Proponent: Jeffrey M. Hugo, CBO, representing the National Fire Sprinkler Association
(hugo@nfsa.org)

Revise as follows:

903.3.1.2.1 (IBC [F] 903.3.1.2.1) Balconies and decks. Sprinkler protection shall be provided for exterior balconies, decks and ground floor patios of *dwelling units* and *sleeping units* where the building is of Type V construction, provided there is a roof or deck above. Sidewall sprinklers that are used to protect such areas shall be permitted to be located such that their deflectors are within 1 inch (25 mm) to 6 inches (152 mm) below the structural members and a maximum distance of 14 inches (356 mm) below the deck of the exterior balconies and decks that are constructed of open wood joist construction.

Reason: According to the current text, a balcony or deck from a sleeping unit would be exempt from fire sprinklers. Sleeping units are common for dormitories, hotel rooms, assisted living, etc. and we do not believe this is the intent of the code to forego protection of these balconies and decks because they lack sanitation or cooking facilities.

DWELLING UNIT. A single unit providing complete, independent living facilities for one or more persons, including permanent provisions for living, sleeping, eating, cooking and sanitation.

SLEEPING UNIT. A room or space in which people sleep, which can also include permanent provisions for living, eating, and either sanitation or kitchen facilities but not both. Such rooms and spaces that are also part of a *dwelling unit* are not sleeping units.

Cost Impact: Will not increase the cost of construction

F137 – 13

202, 903.3.1.2.2 (New) [IBC [F] 903.3.1.2.2 (New)], 1104.21

Proponent: Al Godwin, CBO, CPM, Aon Fire Protection Engineering, representing Aon Fire Protection Engineering Corporation (al.godwin@aon.com)

Add new text as follows:

SECTION 202 GENERAL DEFINITIONS

OPEN-ENDED CORRIDOR. An interior corridor that is open on each end, and connects to an exterior stairway or ramp at each end with no intervening doors or separation from the corridor.

Revise as follows:

903.3.1.2.2 (IBC [F] 903.3.1.2.2) Open-ended Corridors. Sprinkler protection shall be provided in open-ended corridors and associated exterior stairways and ramps as specified in Section 1026.6, exception 4.

1104.21 Exterior stairway protection. Exterior exit stairs shall be separated from the interior of the building as required in Section 1026. Openings shall be limited to those necessary for egress from normally occupied spaces.

Exceptions:

1 through 3 (No change to current text)

4. Separation from the interior open-ended corridor of the building is not required for exterior stairways ~~connected to open-ended corridors~~, provided that:
 - 4.1 ~~— The building, including corridors, and stairs, is equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 or 903.3.1.2.~~
 - 4.2 4.1 The open-ended corridors comply with Section 1018.
 - 4.3 4.2 The open-ended corridors are connected on each end to an exterior exit stairway complying with Section 1026.
 - 4.4 4.3 At any location in an open-ended corridor where a change of direction exceeding 45 degrees (0.79 rad) occurs, a clear opening of not less than 35 square feet (3.3 m²) or an exterior stairway or ramp shall be provided. Where clear openings are provided, they shall be located so as to minimize the accumulation of smoke or toxic gases.

Reason: This is a correlation with code change E153-12 which was approved last cycle. New Section 903.3.1.2.2 is to clarify that when using a 13R system for this provision, extra heads are required in the breezeway.

The Reason statement for E153-12 is as follows:

Reason: Breezeway stairs is what this section is talking about. Whether straight through the building with a stair on each side, or taking a turn somewhere during its path through the building with a stair on either end, it is still a breezeway with exterior stairs. This point is not clear in the current language.

There is this opinion that an open breezeway stairs are allowed by basic code. They are not. 2012 IBC Section 1026.6 states that exterior stairs must be separated from the interior of the building. The breezeway (interior corridor) is part of the interior of the building. I have conferred with the original proponent of this code change many times and confirmed that the intent was to allow the removal of the wall and door that separates the stair from the corridor, creating a breezeway.

Many designers and jurisdictions assume that breezeway stairs are allowed by right. However, in order to not have to build the wall and fire door separating the exterior stair from the interior corridor, exception 4 must be complied with, which includes sprinklers in this breezeway.

The following is a representation of the intent of Exception 4, allowing the removal of the separation wall and door:

We are all familiar with the required protection on each side of the exterior stair as represented in this clip from the 2000 International Building Code Commentary.

So, if the walls on each side of the stair have to be protected, how can a large opening where the door occurs be removed and have an unprotected connection to the interior corridor.

The 2000 IBC Handbook, provided an accurate depiction of what this code change applied to as follows:

OPEN-ENDED CORRIDOR

FIGURE 1005-10

Here is the original code change that inserted the provision. Notice the statement "The purpose of this analysis was to determine if an equivalent level of life safety could be achieved by the design of an open breezeway in comparison to an enclosed corridor or balcony for these multifamily buildings."

technical change.

Public Hearing: Committee: AS AM D
Assembly: ASF DF

1008.7-2

Proponent: Ron Nickson, National Multi Housing Council/National Apartment Association

1. Revise as follows:

1008.7 Exterior exit stairways. Exterior exit stairways that conform to the requirements for interior exit stairways except for the enclosure requirements, are permitted as an element of a required means of egress for buildings not exceeding six stories or 75 feet (22.9 m) in height for occupancies other than Group I-2.

An exterior exit stairway that serves as an exit component shall be open to the outside on at least one side except for required structural columns beams, and open-type handrails and guards. A minimum of 35 square feet (3.22 m²) of aggregate open area shall be provided within the horizontal projection of each floor to ceiling level at each exterior stair or within the horizontal projection of the floor to ceiling level of the stairway landing that is located no more than 1/2 level above the corridor floor.

The adjoining open areas shall be either yards, courts or public ways; the remaining sides are permitted to be enclosed by the exterior walls of the building. Any stairway not meeting the definition of an exterior stairway shall comply with the requirements for interior stairways.

Exterior stairways shall be located in accordance with Section 1009.1.

2. Revise the definition of Stairway, Exterior as follows:

SECTION 1002 DEFINITIONS

STAIRWAY, EXTERIOR A stairway that is open on at least one side, except for required structural columns, beams, and open-type handrails, and guards. The adjoining open areas shall be either yards, courts or public ways; the other sides of the exterior stairway need not be open.

Reason: To establish minimum requirements for open area on exterior exit stairways and permit the use of enclosed guards and handrail systems.

The 35 sq. ft. of open area is based on computer fire studies of six multifamily projects in Virginia containing more than 2000 individual dwelling units. The analysis was completed by the Sullivan Code Group using HAZARD I, a fire hazard assessment method developed by the

United States National Institute of Standards and Technology. The procedures used by the Sullivan Code Group were reviewed by Professor Jonathan Barnett, Ph.D., Associate Professor, Center for Firesafety Studies, Worcester Polytechnic Institute who checked for conformity with the fire modeling expectations and limitations.

The findings, which are based on the provisions in the 1996 BOCA National Building Code, apply equally to the provisions in the IBC. The results, summarized by the Sullivan Code Group in the following Executive Summary, for the six buildings included in the studies were very similar. The buildings studied were multifamily apartments with various configurations of corridors connected to exterior open stairs.

EXECUTIVE SUMMARY

The purpose of this analysis was to determine if an equivalent level of life safety could be achieved by the design of an open breezeway in comparison to an enclosed corridor or a balcony for these multifamily buildings.

The multifamily buildings were analyzed using engineering judgement, referenced literature, the suite of computer programs called FASTlite, and CFAST and, computer-based fire models developed by the United States National Institute of Standards and Technology, Building and Fire Research Laboratory.

The reasonable worst case fire scenario modeled was an arson fire on the breezeway. By assuming that the design fire is a fast growing arson fire, this analysis goes beyond the requirements of the Building Code which does not consider arson fire situations in determining building fire safety regulations. Therefore, this analysis is evaluating the building under more adverse conditions than are addressed in the Building Code. The results of the analysis are:

1. For the life safety of the building occupants on the floor of fire origin, the open breezeway configuration is superior to the enclosed corridor configuration.
2. For the life safety of the building occupants on floors other than the floor of fire origin, the open breezeway configuration meets the intent of the egress provisions in the BOCA Code. With the open breezeway configuration, at least one stairwell should maintain tenable egress conditions depending on the wind direction. In all cases analyzed, one stairwell was capable of handling the occupant load. Therefore, the intent of the code is met.
3. Smoke conditions on floors other than the floor of fire origin will remain safe for a suitable period of time to allow occupant egress with the open breezeway configuration, even without sprinklers. If there is a wind, the tenability in the open breezeways is improved.
4. With the enclosed corridor configuration, sprinkler activation is predicted to occur after the time at which the upper smoke layer reaches a level that could impede egress. With the open breezeway configuration, sprinkler activation is predicted to occur prior to the time at which the upper smoke layer reaches a level that could impede egress.
5. The results of this analysis have demonstrated that an open breezeway protected by quick response automatic sprinklers provides occupant egress conditions which are better than code-complying balcony designs. Therefore an open breezeway protected by quick response sprinklers, as designed for this project, should be regulated by the same requirements as the open balcony which does not require a fire resistance rated floor when standard response automatic sprinklers are present. The design of the open breezeway provides a level of life safety equivalent or superior to that required by the BOCA Code Sections 106.2 and 106.4.

Copies of the Fire Studies are submitted for reference (see NMHC/NAA proposal for Section 1004.7). Additional copies are available from the proponent.

Public Hearing: Committee: AS' AM D
Assembly: ASF DF

In the 09/10 cycle, code change E134-09/10 made it clear that this exception only applied to the wall and door that would normally separate an exterior stair from the interior corridor. This exception does not apply to other separation requirements on the sides of the stairs.

The specific section reasoning for this code change is as follows:

Section 202, provide a definition of an open-corridor. Hopefully this will expand on code change E134-09/10 to clarify that this provision is only to eliminate the separation required between the stair and the interior corridor. Not the units on either side.

Section 1026.6, expanding the same concept, adding clarity.

Section 903.3.1.2.2, providing an explicit requirement that sprinkler protection must be provided in this open-ended corridor when using a residential system. As with Section 903.3.1.2.1, this protection is above the requirements of a standard 13R system. If not checked in the design, these heads will not be installed. As such, the open-ended corridor will not be in compliance with code.

Section 1104.21, deletes the sprinkler protection requirement for existing buildings. Once understood that in order to have breezeway stairs, the building, the breezeway and associated stairs must be sprinklered, this provision is actually a retroactive sprinkler provision for all existing buildings with breezeway stairs.

If not sprinklered, in order to keep the breezeway stairs, the building and corridor must be sprinklered. If already sprinklered with a 13R, retrofit sprinklers in the corridor must be installed.

Cost Impact: Since this is correlation between the IFC and IBC, no extra construction cost is expected. And, removing the retroactive implication to existing non-sprinklered breezeways, or 13R sprinklered breezeways without breezeway sprinklers, will reduce costs.

F137-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

903.3.1.2.2-F-GODWIN

F138 – 13

903.3, 903.3.8 (New), 903.4 (IBC [F] 903.4), 903.3.5.1 (IBC [F] 903.3.5.1), 903.3.5.2 (IBC [F] 903.3.5.2)

Proponent: Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azubiamia@yahoo.com)

Revise as follows:

903.3 Installation requirements. *Automatic sprinkler systems* shall be designed and installed in accordance with Sections 903.3.1 through 903.3.87.

903.3.5.1.1 Limited area sprinkler systems.

~~Limited area sprinkler systems serving fewer than 20 sprinklers on any single connection are permitted to be connected to the domestic service where a wet automatic standpipe is not available. Limited area sprinkler systems connected to domestic water supplies shall comply with each of the following requirements:~~

- ~~1. Valves shall not be installed between the domestic water riser control valve and the sprinklers.~~

Exception: ~~An approved indicating control valve supervised in the open position in accordance with Section 903.4.~~

- ~~2. The domestic service shall be capable of supplying the simultaneous domestic demand and the sprinkler demand required to be hydraulically calculated by NFPA 13, NFPA 13D or NFPA 13R.~~

903.3.5.1 903.3.5.2 (IBC [F] 903.3.5.1 903.3.5.2) Residential combination services. A single combination water supply shall be allowed provided that the domestic demand is added to the sprinkler demand as required by NFPA 13R.

903.3.8 (IBC [F] 903.3.8) Limited area sprinkler systems. Limited area sprinkler systems shall be in accordance with the standards listed in Section 903.3.1 except as provided in Sections 903.3.8.1 through 903.3.8.5.

903.3.8.1 Number of sprinklers. Limited area sprinkler systems shall not exceed 6 sprinklers in any single fire area.

903.3.8.2 Occupancy hazard classification. Only areas classified by NFPA 13 as Light Hazard or Ordinary Hazard Group 1 shall be permitted to be protected by limited area sprinkler systems.

903.3.8.3 Piping arrangement. Where a limited area sprinkler system is installed in a building with an automatic-wet standpipe system, sprinklers shall be supplied by the standpipe system. Where a limited area sprinkler system is installed in a building without a wet-pipe automatic standpipe system, water shall be permitted to be supplied by the plumbing system provided that the plumbing system is capable of simultaneously supplying domestic and sprinkler demands.

903.3.8.4 Supervision. Control valves shall not be installed between the water supply and sprinklers unless the valves are of an approved indicating type that are supervised or secured in the open position.

903.3.8.5 Calculations. Hydraulic calculations in accordance with NFPA 13 shall be provided to demonstrate that the available water flow and pressure are adequate to supply all sprinklers installed in any single fire area with discharge densities corresponding to the hazard classification.

903.3.5.2 903.3.5.3 (IBC [F] 903.3.5.2 903.3.5.3) Secondary water supply. An automatic secondary on-site water supply having a capacity not less than the hydraulically calculated sprinkler demand, including the hose stream requirement, shall be provided for high-rise buildings in Seismic Design Category C, D, E or F as determined by the *International Building Code*. An additional fire pump shall not be required for the secondary water supply unless needed to provide the minimum design intake pressure at the suction side of the fire pump supplying the *automatic sprinkler system*. The secondary water supply shall have a duration of not less than 30 minutes as determined by the occupancy hazard classification in accordance with NFPA 13.

Exception: Existing buildings.

903.4 (IBC [F] 903.4) Sprinkler system monitoring and alarms. All valves controlling the water supply for automatic sprinkler systems, pumps, tanks, water levels and temperatures, critical air pressures, and water-flow switches on all sprinkler systems shall be electrically supervised.

Exceptions:

1. Automatic sprinkler systems protecting one- and two-family dwellings.
2. Limited area systems ~~serving fewer than 20 sprinklers in accordance with Section 903.3.8.~~
3. through 7. (No change to current text)

Reason: This proposal is submitted by the ICC Fire Code Action Committee (FCAC). This ICC committee was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portions thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the Fire-CAC has held 6 open meetings and numerous Regional Work Group and Task Group meetings and conference calls which included members of the committees as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the FAC website at: <http://www.iccsafe.org/cs/CAC/Pages/default.aspx>.

This code section as it exists allows the protection of large areas by a system of automatic sprinklers that is not afforded the same level of protection required by NFPA standards 13, 13R and 25. Some of these include waterflow alarms, components listed for fire protection systems, fire department connections, testing and maintenance. This code change would reduce the number of sprinklers that may be supplied from a building plumbing system to six in a single fire area to eliminate the potential for multiple limited area sprinkler systems and combined water supply demands necessary to control a single fire event. It also limits the six sprinklers to a discharge density of Light Hazard or Ordinary Hazard Group I. The basis for these values provides coordination with longstanding requirements in NFPA 101, Life Safety Code, Section 9.7.1.2, which limits the number and discharge density of automatic sprinklers supplied from a plumbing system. Such a limit is reasonable in that it can allow for a pipe schedule design if the plumbing system is capable of satisfying the NFPA 13 pipe diameter requirements.

Cost Impact: This code change would increase the cost of construction

F138-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

903.3-F-ZUBIA-FCAC

F139 – 13

903.3.5.2 (IBC [F] 903.3.5.2); IBC [F] 403.3

Proponent: Jeffrey M. Hugo, CBO, representing the National Fire Sprinkler Association
(hugo@nfsa.org)

Revise as follows:

IBC [F] 403.3 Automatic sprinkler system. Buildings and structures shall be equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1 and a secondary water supply where required by Section ~~903.3.5.2~~ 403.3.3.

~~903.3.5.2 (IBC [F] 903.3.5.2)~~ **IBC [F] 403.3.3 Secondary water supply.** An automatic secondary on-site water supply having a capacity not less than the hydraulically calculated sprinkler demand, including the hose stream requirement, shall be provided for high-rise buildings assigned to Seismic Design Category C, D, E or F as determined by the International Building Code. An additional fire pump shall not be required for the secondary water supply unless needed to provide the minimum design intake pressure at the suction side of the fire pump supplying the automatic sprinkler system. The secondary water supply shall have a duration of not less than 30 minutes

~~IBC [F] 403.3.3~~ **403.3.4 Fire pump room.** Fire pumps shall be located in rooms protected in accordance with Section 913.2.1.

Reason: Secondary water supply for high rises is in Chapter 9, whereas the requirements for high rises are in Section 403 of the *International Building Code*. Since this secondary water supply requirement only applies to high rises it is more appropriate for designers and users in Section 403.3.3 of the *International Building Code*.

Cost Impact: Will not increase the cost of construction

F139-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

903.3.5.2-FS-HUGO

F140 – 13

903.3.7

Proponent: Brad Emerick, Denver Fire Department representing the Fire Marshal's Association of Colorado (FMAC) and the Colorado Chapter of the ICC (CCICC) (brad.emerick@denvergov.org)

Revise text as follows:

903.3.7 Fire department connections. ~~The location of~~ Fire department connections shall be approved by the fire code official installed in accordance with Section 912.

Reason: Section 912 provides the more comprehensive set of requirements for FDCs and except for "fire code official" vs. "fire chief", Section 903.3.7 is redundant with Section 912.2. Pointing to the comprehensive scope contained in Section 912 reduces the opportunity for any of its requirements to be overlooked.

Cost Impact: This change will not affect the cost of construction.

F140-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

903.3.7-F-EMERICK

F141 – 13

903.3.7, 905.1 (IBC [F] 905.1), 905.2 (IBC [F] 905.2), 912.1, 912.3 (IBC [F] 912.3); IBC [F] 903.3.7 (New), IBC [F] 912.1

Proponent: Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azubiamia@yahoo.com)

Revise as follows:

903.3.7 Fire department connections. ~~The location of fire~~ Fire department connections for automatic fire sprinkler systems shall be ~~approved by the fire code official in accordance with Section 912.~~

905.1 (IBC [F] 905.1) General. Standpipe systems shall be provided in new buildings and structures in accordance with ~~this section Sections 905.2 through 905.10. Fire hose threads used in connection with standpipe systems shall be approved and shall be compatible with fire department hose threads. The location of fire department hose connections shall be approved.~~ In buildings used for high-piled combustible storage, fire protection shall be in accordance with Chapter 32.

905.2 (IBC [F] 905.2) Installation standard. Standpipe systems shall be installed in accordance with this section and NFPA 14. Fire department connections for standpipe systems shall be in accordance with Section 912.

912.1 Installation. Fire department connections shall be installed in accordance with the NFPA standard applicable to the system design and shall comply with Sections 912.2 through ~~912.6~~ 912.7.

912.3 (IBC [F] 912.3) Fire hose threads. Fire hose threads used in connection with standpipe systems shall be approved and shall be compatible with fire department hose threads.

IBC [F] 903.3.7 Fire department connections. Fire department connections for automatic fire sprinkler systems shall be in accordance with Section 912.

IBC [F] 912.1 Installation. Fire department connections shall be installed in accordance with the NFPA standard applicable to the system design and shall comply with Sections 912.2 through ~~912.5~~ 912.6.

(Renumber subsequent sections)

Reason: Currently, there are several sections in the code which contain requirements for fire department connections. This proposal will correlate those requirements and place them into Section 912 where the bulk of the requirements exist. This proposal then either deletes the requirements found elsewhere, as in Section 905.1; or it makes reference to the requirements in Section 912.

Section 903.3.7 is shown as an addition to the IBC, since the section is in the IFC but it is not currently in the IBC.
There is no change in the requirements currently found in the code.

Cost Impact: The code change proposal will not increase the cost of construction.

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

903.3.7-F-ZUBIA-FCAC

F142 – 13

903.4.2 (IBC [F] 903.4.2)

Proponent: Robert Marshall, Contra Costa County Fire Protection District representing self
(rmars@cccfd.org)

Revise as follows:

903.4.2 (IBC [F] 903.4.2) Alarms. An approved audible and visual notification device, located on the exterior of the building at the front of the building or in another ~~an approved~~ location, shall be connected to each *automatic sprinkler system*. Such sprinkler water-flow alarm devices shall be activated by water flow equivalent to the flow of a single sprinkler of the smallest orifice size installed in the system. Where a fire alarm system is installed, actuation of the *automatic sprinkler system* shall actuate the building fire alarm system.

Exceptions:

1. Existing Systems
2. Sprinkler systems utilizing a "Water Motor Gong" device shall not be required to provide visual notification.

Reason: Because of extensive fire department public education efforts, the sound of a fire alarm is recognizable, and distinguishable in nearly all circumstances. When people hear these signals, they instinctively know what to do. In the case of fire sprinkler systems however, flow alarms are typically bells, and do not command the same kind of attention as what is typically called a horn/strobe device. Typically, these appliances are located away from roads, or normal paths of travel, and are often located near burglar alarm devices, making it difficult to distinguish between the fire alarm, and burglar alarm devices. Changing the type of tone pattern does not help, because the public no longer recognizes the sound of a bell as a fire alarm. Bells are also subject to maintenance problems, such as bird nests, and wasp nests built up on the bell itself, rendering the bell useless.

Add to this that fire responders often wear hearing protection to scenes, and it becomes difficult to tell where the alarm is, and what the alarm is. By providing an audible/ visual means of notification in a readily visible location, you combat all of these problems. The audible portion notifies people of a fire event, and the visual portion alerts as to exactly which building has the problem from a distance, which is great for responders.

It also has the added benefit of reducing the long term cost of maintenance of a bell.

This code change is to combat the problems detailed above.

The removal of the reference to 907 is due to the contents of this code change. No changes to 907 need to be made to accommodate this proposal.

The code change also moves the device to a place where it is most likely to be seen or heard. The original idea of bell placement goes back to when water motor gongs were prevalent in systems. Because of this, the bells were usually placed at the riser location due to the physical need to move the water through the device. This is a practice that has continued. Because most systems are monitored, placement of an audible/visual notification device is not dependent on the riser location. While it is best for visibility for it to be on the front of the building, it may still be better to put the device on a different side that is perhaps more visible. In any case, the Fire Code Official still has final say under this proposal.

The first exception is made as to not retroactively require installation of devices, as there may be significant practical difficulties in doing this. The second exception is placed because water motor gongs are still sometimes used in locations without electricity. These are usually in limited area sprinkler systems of less than 20 heads that do not require sprinkler monitoring anyway. This practice should be allowed to continue, and this exception would allow this.

Cost Impact: This proposal will not increase the cost of construction

F142-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

903.4.2-F-MARSHALL

F143 – 13

Proponent: Jesse J. Beitel, Hughes Associates, Inc, representing United Technologies Corporation
(jbeitel@haifire.com)

Revise as follows:

904.2 (IBC [F] 904.2) Where required. Automatic fire-extinguishing systems installed as an alternative to the required automatic sprinkler systems of Section 903 shall be approved by the fire code official. Automatic fire-extinguishing systems shall not be considered alternatives for the purposes of exceptions or reductions allowed by other requirements of this code.

Exception: Automatic water mist systems in accordance with 904.12, where listed for the application and where water supply duration requirements are in accordance with Section 903.3.5 and the listing.

Reason: This proposed change adds the concept of using an automatic water mist system for protection of structures only when the water mist systems are used within the systems' listed applications. The proposed exception recognizes that based on performance, listings and field experience water mist is a viable alternative to the protection provided by automatic sprinklers. As a listed alternative to sprinkler protection for specific classifications such as Light Hazard and Ordinary Hazard, for example, the proposed change allows the proposed exceptions and reductions in the occupancies only where the listings identify the protection as appropriate. No new exceptions and reductions are requested. Water-mist systems are tested in environments identical to automatic sprinkler testing and have been found to achieve at least equal performance using less water than conventional sprinklers. It is intended that the water supply durations be consistent with their listing requirements and to that of sprinklers as noted in NFPA 13 §11.2.3.1.2 (2013) to address sufficient water supplies based on the occupancy protected.

Automatic water mist systems are similar to sprinkler systems in that both are "an integrated system of underground and overhead piping designed in accordance with fire protection engineering standards. The system includes a suitable water supply. The portion of the system above the ground is a network of specially sized or hydraulically designed piping installed in a structure or area, generally overhead, and to which automatic sprinklers are connected in a systematic pattern. The system is usually activated by heat from a fire and discharges water over the fire area" [IFC 2012 Automatic Sprinkler System Definition]. Water mist systems use nozzles, operate at various pressures and are fed from a potable water supply or pressurized bottles.

Water mist systems have been approved by FM Approvals for occupancies similar to light hazard as defined by NFPA 13. The test criteria for these listings are found in FM 5560. Water mist systems have been listed by UL for Ordinary Hazard, Group I occupancies as defined by NFPA 13 (UL ZDPA.EX15843). These listings would permit water mist to be installed as the primary suppression system in a variety of Occupancy Classifications.

Automatic water mists systems provide a water efficient alternative to sprinkler systems. Water mist systems reduce the water supply demand which can be of significance in areas where municipal water supplies may be marginal or inadequate for conventional sprinklers. Reducing the water demand for automatic fire protection systems that are tested in the same manner by recognized laboratories to conventional sprinklers, will encourage the installation of fire protection systems in cities and towns where water shortages due to drought may be a problem. Furthermore, the reduced discharge from water mist systems, compared to conventional sprinklers, in turn reduces the potential water damage.

Water mist systems are listed for several occupancies based on the hazard definitions and have been used for years in buildings and on passenger ships specifically as a "sprinkler equivalent system" per Resolution A.800(19), November 1995 (IMO A800). A.800 details the testing criteria to establish water mist sprinkler equivalency for passenger ships. These passenger ships are similar to small cities in terms of the occupancies located on board, including assembly, business, mercantile, residential, and storage. The wide variety of occupancies located on passenger ships and history of use provides strong support for the equivalency of water mist systems to sprinkler systems. Water mist systems have been used in lieu of automatic sprinklers in buildings and on passenger ships for years due to water efficient design. The listings of the systems have been used as design guidance in buildings.

The acceptance of protecting buildings entirely by water-mist is appropriate and is being done today. Water mist works to extinguish, suppress or control fires in fully open compartments. The performance of these systems depends on pre-wetting of combustibles and cooling of hot gases, the same as conventional sprinklers, and they do not require sealed enclosures. Water-mist systems are tested in environments identical to automatic sprinkler testing and have been found to achieve at least equal performance using less water than conventional sprinklers.

Cost Impact: Water mist systems on original installation can be lower cost than traditional sprinkler system. For example, automatic water mist systems in locations with marginal water supplies would potentially provide cost savings as water tanks would not be required. Obviously, if the tank occupies rentable space, the lifetime costs of the water mist system become even more compelling.

Proponent: Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azubiamia@yahoo.com)

Revise as follows:

904.2 (IBC [F] 904.2) Where required permitted. Automatic fire-extinguishing systems installed as an alternative to the required *automatic sprinkler systems* of Section 903 shall be *approved* by the fire code official. ~~Automatic fire-extinguishing systems shall not be considered alternatives for the purposes of exceptions or reductions allowed by other requirements of this code.~~

904.2.1 (IBC [F] 904.2.1) Restriction on using automatic sprinkler system exceptions or reductions. Automatic fire-extinguishing systems shall not be considered alternatives for the purposes of exceptions or reductions allowed for *automatic sprinkler systems* or by other requirements of this code.

904.2.4 ~~904.2.2~~ (IBC ~~[F]~~ 904.2.4 904.2.2) Commercial hoods and duct systems. (no change)

904.12 (IBC [F] 904.12) Automatic Water Mist Systems. *Automatic water mist systems* shall be permitted in applications that are consistent with the applicable listing or approvals and shall comply with Sections 904.12.1 through 904.12.3.

904.12.1 (IBC [F] 904.12.1) Design and Installation Requirements. *Automatic water mist systems* shall be designed and installed in accordance with Sections 904.12.1.1 through 904.12.1.4.

904.12.1.1 (IBC [F] 904.12.1.1) General. *Automatic water mist systems* shall be designed and installed in accordance with NFPA 750 and the manufacturer's instructions.

904.12.1.2 (IBC [F] 904.12.1.2) Actuation. *Automatic water mist systems* shall be automatically actuated.

904.12.1.3 (IBC [F] 904.12.1.3) Water supplies. Connections to a potable water supply shall be protected against backflow in accordance with the International Plumbing Code.

904.12.1.4 (IBC [F] 904.12.1.4) Secondary water supply. Where a secondary water supply is required for an *automatic sprinkler system*, an *automatic water mist system* shall be provided with an approved secondary water supply.

904.12.2 (IBC [F] 904.12.2) Water mist system supervision and alarms. Supervision and alarms shall be provided as required for *automatic sprinkler systems* in accordance with Section 903.4.

904.12.2.1 (IBC [F] 904.12.2.1) Monitoring. Monitoring shall be provided as required for *automatic sprinkler systems* in accordance with Section 903.4.1.

904.12.2.2 (IBC [F] 904.12.2.2) Alarms. Alarms shall be provided as required for *automatic sprinkler systems* in accordance with Section 903.4.2.

904.12.2.3 (IBC [F] 904.12.2.3) Floor control valves. Floor control valves shall be provided as required for *automatic sprinkler systems* in accordance with 903.4.3.

904.12.3 (IBC [F] 904.12.3) Testing and maintenance. *Automatic water mist systems* shall be tested and maintained in accordance with the International Fire Code.

Add new definition as follows:

SECTION 202 GENERAL DEFINITIONS

AUTOMATIC WATER MIST SYSTEM. A system consisting of a water supply, a pressure source, and a distribution piping system with attached nozzles, which, at or above a minimum operating pressure, defined by its listing, discharges water in fine droplets meeting the requirements of NFPA 750 for the purpose of the control, suppression or extinguishment of a fire. Such systems include wet-pipe, dry-pipe and pre-action types. The systems are designed as engineered, pre-engineered, local-application or total flooding systems.

902.1 Definitions. The following terms are defined in Chapter 2:

AUTOMATIC WATER MIST SYSTEM

Add new standard to Chapter 80 as follows:

NFPA

750-14 Standard on Water Mist Fire Protection Systems

Reason: This proposal is submitted by the ICC Fire Code Action Committee (FCAC). This ICC committee was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portions thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the Fire-CAC has held 6 open meetings and numerous Regional Work Group and Task Group meetings and conference calls which included members of the committees as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the FAC website at: <http://www.iccsafe.org/cs/CAC/Pages/default.aspx>.

This proposal recognizes water mist as an alternative, in some applications, to automatic fire sprinkler systems. However, no exceptions, reductions, or "trade-offs" for water mist systems are granted or permitted by this proposal, as automatic water mist systems are not considered equivalent to automatic sprinkler systems. Automatic water mist systems have been approved by FM Global for occupancies similar to Light Hazard (as defined by NFPA 13) and by UL for occupancies similar to Ordinary Hazard Group I (as defined by NFPA 13). These listings permit automatic water mist systems to be installed as the primary suppression system in a variety of occupancy classifications.

In addition to the above text in Section 904, a definition and the installation standard NFPA 750 *Standard on Water Mist Fire Protection Systems* is added as a referenced standard.

Cost Impact: This code change will not increase the cost of construction

Analysis: A review of the standard proposed for inclusion in the code, NFPA 750-14, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28), will be posted on the ICC website on or before April 1, 2013.

F144-13

	Assembly:	ASF	AMF	DF

904.2-F-ZUBIA-FCAC

F145 – 13

904.11.5 (New) [IBC [F] 904.11.5], Chapter 80

Proponent: Bob Eugene, representing UL LLC (Robert.Eugene@ul.com)

Add new text as follows:

904.11.5 (IBC [F] 904.11.5) Residential range top extinguisher units. Where residential range top cooking appliances are permitted to be used in occupancies regulated by this Code, and an automatic fire-extinguisher unit is required to protect the cooking surface, it shall be listed and labeled in accordance with UL 300A. The extinguisher unit shall be installed in accordance with its listing and the manufacturer's installation instructions.

Add new standard to Chapter 80 as follows:

300A – 06 Outline of Investigation for Extinguishing System Units for Residential Range Top
Cooking Surfaces904.11.5

Reason: The UL 300A Outline of Investigation includes requirements for conducting fire testing with extinguisher units intended to extinguish fires occurring on residential range top cooking surfaces. To date two manufacturers have several automatic extinguisher units that are listed and comply with UL 300A, that include both wet and dry chemical extinguishing agents.

It is recognized that code officials allow residential range tops to be installed in a variety of situations in addition to dwelling units. This includes office break rooms, churches, and similar venues. It is not the intent of the proposal to require all of these installations to be protected by UL 300A extinguisher units. The proposal clearly indicates that these units are only to be provided when required.

One application where UL 300A extinguisher units will be required is for residential range tops installed in Group I-2, Condition 1 occupancies. This was recently required as a result of the public comment to proposal G65-12 that was passed at the Final Action Hearing in Portland.

Cost Impact: None

F145-13

904.11.5 (NEW)-F-EUGENE

F146 – 13

904.12 (IBC [F] 904.12) (New), 904.12.1 (IBC [F] 904.12.1 (New)), 904.12.2 (IBC [F] 904.12.2 (New)), Table 906.1 (IBC [F] Table 906.1), Chapter 80 (IBC Chapter 35)

Proponent: Carl Baldassarra, P.E., FSFPE, Chair, ICC Code Technology Committee
(cbaldassarra@RJAGroup.com)

Revise as follows:

904.12 (IBC [F] 904.12) Domestic cooking system in Group I-2 Condition 1. In Group I-2 Condition 1 occupancies where cooking facilities are installed in accordance with Section 407.2.5 of the *International Building Code*, the domestic cooking hood provided over the cooktop or range shall be equipped with an automatic fire-extinguishing system of a type recognized for protection of domestic cooking equipment. Pre-engineered automatic extinguishing systems shall be tested in accordance with UL 300A and listed and labeled for the intended application. The system shall be installed in accordance with this code, its listing and the manufacturer's instructions.

904.12.1 (IBC [F] 904.12.1) Manual system operation and interconnection. A manual actuation device for the hood suppression system shall be installed in accordance with Section 904.11.1 and 904.11.2

904.12.2 (IBC [F] 904.12.2) Portable fire extinguishers for domestic cooking equipment in Group I-2 Condition 1. A portable fire extinguisher complying with Section 906 shall be installed within 30 feet (9144 mm) travel distance of domestic cooking appliances.

**TABLE 906.1 (IBC [F] TABLE 906.1)
ADDITIONAL REQUIRED PORTABLE FIRE EXTINGUISHERS**

Section	Subject
904.12.2 (IBC 407.2.5)	Domestic cooking hoods in Group I-2 Condition 1 occupancies

(Portions of table not shown remain unchanged)

Add new standard to Chapter 80 (IBC Chapter 35) as follows:

UL

300A-2006 Outline of Investigation for Extinguishing System Units for Residential Range Top Cooking Surfaces

Reason: M76 clarified requirements for domestic appliance located in facilities such as nursing homes and assisted living where they are only used for domestic (not commercial) cooking. G65 requires a range hood with a UL300A protection system in a Group I-2 Condition 1 (nursing home). The purpose of this change is for the standard to be required in the Fire Code. The requirements follow what passed in G65 in Items 6, 7 and 9.

The ICC Board established the ICC Code Technology Committee (CTC) as the venue to discuss contemporary code issues in a committee setting which provides the necessary time and flexibility to allow for full participation and input by any interested party. The code issues are assigned to the CTC by the ICC Board as "areas of study". Information on the CTC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CTC effort can be downloaded from the following website: <http://www.iccsafe.org/cs/CTC/Pages/default.aspx>. Since its inception in April/2005, the CTC has held twenty five meetings - all open to the public.

Cost Impact: None

Analysis: The standard proposed for inclusion in the code, UL 300A, was accepted as a referenced standard in the IBC by approval of Group A code change G65-12 (AMPC).

904.12 (New) [IBC [F] 904.12 (New)], 202 (IBC 202), 902.1 (IBC [F]902.1), Chapter 80 (IBC Chapter 35)

Proponent: Jesse J. Beitel, Hughes Associates, Inc, representing United Technologies Corporation (jbeitel@haifire.com)

Revise as follows:

904.12 (IBC [F] 904.12) Automatic Water Mist Systems. Automatic water mist systems shall be permitted in applications that are consistent with the applicable listing or approvals and shall comply with Sections 904.12.1 through 904.12.3.

904.12.1 (IBC [F] 904.12.1) Design and Installation Requirements. Automatic water mist systems shall be designed and installed in accordance with Sections 904.12.1.1 through 904.12.1.4.

904.12.1.1 (IBC [F] 904.12.1.1) General. Automatic water mist systems shall be designed and installed in accordance with NFPA 750 and the manufacturer's instructions.

904.12.1.2 (IBC [F] 904.12.1.2) Actuation. Automatic water mist systems shall be automatically actuated.

904.12.1.3 (IBC [F] 904.12.1.3) Water supplies. Connections to a potable water supply shall be protected against backflow in accordance with the International Plumbing Code.

904.12.1.4 (IBC [F] 904.12.1.4) Secondary water supply. Where a secondary water supply is required for an automatic sprinkler system, an automatic water mist system shall be provided with an approved secondary water supply.

904.12.2 (IBC [F] 904.12.2) Water mist system supervision and alarms. Supervision and alarms shall be provided as required for automatic sprinkler systems in accordance with Section 903.4.

904.12.2.1 (IBC [F] 904.12.2.1) Monitoring. Monitoring shall be provided as required for automatic sprinkler systems in accordance with Section 903.4.1.

904.12.2.2 (IBC [F] 904.12.2.2) Alarms. Alarms shall be provided as required for automatic sprinkler systems in accordance with Section 903.4.2.

904.12.2.3 (IBC [F] 904.12.2.3) Floor control valves. Floor control valves shall be provided as required for automatic sprinkler systems in accordance with 903.4.3.

904.12.3 (IBC [F] 904.12.3) Testing and maintenance. Automatic water mist systems shall be tested and maintained in accordance with the International Fire Code.

Add new definition as follows:

SECTION 202 (IBC 202) GENERAL DEFINITIONS

AUTOMATIC WATER MIST SYSTEM. A system consisting of a water supply, a pressure source, and a distribution piping system with attached nozzles, which, at or above a minimum operating pressure, defined by its listing, discharges water in fine droplets meeting the requirements of NFPA 750 for the purpose of the control, suppression or extinguishment of a fire. Such systems include wet-pipe, dry-pipe and pre-action types. The systems are designed as engineered, pre-engineered, local-application or total flooding systems.

902.1 Definitions. The following terms are defined in Chapter 2:

AUTOMATIC WATER MIST SYSTEM

Add new standard to Chapter 80 (IBC Chapter 35) as follows:

NFPA

750-14 Standard on Water Mist Fire Protection Systems

Reason: This proposed change adds the concept of using an automatic water mist system for protection of structures only when the water mist systems are used within the systems' listed applications. As a listed alternative to sprinkler protection for specific classifications such as Light Hazard and Ordinary Hazard, for example, the proposed change allows water mist in the occupancies only where the listings identify the protection as appropriate. The proposal recognizes that based on performance, listings and field experience water mist is a viable alternative to the protection provided by automatic sprinklers. No new exceptions and reductions are requested. Water-mist systems are tested in environments identical to automatic sprinkler testing and have been found to achieve at least equal performance using less water than conventional sprinklers.

Automatic water mist systems are similar to sprinkler systems in that both are "an integrated system of underground and overhead piping designed in accordance with fire protection engineering standards. The system includes a suitable water supply. The portion of the system above the ground is a network of specially sized or hydraulically designed piping installed in a structure or area, generally overhead, and to which automatic sprinklers are connected in a systematic pattern. The system is usually activated by heat from a fire and discharges water over the fire area" [IFC 2012 Automatic Sprinkler System Definition]. Water mist systems use nozzles, operate at various pressures and are fed from a potable water supply or pressurized bottles.

Water mist systems have been approved by FM Approvals for occupancies similar to light hazard as defined by NFPA 13. The test criteria for these listings are found in FM 5560. Water mist systems have been listed by UL for Ordinary Hazard, Group I occupancies as defined by NFPA 13 (UL ZDPA.EX15843). These listings would permit water mist to be installed as the primary suppression system in a variety of Occupancy Classifications.

Automatic water mist systems provide a water efficient alternative to sprinkler systems. Water mist systems reduce the water supply demand which can be of significance in areas where municipal water supplies may be marginal or inadequate for conventional sprinklers. Reducing the water demand for automatic fire protection systems that are tested in the same manner by recognized laboratories to conventional sprinklers, will encourage the installation of fire protection systems in cities and towns where water shortages due to drought may be a problem. Furthermore, the reduced discharge from water mist systems, compared to conventional sprinklers, in turn reduces the potential water damage.

Water mist systems are listed for several occupancies based on the hazard definitions and have been used for years in buildings and on passenger ships specifically as a "sprinkler equivalent system" per Resolution A.800(19), November 1995 (IMO A800). A.800 details the testing criteria to establish water mist sprinkler equivalency for passenger ships. These passenger ships are similar to small cities in terms of the occupancies located on board, including assembly, business, mercantile, residential, and storage. The wide variety of occupancies located on passenger ships and history of use provides strong support for the equivalency of water mist systems to sprinkler systems. Water mist systems have been used in lieu of automatic sprinklers in buildings and on passenger ships for years due to water efficient design. The listings of the systems have been used as design guidance in buildings.

The acceptance of protecting buildings entirely by water-mist is appropriate and is being done today. Water mist works to extinguish, suppress or control fires in fully open compartments. The performance of these systems depends on pre-wetting of combustibles and cooling of hot gases, the same as conventional sprinklers, and they do not require sealed enclosures. Water-mist systems are tested in environments identical to automatic sprinkler testing and have been found to achieve at least equal performance using less water than conventional sprinklers.

Cost Impact: Water mist systems on original installation can be lower cost than traditional sprinkler system. For example, automatic water mist systems in locations with marginal water supplies would potentially provide cost savings as water tanks would not be required. Obviously, if the tank occupies rentable space, the lifetime costs of the water mist system become even more compelling.

Analysis: A review of the standard proposed for inclusion in the code, NFPA 750-14, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28), will be posted on the ICC website on or before April 1, 2013.

F147-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

904.12 (NEW)-F-BEITEL

F148 – 13

905.4

Proponent: Al Godwin, CBO, CPM, Aon Fire Protection Engineering, representing Aon Fire Protection Engineering Corporation (al.godwin@aon.com)

Revise as follows:

905.4 Location of Class I standpipe hose connections. Class I standpipe hose connections shall be provided in all of the following locations:

1. In every required interior *exit stairway*, a hose connection shall be provided for each floor level above, ~~and~~ below and at grade. Hose connections shall be located at an intermediate floor level landing between floors, unless otherwise approved by the fire code official.
- 2 through 6 *(No change to current text)*

Reason: Since hose connections are placed at intermediate landings between floors, it is not clear as to which floor the hose connection serves. However, by not listing “at grade” the provision could be read that one is not required to serve the floor at grade, whichever intermediate landing that might be, leading to some challenges of its meaning. Hopefully, this provides clarification.

Cost Impact: This appears to be a correction. As such, it is not an increase in cost over what the original intent of the code provision should require.

F148-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

905.4-F-GODWIN

F149 – 13

905.9 (IBC [F] 905.9)

Proponent: Bob D. Morgan, P.E., Fort Worth, TX Fire Department representing Fire Advisory Board to North Central Texas Council of Governments

Revise as follows:

905.9 (IBC [F] 905.9) Supervision. Supervision of standpipes shall be in accordance with Sections 905.9.1 and 905.9.2.

905.9.1 (IBC [F] 905.9.1) Valve Supervision. *(unchanged)*

905.9.2 (IBC [F] 905.9.2) Manual dry standpipes. Manual dry standpipe systems shall be supervised with a minimum of 10 psig and a maximum of 40 psig air pressure and monitored by a low air pressure alarm.

Reason: Improves the integrity of such systems for utilization in a fire event, which could otherwise have all hose valves opened or develop multiple leaks without anyone knowing until such system is charged with water.

Cost Impact: The code change proposal will increase the cost of construction of such systems to install an air compressor and low air pressure alarm.

F149-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

905.2-F-MORGAN

F150 – 13

901.8.2 (New)

Proponent: William Freer, New York State Office of Fire Prevention and Control
(WFreer@DHSES.ny.gov)

Add new text as follows:

901.8.2 Removal of occupant use hose. Removal of the occupant use hose line attached to a Class II standpipe system or a Class III standpipe system shall be permitted where either of the following conditions exist:

1. The building is equipped with a Class I standpipe system.
2. The building is not required to be equipped with a Class I standpipe system and the building is equipped throughout with an approved automatic sprinkler system in accordance with Section 903.3.1.1.

Reason: The current code does not require occupant use hoses in as many locations as were required in previous codes. There has been a shift in the philosophy of whether or not occupants should be asked to attempt to extinguish the fire or evacuate the structure. Most of the population is now being taught to evacuate the building, not fight the fire. This shift is mainly due to the safety risk of having a non-trained person attempting to fight a fire with more than a fire extinguisher. Many jurisdictions have already enacted local legislation or code changes to address this issue.

The City of Philadelphia has added the following:

F-905.11 Existing buildings. Existing structures with occupied floors located more than 50 feet (15,240 mm) above or below the lowest level of fire department vehicle access shall be equipped with standpipes installed in accordance with Section F-905. The standpipes shall have an approved fire department connection with hose connections at each floor level above or below the lowest level of fire department vehicle access. [The fire code official is authorized to approve the installation of manual standpipe systems to achieve compliance with this section where the responding fire department is capable of providing the required fire flow at the highest standpipe outlet.] *These requirements shall also apply to buildings that were granted variances prior to January 1, 2004 to omit standpipes from the required exit stairways. Buildings or structures that are not in compliance with Section F-905 on the effective date of this code, shall, with written request to and upon written approval from the Fire Department, be granted three years from the effective date of this code to comply.*

Exceptions:

1. In existing buildings having the highest occupied floors located not more than 75 feet above the lowest level of fire department vehicle access, Class I standpipe systems are permitted to be manual wet systems.
2. Standpipe systems installed prior to January 1, 1995 that provide a residual pressure of 65 psi (448 kPa) or greater at the highest hose outlet are exempt from the requirement to provide a residual pressure of 100 psi (690 kPa) at the highest hose outlet.
3. Standpipe systems with a residual pressure of less than 100 psi (690 kPa) at the topmost hose outlet are permitted where:
 - 3.1 The building existing prior to the effective date of this code;
 - 3.2 The building is equipped throughout with an automatic sprinkler system; and
 - 3.3 The highest floor level is not more than 150 feet (45 720 mm) above the lowest level of fire department vehicle access,

F-905.11.1 Removal of occupant use hoseline or Class II standpipe systems. Removal of the hoseline attached to a Class II standpipe system or a Class III standpipe system that is not required by this code, or removal of an entire Class II standpipe system is permitted where the following conditions are met:

1. Removal of hoseline only: The building is equipped with a Class I standpipe system or the building is not required to have a Class I system.
2. Removal of the Class II standpipe system is permitted where one of the following exists:
 - 2.1 The building is equipped throughout with an automatic fire-extinguishing system and has more than one Class I standpipe hose outlet riser in a multi-exit building or at least one riser in a single exit building;
 - 2.2 The building is in the process of being equipped throughout with an automatic fire-extinguishing system and there is more than one standpipe hose outlet riser in a multi-exit building or there is at least one riser in a single exit building. When the sprinklers on a floor have been placed in service, the Class II standpipe hose stations on that floor are permitted to be removed; or
 - 2.3 The building is not equipped throughout with an automatic fire-extinguishing system, there is more than one automatic wet Class I standpipe hose outlet riser in a multi-exit building and there is at least one

automatic wet riser in a single exit building.

The City of San Francisco added:

4.09 Removal of Class II Standpipe Hose Cabinets in Sprinkler Retrofitted Buildings (PDF)

Reference: 2010 S.F.F.C. 901.8

Section 901.8 of the 2010 SFFC requires written approval from the fire code official in order to remove existing fire appliances. In order to speed the permit process, buildings subject to the San Francisco High-rise Sprinkler Ordinance will be permitted to remove Class II Standpipe hose cabinets on individual floors after they have been fully sprinklered. The applicant shall state his or her intention to remove the hose cabinets on the approved sprinkler plans. Buildings not subject to the ordinance will continue to require written approval from the fire code official in order to remove any fire appliance. These written requests will be considered on a case-by-case basis.

Canada also allows the removal of occupant hoses but requires more signage in places where it is done. It should also be noted that occupant use hoses are not required by NFPA 14 as follows:

1. NFPA 14--2007, Standard for the Installation of Standpipe and Hose Systems details the design and installation of standpipe systems.
 - 7.3.4 Class III Systems. Class III systems shall be provided with hose connections as required for both Class I and Class II systems.
 - 7.3.4.1 Where the building is protected throughout by an approved automatic sprinkler system in accordance with NFPA 13, Standard for the Installation of Sprinkler Systems, and NFPA 13R, Standard for the Installation of Sprinkler Systems in Residential Occupancies up to Four Stories in Height, Class II hose stations for use by trained personnel shall not be required, subject to the approval of the local fire department, provided that each Class I hose connection is 2 1/2 in. and is equipped with a 2 1/2 in. x 1 1/2 in. reducer and a cap attached with a chain.

This code change would not increase the cost of construction but would decrease the cost of maintenance and upkeep.

Cost Impact: The code change proposal will not increase the cost of construction.

F150-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

905.11 (NEW)-F-FREER

F151 – 13

906.1 (IBC [F] 906.1)

Proponent: Dave Fable representing U.S. General Services Administration, Public Buildings Service

Revise as follows:

906.1 (IBC [F] 906.1) Where required. Portable fire extinguishers shall be installed in the following locations.

1. In new and existing Group A, B, E, F, H, I, M, R-1, R-2, R-4 and S occupancies.

Exception Exceptions:

1. In Group R-2 occupancies, portable fire extinguishers shall be required only in locations specified in Items 2 through 6 where each *dwelling unit* is provided with a portable fire extinguisher having a minimum rating of 1-A:10-B:C.
2. In new and existing Group B occupancies equipped throughout with quick-response sprinklers, portable fire extinguishers shall be required only in locations specified in Items 2 through 6.
2. Within 30 feet (9144 mm) of commercial cooking equipment.
3. In areas where flammable or *combustible liquids* are stored, used or dispensed.
4. On each floor of structures under construction, except Group R-3 occupancies, in accordance with Section 3315.1.
5. Where required by the sections indicated in Table 906.1.
6. Special-hazard areas, including but not limited to laboratories, computer rooms and generator rooms, where required by the *fire code official*.

Reason: The intent of this code change is to re-introduce an IFC code requirement that was in the past editions of the IFC (i.e., editions 2000 to 2009). However, in the 2012 edition of the IFC, the subject exception was removed from the IFC without any technical substantiation.

Exception #2 acknowledges the reliable advantages of an automatic sprinkler system designed to comply with NFPA 13. Group B occupancies are considered light hazard occupancies and must be protected by quick response sprinklers (see Section 903.3.2). The faster acting sprinklers and the lower fuel load associated with Group B occupancies alleviate the need for portable fire extinguishers to be installed throughout non-hazardous areas within this occupancy. In addition, the evacuation strategy for this occupancy is for occupants to evacuate building or relocate to a safe area within the building in lieu of delaying evacuation/relocation and having occupants attempt to utilize a portable fire extinguisher to try to extinguish a fire.

It should be noted that building occupants in Group B occupancies are not required to be trained in the use of portable fire extinguishers since training building occupants in the use of portable fire extinguishers is not addressed within the IFC nor is there a requirement in the IFC stating that portable fire extinguishers have been installed for occupant use. In addition, fire department personnel typically will also not use the portable fire extinguishers which have been installed within a building due to the uncertainty they have regarding the subject extinguisher operating when needed. Therefore, the installation of this type of manual extinguishing equipment throughout a Group B occupancy equipped with an operational sprinkler system utilizing quick-response sprinklers is questionable and not warranted or cost effective (e.g., installation costs, maintenance costs, etc.) over the life of a building.

Cost Impact: The code change proposal will not increase the cost of construction.

F151-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

906.1-F-FRABLE

F152 – 13

907.1.2 (IBC [F] 907.1.2)

Proponent: Thomas P. Hammerberg, representing Automatic Fire Alarm Association
(TomHammerberg@afaa.org)

Revise as follows:

907.1.2 (IBC [F] 907.1.2) Fire alarm shop drawings. Shop drawings for fire alarm systems shall be submitted for review and approval prior to system installation, and shall include, but not be limited to, all of the following where applicable to the system being installed:

1. A floor plan that indicates the use of all rooms.
2. Locations of alarm-initiating devices.
3. Locations of alarm notification appliances, including candela ratings for visible alarm notification appliances.
4. Design minimum audibility level for occupant notification.
- ~~45.~~ Location of fire alarm control unit, transponders and notification power supplies.
- ~~56.~~ Annunciators.
- ~~67.~~ Power connection.
- ~~78.~~ Battery calculations.
- ~~89.~~ Conductor type and sizes.
- ~~910.~~ Voltage drop calculations.
- ~~1011.~~ Manufacturers' data sheets indicating model numbers and listing information for equipment, devices and materials.
- ~~1412.~~ Details of ceiling height and construction.
- ~~1213.~~ The interface of fire safety control functions.
- ~~1314.~~ Classification of the supervising station.

Reason: The "where applicable" addition is necessary to clarify that only those items applicable to the system being installed are required to be submitted. For example, if the system is only to monitor a sprinkler system and no fire alarm notification appliances are required, there is no need to provide voltage drop calculations or minimum audibility levels that the system will be designed to meet.

The other change is necessary to assist fire alarm designers, installers and authorities having jurisdiction with meeting minimum audibility requirements per NFPA 72. This change will decrease the amount of interpretation issues that usually arise at the final acceptance test and will result in better designed and installed systems.

Cost Impact: none

F152-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

907.1.2-F-HAMMERBERG

F153 – 13

907.2 (IBC [F] 907.2)

Proponent: Gregory Nicholls, AIA, City of Mason, Ohio, representing the City of Mason

Revise as follows:

907.2 (IBC [F] 907.2) Where required—~~new buildings and structures~~. An *approved* fire alarm system installed in accordance with the provisions of this code and NFPA 72 shall be provided in ~~new~~ buildings and structures in accordance with Sections 907.2.1 through 907.2.23 and provide occupant notification in accordance with Section 907.5, unless other requirements are provided by another section of this code.

A minimum of one manual fire alarm box shall be provided in an *approved* location to initiate a fire alarm signal for fire alarm systems employing automatic fire detectors or water-flow detection devices. Where other sections of this code allow elimination of fire alarm boxes due to sprinklers, a single fire alarm box shall be installed.

Exceptions:

1. The manual fire alarm box is not required for fire alarm systems dedicated to elevator recall control and supervisory service.
2. The manual fire alarm box is not required for Group R-2 occupancies unless required by the *fire code official* to provide a means for fire watch personnel to initiate an alarm during a sprinkler system impairment event. Where provided, the manual fire alarm box shall not be located in an area that is accessible to the public.

Reason: In the 2009 IBC and IFC, this section was added based on Fire Code scoping that covered requirements for new buildings in Section 907.2 and existing buildings in Section 907.3. The IBC just had the language copied verbatim for 907.2 only, even though the “new buildings” part is not relevant. All requirements in the IBC, chapters 2-33 are about new construction, and their application is then modified by Chapters 1 and 34 for existing buildings.

In the 2012 IFC, the requirements for existing buildings moved to Chapter 11, thereby making the “new building” designation irrelevant in the Fire Code as well.

The current wording has caused mis-interpretation on the part of some owners and designers, as they have taken this to mean that change of occupancy projects, for example, do not need to comply with Section 907.2, as they are existing buildings and specifically are exempt. Deletion of references to “new” will provide clarity and remove irrelevant language for both the IFC and IBC, and make the text consistent with the rest of these documents.

Cost Impact: The code change proposal will not increase the cost of construction, as this only a matter of clarification for existing requirements.

F153-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

907.2-F-NICHOLLS

F154 – 13

907.2.1 (IBC [F] 907.2.1)

Proponent: Timothy W. Fisher, State of Alaska, Department of Public Safety, Division of Fire and Life Safety, representing Alaska State Fire Marshal's Office & ICC Alaska Central Chapter

Revise as follows:

907.2.1 (IBC [F] 907.2.1) Group A. A manual fire alarm system that activates the occupant notification system in accordance with Section 907.5 shall be installed in Group A occupancies ~~where the occupant load due to the assembly occupancy is 300 or more where a required automatic sprinkler system is installed, the automatic sprinkler system shall be connected to the building fire alarm system. Group A occupancies not separated from one another in accordance with Section 707.3.9 of the International Building Code shall be considered as a single occupancy for the purposes of applying this section.~~ Portions of Group E occupancies occupied for assembly purposes shall be provided with a fire alarm system as required for the Group E occupancy.

Exception: Manual fire alarm boxes are not required when the building is equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1 and the occupant notification appliances will activate throughout the notification zones upon sprinkler waterflow.

Reason: In the 2006 International Code Adoption, the requirement for a Fire Sprinkler System in an A-2 occupancy was reduced to an occupant load of 100 from 300. Currently, a Fire Alarm System is required in an A occupancy when the occupant load is greater than 300. This has left a void of 100 to 300 occupants.

Previously, the Fire Alarm System requirements mirrored the Fire Sprinkler System requirements at 300 occupants; it seemed prudent to also require a fire alarm system at 100 occupants in an A-2 occupancy, same as the sprinkler requirement.

The intent of the revision is to remove a set number of (300) for occupant loading from the Fire Alarm System requirements for Assembly (A) Occupancy, then requiring a Fire Alarm System based on the requirements in the Fire Sprinkler System section. Then it would render the Sentence with Section 707.3.9 "Fire Areas" obsolete as it would be based on the Fire Sprinkler System fire area requirements.

The Station Night Club incident didn't have sprinklers, causing a change in the sprinkler requirements where as the Fire Alarm System requirements were not adjusted for A-2 occupancies in the event of an emergency. This change would require notification appliances that would ensure occupants are alerted within an A-2 occupancy during a sprinkler activation or a kitchen hood and duct suppression system activation.

Revising this code section will realign the fire systems according to the historical requirements; provide an acceptable level of fire and public safety as well as providing notification appliances throughout the facility to notify occupants that there is an emergency in the facility and to promptly evacuate, saving lives.

Cost Impact: Cost varies on location, size, and company for the installation of Fire Alarm System (Notification Appliances Only)

F154-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

907.2.1-F-FISHER

F155 – 13

907.2.1 (IBC [F] 907.2.1)

Proponent: Daniel E. Nichols, P.E., New York State Department of State (dan.nichols@dos.ny.gov)

Revise as follows:

907.2.1 (IBC [F] 907.2.1) Group A. A manual fire alarm system that activates the occupant notification system in accordance with Section 907.5 shall be installed in Group A occupancies where the occupant load due to the assembly occupancy is 300 or more. Group A occupancies that share portions of the exit or exit access or are not separated from one another in accordance with Section 707.3.9 of the *International Building Code* shall be considered as a single occupancy for the purposes of applying this section. Portions of Group E occupancies occupied for assembly purposes shall be provided with a fire alarm system as required for the Group E occupancy.

Reason: This code change proposal is to require a fire alarm system when the exits or exit access of a building is used to serve a combined occupant load of all assembly occupancies within a building above the threshold amount.

The State of New York has had experience in both fire losses and new building construction with this topic. First, the Stouffer's Inn and conference center in 1981 killed 23 top-level executives when a fire in a common hallway trapped occupants in several small (50-100 person) conference rooms. Second, the fire area method of separating A-3 occupancies has provided a way to not protect college and university lecture room buildings by separating the spaces but having room occupant loads approaching 1,000 people in the common hallway.

Cost Impact: This proposal will raise the cost of construction when combined paths of exiting are utilized.

F155-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

907.2.1-F-NICHOLS

F156 – 13

907.2.1.1 (IBC [F] 907.2.1.1), 907.5.2.2.3 (New) (IBC [F] 907.5.2.2.3 (New))

Proponent: Vince Baclawski, representing National Electrical Manufacturers Association (NEMA)
(vin_baclawski@nema.org)

Revise as follows:

907.2.1.1 (IBC [F] 907.2.1.1) System initiation in Group A occupancies with an occupant load of 1,000 or more. Activation of the fire alarm in Group A occupancies with an *occupant load* of 1,000 or more shall initiate a signal using an emergency voice/alarm communications system in accordance with Section 907.5.2.2.

Exception: ~~Where approved, the prerecorded announcement is allowed to be manually deactivated for a period of time, not to exceed 3 minutes, for the sole purpose of allowing a live voice announcement from an approved, constantly attended location.~~

907.5.2.2.3 (IBC [F] 907.5.2.2.3) Resumption of Pre-recorded Voice Messages. Where approved, the pre-recorded voice announcement shall be manually deactivated for a period of time for the sole purpose of allowing a live voice announcement from an approved, constantly attended location. A risk analysis in accordance with NFPA 72 shall be used to determine the resumption of the pre-recorded voice announcement.

(Renumber subsequent sections)

Reason: The intent of this proposal is to:

1. Relocate the resumption of pre-recorded voice message requirement from a section covering assembly occupancies only to section dealing with emergency voice alarm communication systems.
2. Leaves the decision for the length of the live voice message and automatic resumption of pre-recorded voice message up to the stakeholders after completion of the risk analysis.

This proposal relocates the resumption of pre-recorded voice message requirement so it will be applied to all occupancies requiring emergency voice alarm communication systems not just assembly occupancies.

The mandatory 3 minute time limit for live voice announcements has the potential of interrupting critical life safety instructions to the building occupants. These live instructions could exceed 3 minutes because they are usually very specific and have the potential for changing rapidly.

Every facility is unique and has specific risks. The stakeholders must clearly define the potential risks to their facility and design a system that accounts for them. The requirement for the automatic resumption of the pre-recorded announcement instructions may jeopardize the life safety of the building occupants because pre-recorded instructions could be different and in direct conflict with the live instructions by the emergency responders. The key to defining these risks is to perform a risk analysis before designing and installing an emergency voice/alarm communication system.

Cost Impact: None

907.2.1.1-F-BACLAWSKI

F157 – 13

907.2.3 (IBC [F] 907.2.3)

Proponent: Frank G. Castelvechi, III, PE, representing County of Henrico, Virginia
(cas13@co.henrico.va.us)

Revise as follows:

907.2.3 (IBC [F] 907.2.3) Group E. A manual fire alarm system that initiates the occupant notification signal utilizing an emergency voice/alarm communication system meeting the requirements of Section 907.5.2.2 and installed in accordance with Section 907.6 shall be installed in Group E occupancies. When *automatic sprinkler systems* or smoke detectors are installed, such systems or detectors shall be connected to the building fire alarm system.

Exceptions:

1. A manual fire alarm system is not required in Group E occupancies with an *occupant load* of ~~30~~ 50 or less.
2. Manual fire alarm boxes are not required in Group E occupancies where all of the following apply:
 - 2.1. Interior *corridors* are protected by smoke detectors.
 - 2.2. Auditoriums, cafeterias, gymnasiums and similar areas are protected by *heat detectors* or other *approved* detection devices.
 - 2.3. Shops and laboratories involving dusts or vapors are protected by *heat detectors* or other *approved* detection devices.
3. Manual fire alarm boxes shall not be required in Group E occupancies where the building is equipped throughout with an *approved automatic sprinkler system* installed in accordance with Section 903.3.1.1, the emergency voice/alarm communication system will activate on sprinkler water flow and manual activation is provided from a normally occupied location.

Reason: Changing the threshold from 50 to 30 imposed this requirement on most school trailers and small daycare centers by moving the classroom size from 1000 sq ft to 600 sq ft. Requiring an expensive voice alarm system in a school trailer or small storefront daycare center is a ludicrous imposition of significant costs to schools and small businesses. In these small buildings any emergency situation would be readily apparent to all occupants—if you cannot see the flames, smell the smoke or feel the heat in a one room schoolhouse-- a synthesized voice is not going to do any good and may well interfere with the children understanding the teachers instructions.

There is no record of fire deaths and injuries in these occupancies to justify these added expenses. The children in these occupancies are required to be under competent adult supervision.

Cost Impact: This will reduce the cost of construction

F157-13

	Assembly:	ASF	AMF	DF

907.2.3 #1-F-CASTELVECCHI

F158 – 13

907.2.3 (IBC [F] 907.2.3)

Proponent: Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azubiamia@yahoo.com)

Revise as follows:

907.2.3 (IBC [F] 907.2.3) Group E. A manual fire alarm system that initiates the occupant notification signal utilizing an emergency voice/alarm communication system meeting the requirements of Section 907.5.2.2 and installed in accordance with Section 907.6 shall be installed in Group E occupancies. When automatic sprinkler systems or smoke detectors are installed, such systems or detectors shall be connected to the building fire alarm system.

Exceptions:

1. A manual fire alarm system is not required in Group E occupancies with an occupant load of ~~30~~ 50 or less.
2. Emergency voice/ alarm communication systems meeting the requirements of Section 907.5.2.2 and installed in accordance with Section 907.6 shall not be required in Group E occupancies with occupant loads of 100 or less, provided that activation of the manual fire alarm system initiates an approved occupant notification signal in accordance with Section 907.5.
- ~~23.~~ Manual fire alarm boxes are not required in Group E occupancies where all of the following apply:
 - ~~2-1~~ 31. Interior corridors are protected by smoke detectors.
 - ~~2-2~~ 32. Auditoriums, cafeterias, gymnasiums and similar areas are protected by heat detectors or other approved detection devices.
 - ~~2-3~~ 33. Shops and laboratories involving dusts or vapors are protected by heat detectors or other approved detection devices.
- ~~34.~~ Manual fire alarm boxes shall not be required in Group E occupancies where the building is equipped throughout with an approved automatic sprinkler system installed in accordance with Section 903.3.1.1, the emergency voice/alarm communication system will activate on sprinkler water flow and manual activation.

Reason: Many small schools or day cares consist of one or two rooms. For such small buildings, there is no need to install a notification system to warn occupants of fires or other emergencies, as occupants are typically in close visual or audible contact with all occupied spaces and with each other. This arrangement provides for adequate means to notify all occupants of the building of potential hazardous conditions to initiate emergency actions, including evacuation.

The threshold in Exception 1 has been reduced from 50 to 30 with no apparent loss history. The testimony presented by the proponent of Code Change F107-09/10 was that the number was modified to correlate the occupant load trigger for 1-HR rated corridors. It is common that individual classrooms contain an occupant load of 30 students. It seems that a more appropriate occupant load trigger is the egress provision which requires a second exit at an occupant load of 50, not 30.

An alarm system in a single classroom, or set of small classrooms, does not appear justified. It appears that the appropriate 'occupant load trigger' is 50 since that is when a fire alarm system has been required for many years without any major incidents. Therefore, this proposal will move the trigger to an occupant load of 50 to determine when a manual fire alarm system is required.

Exception 2 is proposed to be added. This exception would require the emergency voice communication system when the occupant load exceeds 100, as buildings with larger numbers of occupants may necessitate detailed instructions regarding evacuation, relocation, or other actions to ensure safety of building occupants. Often, these buildings include multiple floors, fire areas, and egress paths, and occupants may require notification of more detailed or modified instructions on alternate courses action other than those stated in a standard evacuation plan.

The result of this proposal is that when the occupant load is:

- 50 or less – fire alarm system is not required
- 51 to 100 – manual fire alarm system is required
- 101 or more – manual fire alarm system with emergency voice/alarm communication system

Cost Impact: The code change proposal will reduce the cost of construction.

F158-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

907.2.3-F-ZUBIA-FCAC

F159 – 13

907.2.3 (IBC [F] 907.2.3)

Proponent: Frank G. Castelvechi, III, PE, representing County of Henrico, Virginia
(cas13@co.henrico.va.us)

Revise as follows:

907.2.3 (IBC [F] 907.2.3) Group E. A manual fire alarm system that initiates the occupant notification signal utilizing an emergency voice/alarm communication system meeting the requirements of Section 907.5.2.2 and installed in accordance with Section 907.6 shall be installed in Group E occupancies. When *automatic sprinkler systems* or smoke detectors are installed, such systems or detectors shall be connected to the building fire alarm system.

Exceptions:

1. A manual fire alarm system is not required in Group E occupancies with an *occupant load* of 30 or less.
2. Manual fire alarm boxes are not required in Group E occupancies where all of the following apply:
 - 2.1. Interior *corridors* are protected by smoke detectors.
 - 2.2. Auditoriums, cafeterias, gymnasiums and similar areas are protected by *heat detectors* or other *approved* detection devices.
 - 2.3. Shops and laboratories involving dusts or vapors are protected by *heat detectors* or other *approved* detection devices.
3. Manual fire alarm boxes shall not be required in Group E occupancies where the building is equipped throughout with an *approved automatic sprinkler system* installed in accordance with Section 903.3.1.1, the emergency voice/alarm communication system will activate on sprinkler water flow and manual activation is provided from a normally occupied location.
4. An occupant notification system meeting the requirements of Section 907.5.2 without emergency voice/alarm communication system features is permitted where the occupant load is 1000 or less.

Reason: Requiring a voice alarm system for educational uses imposes significant unnecessary costs on daycares and school systems that are already short of funds. Most schools already have public address systems that can be used for emergency notification. The 1000 occupant threshold proposed here is the same as that for assembly buildings with occupants that are less familiar with the building, often do not have public address systems and may involve the consumption of alcoholic beverages. Requiring an expensive voice alarm system in a small storefront daycare center, a small school, or a school trailer is a ludicrous imposition of significant costs on schools and small businesses.

The fire record these occupancies does not justify these added expenses. The children in these occupancies are required to be under competent adult supervision.

Cost Impact: This will reduce the cost of construction

907.2.3 #2-F-CASTELVECCHI

F160 – 13

907.2.6 (IBC [F] 907.2.6), 907.5.2.1 (IBC [F] 907.5.2.1), 907.5.2.3 (IBC [F] 907.5.2.3)

Proponent: John Williams, CBO, Chair, ICC Ad Hoc Committee on Health Care
(john.williams@doh.wa.gov)

Revise as follows:

907.2.6 (IBC [F] 907.2.6) Group I. A manual fire alarm system that activates the occupant notification system in accordance with Section 907.5 shall be installed in Group I occupancies. An automatic smoke detection system that activates the occupant notification system in accordance with Section 907.5 shall be provided in accordance with Sections 907.2.6.1, 907.2.6.2 and 907.2.6.3.3.

Exceptions:

1. Manual fire alarm boxes in sleeping units of Group I-1 and I-2 occupancies shall not be required at exits if located at all care providers' control stations or other constantly attended staff locations, provided such stations are visible and continuously accessible and that travel distances required in Section 907.4.2.1 are not exceeded.
2. Occupant notification systems are not required to be activated where private mode signaling installed in accordance with NFPA 72 is approved by the fire code official and staff evacuation responsibilities are included in the fire safety and evacuation plan required by Section 404.

907.5.2.1 (IBC [F] 907.5.2.1) Audible alarms. Audible alarm notification appliances shall be provided and emit a distinctive sound that is not to be used for any purpose other than that of a fire alarm.

Exceptions:

1. ~~Visible alarm notification appliances shall be allowed in lieu of audible alarm notification appliances in critical care areas of Group I-2 occupancies.~~ Audible alarm notification appliances are not required in critical care areas of Group I-2 Condition 2 occupancies that are in compliance with Section 907.2.6, Exception 2.
2. A visible alarm notification appliance installed in a nurses' control station or other continuously attended staff location in a Group I-2 Condition 2 suite shall be an acceptable alternative to the installation of audible alarm notification appliances throughout the suite in Group I-2 Condition 2 occupancies that are in compliance with Section 907.2.6, Exception 2.
- 2.3. Where provided, audible notification appliances located in each occupant evacuation elevator lobby in accordance with Section 3008.10.1 of the *International Building Code* shall be connected to a separate notification zone for manual paging only.

907.5.2.3 (IBC [F] 907.5.2.3) Visible alarms. Visible alarm notification appliances shall be provided in accordance with Sections 907.5.2.3.1 through 907.5.2.3.4.

Exceptions:

1. Visible alarm notification appliances are not required in alterations, except where an existing fire alarm system is upgraded or replaced, or a new fire alarm system is installed.
2. Visible alarm notification appliances shall not be required in exits as defined in Section 1002.1.
3. Visible alarm notification appliances shall not be required in elevator cars.
4. Visual alarm notification appliances are not required in critical care areas of Group I-2 Condition 2 occupancies that are in compliance with Section 907.2.6, Exception 2.

Reason: This proposal is submitted by the ICC Ad Hoc Committee for Healthcare (AHC). The AHC was established by the ICC Board of Directors to evaluate and assess contemporary code issues relating to hospitals and ambulatory healthcare facilities. The AHC is composed of building code officials, fire code officials, hospital facility engineers, and state healthcare enforcement representatives. The goals of the committee are to ensure that the ICC family of codes appropriately addresses the fire and life safety concerns of a highly specialized and rapidly evolving healthcare delivery system. This process is part of a joint effort between ICC and the American Society for Healthcare Engineering (ASHE), a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. Since its inception in April, 2011, the AHC has held 8 open meetings and over 100 workgroup calls which included members of the AHC as well as any interested party to discuss and debate the proposed changes. All meeting materials and reports are posted on the AHC website at: <http://www.iccsafe.org/cs/AHC/Pages/default.aspx>

The proposed changes are a clarification of the application of 'private mode' signaling as allowed by NFPA 72 and provide linkage to the emergency action plan necessary for 'private mode' to be safely implemented. A section-by-section summary follows:

Section 907.2.6: The change to Exception 2 links the use of "private mode" signaling under NFPA 72 to the emergency action plan portion of the code. The use of private mode appliances relies on a trained staff to respond and provide for occupant evacuation/defend in place actions.

Section 907.5.2.1: Exception 1 is proposed for modification to eliminate the requirement for the visible signal and the audible signal in Group I-2 hospital critical care areas, operating rooms for example. In private mode, as permitted by Section 907.2.6, Exception 1, there is still a requirement for an audible alarm notification from appliances, though at a much lower decibel level meant to alert staff of the alarm activation. The current language at Section 907.5.2.1, Exception 1 allows that audible alarm to be eliminated from critical care areas (operating rooms) in exchange for a visual notification device. However, the visual signal device also creates a distraction in critical care areas that may not be able to immediately stop a patient procedure and this proposal is to eliminate the visual alarm notification and to link the exception back to the primary allowance for private mode where we have provided for a link to the emergency action plan. The emergency action plan would include provisions for alerting of critical area staff and the actions to be taken.

A new second exception is added to this section to allow for an alarm indicator in a control area of a hospital suite in lieu of audible devices throughout the suite. In a suite arrangement the "control area" is the centrally manned location for staff monitoring patients in the separate rooms. An alarm indicator at this location will alert staff for response in a more effective and efficient manner.

Section 907.5.2.3: A fourth exception is added here to correlate the allowance for eliminating the audible and visual alarm devices from the critical care areas and to link the exception back to the primary allowance for private mode where we have provided for a link to the emergency action plan.

The emergency plan should reflect the response to the private mode alarm signals including the response necessary in critical care areas and who is responsible for alerting critical care area staff.

Cost Impact: This proposal will not increase the cost of construction.

907.2.6-F-WILLIAMS-ADHOC

F161 – 13

907.2.9.3 (IBC [F] 907.2.9.3)

Proponent: Jeffrey M. Shapiro, International Institute of Ammonia Refrigeration
(jeff.shapiro@intlcodeconsultants.com)

Revise as follows:

907.2.9.3 (IBC [F] 907.2.9.3) Group R-2 college and university buildings. An automatic smoke detection system that activates the occupant notification system in accordance with Section 907.5 shall be installed in Group R-2 occupancies operated by a college and or university for student or staff housing buildings in the following locations:

1. Common spaces outside of *dwelling units* and *sleeping units*.
2. Laundry rooms, mechanical equipment rooms, and storage rooms.
3. All interior corridors serving *sleeping units* or *dwelling units*.

Exception: An automatic smoke detection system is not required in buildings that do not have interior corridors serving sleeping units or dwelling units and where each sleeping unit or dwelling unit either has a means of egress door opening directly to an exterior exit access that leads directly to an exit or a means of egress door opening directly to an exit.

Required smoke alarms in *dwelling units* and *sleeping units* in Group R-2 occupancies operated by a college and or university for student or staff housing buildings shall be interconnected with the fire alarm system in accordance with NFPA 72.

~~**Exception:** An automatic smoke detection system is not required in buildings that do not have interior corridors serving sleeping units or dwelling units and where each sleeping unit or dwelling unit either has a means of egress door opening directly to an exterior exit access that leads directly to an exit or a means of egress door opening directly to an exit.~~

Reason: This proposal intends to better define what constitutes “college and university buildings.” As proposed, such buildings would include those that are operated by a college or university for student or staff housing (regardless of whether the college or university actually owns the building). The difficulty with the current text is determining how it applies to off-campus housing that is open to the general public. Most apartment complexes near a university will probably contain some percentage of student tenants, and for that matter, complexes many miles away from a campus may have student tenants as well. The current code text provides no guidance in determining a threshold at which a “normal” apartment building becomes subject to the provisions of this section.

Based on a discussion last cycle with the proponents of this section, when it was added to the code, it is our understanding that the intent was to address “dormitory style” student housing that is operated by a college or university, and the proposed text intends to clarify that point so that the intended application of the code will be clearly conveyed.

In addition, the existing exception has been relocated in the section so that it is properly placed with respect to the paragraph that it applies to. No change has been made to the exception text.

Cost Impact: The code change proposal will not increase the cost of construction.

F161-13

	Assembly:	ASF	AMF	DF

907.2.9.3-F-SHAPIRO

F162 – 13

IFC: 907.2.11 (IBC [F] 907.2.11), 907.10 (New) (IBC [F] 907.10 (New)); IPMC: [F] 704.5

Proponent: Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azubiamia@yahoo.com)

Revise as follows:

907.2.11 Single- and multiple-station smoke alarms. *Listed* single- and multiple-station smoke alarms complying with UL 217 shall be installed in accordance with Sections 907.2.11.1 through 907.2.11.4 and NFPA 72. Single- and multiple-station smoke alarms shall be maintained in accordance with Section 907.10.

907.10 Single- and multiple-station smoke alarms. Single- and multiple-station smoke alarms shall be tested and maintained in accordance with the manufacturer's instructions. Smoke alarms that no longer function shall be replaced. Smoke alarms installed in one- and two-family dwellings shall be replaced not more than 10 years from the date of manufacture marked on the unit, or if the date of manufacture cannot be determined.

Add new text as follows:

IPMC [F] 704.5 Maintenance. Smoke alarms shall be tested and maintained in accordance with the manufacturer's instructions. Smoke alarms that no longer function shall be replaced. Smoke alarms installed in Group R or I-1 occupancies shall be replaced not more than 10 years from the date of manufacture marked on the unit, or if the date of manufacture cannot be determined.

Reason: This proposal is submitted by the ICC Fire Code Action Committee (FCAC). This ICC committee was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portions thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the Fire-CAC has held 6 open meetings and numerous Regional Work Group and Task Group meetings and conference calls which included members of the committees as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the FAC website at: <http://www.iccsafe.org/cs/CAC/Pages/default.aspx>.

This proposal supplements the requirements in Section 901.4 for testing and maintaining smoke alarms, and specifies when the devices need to be replaced. The proposed requirements are consistent with NFPA 72 provisions. In particular NFPA 72 requires smoke alarms installed in one- and two-family dwellings to not remain in service longer than 10 years from the date of manufacture, and UL 217 requires the date of manufacture to be marked on the smoke alarms.

It is recognized that it may not always be practical for the code official to enforce the requirements for testing, maintenance and replacement of smoke alarms in residential dwelling units. However realtors and landlords often have checklists that verify that these dwellings comply with codes and other requirements, and they may be in a position to verify compliance with the proposed provisions when the units are sold or leased.

UL 217 has required the month and date of manufacture be marked on smoke alarms for more than 10 years.

Cost Impact: This code change will not increase the cost of construction

F163 – 13

907.2.11.2 (IBC [F] 907.2.11.2), 907.2.11.5 (New) (IBC [F] 907.2.11.5 (New))

Proponent: Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azubiamia@yahoo.com)

Revise as follows:

907.2.11.2 (IBC [F] 907.2.11.2) Groups R-2, R-3, R-4 and I-1. Single or multiple-station smoke alarms shall be installed and maintained in Groups R-2, R-3, R-4 and I-1 regardless of *occupant load* at all of the following locations:

1. On the ceiling or wall outside of each separate sleeping area in the immediate vicinity of bedrooms.
2. In each room used for sleeping purposes.

~~**Exception:** Single or multiple station smoke alarms in Group I-1 shall not be required where smoke detectors are provided in the sleeping rooms as part of an automatic smoke detection system.~~

907.2.11.5 (IBC [F] 907.2.11.5) Smoke detection system. Smoke detectors listed in accordance with UL 268 and provided as part of the building's fire alarm system shall be an acceptable alternative to single and multiple-station smoke alarms and shall comply with the following:

1. The fire alarm system shall comply with all applicable requirements in Section 907.
2. Activation of a smoke detector in a dwelling unit or sleeping unit shall initiate alarm notification in the dwelling unit or sleeping unit in accordance with Section 907.5.2.
3. Activation of a smoke detector in a dwelling unit or sleeping unit shall not be required to activate alarm notification appliances outside of the dwelling unit or sleeping unit, provided that a supervisory signal is generated and monitored in accordance with Section 907.6.5.

Reason: This proposal is submitted by the ICC Fire Code Action Committee (FCAC). This ICC committee was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portions thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the Fire-CAC has held 6 open meetings and numerous Regional Work Group and Task Group meetings and conference calls which included members of the committees as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the FAC website at: <http://www.iccsafe.org/cs/CAC/Pages/default.aspx>.

This proposal allow smoke detectors, provided as part of the buildings fire alarm system, to be used as an alternative to single and multiple-station smoke alarms in dwelling units or sleeping units. When a smoke detector activates, the system is required to generate an alarm signal in the dwelling unit or sleeping unit, which can easily be accomplished with an addressable fire alarm system.

There are some jurisdictions that currently allow smoke detectors to be installed in dwelling units and sleeping units under the alternate materials and methods provisions of the code. These systems may only generate alarm signals in the dwelling unit or sleeping unit, or may activate alarm notification appliances throughout the building. Both options are allowed in this proposal.

Item (3) requires smoke detection systems that only generate alarm notification in the dwelling unit or sleeping unit to transmit a supervisory alarm to an approved supervising station as required by Section 907.6.5. This monitoring is already required for fire alarm system if it also provides protection for the common areas of the building.

There are advantages if the smoke detection system option provides protection in these facilities. These include being able to automatically test smoke detector sensitivity, receive and act on trouble signals, and not have to provide both a fire alarm system and interconnected smoke alarms in the building. However, the code proposal does not prevent the smoke alarm option from being provided.

The proposal also deletes the exception to Section 907.2.11.2 that already allows these systems to be used in Group I-1 occupancies. The addition of Section 907.2.11.5 makes this exception unnecessary.

Cost Impact: This code change will not increase the cost of construction

F163-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

907.2.11.5 (NEW)-F-ZUBIA-FCAC

F164 – 13

907.2.11.5 (New) (IBC [F] 907.2.11.5 (New))

Proponent: Thomas P. Hammerberg, representing Automatic Fire Alarm Association
(TomHammerberg@afaa.org)

Revise as follows:

907.2.11.5 (IBC [F] 907.2.11.5) Automatic sprinkler system waterflow. Where an automatic sprinkler system installed in accordance with Section 903.3.1.2 or 903.3.1.3 is provided a sprinkler waterflow alarm-initiating device shall be connected to the multiple-station alarm or household fire alarm system to activate an alarm signal.

Reason: This language is currently used in NFPA-72-2013, 29.7.7.7.3. The purpose is to provide notification to occupants of waterflow activation. If a sprinkler activates in another part of the dwelling unit, this provides earlier warning of the fire situation and will allow additional time to leave the premises. Since the time to escape has reduced significantly in recent years, this will improve fire safety for the occupants.

Cost Impact: minimal

Proponent: David Frederick Scarelli representing DBA-Sentry Signal Company

THIS IS A 2 PART CODE CHANGE PROPOSAL. PART I WILL BE HEARD BY THE IFC COMMITTEE. PART 2 OF THIS PROPOSAL WILL BE HEARD BY THE IRC BUILDING/ENERGY COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THE IFC AND IRC BUILDING/ENERGY CODE DEVELOPMENT COMMITTEES.

Part I - IFC

907.2.12 (IBC [F] 907.2.12) Line type heat detection. A line type heat detection system that activates at 475°F (246°C) shall be installed in Group R Occupancies in accordance with Sections 907.2.12.1 through 907.2.12.2, NFPA 72, NFPA 70 and manufacturer's instructions.

907.2.12.1 (IBC [F] 907.2.12.1) Location. Line type heat detection shall be installed in the following locations:

1. Above all NM-B Cable
2. Above all electrical boxes
3. Above or near all raceways.

(Renumber subsequent sections)

907.2.12.2 (IBC [F] 907.2.12.2) Interconnection. The line type heat detection system shall be interconnected with the smoke alarms required by Section 907.2.11 in such a manner that when the line type heat detection activates such detection shall activate the smoke alarms in all sleeping units and dwelling units.

Add new text as follows:

1103.9 Line type heat detection. A line type heat detection system that activates at 475°F (246°C) shall be installed in existing Group R Occupancies in accordance with Sections 1103.9.1 through 1103.9.3, NFPA 72, NFPA 70 and manufacturer's instructions.

1103.9.1 Location. Line type heat detection shall be installed in the following locations:

1. Above all exposed NM-B Cable
2. Above all electrical boxes
3. Above or near all raceways.

1103.9.2 Interconnection. The line type heat detection system shall be interconnected with the smoke alarms required by Section 907.2.11 in such a manner that when the line type heat detection activates such detection shall activate the smoke alarms in all sleeping and dwelling units.

1103.9.3 Power source. In existing construction required line type heat detection shall receive primary power from the building wiring where such wiring is served from a commercial source and shall be equipped with a battery backup.

Exception: Line type heat detection is not required to be equipped with battery backup where connected to an emergency electrical system.

PART II – IRC

Add new text as follows:

R314.5 Line type heat detection. Line type heat detection that activates at 475⁰F (246⁰C) shall be installed in accordance with Sections 314.5.1 through 314.5.3, NFPA 72, NFPA 70 and manufacturer's instructions.

R314.5.1 Location. Line type heat detection shall be installed in the following locations:

1. Above all NM-B Cable
2. Above all electrical boxes
3. Above or near all raceways

R314.5.2 Interconnection. The line type heat detection shall be interconnected with the smoke alarms in such a manner that when the line type heat detection activates such detection shall activate all of the alarms in the dwelling unit. Where there are two dwelling units the line type heat detection shall be interconnected with the smoke alarms in both dwelling units.

R314.5.3 Power source. Line type heat detection shall receive primary power from the building wiring where such wiring is served from a commercial source and shall be equipped with a battery backup.

Exception: Line type heat detection is not required to be equipped with battery backup where connected to an emergency electrical system.

(Renumber subsequent sections)

Reason:

Part I According to death certificate data, 25% of fire and flame deaths in 2002 were due to smoke inhalation alone, 26% due to burns and 21% to a combination of burns and smoke inhalation. There were 517,000 structural, 3,140 civilian deaths and 17,730 civilian injuries. *(page 37).

ESCAPING – all seemed savable....; SLEEPING – 1/3 estimated as savable; RESCUING OR FIREFIGHTING – ¾ estimated savable...*

Deterioration of electrical wiring caused by time or the environment is a predominant cause of ignition. *(page 24).

Fires in electrical distribution systems contribute significantly to the U.S. fire problem, accounting for a consistent portion of the problem year after year. *(page 69).

In 2006 an estimated 71,360 injuries involving electrical distribution or lighting equipment began with the ignition of products and materials often found in structural areas, including wire or cable insulation (30%), structural members or framing (12%), insulation within the structural area (5%). *(page 6).

Three-fourths (75%) of deaths in 2002-2005 home fires involving electrical distribution or lighting equipment involved victims who were outside the area of origin when the fire began. (page 6).

Branch circuit wiring (51%) accounted for half of the 2005-2005 non-confined home structure fires involving wiring. *(page 54).

Half (52%) of 2002-2005 non-confined home structure fires involving wiring began in fire areas of origin that are all concealed or exterior spaces. *(page 55).

The majority (57%) of 2002-2005 non-confined home structure fires involving overcurrent protection devices began with ignition wire or cable insulation. *(page 89).

INTENT: THE LINE TYPE HEAT DETECTION SWITCH WILL SOUND THE ALARM AT THE ORIGIN OF FIRE IGNITION WITHIN THE HOME STRUCTURE YIELDING THE MAXIMUM TIME THAT MAY BE NECESSARY TO VACATE THE HOME THEREBY MINIMIZING THE INCIDENTS OF CIVILIAN AND FIREFIGHTER INJURIES AND DEATHS AND LOSS OF PROPERTY.

Part II . According to death certificate data, 25% of fire and flame deaths in 2002 were due to smoke inhalation alone, 26% due to burns and 21% to a combination of burns and smoke inhalation. There were 517,000 structural, 3,140 civilian deaths and 17,730 civilian injuries.

ESCAPING – all seemed savable....; SLEEPING – 1/3 estimated as savable; RESCUING OR FIREFIGHTING - ¾ estimated savable...* Reanalysis of who can be saved.

Deterioration of electrical wiring caused by time or the environment is a predominant cause of ignition.

Fires in electrical distribution systems contribute significantly to the U.S. fire problem, accounting for a consistent portion of the problem year after year.

In 2006 an estimated 71,360 injuries involving electrical distribution or lighting equipment were reported to hospital emergency rooms.

Electrical distributions and lighting equipment dwelling fires are the only type of home fires that have been shown to increase in frequency with increasing dwelling age.

The majority of 2002-2005 non-confined home structure fires involving electrical distribution or lighting equipment began with the ignition of products and materials often found in structural areas, including wire or cable insulation (30%), structural members or framing (12%), and insulation within the structural area (5%).

Three-fourths (75%) of deaths in 2002-2005 home fires involving electrical distribution or lighting equipment involved victims who were outside the area of origin when the fire began.

Branch circuit wiring (51%) accounted for half of the 2002-2005 non-confined home structure fires involving wiring.

Half (52%) of 2002-2005 non-confined home structure fires involving wiring began in fire areas of origin that are all concealed or exterior spaces.

The majority (57%) of 2002-2005 non-confined home structure fires involving overcurrent protection devices began with ignition wire or cable insulation.

SUMMARY: Electrical distribution equipment is a highly significant contributor to the high number of civilian deaths and civilian injuries resulting year after year in home fires. Many lives can be saved and injuries prevented if earlier warning can be sounded.

CONCLUSION: The line type open switch activated by heat and/or fire is designed by earliest warning to prevent death by asphyxiation and burning.

Circuitry short circuits and overloads trip the circuit breakers when the breaker rating is reached. Lower leakage causes hot spots along the line and eventually causes fires that could be detected long before they could become autocatalytic. The line type open switch is designed to detect this hazard long before life is endangered.

907.2.12 (NEW)-F-SCARELLI

F166 – 13

907.2.13.1.1 (IBC [F] 907.2.13.1.1)

Proponent: Thomas P. Hammerberg, representing Automatic Fire Alarm Association (TomHammerberg@afaa.org)

Revise as follows:

907.2.13.1.1 (IBC [F] 907.2.13.1.1) Area smoke detection. Area smoke detectors shall be provided in accordance with this section. Smoke detectors shall be connected to an automatic fire alarm system. The activation of any detector required by this section shall activate the emergency voice/alarm communication system in accordance with Section 907.5.2.2. In addition to smoke detectors required by Sections 907.2.1 through 907.2.10, smoke detectors shall be located as follows:

1. In each mechanical equipment, ~~electrical, transformer,~~ telephone equipment or similar room which is not provided with sprinkler protection.
2. In each elevator machine room and in elevator lobbies
3. In each electrical transformer room

Reason: This code change proposal will provide the minimum level of fire and life safety in high rise electrical transformer rooms. 11% of High Rise fires start in the electrical distribution or lighting equipment (Source NFPA Dr. Hall-High Rise Building Fires, Dec 2011)

Electrical fires often start as smoldering fires generating smoke and toxic gases. Many of these fires can be too small to activate fire sprinklers, but can cause serious damage to building electrical equipment and hazards to first responders. There are studies to support the facts on "fires too small to activate fire sprinklers", but activate smoke detectors. In Healthcare facilities research shows that 65.4% of fires were too small to activate sprinklers. (Source Dr. Milke-Univ of Maryland, 5.14.2006)

Early warning smoke detection will bring attention to these isolated rooms for action by first responders and building engineers. Concerns about unwanted alarms is minimized the fact that these rooms are generally kept very clean and do not have sources of deceptive phenomena (cooking etc)

Key Propositions

- Fires do occur in electrical transformer rooms
- Fires often develop smoke and toxic gases
- Fires can be too small for fire sprinkler activation, but need attention
- Smoke detection is shown as effective means of detecting fires in an early stage in electrical fires

Please support this code change for the value of first responder safety, building occupant safety and protection of building system integrity. The following research sources are for your review.

Research Source 1

FM Global Standard Loss Prevention Data Sheet 5-19 (Jan 2006)

2.2.2 Provide photoelectric or combination photoelectric and ionization smoke detectors in electrical rooms to sound an alarm at a constantly attended location, regardless of any automatic sprinkler protection or heat detection that may exist. Ensure response includes notification of personnel capable of de-energizing the electrical equipment. The presence or absence of smoke detectors does not change the need for sprinklers. Ensure smoke detector spacing is in accordance with Data Sheet 5-48, *Automatic Fire Detectors*.

Research Source 2

U.S. Fire Administration TOPICAL FIRE RESEARCH SERIES, Volume 2, Issue 18 January 2002

Reports show that electrical fires are an issue in high rise buildings. This will provide for both early warning detection and fire sprinklers in the key hazard areas of electrical transformer. Many fires in these areas can be smoldering and slow developing in nature, smoke detection is of great value in these cases, when the fire develops the level of heat and flame the fire sprinklers will control the situation.

Early notification to the fire service and building occupants of these developing fires is very important.

Example A

Electrical room fire evacuates condos in Bethany Beach

No serious injuries reported at the Sea Colony

June 24, 2010|By Jessica Anderson, the Baltimore Sun

An electrical fire forced an evacuation of the Sea Colony high-rise complex in Bethany Beach Thursday.

A power surge caused a small fire inside an electrical room in one of the buildings, causing the evacuation at about 4 p.m., said Joe Hopple, spokesman with Bethany Beach Fire Company. He said the surge was caused by a downed wire.

Example B

Friday, March 6, 2009 08:48 The Norristown Fire Department responded to Building 14 of the Norristown State Hospital for a fire in the electrical room. It took firefighters over two hours to extinguish the fire due to the energized equipment and the difficulty of reaching the fire inside the electrical equipment. Firefighters from Center Square, East Norriton, Plymouth and Swedeland assisted at the scene.

Example C

Wednesday, November 12, 2008 This morning Monroeville FD was called to one of the Office Buildings in the Oxford development for a fire alarm. Crews arrived on scene and found a small fire in the electrical room where the motors for the elevators are located. Crews extinguished and contained the fire with dry chem. Fire was caused by a cardboard box left near the motor. Crews remained on scene for minor ventilation. **ALL PICTURES COURTESY OF MONROEVILLE TV-15** Command: C-55 (R. Douthit) Units: E-12, E-31, E-42, T-5

Example D

Electrical Room Sparks Fire in Parking Garage

August 7, 2012

BOCA RATON– Boca Raton Fire Rescue Services responded to a report of an electrical room fire in the parking garage at 301 E. Yamato Road just after 11:30 a.m. Friday, Aug. 3, said fire officials.

Firefighters discovered that the electrical transformer had malfunctioned and caused the burning of some of the attached wiring. The fire was extinguished within minutes after the arrival of firefighters, preventing further damage to the electrical room of the 5-story parking garage.

No injuries were reported. Boca Raton Fire Rescue Services investigators determined that the cause was an apparent electrical malfunction

Example E

Minneapolis fire started in apartment building's electrical room

By Brady Gervais

bgervais@pioneerpress.com

Posted: 03/12/2012 12:01:00 AM CDT

Updated: 03/12/2012 10:19:03 AM CDT

Fire investigators say a three-alarm fire at a Minneapolis apartment building Friday started in an electrical room.

The fire's cause remains undetermined, Assistant Minneapolis Fire Chief Cherie Penn said in a written statement. The probable cause is an "unspecified electrical malfunction" in the electrical room.

Fire crews were called around 2 a.m. Friday to a fire that started in the basement of the building at 137 17th St. E. The fire went to a second alarm shortly before 3 a.m. and then to a third alarm because of the size of the building and the spread of the fire. One firefighter suffered a minor injury but continued working.

Cost Impact: Estimated 250.00 per detector installed, minimal cost impact to overall construction cost.

F166-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

907.2.13.1.1-F-HAMMERBERG

F167 – 13

907.2.14 (IBC [F] 907.2.14)

Proponent: Gene Boecker, AIA, Code Consultants, Inc. representing Code Consultants, Inc.

Revise as follows:

907.2.14 (IBC [F] 907.2.14) Atriums Connecting more than two stories. A fire alarm system shall be installed in occupancies with an atrium connecting more than two stories, with smoke detection installed ~~throughout the atrium in locations required by a rational analysis in Section 909.4 and in accordance with the system operation requirements in Section 909.17.~~ The system ~~must~~ shall be activated in accordance with Section 907.5. Such occupancies in Group A, E or M shall be provided with an emergency voice/alarm communication systems complying with the requirements of Section 907.5.2.2.

Reason: The purpose of this code change proposal is to correct a substantial change to the requirements for smoke detection in atriums that was made with the intent of only clarifying the existing requirements.

In the 2003 and 2006 editions, the code required smoke detection in atriums only where required by a rational analysis in accordance with Section 909. Section 909.12.3 of the 2012 edition still indicates that automatic activation of a smoke control system is required to be by, "any smoke detection required by engineering analysis." However, modifications made to Section 907.2.13 in the 2009 edition (now Section 907.2.14 in the 2012 edition), that were intended only to clarify existing requirements, appear to require smoke detection in atriums regardless of the need for smoke detection as determined by a rational analysis.

When Section 907 was modified in the 2009 edition by code change proposal F163-07/08, the intent of the code change was to correlate the organization of Section 907 with Section 903. The main purpose of the code change was to correlate the terms "automatic smoke detection systems" and "manual fire alarm system". During the course of the code change process Section 907.2.13 was modified to require both a fire alarm system and a smoke detection system in atriums, although a smoke detection system had not been required in atriums by Section 907 of the prior edition. This is clear because code change proposal F58-01 that removed the requirement for smoke detection in atriums stated in its justification, "[t]he engineering analysis would determine if (or if not) smoke detectors would be required to maintain a tenable environment for the evacuation or relocation for the occupants of the building."

The modification in this code change proposal maintains the appropriate terminology, but returns the requirements to their original intent: that the requirements for smoke detection in atriums are unique to each atrium and should be determined by the required rational analysis.

Cost Impact: The code change proposal will not increase the cost of construction.

907.2.14-F-BOECKER

F168 – 13

907.2.22 (IBC [F] 907.2.22), 907.2.22.1 (New) [IBC [F] 907.2.22.1(New)], 907.2.22.2 (New) [IBC [F] 907.2.22.2(New)]

Proponent: Eric R. Rosenbaum, Hughes Associates, Inc. representing the Air Traffic Control Tower Fire Life Safety Task Group (erosenbaum@haifire.com+)

Revise as follows:

907.2.22 (IBC [F] 907.2.22) Airport traffic control towers. An automatic smoke detection system that activates the occupant notification system in accordance with Section 907.5 shall be provided in airport traffic control towers in all occupiable and equipment spaces accordance with Sections 907.2.22.1 and 907.2.22.2.

Exception: Audible appliances shall not be installed within the control tower cab.

907.2.22.1 (IBC [F] 907.2.22.1) Airport traffic control towers with multiple exits and automatic sprinklers. Airport traffic control towers with multiple exits and equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.3, shall be provided with smoke detectors in the following locations.

1. Airport traffic control cab
2. Electrical and mechanical equipment rooms
3. Airport terminal radar and electronics rooms
4. Outside each opening into exit enclosures
5. Along the single means of egress permitted from observation levels
6. Outside each opening into the single means of egress permitted from observation levels.

907.2.22.2 (IBC [F] 907.2.22.2) Other airport traffic control towers. -Airport traffic control towers with a single exit or where sprinklers are not equipped throughout, shall be provided with smoke detectors in the following locations.

1. Airport traffic control cab
2. Electrical and mechanical equipment rooms
3. Airport terminal radar and electronics rooms
4. Office spaces incidental to the tower operation.
5. Lounges for employees, including sanitary facilities.
6. Means of egress
7. Accessible utility shafts

Reason: The proposed change is the recommendation of the Air Traffic Control Tower Fire/Life Safety Task Group, and reflects the current approach to fire protection and life safety in airport traffic control towers and the provisions of the Life Safety Code. It is suggested that the proposed revisions provide the proper level of protection for facilities with single exits and multiple exits where delayed evacuation of the cab may be required. The change reduces the amount of detection required in multiple exit ATCT with automatic sprinkler protection based on the accepted revision to Section 412.3 of the IBC to require automatic sprinkler protection in towers where an occupied floor is located 35 ft or greater from the lowest level of fire department vehicle access. Automatic sprinklers are provided for detection and control of the fire. Smoke detection is specified as required to also detect a fire that may affect the means of egress for the tower. The changes also are intended to clarify the required locations of smoke detection in single exit ATCT based on the allowed uses in an airport traffic control tower in Section 412.3. The following is the accepted proposal to Section 412.3:

412.3 Airport traffic control towers. The provisions of Sections 412.3.1 through 412.3.511 shall apply to airport traffic control towers occupied only for the following uses:

1. Airport traffic control cab.
2. Electrical and mechanical equipment rooms.
3. Airport terminal radar and electronics rooms.
4. Office spaces incidental to the tower operation.
5. Lounges for employees, including sanitary facilities.

412.3.1 Type of construction. Airport traffic control towers shall be constructed to comply with the height limitations of Table 412.3.2.

**TABLE 412.3.2
HEIGHT LIMITATIONS FOR AIRPORT TRAFFIC CONTROL TOWERS**

TYPE OF CONSTRUCTION	HEIGHT ^a (feet)
IA	Unlimited
IB	240
IIA	100
IIB	85
IIIA	65

a. Height to be measured from grade plane to cab floor

412.3.2 Stairway Stairways in Airport traffic control towers shall conform to the requirements of Section 1009. Such *stairways* shall be a smokeproof enclosure in accordance with Section 909.20. The stair pressurization alternative in accordance with Section 909.20.5 shall be permitted to be used. *Stairways* shall not be required to extend to the roof as specified in Section 1009.11.

412.3.3 Exit access. From observation levels, airport traffic control towers shall be permitted to have a single means of exit access for a distance of travel not exceeding 100 ft (30 m). This means of egress shall be permitted to include exit access utilizing an unenclosed stair at the observation level.

412.3.4 Single means of egress. Not less than one *exit stairway* shall be permitted for airport traffic controls towers of any height provided that the *occupant load* per floor is not greater than 15 and the area per floor does not exceed 1,500 square feet (140 m²).

412.3.4.1 Arrangement of single means of egress. Airport traffic control towers permitted a single exit and located above another building shall be provided with one of the following:

1. Exit enclosure separated from the other building with no door openings to or from the other building
2. Exit enclosure leading directly to an exit enclosure serving the other building, with walls and door separating the exit enclosures from each other, and another door allowing access to the top floor of the building that provides access to a second exit serving that floor.

412.3.4.2 Interior Finish. Airport traffic control towers permitted a single exit in accordance with Section 412.3.4 shall be restricted to interior wall and ceiling finishes of Class A or Class B.

412.3.5 Automatic fire detection systems. Airport traffic control towers shall be provided with an automatic fire detection system installed in accordance with Section 907.2.

412.3.6 Automatic sprinkler system. Airport traffic control towers shall be equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1.

412.3.7 Standby power. A standby power system that conforms to Chapter 27 shall be provided in airport traffic control towers more than 65 feet (19 812 mm) in height. Power shall be provided to the following equipment:

1. Pressurization equipment, mechanical equipment and lighting.
2. Elevator operating equipment.
3. Fire alarm and smoke detection systems.

412.3.8 Elevator Protection. Wires or cables that provide normal and standby power, control signals, communication with the car, lighting, heating, air conditioning, ventilation and fire-detecting systems to elevators shall be protected by construction having a minimum 1-hour *fire resistance rating* or shall be circuit integrity cable having a minimum 1-hour *fire-resistance rating*.

412.3.9 Accessibility. Airport traffic control towers need not be *accessible* as specified in the provisions of Chapter 11.

Cost Impact: This code change will increase the cost of construction from the current code requirements in some instances; however, reflects current building practices of the FAA. Cost will be reduced in instances where detection is not required.

	Assembly:	ASF	AMF	DF

907.2.22-F-ROSENBAUM

F169 – 13

907.3.1 (IBC [F] 907.3.1)

Proponent: Barry Greive, representing Target Corporation (barry.greive@target.com)

Revise as follows:

907.3.1 (IBC [F] 907.3.1) Duct smoke detectors. Smoke detectors installed in ducts shall be listed for the air velocity, temperature and humidity present in the duct. Duct smoke detectors shall be connected to the building's fire alarm control unit when a fire alarm system is required by Section 907.2. Activation of a duct smoke detector shall initiate a visible and audible supervisory signal at a constantly attended location and shall perform the intended fire safety function in accordance with this code and the International Mechanical Code. Duct smoke detectors shall report as a supervisory signal not a fire alarm, and they shall not be used as a substitute for required open area detection.

Exceptions:

1. The supervisory signal at a constantly attended location is not required where duct smoke detectors activate the building's alarm notification appliances.
2. In occupancies not required to be equipped with a fire alarm system, actuation of a smoke detector shall activate a visible and an audible signal in an approved location. Smoke detector trouble conditions shall activate a visible or audible signal in an approved location and shall be identified as air duct detector trouble.

Reason: Duct detectors are widely known to be a cause of false alarms which is a safety concern for first responders. Duct detectors need to report as a supervisory signal to indicate that there is an issue and need to be repaired or replaced but should not report as a fire alarm like a water flow device. This adds clarity to a section that is not enforced uniformly and will add to fire fighter safety by lessening the amount of potential false alarms.

Cost Impact: This will not increase the cost of construction

F169-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

907.3.1-F-GRIEVE

F170 – 13

907.4.2.1 (IBC [F] 907.4.2.1)

Proponent: Daniel E. Nichols, P.E., New York State Department of State (dan.nichols@dos.ny.gov)

Revise as follows:

907.4.2.1 (IBC [F] 907.4.2.1) Location. Manual fire alarm boxes shall be located not more than 5 feet (1524 mm) from the entrance to each exit. In buildings not protected by an automatic sprinkler system in accordance with 903.3.1.1 or 903.3.1.2, additional manual fire alarm boxes shall be located so that the exit access travel distance to the nearest box does not exceed 200 feet (60 960 mm).

Reason: This code change proposal both addresses the current situation of manual pull boxes being seldom used to report fires and coordinates with Table 1016.2 on exit access travel distance.

With the exception of F-2, S-2, and U. Travel distance in unsprinklered buildings is a maximum of 200 feet (when such occupancy is permitted not to be sprinklered. Exit access travel distance is permitted to be increased by 50 feet (to 250 feet) for sprinkler installation in A, E, F-1, M, R, S-1 and 100 feet (to 300 feet) for Group B. What this proposal does is it permits the increased travel distance allowed by the sprinkler system to not then require an additional manual pull box.

The second part of the change is to coordinate with the defined term 'exit access' travel distance for the requirements for which measurements should be taken. The first part of 907.4.2.1 states the measurement is taken from each 'exit', which is the end of 'exit access'.

Cost Impact: This proposal will not affect the cost of construction.

F170-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

907.4.2.1-F-NICHOLS

F171 – 13

202, 907.5.2.3.1 (IBC [F] 907.5.2.3.1). 907.5.2.3.2 (IBC [F] 907.5.2.3.2)

Proponent: Carl Baldassarra, P.E., FSFPE, Chair, ICC Code Technology Committee
(cbaldassarra@RJAGroup.com)

Revise as follows:

IFC 907.5.2.3.1 (IBC [F] 907.5.2.3.1) *Public use areas* and *common use areas*. Visible alarm notification appliances shall be provided in *public use areas* and *common use areas*.

~~IFC 907.5.2.3.2 (IBC [F] 907.5.2.3.2) *Employee work areas*.~~ Exception: Where *employee work areas* have audible alarm coverage, the notification appliance circuits serving the *employee work areas* shall be initially designed with a minimum of 20-percent spare capacity to account for the potential of adding visible notification appliances in the future to accommodate hearing impaired employee(s).

Add new definitions as follows:

SECTION 202 GENERAL DEFINITIONS

[B] COMMON USE. Interior or exterior *circulation paths, rooms, spaces or elements that are not for public use and are made available for the shared use of two or more people.*

[B] PUBLIC-USE AREAS. Interior or exterior rooms or spaces that are made available to the general public.

[B] EMPLOYEE WORK AREA. All or any portion of a space used only by employees and only for work. *Corridors, toilet rooms, kitchenettes and break rooms are not employee work areas.*

Reason: The intent of this proposal is to use defined terms for public use and common use to avoid confusion for where visible alarms are required. The definitions are copied from IBC. This requirement would be consistent with ADA 215.2.

The ICC Board established the ICC Code Technology Committee (CTC) as the venue to discuss contemporary code issues in a committee setting which provides the necessary time and flexibility to allow for full participation and input by any interested party. The code issues are assigned to the CTC by the ICC Board as “areas of study”. Information on the CTC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CTC effort can be downloaded from the following website: <http://www.iccsafe.org/cs/CTC/Pages/default.aspx>. Since its inception in April/2005, the CTC has held twenty five meetings - all open to the public.

Cost Impact: None – This will be required by the 2010 ADA Standard for Accessible Design.

F173 – 13

907.6 (IBC [F] 907.6)

Proponent: Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azubiamia@yahoo.com)

Revise as follows:

907.6 (IBC [F] 907.6) Installation and monitoring. A fire alarm system shall be installed and monitored in accordance with Sections 907.6.1 through 907.6.5.2 and NFPA 72.

Reason: This section addresses installation and monitoring. The proposal simply clarifies that monitoring is part of the installation. This proposal does not change or alter the exceptions to Section 907.6.5.

Cost Impact: This code change will not increase the cost of construction

F173-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

907.6-F-ZUBIA-FCAC

F174 – 13

907.6.3 (New) (IBC [F] 907.6.3), 907.6.3.1 (New) (IBC [F] 907.6.3.1)

Proponent: Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azubiamia@yahoo.com)

Add new text as follows:

907.6.3 (IBC [F] 907.6.3) Initiating device identification. The fire alarm system shall identify the specific initiating device address, location, device type, floor level where applicable and status including indication of normal, alarm, trouble and supervisory status, as appropriate.

Exception:

1. Fire alarm systems in single story buildings less than 22,500 square feet (2090 m²) in area
2. Fire alarm systems that only include manual fire alarm boxes, water flow initiating devices, and not more than 10 additional alarm initiating devices.
3. Special initiating devices that do not support individual device identification.
4. Fire alarm systems or devices that are replacing existing equipment.

907.6.3.1 (IBC [F] 907.6.3.1) Annunciation. The initiating device status shall be annunciated at an approved on-site location.

Reason: This proposal is submitted by the ICC Fire Code Action Committee (FCAC). This ICC committee was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portions thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the Fire-CAC has held 6 open meetings and numerous Regional Work Group and Task Group meetings and conference calls which included members of the committees as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the FAC website at: <http://www.iccsafe.org/cs/CAC/Pages/default.aspx>.

This proposal improves the ability of emergency responders to identify the status of initiating devices at the time of an emergency. This proposal will help identify problematic initiating devices and thus reduce nuisance alarms. It also eliminates the requirements for providing zone indication of system status. This is considered particularly important in high-rise buildings, where the number of initiating devices and the geometry of the building warrant a need for point monitoring of individual devices, which is not currently accommodated by single floor zones.

This proposal would allow the fire code official the flexibility to not require individual detection device identification in smaller buildings, where the source of alarm and trouble signals can be more easily determined.

Cost Impact: The code change proposal will increase the cost of construction.

F174-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

907.6.3 (NEW)-F-ZUBIA-FCAC

F175 – 13

907.6.5.3 (New) (IBC [F] 907.6.5.3 (New)), 907.6 (IBC [F] 907.6)

Proponent: Anthony C. Apfelbeck, City of Altamonte Springs Building/Fire Safety Division, representing self (ACApfelbeck@Altamonte.org)

Revise as follows:

907.6.5.3 (IBC [F] 907.6.5.3) Alarm Signal Verification. Where required by the Fire Chief, alarm signal verification shall be provided in accordance with NFPA 72.

907.6 (IBC [F] 907.6) Installation. A fire alarm system shall be installed in accordance with Sections 907.6.1 through ~~907.6.5.2~~ 907.6.5.3 and NFPA 72.

Reason: NFPA 72 was revised in the last cycle to provide specific provisions for fire departments to require Alarm Signal Verification procedures by the supervision station prior to dispatch. This code change proposal provides a pointer to NFPA 72 so that the user is aware that this type of activity is specifically allowed under the code. This code change also ensures that both the IFC and NFPA 72 match in their provisions for Alarm Signal Verification. Ensuring that the documents are consistent in their provisions is important in eliminating confusion regarding the appropriate actions and compliance expectations for the installer, supervising station, owner and fire code official.

Cost Impact: This code change will not increase the cost of construction.

F175-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

907.6.5.3 (NEW)-F-APFELBECK

F176 – 13

907.6.5.3 (New) (IBC [F] 907.6.5.3 (New)), 401.3.2

Proponent: Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azubiamia@yahoo.com)

Revise as follows:

907.6.5.3 Alarm Signal Verification. Where permitted by the Fire Chief, an approved supervising station shall be allowed to verify an alarm signal prior to reporting it to the public safety communications center. The verification process shall be in compliance with NFPA 72.

401.3 Emergency responder notification. Notification of emergency responders shall be in accordance with Sections 401.3.1 through 401.3.3.

401.3.1 Fire events. In the event an unwanted fire occurs on a property, the *owner* or occupant shall immediately report such condition to the fire department.

401.3.2 Alarm activations. Upon activation of a fire alarm signal employees or staff shall immediately notify the fire department.

Exception: Alarm signal verification permitted by section 907.6.5.3.

401.3.3 Delayed notification. A person shall not, by verbal or written directive, require any delay in the reporting of a fire to the fire department.

Reason: This proposal is submitted by the ICC Fire Code Action Committee (FCAC). This ICC committee was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portions thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the Fire-CAC has held 6 open meetings and numerous Regional Work Group and Task Group meetings and conference calls which included members of the committees as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the FAC website at: <http://www.iccsafe.org/cs/CAC/Pages/default.aspx>.

The intent is to allow fire departments to require verification on both commercial and residential alarm signals in order to assist in effective dispatching of resources and/or reducing the impact of nuisance alarms. Currently NFPA 72 allows verification on residential systems (but gives choice of using it to the monitoring company). This would give discretion to the fire chief, and expand use to include commercial alarms which accounts for the majority of false alarms in the U.S.

These provisions allow fire departments to require that alarm monitoring centers attempt to verify an alarm signal before reporting to the 9-1-1 center. Having better information about the cause of alarm activation is critical as many departments have much smaller responses for an automatic alarm signal than for a working structure fire. Additionally, verification has been proven effective in reducing unwanted nuisance alarms. Alarm Verification is already performed extensively on residential fire alarms; this would allow it to be mandated on some or all systems, including commercial occupancies, when required by the Chief.

The revision to Section 401.3 will clarify the intent of the code and alleviate potential interpretation and enforcement conflicts with proposed new section - Section 907.6.5.3 Alarm Signal Verification

Cost Impact: This code change will not increase the cost of construction

F176-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

907.6.5.3 (NEW)-F-ZUBIA-FCAC

F177 – 13

907.8.5.1 (New)

Proponent: Anthony C. Apfelbeck, City of Altamonte Springs Building/Fire Safety Division, representing self (ACApfelbeck@Altamonte.org)

Add new text as follows:

907.8.5.1 Fire alarm systems that cannot be repaired or serviced to eliminate reoccurring nuisance alarms or system impairments shall be replaced.

Reason: Fire Code Officials are frequently confronted with fire alarm systems that have are the end of their serviceable life and should be replaced in order to maintain system reliability. The need for system replacement is typically recommended by the fire alarm service company but, on some occasions, the owner refuses to upgrade/replace the system. Other than the maintenance requirements of NFPA 72, there is no language in the code that would allow the Fire Code Official to enforce the recommendation of the fire alarm service company to replace the system. The failure to replace an end of life fire alarm system can be a significant factor in generating nuisance alarms.

Cost Impact: This proposal will increase the cost of construction.

F177-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

907.8.5.1 (NEW)-F-APFELBECK

F178 – 13

907.8.6 (New)

Proponent: Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azubiamia@yahoo.com)

Add new text as follows:

907.8.6 Problematic systems. Where required by the fire code official, fire alarm systems that produce chronic, unwanted or nuisance alarms shall be monitored with central station service in accordance with NFPA 72 requirements. A copy of the certificate, placard or other documentation issued by the organization that listed the central station, or the prime fire alarm system contractor, shall be provided to the fire code official.

Reason: This section is intended to address the situation where a fire alarm system has not been repaired to make it fully functional or eliminate chronic unwanted or nuisance alarms. The determination of what constitutes chronic unwanted or nuisance alarms is up to the fire code official to decide based on local policies and practices. By requiring central station service it is understood that the system at the protected premise is now covered by an audit program administered by the company that listed the central station. These audit programs have shown significant success in reducing nuisance and unwanted alarms.

Cost Impact: This proposal will increase the cost of construction.

F178-13

F179 – 13

105.7.5 (New), 908 (IBC[F] 908)

Proponent: Daniel P Finnegan, representing Siemens Industry (daniel.finnegan@siemens.com)

Add new text as follows:

105.7.5 Emergency alarm systems. A construction permit is required for installation of or modification to emergency alarm systems. Maintenance performed in accordance with this code is not considered a modification and does not require a permit.

Revise as follows:

SECTION 908 EMERGENCY ALARM SYSTEMS

908.1 (IBC [F] 908.1) General. This section covers the application, installation, performance and maintenance of emergency alarm systems.

908.2 (IBC [F] 908.2) Construction documents. The fire code official shall have the authority to require construction documents and calculations for all emergency alarm systems and to require permits be issued for the installation, rehabilitation or modification of any emergency alarm system. Construction documents for emergency alarm systems shall be submitted for review and approval prior to system installation.

908.3 (IBC [F] 908.3) Permits. Permits shall be required as set forth in Section 105.7.

908.4 (IBC [F] 908.4) Equipment. Emergency alarm system control units and components shall be listed or approved for the purpose for which they are installed.

908.5 (IBC [F] 908.5) Acceptance tests and completion. Upon completion of the installation, the emergency alarm system shall be tested in accordance with the manufacturer's instructions and as required by the fire code official to verify it provides the required protection.

908.6 (IBC [F] 908.6) Where required. An approved emergency alarm system installed in accordance with the provisions of this code shall be provided in accordance with Sections 908.6.1 through 908.6.6.

908.1-908.6.1 (IBC [F] 908.6.1) Group H occupancies. Emergency alarms for the detection and notification of an emergency condition in Group H occupancies shall be provided as required in Chapter 50.

908.2-908.6.2 (IBC [F] 908.6.2) Group H-5 occupancy. Emergency alarms for notification of an emergency condition in an HPM facility shall be provided as required in Section 2703.12. A continuous gas detection system shall be provided for HPM gases in accordance with Section 2703.13.

908.3-908.6.3 (IBC [F] 908.6.3) Highly toxic and toxic materials. Where required by Section 6004.2.2.10, a gas detection system shall be provided for indoor storage and use of highly toxic and toxic compressed gases.

908.4-908.6.4 (IBC [F] 908.6.4) Ozone gas-generator rooms. A gas detection system shall be provided in ozone gas-generator rooms in accordance with Section 6005.3.2.

908.5-908.6.5 (IBC [F] 908.6.5) Repair garages. A flammable-gas detection system shall be provided in repair garages for vehicles fueled by nonodorized gases in accordance with Section 2311.7.2.

~~908.6~~ 908.6.6 (IBC [F] 908.6.6) Refrigeration systems. Refrigeration system machinery rooms shall be provided with a refrigerant detector in accordance with Section 606.8.

908.7 (IBC [F] 908.7) Maintenance. Emergency alarm systems shall be maintained in accordance with the original installation standards for that system. Required systems shall be extended, altered or augmented as necessary to maintain and continue protection whenever the building is altered, remodeled or added to. Alterations to emergency alarm systems shall be done in accordance with applicable standards.

908.8 (IBC [F] 908.8) Responsibility and records. The building owner shall be responsible to maintain emergency alarm systems in an operable condition at all times. A written record of the maintenance inspection and testing shall be maintained and shall be made available to the fire code official.

SECTION 915 **CARBON MONOXIDE ALARMS**

~~908.7 (IBC [F] 908.7) Carbon monoxide alarms.~~ 915.1 (IBC [F] 915.1) General. Group I or R occupancies located in a building containing a fuel-burning appliance or in a building which has an attached garage shall be equipped with single-station carbon monoxide alarms. The carbon monoxide alarms shall be listed as complying with UL 2034 and be installed and maintained in accordance with NFPA 720 and the manufacturer's instructions. An open parking garage, as defined in Chapter 2 of the *International Building Code*, or an enclosed parking garage ventilated in accordance with Section 404 of the *International Mechanical Code* shall not be considered an attached garage.

Exception: *Sleeping units or dwelling units* which do not themselves contain a fuel-burning appliance or have an attached garage, but which are located in a building with a fuel-burning appliance or an attached garage, need not be equipped with single-station carbon monoxide alarms provided that:

1. The *sleeping unit* or *dwelling unit* is located more than one story above or below any story which contains a fuel-burning appliance or an attached garage;
2. The *sleeping unit* or *dwelling unit* is not connected by duct work or ventilation shafts to any room containing a fuel-burning appliance or to an attached garage; and
3. The building is equipped with a common area carbon monoxide alarm system.

~~908.7.4~~ 915.1.1 (IBC [F] 915.1.1) Carbon monoxide detection systems. Carbon monoxide detection systems, which include carbon monoxide detectors and audible notification appliances, installed and maintained in accordance with this section for carbon monoxide alarms and NFPA 720 shall be permitted. The carbon monoxide detectors shall be *listed* as complying with UL 2075.

Reason: As written the emergency alarm system section has no specific requirements for the basic installation, testing and maintenance of these systems, and by definition these systems are not considered to be fire protection systems and are not subject to the general requirements in Section 901.

The proposal makes no changes to where emergency alarm systems are required, which are retained verbatim in Sections 908.6.1 through 908.6.6. It does include basic system requirements as noted below:

Sections 908.2, 908.3 and 908.7 are based on similar requirements in section 901.1. These sections are required in Section 908 since the Section 901 requirements only apply to fire protection systems.

Section 908.4 is based on Section 907.1.3. However, instead of requiring emergency alarm system equipment to be listed and approved, it recognizes that listed equipment is not always available for the systems covered by these requirements. Accordingly this section allows this equipment to be listed or approved.

Sections 908.5 and 908.8 include requirements similar to those in Sections 907.7 and 907.8.5.

Sections 908.6.1 through 908.6.6 are taken verbatim from Section 908.

Additionally, this proposal simply relocates CO alarm system requirements from Section 908.7 to a new Section 915, with no technical changes whatsoever. This is being done for the following reasons:

1. By definition emergency alarm systems provide indication and warning of emergency situations involving hazardous materials, which relates more closely to warning systems required by the hazardous materials chapters of this code (e.g. Chapter 50 to 67). Carbon monoxide that is generated by motor vehicle exhaust and damaged fuel burning appliances is not regulated by those chapters.

2. As currently written the CO alarm requirements in Section 908.7 stand alone, and do not relate in any way to the emergency alarm requirements in Sections 908.1 through 908.6. Thus there is no advantage to having both emergency alarm and carbon monoxide alarm requirements in the same Section.
3. This proposal relocates the carbon monoxide alarm requirements to a new Section 915, which was done so the current Sections 909 through 914 don't need to be renumbered.
4. It is recognized that there is at least one other proposal to revise the Section 908.7 CO alarm requirements. If that proposal succeeds, approval of this proposal is intended to retain the changes from the other proposal, and relocate the revised provisions into Section 915.
5. This is consistent with a similar proposal submitted by the FCAC

Cost Impact: Clarifies what should be done already-minimal cost impact

915 (New) [IBC [F] 915 (New)], 908.7(IBC [F] 908.7), 908.7.1 (IBC [F] 908.7.1)

Proponent: Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azumiamia@yahoo.com)

Revise as follows:

SECTION 915 **CARBON MONOXIDE DETECTION**

~~908.7(IBC [F] 908.7)~~ 915.1 (IBC [F] 915.1) Carbon monoxide alarms. Group I or R occupancies located in a building containing a fuel-burning appliance or in a building which has an attached garage shall be equipped with single-station carbon monoxide alarms. The carbon monoxide alarms shall be listed as complying with UL 2034 and be installed and maintained in accordance with NFPA 720 and the manufacturer's instructions. An open parking garage, as defined in Chapter 2 of the *International Building Code*, or an enclosed parking garage ventilated in accordance with Section 404 of the *International Mechanical Code* shall not be considered an attached garage.

Exception: *Sleeping units* or *dwelling units* which do not themselves contain a fuel-burning appliance or have an attached garage, but which are located in a building with a fuel-burning appliance or an attached garage, need not be equipped with single-station carbon monoxide alarms provided that:

1. The *sleeping unit* or *dwelling unit* is located more than one story above or below any story which contains a fuel-burning appliance or an attached garage;
2. The *sleeping unit* or *dwelling unit* is not connected by duct work or ventilation shafts to any room containing a fuel-burning appliance or to an attached garage; and
3. The building is equipped with a common area carbon monoxide alarm system.

~~908.7.1 (IBC [F] 908.7.1)~~ 915.2 (IBC [F] 915.2) Carbon monoxide detection systems. Carbon monoxide detection systems, which include carbon monoxide detectors and audible notification appliances, installed and maintained in accordance with this section for carbon monoxide alarms and NFPA 720 shall be permitted. The carbon monoxide detectors shall be *listed* as complying with UL 2075.

Reason: This proposal is submitted by the ICC Fire Code Action Committee (FCAC). This ICC committee was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portions thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the Fire-CAC has held 6 open meetings and numerous Regional Work Group and Task Group meetings and conference calls which included members of the committees as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the FAC website at: <http://www.iccsafe.org/cs/CAC/Pages/default.aspx>.

This proposal simply relocates CO alarm system requirements from Section 908.7 to a new Section 915, with no technical changes whatsoever. This is being done for the following reasons:

1. By definition emergency alarm systems provide indication and warning of emergency situations involving hazardous materials, which relates more closely to warning systems required by the hazardous materials chapters of this code (e.g. Chapter 50 to 67). Carbon monoxide that is generated by motor vehicle exhaust and damaged fuel burning appliances is not regulated by those chapters.
2. As currently written the CO alarm requirements in Section 908.7 stand alone, and do not relate in any way to the emergency alarm requirements in Sections 908.1 through 908.6. Thus there is no advantage to having both emergency alarm and carbon monoxide alarm requirements in the same Section.
3. This proposal relocates the carbon monoxide alarm requirements to a new Section 915, which was done so the current Sections 909 through 914 don't need to be renumbered.
4. It is recognized that there is at least one other proposal to revise the Section 908.7 CO alarm requirements. If that proposal succeeds, approval of this proposal is intended to retain the changes from the other proposal, and relocate the revised provisions into Section 915.

Cost Impact: The proposal will not increase the cost of construction.

F181 – 13

908.7 (IBC [F] 908.7); 1103.9

Proponent: Thomas G. Daly, The Hospitality Security Consulting Group, LLC, representing Hilton Worldwide, Inc.

Delete and substitute as follows:

908.7 (IBC [F] 908.7) Carbon monoxide alarms. ~~Group I or R occupancies located in a building containing a fuel-burning appliance, or a building which has an attached garage shall be equipped with single station carbon monoxide alarms. The carbon monoxide alarms shall be listed as complying with UL 2034 and be installed and maintained in accordance with NFPA 720 and the manufacturer's instructions. An open parking garage, as defined in Chapter 2, or an enclosed parking garage ventilated in accordance with Section 404 of the International Mechanical Code shall not be considered an attached garage.~~

Exception: ~~Sleeping units or dwelling units which do not themselves contain a fuel-burning appliance or have an attached garage, but which are located in a building with a fuel-burning appliance or an attached garage, need not be equipped with single station carbon monoxide alarms provided that:~~

- ~~1. The sleeping unit or dwelling unit is located more than one story above or below any story which contains a fuel-burning appliance or an attached garage;~~
- ~~2. The sleeping unit or dwelling unit is not connected by duct work or ventilation shafts to any room containing a fuel-burning appliance or to an attached garage; and~~
- ~~3. The building is equipped with a common area carbon monoxide alarm system.~~

908.7 (IBC [F] 908.7) Carbon monoxide alarms detection and warning equipment. Group I or R occupancies located in a building containing a fuel-burning appliance, fireplace or a building which has an attached garage shall be equipped with carbon monoxide detection and warning equipment.

908.7.1 (IBC [F] 908.7.1 Listings and installation. Single station carbon monoxide alarms shall be listed as complying with UL 2034 and be installed and maintained in accordance with NFPA 720 and the manufacturer's instructions.

908.7.2 (IBC [F] 908.7.2) Attached garage. An open parking garage as defined in Chapter 2 or an enclosed parking garage ventilated in accordance with Section 404 of the *International Mechanical Code* shall not be deemed to be an attached garage.

908.7.3 (IBC [F] 908.7.3) Locations. A supervised carbon monoxide detector with an integral sounding device shall be installed within 15 feet of each fuel-burning appliance or fireplace and be monitored at a constantly attended location. Connection to an existing fire alarm system to report as a supervisory signal shall be an acceptable alternative to the detector being monitored at a constantly attended location.

908.7.4 (IBC [F] 908.7.4) Sleeping and dwelling units. *Sleeping units or dwelling units* which do not themselves contain a fuel-burning appliance, fireplace or have an attached garage, but which are located in a building with a fuel-burning appliance, fireplace or an attached garage, shall be equipped with 120 vac powered single-station carbon monoxide alarms with battery back-up provided that:

1. The sleeping unit or dwelling unit is located directly above, below or immediately adjacent to any room or space containing a fuel-burning appliance, fireplace or an attached garage.
2. The sleeping unit or dwelling unit is connected by duct work or ventilation shafts to any room containing a fuel-burning appliance or to an attached garage.
3. Affected hotel guest suites and multi-room dwelling units shall be equipped with a single station carbon monoxide alarm in each sleeping and living area and such units shall be interconnected.
4. Affected accessible sleeping units and accessible dwelling units single station carbon monoxide alarms shall activate a visual alarm within such units in accordance with NFPA 720.

908.7.5 (IBC [F] 908.7.5) Combination devices. Combination single station carbon monoxide and smoke alarms and combination carbon monoxide and smoke detectors shall be permitted.

908.7.4 (IBC [F] 908.7.4) 908.7.6 (IBC [F] 908.7.6) Carbon Monoxide detection systems. *(No change to current text)*

Delete and substitute as follows:

1103.9 Carbon monoxide alarms. Existing Group I or R occupancies located in a building containing a fuel-burning appliance or a building which has an attached garage shall be equipped with single-station carbon monoxide alarms. The carbon monoxide alarms shall be listed as complying with UL 2034, and be installed and maintained in accordance with NFPA 720 and the manufacturer's instructions. An open parking garage, as defined in the International Building Code, or an enclosed parking garage ventilated in accordance with Section 404 of the International Mechanical Code shall not be deemed to be an attached garage.

Exception: ~~Sleeping units or dwelling units which do not themselves contain a fuel-burning appliance or have an attached garage, but which are located in a building with a fuel-burning appliance or an attached garage, need not be equipped with single-station carbon monoxide alarms provided that:~~

- ~~1. The sleeping unit or dwelling unit is located more than one story above or below any story that contains a fuel-burning appliance or an attached garage;~~
- ~~2. The sleeping unit or dwelling unit is not connected by duct work or ventilation shafts to any room containing a fuel-burning appliance or to an attached garage; and~~
- ~~3. The building is provided with a common area carbon monoxide alarm system.~~

1103.9 Carbon Monoxide detection and warning equipment. Existing Group I or R occupancies located in a building containing a fuel-burning appliance, fireplace or a building which has an attached garage shall be equipped with carbon monoxide detection and warning equipment.

1103.9.1 Listings and installation. Single station carbon monoxide alarms shall be listed as complying with UL 2034, and be installed and maintained in accordance with NFPA 720 and the manufacturer's instructions. Carbon monoxide detectors shall be listed as complying with UL 2075 and be installed and maintained in accordance with NFPA 720 and the manufacturer's instructions.

1103.9.2 Attached garage. An open parking garage, as defined in the *International Building Code*, or an enclosed parking garage ventilated in accordance with Section 404 of the *International Mechanical Code* shall not be deemed to be an attached garage.

1103.9.3 Locations. A supervised carbon monoxide detector with an integral sounding device shall be installed within 15 feet of each fuel burning appliance or fireplace and be monitored at a constantly attended location. Connection to an existing fire alarm system to report as a supervisory signal shall be an acceptable alternative to the detector being monitored at a constantly attended location.

1103.9.4 Sleeping and dwelling units. *Sleeping units or dwelling units* which do not themselves contain a fuel-burning appliance or have an attached garage, but which are located in a building with a fuel-burning appliance, fireplace or an attached garage, shall be equipped with 120 vac powered single-station carbon monoxide alarms with battery back-up provided that:

1. The sleeping unit or dwelling unit is located directly above, below or immediately adjacent to any room or space containing a fuel-burning appliance, fireplace or an attached garage.
2. The sleeping unit or dwelling unit is connected by duct work or ventilation shafts to any room containing a fuel burning appliance or to an attached garage.
3. Affected hotel guest suites and multi-room dwelling units shall be equipped with a single station carbon monoxide alarm in each sleeping and living area and such units shall be interconnected.

4. Affected accessible sleeping units and accessible dwelling units single station carbon monoxide alarms shall activate a visual alarm within such units in accordance with NFPA 720.

1103.9.5 Combination devices. Combination single station carbon monoxide and smoke alarms and combination carbon monoxide and smoke detectors shall be permitted.

Reason – Chapter 9: The requirements are organized in a more reader friendly format.

The proposed changes will provide for earlier detection of potential carbon monoxide (CO) exposure and as a result allow for corrective action before CO can reach occupied areas of Group R & I facilities by placing a supervised and monitored CO detector at the source of potential CO. Sleeping and dwelling units in proximity to such sources of CO exposure would also have local CO alarms therein.

The requirements mirror successful CO regulation in Massachusetts, see 527 CMR 31.00 et seq., and New Jersey, see N.J.A.C. 5:23-3.21, which have no records of CO exposure related deaths in such equipped facilities in the 7 years since those regulations similar to this proposal have been in place.

CO detectors would be permitted to be a part of existing fire alarm systems making their installation more efficient and cost effective. Cost of construction would not be increased but would be diminished.

Reliability would be improved as such systems have secondary power requirements ensuring operation of the CO detector in the event of a power failure.

Listing and installation criteria for CO detectors are added.

CO alarm requirements for multi-room sleeping and dwelling units are clarified. In such units, where the means of egress from a sleeping areas is thru the living area, typical of all suite hotels, the current requirement for a CO alarm only within the sleeping area is insufficient to warn the occupant and may result in a CO exposure when attempting to exit. CO alarms would be required in both sleeping and living units and would be interconnected similar to requirements for smoke alarms.

The use of combination CO/smoke alarms and detectors would be specifically allowed. Such units will allow for a more cost effective installation by avoiding new electrical work as those units may be replace existing 120vac smoke alarms and system smoke detectors. Cost of construction would not be increased but would be diminished.

Fireplaces, a potential source of CO exposure, would be added for clarity as this term is defined separately from 'fuel burning appliances' in NFPA 720.

Undefined terms, e.g., 'common areas' are deleted.

Battery backup for CO alarms is specified to ensure operation in the event of power failure.

Reason – Chapter 11: The 2012 IFC language (new) had the unintended consequences of requiring CO alarms in areas of buildings where there is little likelihood and little historical occurrence of CO exposures while at the same time not requiring CO warning equipment in locations where there is a greater likelihood of an adverse CO exposures. The historical record of CO exposures in commercial buildings is so rare that the CPSC which reports on such exposure incidents does not list commercial buildings as an occupancy group. See this link for the latest such report:

Non-Fire Carbon Monoxide Deaths Associated with the Use of Consumer Products: 2008 Annual Estimates (released 01/12) <http://www.cpsc.gov/LIBRARY/dataCO.html>

The changes proposed would focus the requirement for such warning equipment at the potential source of such exposure and provide a local and remote alarm to building staff to initiate corrective action. Early detection and warning would be provided under this proposal vs. the current delayed warning based on the 2012 IFC language.

Cost Impact – Chapter 9: Cost of construction would not be increased but would be diminished.

Cost Impact – Chapter 11: Compared to the 2012 IFC these changes would reduce compliance costs by 90% for a typical commercial building with a small number of gas fired appliances (e.g., boiler, emergency generator, pool heater, kitchen). The proposal would allow CO detectors to be incorporated into existing fire alarm systems ensuring proper operation, maintenance and inspections per the Fire Code provisions for such systems.

908.7 (IBC[F] 908.7) , 908.7.1 (New) [IBC [F] 908.7.1 (New)], 908.7.1.1 (New) [IBC [F] 908.7.1.1 (New)], 908.7.1.2 (New) [IBC [F] 908.7.1.2 (New)]

Proponent: Roger Evans, Park City Municipal Corporation, representing the Utah Chapter of ICC (revans@parkcity.org)

Revise as follows:

908.7 (IBC[F] 908.7) Carbon monoxide alarms detection. Group I or R and E occupancies located in a building containing a fuel-burning appliance or in a building which has an attached garage shall be equipped with single-station carbon monoxide alarms detection. ~~The Group I and R occupancies shall be equipped with single-station carbon monoxide alarms shall be listed as complying with UL 2034 and be installed and be installed and maintained in accordance with NFPA 720 and the manufacturer's instructions. Group E occupancies shall be equipped with carbon monoxide detection in accordance with 907.1 and 907.2.~~ An open parking garage ventilated in accordance with Section 404 of the International Mechanical Code shall not be considered an attached garage.

Exception: *Sleeping units or dwelling units* which do not themselves contain a fuel-burning appliance or have an attached garage, but which are located in a building with a fuel-burning appliance or an attached garage, need not be equipped with single-station carbon monoxide alarms provided that:

1. The *sleeping unit or dwelling unit* is located more than one story above or below any story which contains a fuel-burning appliance or an attached garage;
2. The *sleeping unit or dwelling unit* is not connected by duct work or ventilation shafts to any room containing a fuel-burning appliance or to an attached garage; and
3. The building is equipped with a common area carbon monoxide alarm system.

908.7.1 (IBC[F] 908.7.1) Group E Occupancy Locations. Where required by Section 908.7, carbon monoxide detectors in Group E occupancies shall be installed in the locations specified in Sections 908.7.2 through 908.7.2.2.

908.7.1.1 (IBC[F] 908.7.1.1) Fuel-burning appliances and fuel burning fireplaces. Carbon monoxide detectors shall be installed on the ceiling of a room containing a fuel-burning appliance or a fuel burning fireplace. The carbon monoxide alarm signal shall be automatically transmitted to a constantly attended on site location.

908.7.1.2 (IBC[F] 908.7.1.2) Forced air furnaces. Carbon monoxide detectors shall be installed on the ceiling of a room containing a fuel-burning forced air furnace or in occupied rooms served by a fuel-burning, forced air furnace. The carbon monoxide alarm signal shall be automatically transmitted to a constantly attended on site location.

908.7.1 (IBC[F] 908.7.1) 908.7.2 (IBC[F] 908.7.2) Carbon monoxide detection systems. Carbon monoxide detection systems, which include carbon monoxide detectors and audible notification appliances, installed and maintained in accordance with this section for carbon monoxide alarms and NFPA 720 shall be permitted. The carbon monoxide detectors shall be listed as complying with UL 2075.

Reason: This proposal is intended to protect students and faculty from serious injury or possibly death from unintentional non-fire related carbon monoxide (CO) exposure by mandating the installation of CO detection devices in education occupancies. In the absence of a model code for the installation of CO detection in education occupancies each jurisdiction is developing its own regulations with varying installation requirements. For example, after several CO incidents in Connecticut (Public Act 11-248) and in Maryland (SB 173), the Governors signed bills into law for the installation CO detection in education occupancies and left the location, performance, inspection, testing and maintenance of CO detection and warning equipment up to the Building Commission or the State Fire Marshal. Section 610 of the 2010 Fire Code New York State (FCNYS) requires CO detection in Group E occupancies.

Also a result of the national publicity generated from an incident at an Atlanta school (ABC News) that sent 42 students to hospitals, three states have introduced legislation requiring CO detection in schools.

. Pennsylvania:

<http://www.legis.state.pa.us/cfdocs/Legis/CSM/showMemoPublic.cfm?chamber=H&SPick=20130&cosponId=9878>

. Florida: <http://www.flsenate.gov/Session/Bill/20130116/BillText/Filed/HTML>

. Georgia: **HB 23**

Attached are fifty three (53) reports of CO incidents in schools from 2005 through 2012. Thirty (30) of these incidents were caused by problems with a permanently installed fuel burning appliance.

This proposal models the location requirements for schools after the current requirements in the 2012 edition of the IFC for detection in hotels, dormitories and apartment buildings as a basis.

The efficacy of voluntary national consensus codes, such as the IFC, ensures a collaborative, balanced and consensus-based process.

Cost Impact: Minimal cost as a percentage of the building valuation.

IFC: 908.7.2 (New) (IBC [F] 908.7.2 (New)), 1103.9 (New); IRC: R315.1.1 (New), R315.3.1 (New)

THIS IS A 2 PART CODE CHANGE PROPOSAL. PART 1 WILL BE HEARD BY THE IFC COMMITTEE. PART 2 OF THIS PROPOSAL WILL BE HEARD BY THE IRC BUILDING/ENERGY COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THE IFC AND IRC BUILDING/ENERGY CODE DEVELOPMENT COMMITTEES.

Proponent: Al Godwin, CBO, CPM, Aon Fire Protection Engineering, representing Aon Fire Protection Engineering Corporation (al.godwin@aon.com)

PART I – INTERNATIONAL FIRE CODE

Add new text as follows:

908.7.2 (IBC [F] 908.7.2) Power source. In new construction, required carbon monoxide alarms shall receive their primary power from the building wiring where such wiring is served from a commercial source and shall be equipped with a battery backup. Wiring shall be permanent and without a disconnecting switch other than as required for overcurrent protection.

Exception: Carbon monoxide alarms are not required to be equipped with battery backup where they are connected to an emergency electrical system.

Add new text as follows:

1103.9 Power source. Single-station carbon monoxide alarms shall receive their primary power from the building wiring where such wiring is served from a commercial source and shall be equipped with a battery backup. Wiring shall be permanent and without a disconnecting switch other than as required for overcurrent protection.

Exceptions:

1. Carbon monoxide alarms are not required to be equipped with battery backup where they are connected to an emergency electrical system.
2. Carbon monoxide alarms are permitted to be solely battery operated in existing buildings where no construction is taking place.
3. Carbon monoxide alarms are permitted to be solely battery operated in buildings that are not served from a commercial power source.
4. Carbon monoxide alarms are permitted to be solely battery operated in existing areas of buildings undergoing alterations or repairs that do not result in the removal of interior walls or ceiling finishes exposing the structure, unless there is an attic, crawl space or basement available which could provide access for building wiring without the removal of interior finishes.

PART II – INTERNATIONAL RESIDENTIAL CODE

Add new text as follows:

R315.1.1 Power source. In new construction, required carbon monoxide alarms shall receive their primary power from the building wiring where such wiring is served from a commercial source and shall be equipped with a battery backup. Wiring shall be permanent and without a disconnecting switch other than as required for overcurrent protection.

R315.3.1 Power source. Single-station carbon monoxide alarms shall receive their primary power from the building wiring where such wiring is served from a commercial source and shall be equipped with a battery backup. Wiring shall be permanent and without a disconnecting switch other than as required for overcurrent protection.

Exceptions:

1. Carbon monoxide alarms are permitted to be solely battery operated in existing buildings where no construction is taking place.
2. Carbon monoxide alarms are permitted to be solely battery operated in buildings that are not served from a commercial power source.
3. Carbon monoxide alarms are permitted to be solely battery operated in existing areas of buildings undergoing *alterations* or repairs that do not result in the removal of interior walls or ceiling finishes exposing the structure, unless there is an attic, crawl space or *basement* available which could provide access for building wiring without the removal of interior finishes.

Reason: This proposal copies the same installation requirements as specified for smoke alarms. It would seem to be appropriate if these alarms are a life saving device.

Costs: Assuming that the original wording seems to allow carbon monoxide alarms to be only battery powered, even in new construction, this would increase the cost of construction.

908.7.2 (NEW)-F-GODWIN

F184 – 13

909.4.6 (IBC [F] 909.4.6, IMC [F] 513.4.6)

Proponent: Dave Frable representing U.S. General Services Administration, Public Buildings Service

Revise as follows:

909.4.6 (IBC [F] 909.4.6, IMC [F] 513.4.6) Duration of operation. All portions of ~~active or~~ ~~passive engineered~~ smoke control systems shall be capable of continued operation after detection of the fire event for a period of not less than either 20 minutes or 1.5 times the calculated egress time, whichever is ~~less~~ greater.

Reason: The intent of this code change is to provide clarification for determining the duration of operation for smoke control systems to ensure a tenable environment for occupants to either evacuate or relocate to a safe location within a building. In addition, the requirement has also been revised to determine the proper duration for the operation of the smoke control system to run during an emergency by correctly stating “whichever is greater” in lieu of “whichever is less”. The 20 minute maximum time duration for the operation of the smoke control system is not sufficient for all evacuation situations and by revising the subject text, a more realistic and reasonable time duration for the operation of the smoke control system will be achieved.

Cost Impact: The code change proposal will not increase the cost of construction.

F184-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

909.4.6-F-FRABLE

F185 – 13

909.4 (IBC [F] 909.4, IMC [F] 513.4), 909.4.7 (New) [IBC [F] 909.4.7 (New), IMC [F] 513.4.7 (New)]

Proponent: Carl Baldassarra, P.E., FSFPE, Chair, ICC Code Technology Committee
(cbaldassarra@RJAGroup.com)

Revise as follows:

909.4 (IBC [F] 909.4, IMC [F] 513.4) Analysis. A rational analysis supporting the types of smoke control systems to be employed, their methods of operation, the systems supporting them and the methods of construction to be utilized shall accompany the submitted *construction documents* and shall include, but not be limited to, the items indicated in Sections 909.4.1 through ~~909.4.6~~ 909.4.6.7. [F]

909.4.7 (IBC [F] 909.4.7, IMC [F] 513.4.7) Smoke control system interaction. The design shall consider the interaction effects of the operation of multiple smoke control systems for all design scenarios.

Reason: The focus of this proposal is related to the interaction of multiple mechanical smoke control systems by asking for a specific analysis of the interaction of such systems similar to that required for the interaction of HVAC systems. The study of hoistway pressurization as an option for compliance with enclosed elevator lobby provisions drives the need to understand these interactions as stair pressurization will almost always be present in these buildings as well.

The CTC studied the need for elevator lobbies for traditional elevators (Section 713.14.1), FSAE (3007) and Occupant Evacuation elevators (3008). The Study Group assigned by the CTC conducted a technical analysis that concluded with several recommendations for the need for such lobbies and in addition provided a recommendation on the need for a closer analysis of buildings with more complexities. From this technical analysis the following excerpt is relative to this proposal.

In fact in many cases a traditional enclosed elevator lobby was determined to be unnecessary but for unusual building configurations there was more of a concern for interaction of systems and the negative impact of stack effect based upon the findings of the analysis. For instance, high-rise buildings may contain an atrium and will also use stair pressurization. In some cases hoistway pressurization could also be used as an option for compliance with the enclosed elevator lobby requirements. These are three smoke control systems that when running simultaneously may not work as intended. Below is recommendation 5 from the technical analysis.

5. Elevator hoistway pressurization design

- **The design of pressurization systems for elevator hoistways shall be based on a rational analysis in accordance with Section 909.4 that utilizes a network model approved by the AHJ and which includes an analysis of possible interactions between building shafts pressurized by different systems, and between pressurized and unpressurized shafts that exceed 420 feet in height.**

Add guidance to commentary for 909.4 that the rational analysis should show that the pressurization design will maintain the estimated Fractional Effective Dose (FED) below 0.5 and the estimated visibility distance above 25 feet within the stairway for 1.5 times the estimated evacuation time for each of the design fires selected.

- *Rationale: Taller buildings with more complex flow paths require analysis utilizing a network model that can account for these interacting flow paths. The criteria suggested for commentary represents the standard of practice for a fire hazard analysis performed as the required rational analysis.*

This proposal is one of several proposals submitted by the CTC Elevator lobby SG. The ICC Executive Board directed the Code Technology Committee (CTC) to study the issue of elevator lobby separations in November 2010 due to the number of code change proposals submitted addressing this issue over a number of code change cycles. The Code Technology Committee formed a study group on the elevator lobby separation issue in December 2010. Note that this subject had been previously addressed by CABO/BCMC in 1986 with a similar conclusion. The code change proposals submitted are the result of the CTC's study of the issue. Note that the scope of the activity was as follows:

Scope

- ☐ Review the need for elevator lobbies, with emphasis on building use, building and hoistway height, active and passive fire protection features associated with the aforementioned.
- ☐ Review the differences and specific needs when dealing with elevator lobbies of traditional-use elevators, fire service elevators, and occupant evacuation elevators.
- ☐ Review related code provisions, such as egress from and through elevator lobbies.

- ☐ Review the appropriate use of alternatives including pressurization of hoistways, additional doors, roll-down style barriers, and gasketing systems.
- ☐ Review with members of elevator industry to scope the requirements of applicable elevator reference standards as it deals with elevator lobby design, use and construction.
- ☐ Review design and construction requirements for elevator lobbies, including but not limited to dimensions, location and separation.
- ☐ Review applicable code change history, technical studies and loss statistics as part of this review.

Several proposals were submitted during the Group A Cycle and discussion of the content and outcome of these proposals and the full content of the technical analysis can be found at the following link. <http://www.iccsafe.org/cs/CTC/Pages/ElevatorLobbies.aspx>

Cost Impact: This proposal will increase the cost of construction where such analysis are not currently undertaken. It can be argued that such an analysis may possibly decrease the cost of construction. Potential delays can be avoided by reducing the need for rework after problems arise during commissioning as result of an upfront analysis. Also the upfront design analysis may eliminate possible excess capacity in the equipment.

F185-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

909.4-F-BALDASSARRA-CTC

F186 – 13

909.5 (IBC [F] 909.5, IMC [F] 513.5), 909.5.1 (IBC [F] 909.5.1, IMC [F] 513.5.1), 909.5.2 (IBC [F] 909.5.2, IMC [F] 513.5.2),

Proponent: Jeffrey Tubbs, PE, FSFPE, Arup USA, Inc., representing self (jeff.tubbs@arup.com)

Revise as follows:

909.5 (IBC [F] 909.5, IMC [F] 513.5) Smoke barrier construction. Smoke barriers required for passive smoke control and a smoke control system using the pressurization method shall comply with Section 709, and shall be constructed and sealed to limit leakage areas exclusive of protected openings. The maximum allowable leakage area shall be the aggregate area calculated using the following leakage area ratios:

1. Walls: $A/A_w = 0.00100$
2. Interior *exit stairways* and *ramps* and *exit passageways*: $A/A_w = 0.00035$
3. Enclosed *exit access stairways* and *ramps* and all other shafts: $A/A_w = 0.00150$
4. Floors and roofs: $A/A_F = 0.00050$

where:

A = Total leakage area, square feet (m^2).
 A_F = Unit floor or roof area of barrier, square feet (m^2).
 A_w = Unit wall area of barrier, square feet (m^2).

The leakage area ratios shown do not include openings due to gaps around doors, and operable windows, or similar gaps. The total leakage area of the smoke barrier shall be determined in accordance with Section 909.5.1 and tested in accordance with Section 909.5.2.

909.5.1 (IBC [F] 909.5.1, IMC [F] 513.5.1) Total Leakage area. The total leakage area of the barrier is the product of the *smoke barrier* gross area multiplied by the allowable leakage area ratio, plus the area of other openings such as gaps around doors and operable windows.

909.5.2 (IBC [F] 909.5.2, IMC [F] 513.5.2) Testing of leakage area. Compliance with the maximum total leakage area shall be determined by achieving the minimum air pressure difference across the barrier with the system in the smoke control mode for mechanical smoke control systems utilizing the pressurization method. Compliance with the maximum total leakage area of passive smoke control systems shall be verified through methods such tested using other approved means such as door fan testing or other methods shall be as approved by the fire code official.

Reason: This code change clarifies leakage area calculation and testing, and clarifies requirements for passive smoke control systems.

Cost Impact: The code change may introduce a small to negligible cost impact to smoke control systems.

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

909.5-F-TUBBS

F187 – 13

909.5.2 (IBC [F] 909.5.2, IMC [F] 513.5.2), 909.5.2.1 (New) [IBC [F] 909.5.2.1 (New), IMC [F] 513.5.2.1 (New)],

Proponent: Al Godwin, CBO, CPM, Aon Fire Protection Engineering, representing Aon Fire Protection Engineering Corporation (al.godwin@aon.com)

Revise as follows:

909.5.2 (IBC [F] 909.5.2, IMC [F] 513.5.2) Opening protection. Openings in *smoke barriers* shall be protected by automatic-closing devices actuated by the required controls for the mechanical smoke control system. Door openings shall be protected by fire door assemblies complying with Section 716.5.3 of the *International Building Code*.

Exceptions:

1. Passive smoke control systems with automatic-closing devices actuated by spot-type smoke detectors *listed* for releasing service installed in accordance with Section 907.3.
2. Fixed openings between smoke zones that are protected utilizing the airflow method.
3. In Group I-1 Condition 2, Group I-2 and ambulatory health care facilities, where ~~such doors are installed across corridors~~, a pair of opposite-swinging doors are installed across a corridor in accordance with Section 909.5.2.1, the doors shall not be required to be protected in accordance with Section 716 of the *International Building Code* ~~without a center mullion shall be installed having vision panels with fire-protection-rated glazing materials in fire protection-protection-rated frames, the area of which shall not exceed that tested~~. The doors shall be close-fitting within operational tolerances and shall not have a center mullion or undercuts in excess of 3/4-inch, louvers or grilles. The doors shall have head and jamb stops, and astragals or rabbets at meeting edges and ~~shall automatic-closing by smoke detection in accordance with Section 716.5.9.3 of the International Building Code~~. Where permitted by the door manufacturer's listing, ~~Positive-latching~~ devices are not required.
4. Group I-3.
5. Openings between smoke zones with clear ceiling heights of 14 feet (4267 mm) or greater and bank-down capacity of greater than 20 minutes as determined by the design fire size.

909.5.2.1 (IBC [F] 909.5.2.1, IMC [F] 513.5.2.1) Group I-1 Condition 2, I-2 and ambulatory care facilities. In Group I-1 Condition 2, Group I-2 and ambulatory care facilities, where doors are installed across a corridor, the doors shall be automatic closing by smoke detection in accordance with Section 716.5.9.3 of the *International Building Code* and shall have a vision panel with fire-protection rated glazing materials in fire-protection-rated frames, the area of which shall not exceed that tested.

909.5.2.1 (IBC [F] 909.5.2.1, IMC [F] 513.5.2.1) 909.5.2.2 (IBC [F] 909.5.2.2, IMC [F] 513.5.2.2) Ducts and air transfer openings. (No change to current text)

Reason: Code changes FS76-07/08, G15-09/10 and FS40-12 have made amendments to IBC Section 709.5, exception 1 that are not reflected in Section 909.5.2. G31-12 added a new requirement for Group I-1 Condition 2 that needs to be picked up in 909.5.2.

Cost Impact: This is just a correlation between the two codes. Thus, there will be no increase in cost not already encountered.

F187-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

909.5.2-F-GODWIN

F188 – 13

909.5.2 (IBC [F] 909.5.2, IMC [F] 513.5.2)

Proponent: John Woestman, Kellen Company, representing Builders Hardware Manufacturers Association (BHMA) (jwoestman@kellencompany.com)

Revise as follows:

909.5.2 (IBC [F] 909.5.2, IMC [F] 513.5.2) Opening protection. Openings in *smoke barriers* shall be protected by automatic-closing devices actuated by the required controls for the mechanical smoke control system. Door openings shall be protected by fire door assemblies complying with Section 716.5.3 of the *International Building Code*.

Exceptions:

1. Passive smoke control systems with automatic closing devices actuated by spot-type smoke detectors *listed* for releasing service installed in accordance with Section 907.10.
2. Fixed openings between smoke zones that are protected utilizing the airflow method.
3. In Group I-2 and ambulatory care facilities, where such doors are ~~installed across corridors, a pair of opposite-swinging doors installed across a corridor and without a center mullion, shall be installed having vision panels with fire protection-rated glazing materials in fire protection-rated frames, the area of which shall not exceed that tested.~~ The doors shall be close-fitting within operational tolerances and shall not have undercuts in excess of 1 inch, louvers or grilles. The doors shall have head and jamb stops, astragals or rabbets at meeting edges. Vision panels shall have fire-protection rated glazing materials in fire-protection-rated frames. The doors and shall be automatic-closing by smoke detection in accordance with Section 716.5.9.3 of the *International Building Code*. Where permitted by the door manufacturer's listing, Ppositive-latching devices are not required.
4. In Group I-2 and ambulatory care facilities, where such doors are special purpose horizontal sliding, accordion, or folding door assemblies installed in accordance with Section 1008.1.4.3 and are automatic closing by smoke detection in accordance with Section 716.5.9.3 of the *International Building Code*.
45. Group I-3.
56. Openings between smoke zones with clear ceiling heights of 14 feet (4267 mm) or greater and bank-down capacity of greater than 20 minutes as determined by the design fire size.

Reason: IFC Section 909.5.2 (and IBC Section 909.5.2) addresses requirements for opening protection in smoke barriers, as does IBC Section 709.5. This proposal updates IFC Section 909.5.2 (and IBC Section 909.5.2). The charging language, in IFC Section 909.5, requires smoke barriers to comply with the IBC, thus this language provides greater consistency with pertinent IBC requirements.

Also, IBC Section 709.5 includes an exception for doors complying with 1008.1.4.3 of the IBC, and IBC Section 1008.1.4.3 was revised for the 2015 IBC. The proposed language in Exception 4 for special purpose horizontal sliding, accordion, or folding door assemblies is intended to reflect this.

Cost Impact: None

	Assembly:	ASF	AMF	DF

909.5.2-F-WOESTMAN

F189 – 13

909.6.3 (New) [IBC [F] 909.6.3 (New), IMC [F] 513.6.3 (New)]

Proponent: Bob D. Morgan, P.E., Fort Worth, TX Fire Department representing Fire Advisory Board to North Central Texas Council of Governments

Revise as follows:

909.6.3 (IBC [F] 909.6.3, IMC [F] 513.6.3) Pressurized stairways and elevator hoistways. When stairways or elevator hoistways are pressurized, such pressurization systems shall comply with Section 909 as smoke control systems, in addition to the requirements of the Building Code Sections 909.20 and 909.21.

Reason: Section 909.6.3 specifically requires that stairway pressurization systems must comply as smoke control systems. Currently, Sections 909.20 and 909.21 of the Building Code are not copied into the Fire Code, leading to inconsistency with regards to design and controls for such systems, as well as, uncertainty on the part of designers as to the appropriate authority with regards to such. These are complicated systems and involve coordination between fire alarm systems and mechanical components – such should be a coordinated effort between Building and Fire Code Officials.

Cost Impact: The code change proposal will not increase the cost of construction.

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

909.6.3 (NEW)-F-MORGAN

F190 – 13

909.7 (IBC [F] 909.7, IMC [F] 513.7), 909.7.1 (IBC [F] 909.7.1, IMC [F] 513.7.1), 909.7.2 (IBC [F] 909.7.2, IMC [F] 513.7.2)

Proponent: Jeffrey Tubbs, PE, FSFPE, Arup USA, Inc., representing self (jeff.tubbs@arup.com)

Revise as follows:

909.7 (IBC [F] 909.7, IMC [F] 513.7) Airflow design method. When *approved* by the fire code official, smoke migration through openings fixed in a permanently open position, which are located between smoke control zones by the use of the airflow method, shall be permitted. The design airflow shall be in accordance with this section. Airflow shall be directed to limit smoke migration from the fire zone. The geometry of openings shall be considered to prevent flow reversal from turbulent effects. Smoke control systems using the airflow method shall be designed in accordance with NFPA 92.

~~**909.7.1 (IBC [F] 909.7.1, IMC [F] 513.7.1) Velocity.** The minimum average velocity through a fixed opening shall not be less than:~~

$$n = 217.2 [h(T_f - T_o)/(T_f + 460)]^{1/2} \text{ --- (Equation 9-2)}$$

$$\text{For SI: } n = 119.9 [h(T_f - T_o)/T_f]^{1/2}$$

where:

~~h = Height of opening, feet (m).~~

~~T_f = Temperature of smoke, °F (K).~~

~~T_o = Temperature of ambient air, °F (K).~~

~~n = Air velocity, feet per minute (m/minute).~~

~~**909.7.2 (IBC [F] 909.7.2, IMC [F] 513.7.2) 909.7.1 (IBC [F] 909.7.1, IMC [F] 513.7.1) Prohibited conditions.** This method shall not be employed where either the quantity of air or the velocity of the airflow will adversely affect other portions of the smoke control system, unduly intensify the fire, disrupt plume dynamics or interfere with exiting. In no case shall airflow toward the fire exceed 200 feet per minute (1.02 m/s). Where the formula in Section 909.7.1 calculated requires airflow to exceed this limit, the airflow method shall not be used.~~

Reason: This code change follows previous changes made to the exhaust method and references NFPA 92 Standard for Smoke Control Systems. NFPA 92 Section 5.10 details the use of the airflow method. Referencing NFPA 92 for the exhaust and airflow method provides a consistent approach for smoke control in atrium and other large volume spaces.

Cost Impact: The code change may introduce a small to negligible cost impact to smoke control systems.

Analysis: ADMIN UPDATE

F191 – 13

909.10.2 (IBC [F] 909.10.2, IMC [F] 513.10.2)

Proponent: Jeffrey Tubbs, PE, FSFPE, Arup USA, Inc., representing self (jeff.tubbs@arup.com)

Revise as follows:

909.10.2 (IBC [F] 909.10.2, IMC [F] 513.10.2) Ducts. Duct materials and joints shall be capable of withstanding the probable temperatures and pressures to which they are exposed as determined in accordance with Section 909.10.1. Ducts shall be constructed and supported in accordance with the *International Mechanical Code*. Ducts shall be leak tested to 1.5 times the maximum design pressure in accordance with nationally accepted practices. Measured leakage shall not exceed 5 percent of design flow. Results of such testing shall be a part of the documentation procedure. Ducts shall be supported directly from fire-resistance-rated structural elements of the building by substantial, noncombustible supports.

~~**Exception:** Flexible connections, (for the purpose of vibration isolation) complying with the *International Mechanical Code*, that are constructed of approved fire-resistance-rated materials.~~

Reason: As written, flexible duct work may present a potential failure mode for smoke control systems. Flexible ducts that are part of a required smoke control system should be subject to requirements for rigid duct work.

Cost Impact: The code change may introduce a small to negligible cost impact to smoke control systems.

F191-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

909.10.2-F-TUBBS

F192 – 13

909.12.1 (IBC [F] 909.12.1, IMC [F] 513.12.1), 909.20.6 (New)

Proponent: Jeffrey Tubbs, PE, FSFPE, Arup USA, Inc., representing self (jeff.tubbs@arup.com)

Revise as follows:

909.12 (IBC [F] 909.12, IMC [F] 513.12) Detection and control systems. Fire detection systems providing control input or output signals to mechanical smoke control systems or elements thereof shall comply with the requirements of Section 907. Such systems shall be equipped with a control unit complying with UL 864 and *listed* as smoke control equipment.

909.12.1 (IBC [F] 909.12.1, IMC [F] 513.12.1) Verification. Control systems for mechanical smoke control systems shall include provisions for verification. Verification shall include positive confirmation of actuation, testing, manual override, and the presence of power downstream of all disconnects. A and, through a preprogrammed weekly test sequence shall, report abnormal conditions audibly, visually and by printed report. The preprogrammed weekly test shall operate all devices, equipment, and components.

Exception: Where verification of individual components tested through the preprogrammed weekly testing sequence will interfere with normal building operation and produce unwanted effects to normal building operation, such individual components are permitted to be bypassed from the weekly preprogrammed weekly testing, where approved by the code official and in accordance with the following:

1. Power supplies for components that are bypassed from the preprogrammed weekly test, such as power breakers, power disconnects, automatic transfer switches, motor starters, and motor controls, shall be electrically supervised by the listed control unit.
2. Testing of all components bypassed from the preprogrammed weekly test shall be in accordance with Section 909.20.6.

(Renumber subsequent sections)

909.20.6 Components bypassing weekly test. Where components of the smoke control system are bypassed by the preprogrammed weekly test required by Section 909.12.1 such components shall be tested semi-annually. The system shall also be tested under standby power conditions.

Reason: The current provisions require weekly tests of smoke control systems. For many systems, the weekly test requires the introduction of untreated air into the smoke zone. This can be impractical in areas with cold or hot climates, and for buildings that require close control of temperature and humidity, such as art museums and similar facilities. The introduction of the untreated air can also result in wasting energy to reheat, re-cool, humidify, or dehumidify the smoke control zone.

The intent of the current code provisions is to provide means to verify that the required systems will be available when needed. The code requires and will continue to require control units to comply with UL 864, thus all components of the control system will be supervised. The code change adds requirements for supervision of all power supply components such as power breakers, power disconnects, automatic transfer switches, motor starters, and motor controls. This will provide reasonable assurance that power will be available for all smoke control components, such as fans, dampers, doors, and windows. The code change also adds the semi-annual requirement for a complete system test. This allows the building owner to schedule complete system testing on days that will reduce the impact to the building and energy needs. The combination of additional supervision and additional testing provides a reasonable alternative to weekly testing.

Cost Impact: The code change allows optional additional features that may increase initial costs but reduce long-term operational costs.

	Assembly:	ASF	AMF	DF

909.12.1 (NEW)-F-TUBBS

F193 – 13

909.18.8.3 (IBC [F] 909.18.8.3)

Proponent: Douglas H. Evans, P.E., Clark County Building, representing Southern Nevada Chapter ICC (DHE@ClarkCountyNV.gov)

Revise as follows:

909.18.8.3 (IBC [F] 909.18.8.3) Reports. A complete report of testing shall be prepared by the special inspector or special inspection agency. The report shall include identification of all devices by manufacturer, nameplate data, design values, measured values and identification tag or mark. The report shall be reviewed by the responsible registered design professional and, when satisfied that the design intent has been achieved, the responsible registered design professional shall seal, sign and date the report with a statement as follows:

I have reviewed this report and by personal knowledge and on-site observation certify that the smoke-control system is in substantial compliance with the design intent, and to the best of my understanding complies with requirements of the code.

909.18.8.3.1 Report filing. A copy of the final report shall be filed with the fire code official and an identical copy shall be maintained in an approved location at the building.

Reason: This revision requires the engineer of record to observe the actual installation to help ensure the smoke control system is in accordance with the design. When physics based smoke-control systems initially appeared in the model code, this was initially required and has been shown to make good engineering sense.

This provision gives code officials an enforcement tool to ensure that the designer of record visits the jobsite to verify the system has been installed in accordance with their design. From a designers' standpoint, it makes sense to ensure that the smoke control system is designed in accordance with the original design intent and construction documents. Engineers are required to take an oath that holds them to a certain ethical standard. By requiring the engineer/registered design professional to sign the report with the above listed statement, it holds that person accountable consistent with the oath previously taken. This specific issue has come up on various projects in Southern Nevada. Without this provision in the code, out of state designers would likely not visit the site. Although local designers may be more apt to visit the jobsite to verify the system has been installed in accordance with the design, without this provision, it's possible that even in-state designers will not visit the site if they get too busy, or have not been contracted to perform this function. This provision serves a necessary and useful purpose.

Cost Impact: Can increase costs over base code.

	Assembly:	ASF	AMF	DF

909.18.8.3-F-EVANS

F194 – 13

[B] 909.21 (New)

Proponent: Joanne T. McCaughan, Code Specialist, Washington State Building Code Council, representing Washington State (joanne.mccaughan@des.wa.gov)

Add new text as follows:

[B] 909.21 Elevator hoistway pressurization alternative. Where elevator hoistway pressurization is provided in lieu of required enclosed elevator lobbies, the Pressurization system shall comply with Sections 909.21.1 through 909.21.11.

[B] 909.21.1 Pressurization requirements. Elevator hoistways shall be pressurized to maintain a minimum positive pressure of 0.10 inches of water (25 Pa) and a maximum positive pressure of 0.25 inches of water (67 Pa) with respect to adjacent occupied space on all floors. This pressure shall be measured at the midpoint of each hoistway door, with all elevator cars at the floor of recall and all hoistway doors on the floor of recall open and all other hoistway doors closed. The opening and closing of hoistway doors at each level must be demonstrated during this test. The supply air intake shall be from an outside uncontaminated source located a minimum distance of 20 feet (6096 mm) from any air exhaust system or outlet.

[B] 909.21.2 Rational analysis. A rational analysis complying with Section 909.4 shall be submitted with the construction documents.

[B] 909.21.3 Ducts for system. Any duct system that is part of the pressurization system shall be protected with the same fire-resistance rating as required for the elevator shaft enclosure.

[B] 909.21.4 Fan system. The fan system provided for the pressurization system shall be as required by Sections 909.21.4.1 through 909.21.4.4.

[B] 909.21.4.1 Fire resistance. When located within the building, the fan system that provides the pressurization shall be protected with the same fire-resistance rating required for the elevator shaft enclosure.

[B] 909.21.4.2 Smoke detection. The fan system shall be equipped with a smoke detector that will automatically shut down the fan system when smoke is detected within the system.

[B] 909.21.4.3 Separate systems. A separate fan system shall be used for each elevator hoistway.

[B] 909.21.4.4 Fan capacity. The supply fan shall either be adjustable with a capacity of at least 1,000 cfm (0.4719 m³/s) per door, or that specified by a registered design professional to meet the requirements of a designed pressurization system.

[B] 909.21.5 Standby power. The pressurization system shall be provided with standby power from the same source as other required emergency systems for the building.

[B] 909.21.6 Activation of pressurization system. The elevator pressurization system shall be activated upon activation of the building fire alarm system or upon activation of the elevator lobby smoke detectors.

Where both a building fire alarm system and elevator lobby smoke detectors are present, each shall be independently capable of activating the pressurization system.

[B] 909.21.7 Special inspection. Special inspection for performance shall be required in accordance with Section 909.18.8. System acceptance shall be in accordance with Section 909.19.

[B] 909.21.8 Marking and identification. Detection and control systems shall be marked in accordance with Section 909.14.

[B] 909.21.9 Control diagrams. Control diagrams shall be provided in accordance with Section 909.15.

[B] 909.21.10 Control panel. A control panel complying with Section 909.16 shall be provided.

[B] 909.21.11 System response time. Hoistway pressurization systems shall comply with the requirements for smoke control system response time in Section 909.17.

Reason: In the 2012 IBC, a new sub-section, 909.21 Elevator hoistway pressurization, was provided in Chapter 9. This same sub-section was not added to the 2012 IFC. For code consistency between these two codes, this sub-section should be located in both codes. Instead of the IBC being the primary code for this section, it should be maintained under the Fire Code. Currently, there is potential conflict between Building and Fire Code enforcement and interpretation of the Codes in relation to these provisions. Adoption of this language into the 2015 IFC would eliminate the potential conflict.

Cost Impact: The code change proposal will not increase the cost of construction.

910 (IBC [F] 910), Table 901.6.1, Table 3206.2, 3206.7, Chapter 80 (IBC Chapter 35)

Proponent: Carl Baldassarra, P.E., FSFPE, Chair, ICC Code Technology Committee
(cbaldassarra@RJAGroup.com)

Revise as follows:

SECTION 910 (IBC [F] 910) SMOKE AND HEAT REMOVAL

910.1 (IBC [F] 910.1) General. Where required by this code ~~or otherwise installed~~, smoke and heat vents or mechanical smoke ~~exhaust~~ removal systems ~~and draft curtains~~ shall conform to the requirements of this section.

Exceptions:

- ~~1. Frozen food warehouses used solely for storage of Class I and II commodities where protected by an approved automatic sprinkler system.~~
- ~~2. Where areas of buildings are equipped with early suppression fast-response (ESFR) sprinklers, automatic smoke and heat vents shall not be required within these areas.~~

910.2 (IBC [F] 910.2) Where required. Smoke and heat vents or a mechanical smoke removal system shall be installed in the roofs of buildings or portions thereof occupied for the uses set forth in as required by Sections 910.2.1 and 910.2.2. In occupied portions of a building where the upper surface of the story is not a roof assembly, a mechanical smoke removal system in accordance with Section 910.4 shall be installed.

Exceptions:

1. Frozen food warehouses used solely for storage of Class I and II commodities where protected by an approved automatic sprinkler system.
- ~~2. In occupied portions of a building where the upper surface of the story is not a roof assembly, mechanical smoke exhaust in accordance with Section 910.4 shall be an acceptable alternative.~~
2. Where areas of buildings are equipped with early suppression fast-response (ESFR) sprinklers, smoke and heat removal shall not be required within these areas.

910.2.1 (IBC [F] 910.2.1) Group F-1 or S-1. Smoke and heat vents installed in accordance with Section 910.3 or a mechanical smoke removal system installed in accordance with Section 910.4 shall be installed in buildings and portions thereof used as a Group F-1 or S-1 occupancy having more than 50,000 square feet (4645 m²) of undivided area.

Exception: Group S-1 aircraft repair hangars.

910.2.2 (IBC [F] 910.2.2) High-piled combustible storage. Smoke and heat removal required by Table 3206.2, for buildings and portions thereof containing high-piled combustible ~~stock or rack~~ storage shall be installed in accordance with Section 910.3 in unsprinklered buildings. In buildings and portions thereof containing high-piled combustible storage equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 in any occupancy group when required by Section 3206.7, a smoke and heat removal system shall be installed in accordance with Section 910.3 or 910.4.

910.3 (IBC [F] 910.3) Smoke and heat vents ~~Design and installation~~. The design and installation of smoke and heat vents ~~and draft curtains~~ shall be as specified in accordance with Sections 910.3.1 through 910.3.3 910.3.5.2 and Table 910.3.

**TABLE 910.3 (IBC [F] TABLE 910.3)
REQUIREMENTS FOR DRAFT CURTAINS AND SMOKE AND HEAT VENTS**

910.3.1 (IBC [F] 910.3.1) Design Listing and labeling. Smoke and heat vents shall be *listed* and labeled to indicate compliance with UL 793 or FM 4430.

910.3.2 (IBC [F] 910.3.2) Vent operation. Smoke and heat vents shall be capable of being operated by *approved* automatic and manual means. Automatic operation of smoke and heat vents shall conform to the provisions of Sections 910.3.2.1 through 910.3.2.3.

910.3.2.1 (IBC [F] 910.3.2.1) Gravity-operated drop-out vents. Automatic smoke and heat vents containing heat-sensitive glazing designed to shrink and drop out of the vent opening when exposed to fire shall fully open within 5 minutes after the vent cavity is exposed to a simulated fire, represented by a time-temperature gradient that reaches an air temperature of 500°F (260°C) within 5 minutes.

910.3.2.2 (IBC [F] 910.3.2.2) Sprinklered buildings. Where installed in buildings provided with an *approved automatic sprinkler system*, smoke and heat vents shall be designed to operate automatically.

910.3.2.3 (IBC [F] 910.3.2.3) Nonsprinklered buildings. Where installed in buildings not provided with an *approved automatic sprinkler system*, smoke and heat vents shall operate automatically by actuation of a heat-responsive device rated at between 100°F (38°C) and 220°F (104°C) above ambient.

Exception: Gravity-operated drop-out vents complying with Section 910.3.2.1.

910.3.3 (IBC [F] 910.3.3) Vent dimensions. The effective venting area shall not be less than 16 square feet (1.5 m²) with no dimension less than 4 feet (1219 mm), excluding ribs or gutters having a total width not exceeding 6 inches (152 mm).

910.3.2 (IBC [F] 910.3.2) - 910.3.4 (IBC [F] 910.3.4) Smoke and heat vent locations. Smoke and heat vents shall be located 20 feet (6096 mm) or more from adjacent *lot lines* and *fire walls* and 10 feet (3048 mm) or more from *fire barriers*. Vents shall be uniformly located within the roof in the areas of the building where the vents are required to be installed by Section 910.2, with consideration given to roof pitch, ~~draft curtain location~~, sprinkler location and structural members.

910.3.3 Smoke and heat vents area. The required aggregate area of smoke and heat vents shall be calculated as follows:

For buildings equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1:

$$A_{VR} = V/9000 \quad \text{(Equation 9-4)}$$

Where:

A_{VR} = the required aggregate vent area (ft²)
 V = volume (ft³) of the area that requires smoke removal

For unsprinklered buildings:

$$A_{VR} = A_{FA}/50 \quad \text{(Equation 9-5)}$$

Where:

A_{VR} = the required aggregate vent area (ft²)
 A_{FA} = the area of the floor of the area that requires smoke removal.

910.3.5 (IBC [F] 910.3.5) Draft curtains. Where required by Table 910.3, draft curtains shall be installed on the underside of the roof in accordance with this section.

Exception: Where areas of buildings are equipped with ESFR sprinklers, draft curtains shall not be provided within these areas. Draft curtains shall only be provided at the separation between the ESFR sprinklers and the non-ESFR sprinklers.

910.3.5.1 (IBC [F] 910.3.5.1) Construction. Draft curtains shall be constructed of sheet metal, lath and plaster, gypsum board or other approved materials that provide equivalent performance to resist the passage of smoke. Joints and connections shall be smoke tight.

910.3.5.2 (IBC [F] 910.3.5.2) Location and depth. The location and minimum depth of draft curtains shall be in accordance with Table 910.3.

910.4 (IBC [F] 910.4) Mechanical smoke removal systems exhaust. Where approved by the fire code official, engineered mechanical smoke removal systems exhaust shall be designed and installed in accordance with Sections 910.4.1 through 910.4.7 an acceptable alternative to smoke and heat vents.

910.4.1 Automatic sprinklers required. The building shall be equipped throughout with an approved automatic sprinkler system in accordance with Section 903.3.1.1.

910.4.2 (IBC [F] 910.4.2) Exhaust fan construction. Exhaust fans that are part of a mechanical smoke removal system shall be rated for operation at 105 deg. C. Exhaust fan motors shall be located outside of the exhaust fan air stream.

910.4.3 (IBC [F] 910.4.3) System design criteria. The mechanical smoke removal system shall be sized to exhaust the building at a minimum rate of two air changes per hour based upon the volume of the building or portion thereof without contents. The capacity of each exhaust fan shall not exceed 30,000 cubic feet per minute.

910.4.3.1 Make-up air. Make-up air openings shall be provided within six feet (add metric) of the floor level. Operation of makeup air openings shall be manual or automatic. The minimum gross area of make-up air inlets shall be 8 ft² per 1000 cfm of smoke exhaust.

910.4.4 (IBC [F] 910.4.4) Activation. The mechanical smoke removal system shall be activated by manual controls only.

910.4.5 (IBC [F] 910.4.5) Manual control location. Manual controls shall be located so as to be accessible to the fire service from an exterior door of the building and be protected against interior fire exposure by not less than 1-hour fire barriers constructed in accordance with Section 707 of the *International Building Code* or horizontal assemblies constructed in accordance with Section 712 of the *International Building Code*, or both.

910.4.1 (IBC [F] 910.4.1) Location. Exhaust fans shall be uniformly spaced within each draft-curtained area and the maximum distance between fans shall not be greater than 100 feet (30 480 mm).

910.4.2 (IBC [F] 910.4.2) Size. Fans shall have a maximum individual capacity of 30,000 cfm (14.2 m³/s). The aggregate capacity of smoke exhaust fans shall be determined by the equation:

$$C = A \times 300 \text{ — (Equation 9-4)}$$

where:

C = Capacity of mechanical ventilation required, in cubic feet per minute (m³/s).

~~A = Area of roof vents provided in square feet (m²) in accordance with Table 910.3.~~

910.4.3 (IBC [F] 910.4.3) Operation. Mechanical smoke exhaust fans shall be automatically activated by the ~~automatic sprinkler system or by heat detectors~~ having operating characteristics equivalent to those described in Section 910.3.2. Individual manual controls for each fan unit shall also be provided.

910.4.6 (IBC [F] 910.4.6) 910.4.4 (IBC [F] 910.4.4) Control wiring and control. Wiring for operation and control of mechanical smoke removal systems ~~exhaust fans~~ shall be connected ahead of the main disconnect in accordance with Section 701.12E of NFPA 70 and be protected against interior fire exposure to temperatures in excess of 1,000°F (538°C) for a period of not less than 15 minutes. ~~Controls shall be located so as to be immediately accessible to the fire service from the exterior of the building and protected against interior fire exposure by not less than 1-hour fire barriers constructed in accordance with Section 707 of the International Building Code or horizontal assemblies constructed in accordance with Section 711 of the International Building Code, or both.~~

910.4.5 (IBC [F] 910.4.5) Supply air. Supply air for exhaust fans shall be provided at or near the floor level and shall be sized to provide a minimum of 50 percent of required exhaust. Openings for supply air shall be uniformly distributed around the periphery of the area served.

910.4.7 (IBC [F] 910.4.7) 910.4.6 (IBC [F] 910.4.6) Interlocks Controls. ~~On combination comfort air-handling/smoke removal systems or independent comfort air-handling systems, fans shall be controlled to shut down in accordance with the approved smoke control sequence. Where building air handling and mechanical smoke removal systems are combined or where independent building air-handling systems are provided, fans shall automatically shut down in accordance with the International Mechanical Code. The manual controls provided for the smoke removal system shall have the capability to override the automatic shutdown of fans that are part of the smoke removal system.~~

910.5 Maintenance. Smoke and heat vents and mechanical smoke removal ~~exhaust~~ systems shall be maintained in an operative condition in accordance with Section 910.5.1 or 910.5.2, respectively ~~NFPA 204.~~

910.5.1 Smoke and heat vents. Smoke and heat vents shall be maintained ~~in an operative condition in~~ accordance with NFPA 204 and Section 910.5.1.1

910.5.1.1 Fusible links. Fusible links ~~for smoke and heat vents~~ shall be ~~promptly~~ replaced whenever fused, damaged or painted. ~~Smoke and heat vents and mechanical smoke exhaust systems shall not be modified.~~

910.5.2 Mechanical smoke removal systems. Mechanical smoke removal systems shall be maintained in accordance with the equipment manufacturer's maintenance instructions and Sections 910.5.2.1 through 910.5.2.4.

910.5.2.1 Frequency. Systems shall be operationally tested not less than once per year. Testing shall include the operation of all system components including control elements.

910.5.2.2 Testing. Operational testing of the mechanical smoke removal system shall include all equipment such as fans, controls and make-up air openings.

910.5.2.3 Schedule. A routine maintenance and operational testing program shall be initiated and a written schedule for routine maintenance and operational testing shall be established.

910.5.2.4 Written record. A written record of mechanical smoke exhaust system testing and maintenance shall be maintained on the premises. The written record shall include the date of the maintenance, identification of the servicing personnel and notification of any unsatisfactory condition and the corrective action taken, including parts replaced.

901.6.1 Standards. Fire protection systems shall be inspected, tested and maintained in accordance with the referenced standards listed in Table 901.6.1.

**TABLE 901.6.1
FIRE PROTECTION SYSTEM MAINTENANCE STANDARDS**

SYSTEM	STANDARD
Portable fire extinguishers	NFPA 10
Carbon dioxide fire-extinguishing system	NFPA 12
Halon 1301 fire-extinguishing systems	NFPA 12A
Dry-chemical extinguishing systems	NFPA 17
Wet-chemical extinguishing systems	NFPA 17A
Water-based fire protection systems	NFPA 25
Fire alarm systems	NFPA 72
Mechanical smoke exhaust systems	NFPA 204
Smoke and heat vents	NFPA 204
Water-mist systems	NFPA 750
Clean-agent extinguishing systems	NFPA 2001

Revise as follows:

**TABLE 3206.2
GENERAL FIRE PROTECTION AND LIFE SAFETY REQUIREMENTS**

COMMODITY CLASS	SIZE OF HIGH-PILED STORAGE AREA ^a (square feet) (see Sections 3206.2 and 3206.4)	ALL STORAGE AREAS (See Sections 3206, 3207 and 3208) ^b					SOLID-PILED STORAGE, SHELF STORAGE AND PALLETIZED STORAGE (see Section 3207.3)		
		Automatic fire-extinguishing system (see Section 3206.4)	Fire detection system (see Section 3206.5)	Building access (see Section 3206.6)	Smoke and heat removal (see Section 3206.7)	Draft curtains (see Section 3206.7)	Maximum pile dimension ^c (feet)	Maximum permissible storage height ^d (feet)	Maximum pile volume (cubic feet)

(Portions of table not shown remain unchanged)

3206.7 Smoke and heat removal. Where smoke and heat removal is are required by Table 3206.2, smoke and heat vents it shall be provided in accordance with Section 910. Where draft curtains are required by Table 3206.2, they shall be provided in accordance with Section 910.3.5.

Add new standard to Chapter 80 (IBC Chapter 35) as follows:

FM

4430-12 Approval Standard for Heat and Smoke Vents 910.3.1

Reason: The ICC Board established the ICC Code Technology Committee (CTC) as the venue to discuss contemporary code issues in a committee setting which provides the necessary time and flexibility to allow for full participation and input by any interested party. The code issues are assigned to the CTC by the ICC Board as "areas of study". Information on the CTC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CTC effort can be downloaded from the following website: <http://www.iccsafe.org/cs/CTC/Pages/default.aspx>. Since its inception in April/2005, the CTC has held twenty-five meetings - all open to the public.

This proposed code change is a result of the CTC's investigation of smoke and heat removal through the Roof Vent Study Group (RVSG), which is part of the area of CTC study entitled "Balanced Fire Protection" the scope of

which is: *"To investigate what constitutes an acceptable balance between active fire protection and passive fire protection measures with respect to meeting the fire and life safety objectives of the IBC."* As part of the CTC's review of the "balanced" fire protection issue, the CTC formed the RVSG to study the issue of smoke and heat vents with specific emphasis on: building area; sprinkler versus non sprinkler operation; impact on fire-fighting operations; relationship to the on-going updating of NFPA 204; the need for smoke and heat vent design requirements, regardless if smoke and heat vents are mandated by the code. The RVSG was formed in October 2006 and has been working on this issue since January 2007 and developed code change proposal F144-09/10 which was disapproved by the ICC membership. This subsequent code change proposal is a result of continued RVSG study on the issue.

The purpose of this code change proposal is to update the provisions which mandate roof smoke and heat removal systems in industrial and storage buildings based upon technical information on the operation of roof vents which has been developed in the United States over the last 20 years. The RVSG has developed its proposed revisions to the roof vent provisions based upon the following:

- ❖ Research on the interaction of sprinklers, roof vents and draft curtains funded by the National Fire Protection Research Foundation (NFPRF) and conducted at Underwriters Laboratories (UL) in 1997/1998. This research is summarized in a document referred to as National Institute of Science and Technology Interagency Report (NISTIR) 6196-1 dated September, 1998.
- ❖ Provisions for the use of roof vents in sprinklered buildings included in the 2010 and 2013 edition of NFPA 13, including the substantiation statement for the NFPA 13 roof vent provisions.
- ❖ The capability of standard spray sprinklers to both control and/or extinguish a fire within 30 minutes of sprinkler operation, without supplemental fire department activity has been documented.
- ❖ Recommendations contained in National Institute for Occupational Safety and Health (NIOSH) 2005-132, *Preventing Injuries and Deaths of Fire Fighters Due to Truss Systems*, and NIOSH 2010-153, *Preventing Deaths and Injuries of Fire Fighters using Risk Management Principles at Structure Fires*.
- ❖ Recommendations contained in the Initial Report of the Federal Emergency Management Agency (FEMA)/National Fallen Firefighter Foundation (NFFF[®]) Firefighter Life Safety Summit held on April 14, 2004 in Tampa, Florida.

The RVSG determined that the primary purpose of smoke and heat removal from the perspective of the building code requirement is to assist fire-fighting operations after control of the fire has been achieved by the automatic sprinkler system.. Automatic smoke and heat vents and automatic sprinkler systems were developed independently of one another and their interaction has been a concern for many years. Even today, there is no accepted method of analyzing their interaction and, therefore, the installation standards for each (NFPA 204 and NFPA 13, respectively) give cautions to the designers of buildings having both systems.

The RVSG also determined that a manually-activated mechanical smoke removal system could perform the same function as roof vents. This code change increases the emphasis and acceptability of mechanical smoke removal systems as an acceptable alternative to smoke and heat vents. Mechanical smoke removal systems as prescribed in this code change provide fire-rated, grade-level enclosures for the control of the mechanical smoke removal system. This provides greater control of the system for the fire incident commander and reduces the need to place fire fighters on roofs or in other hazardous situations to operate smoke and heat venting systems. This methodology is consistent with the latest recommendations from NIOSH and NFFF for fire fighter safety, risk management and recommended fire-fighting tactics.

Summary of general provisions of the proposal:

- Either automatic roof vents or a manually-activated mechanical smoke removal system are permitted to be provided in industrial and storage buildings protected by a sprinkler system (in buildings where these provisions are applicable).
- Only roof vents should be permitted to be provided in storage buildings with high-piled storage which are not protected by a sprinkler system (i.e., buildings which contain high-piled storage with an area between 2,500 and 12,000 square feet). The rationale for this provision is that a mechanical smoke removal system capable of handling temperatures between 1,000° F and 2,000° F cannot be practically provided at a reasonable cost.
- Provisions for the design of a manually-activated mechanical smoke removal system have been included. These provisions require that the mechanical smoke removal system be sized to provide a minimum exhaust rate of 2 air changes per hour based upon the enclosed volume of the building space to be exhausted, without any deductions for the space occupied by storage or equipment. An exhaust rate of 2 air changes per hour is based on an analysis assuming a conservative approach using a Factory Mutual Research Corporation (FMRC) Standard Plastic Commodity (polystyrene cups in compartmented cartons). This commodity is recognized to represent a severe fire hazard of high density plastics. In a calculation based on this commodity, a

maximum of 68,960 cfm of smoke was generated by the design fire. Based upon an empty building volume of 2.659 million cubic feet, the exhaust rate required to achieve two air changes per hour is 88,633 cfm. Because no single fan can exceed 30,000 cfm, this building required five fans, each exhausting 25,570 cfm for a total of 127,850 cfm. This exceeds the minimum two air changes per hour by more than 40 percent. Even at the minimum required rate of two air changes per hour, the calculation results show that the mechanical smoke removal system proposed will be capable of removing the smoke from the building faster than it will be generated, ultimately removing smoke from the building once the fire is extinguished. A degree of conservatism is added to this by the calculation using an empty building volume.

- Provisions for the design of roof vents in buildings protected by a sprinkler system have been modified to require that the area of roof vents provide equivalent venting to that required for the mechanical smoke removal system (2 air changes per hour) based upon an assumption that each square foot of vent area will provide 300 cubic feet per minute (cfm) of ventilation. The reason for this requirement is that the roof vents should at least provide venting equivalent to the minimum venting provided by the mechanical smoke removal system. A factor of 300 cfm of venting per square foot of vent area is presently included in the 2012 edition of the *International Building Code*, although the use of this conversion factor is questionable at best. The actual ventilation provided by each square foot of vent area will depend upon the temperature differential between ambient conditions and the smoke layer under the roof deck or the pressure achieved if positive pressure ventilation is utilized. If the prescribed value is not practical for a given building design, designers have the option of demonstrating other values which provide the same performance under the alternate method of design provisions in the code.

- Provisions for the design of roof vents in buildings not protected by a sprinkler system have been revised (simplified) to require that the ratio of the area of the vents to the floor area be a minimum of 1:50. The rationale for this revision is that the case where roof vents will be provided without sprinkler protection will be rare: buildings which contain high-piled storage with an area between 2,500 and 12,000 square feet. Given that this situation will be rare, a complex analysis to determine the required area of roof vents is unnecessary. The ratio of vent area to floor area of 1:50 is conservative based upon the present requirements included in the International Building and Fire Codes.

- Provisions for the mechanical smoke removal system permit the system to be designed to handle air at ambient temperature provided that the fan motors are located outside the air stream. The basis for this provision is the thermocouple temperature data for the large-scale fire tests conducted at UL in 1997/1998, specifically Tests P-1 and P-4. (In Tests P-1 and P-4, no vents opened so the ceiling temperatures recorded would be unaffected by the activation of vents. See Pages 40 and 52 of the NISTIR 6196-1 report dated September 1998 (on the CTC web site) for the thermocouple temperature data recorded as a function of time.)

- The exposing temperatures and time periods were reviewed and not considered to pose a threat to the building structure, fans or power wiring.

- The sprinkler activation times and ceiling temperature data for the five large-scale fire tests summarized in NISTIR 6196-1 indicate that the exposure of mechanical exhaust fans and ducts located at the ceiling to high temperatures will be relatively short. Since it is anticipated that the exhaust system will only be activated after the arrival of fire fighters at the scene (estimated to be 7 minutes or longer after ignition), ceiling temperatures should be reduced sufficiently to allow fans rated for only ambient temperatures to be used for the exhaust system.

- The existing provisions for the design of a mechanical exhaust system indicate that the electrical power supply for the system is to be wired ahead of the main building disconnect for increased reliability and to facilitate fire-fighting operations. This existing provision will remain as no adverse experience has been cited.

- The provisions for the design of a mechanical smoke removal system indicate that wiring providing power to exhaust fans located in the interior of the building is to be protected by materials which will provide a 15 minute finish rating protection. The ceiling temperature data collected in the five large-scale fire tests summarized in NISTIR 6196-1 (cited above) show that temperatures at the ceiling will be far less than the exposure temperatures defined by the ASTM E119 time-temperature curve and that the ceiling temperatures will rapidly decrease once sprinklers activate. The ceiling temperature data included in NISTIR 6196-1 indicates that providing 15 minute finish rating protection for the interior electrical power supply is more than adequate to prevent damage to the power supply wiring for the exhaust system.

- The provisions pertaining to draft curtains included in the code have been removed. The rationale for removing the provisions for draft curtains is that research conducted by Factory Mutual Research Corporation (FMRC) in 1994 and the research conducted at UL in 1997/1998 demonstrated that draft curtains affect the sequence of operation of sprinklers and may have an adverse effect on sprinkler operation.

Although the mechanical smoke removal system or roof vent system outlined above are intended to be utilized to assist fire fighters after fire control has been achieved, either one of these systems can be utilized to assist interior manual fire-fighting operations. In order to utilize the roof vent system to assist with manual interior fire-fighting, it will likely be necessary that the vents will have to be opened manually by sending fire fighters to the roof if this is within the responding fire department's operating procedures.

It should be noted that the effectiveness of manually-opened roof vents will be marginal at best once sprinklers have operated and the ceiling temperatures drop to near ambient. Hence, in order for roof vents to be of assistance for interior manual fire-fighting, fire fighters will likely either need to pressurize the building using positive pressure ventilation (PPV) or exhaust the building with supplemental equipment.

It should also be noted that this proposed code change does not make reference to NFPA 204 for the design of

roof vent systems in either buildings protected by a sprinkler system or unsprinklered buildings. The rationale for this is that NFPA 204 does not address the use of roof vents in sprinklered buildings and the design provisions for roof vents presently included in NFPA 204 are too complex for application to relatively small buildings where vents would be permitted without sprinkler protection (i.e., buildings with high-piled storage less than 12,000 square feet in floor area).

The proposed code change developed by the RVSG is intended to incorporate the latest technology and research available on the interaction of sprinklers, roof vents and draft curtains, as well as the evolving thinking on fire fighter safety promoted by NIOSH and the NFFF into the code provisions.

The information on which this code change proposal is based did not exist when the provisions for roof vents were first included in the building and fire codes in the 1970s and 1980s. This proposal is a much needed update in the fire protection provisions for large industrial and storage buildings. A section-by-section summary follows:

910.1: The phrase "...or otherwise installed..." has been removed to clarify that these provisions are specific to required systems. None of the requirements in the section must be mandatory for non-required systems. Terminology was changed from "exhaust" to "removal" for consistency of terminology. This section is a general section but the exceptions are specific to when a smoke and heat removal system is required; therefore, the exceptions have been relocated to Section 910.2.

910.2: Exceptions 1 and 3 in this section have been relocated here from Section 910.1 as they are specific to when a smoke and heat removal system is required. In Exception 2, terminology has been changed from "exhaust" to "removal" for consistency of terminology. Additionally, the use of a mechanical smoke removal system is made mandatory instead of optional since it is the only practical way to provide smoke and heat removal in multi-story buildings.

910.2.1: This section has been editorially reworded into a complete sentence and mechanical smoke removal has been made an option for smoke and heat removal without requiring specific approval. Companion changes to the remainder of Section 910 have been made to move mechanical smoke removal as an option to smoke and heat venting.

910.2.2: This section has had a reference to IFC Table 3206.2 added and the reference to Section 3206.7 removed because Section 3206.2 sends the code user to the table first and then the table sends the user to Section 3206.7. The phrase "...stock or rack..." were removed because high-piled storage is not limited to stock or rack storage. The intent of the overall code change is to require smoke and heat vents as the method for protecting unsprinklered buildings and provide the option of vents or mechanical smoke removal for sprinklered buildings. This section was revised to accomplish that goal by referencing Section 910.3 for design of roof vents in non-sprinklered buildings and either Section 910.3 or 910.4 for sprinklered buildings.

910.3: This section has been revised to remove the reference to draft curtains as explained in the general reason statement. Additionally, the section and table references were updated to address section format changes.

Table 910.3: The table has been deleted and replaced with new Section 910.3.3 for calculation of required roof vent area.

910.3.1: The option to use FM Standard 4430 as an alternative to UL 793 has been added. Some manufacturers of roof vents only maintain an FM approval of their product, not a UL listing. Hence, making the UL standard the sole standard would require vents with only a FM approval to have their products tested by UL. FM 4430 and UL 793 are very similar in content. Permissive language contained in previous FM standards has been replaced with mandatory language in the most recent edition of the FM standard.

Current 910.3.2: Specific requirements for vent operation have been deleted. In (storage) buildings protected by a sprinkler system, the roof vent provisions contained in NFPA 13 dictate the temperature rating of the fusible element. Hence, there is no need to specify the temperature rating of the fusible element of the vent. With respect to the use of vents in unsprinklered high-piled storage areas, the temperature rating of the fusible element is not all that important. A listed fusible link or listed drop-out vent will operate when exposed to temperatures in excess of 1,000 degrees F. This issue is addressed in both the UL and FM standards for roof vents.

Proposed 910.3.2: This section has been relocated as indicated and revised to remove the reference to draft curtains as previously explained in the general reason statement.

Current 910.3.3: This section is to be deleted and replaced with new Section 910.3.3 that provides a simplified calculation for vent area. With respect to the minimum size of the vents, installing vents with dimensions less than 4

feet is not practical or economical. The more holes put in the roof, the more likely there is to be roof leakage problems. Hence, the minimum size of vents is "self-policing" from a practical and economic standpoint.

Proposed 910.3.3: The design of roof vent area has been simplified with two equations, one for sprinklered buildings and one for non-sprinklered buildings. A detailed explanation of the derivation of the equations is provided in the general reason statement.

910.3.5: The section on draft curtains has been removed. As detailed in the general reason statement, draft curtains can interfere with sprinkler operation and the RVSG found no evidence that they provided a valuable enhancement to roof vent performance.

910.4: This section has been revised to remove the qualification that a fire code official must approve the use of mechanical smoke removal systems. This code change changes mechanical smoke removal from an optional method that requires additional approval to an equally recognized, ~~if not superior~~, method of smoke removal that can be chosen without additional approval required. To address the qualifications for mechanical system use, additional prescriptive conditions were added to replace the case-by-case approval method.

910.4.1: This condition of mechanical system use requires that the building be sprinklered to protect the mechanical equipment from excessive heat.

Current 910.4.2: This section is deleted and replaced by new Section 910.4.3.

Proposed 910.4.2: This section requires exhaust fan motors be located out of the exhaust stream to protect the mechanical equipment from excessive heat.

Current 910.4.3: This section was deleted and replaced with **Section 910.4.4** and requires that mechanical systems are to be activated manually so that the fire department is in control of the system. In some situations, automatic operation could cause a fire to grow or spread, opening an excessive number of sprinklers. Automatic operation of the mechanical smoke removal system could be detrimental to the operation of the sprinkler system in a manner similar to draft curtains. The effect of the automatic mechanical smoke removal system on sprinkler operation would depend upon when the system was activated. The sooner the system is automatically activated, the greater the detrimental effect. The fire department will retain the option to shut down the exhaust system, as well.

Proposed 910.4.3. and 910.4.3.1: These sections specify the design requirement for the minimum number of air changes, maximum fan capacity, and requirements for the provision of make-up air. Based on NFPA 92-2012, Annex Section A-4.4.4.1, the maximum air velocity through the make-up air inlet is 1 m/sec or 200 ft/min. The area requirement is then derived as follows:

- Effective Vent Area = $(1000 \text{ ft}^3/\text{min}) / (200 \text{ ft}/\text{min}) = 5 \text{ ft}^2$ per 1000 cfm
- Assume an orifice coefficient of 0.6
- Gross Vent Area = $5 \text{ ft}^2 / (0.6) = 8.33 \text{ ft}^2$ per 1000 cfm, which is rounded down due to the conservative nature of the requirement

The reason for this limitation is to prevent significant deflection of the plume, which will cause more air entrainment into the plume and more smoke production. This criteria is conservative as the requirement above assumes an active fire and the design philosophy for this code proposal is to provide post-fire smoke exhaust.

Current 910.4.5: This section has been deleted and replaced with more specific make-up air requirements in Section 910.4.3.

Proposed 910.4.5: This section establishes the required placement, access and protection of the manual controls to ensure the fire fighters will have quick and protected access to the controls.

910.4.6: This current section has been renumbered from 906.4.4 and addresses wiring and control. New Section 910.4.5 addresses the control system so the control provisions were removed from this section. The remaining text is unchanged.

910.4.7: This section has been revised to require that if a mechanical smoke removal system is integrated with a standard HVAC system, then the system must shut down upon detection of smoke as required by the IMC. This is a companion change to the new requirement in proposed Section 910.4.4 that mechanical smoke removal systems shall be manually operated only.

910.5 and Table 901.6.1. The reference to NFPA 204 for the maintenance of smoke and heat vents was retained; however, the reference to NFPA 204 for mechanical systems was removed and replaced with prescriptive testing and maintenance requirements placed in proposed Section 910.5.2. The RVSG determined that the maintenance requirements in NFPA 204 were not specific enough to ensure the necessary maintenance. In Section 910.5.1.1, the statement that vents cannot be modified was removed because it is not a maintenance issue. Modification of vents can be accomplished in a code compliant manner and such modification would require a building permit.

Table 3206.2: As previously noted, draft curtain requirements have been deleted and as a companion change, the column in IFC Table 3206.2 that prescribes draft curtain installation has been deleted.

Cost Impact: This proposal will not increase the cost of constructing industrial and storage buildings, and, in many cases, will reduce the cost of constructing these types of buildings.

Analysis: A review of the standard proposed for inclusion in the code, FM 4430-12, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28), will be posted on the ICC website on or before April 1, 2013.

F195-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

910.1-F-BALDASSARRA-CTC

F196 – 13

910.1 (IBC [F] 910.1), 910.3.5 (IBC [F] 910.3.5), 202, 3202, Table 3206.2

Proponent: Jeffrey M. Shapiro, International Institute of Ammonia Refrigeration
(jeff.shapiro@intlcodeconsultants.com)

Revise as follows:

910.1 General. Where required by this code or otherwise installed, smoke and heat vents, or mechanical smoke exhaust systems, and draft curtains shall conform to the requirements of this section.

Exceptions:

1. Frozen food warehouses used solely for storage of Class I and II commodities where protected by an *approved automatic sprinkler system*.
2. Where areas of buildings are equipped with early suppression fast-response (ESFR) or quick-response storage (QRS) sprinklers, automatic smoke and heat vents shall not be required within these areas.

910.3.5 (IBC [F] 910.3.5) Draft curtains. Where required by Table 910.3, draft curtains shall be installed on the underside of the roof in accordance with this section.

Exception: Where areas of buildings are equipped with ESFR or QRS sprinklers, draft curtains shall not be provided within these areas. Draft curtains shall only be provided at the separation between the ESFR sprinklers and the non-ESFR sprinklers, and between QRS and the non-QRS sprinklers.

Add new definition as follows:

SECTION 202 GENERAL DEFINITIONS

QUICK RESPONSE STORAGE (QRS) SPRINKLER. A sprinkler with a response time index of 50 or less that is listed to control a specified fire in stored commodities with 12 or fewer sprinklers.

Revise as follows:

SECTION 3202 DEFINITIONS

QUICK RESPONSE STORAGE (QRS) SPRINKLER.

**TABLE 3206.2
GENERAL FIRE PROTECTION AND LIFE SAFETY REQUIREMENTS**

COMMODITY CLASS	SIZE OF HIGH-PILED STORAGE AREA ^a (square feet) (see Sections 3206.2 and 3206.4)	ALL STORAGE AREAS (See Sections 3206, 3207 and 3208) ^b					SOLID-PILED STORAGE, SHELF STORAGE AND PALLETIZED STORAGE (see Section 3207.3)		
		Automatic fire-extinguishing system (see Section 3206.4)	Fire detection system (see Section 3206.5)	Building access (see Section 3206.6)	Smoke and heat removal (see Section 3206.7)	Draft curtains (see Section 3206.7)	Maximum pile dimension ^c (feet)	Maximum permissible storage height ^d (feet)	Maximum pile volume (cubic feet)

(Portions of table not shown remain unchanged)

a through i (No change to current text)

j. Not required when storage areas are protected by early suppression fast response (ESFR) or quick-response storage (QRS) sprinkler systems installed in accordance with NFPA 13.

Reason: Factory Mutual data sheets no longer reference special sprinkler classifications, such as ESFR. Instead, FM now classifies sprinklers as “storage” and “non-storage” and provides appropriate installation parameters. Storage sprinklers now encompass a new category of quick-response sprinklers that share the key characteristics of ESFR sprinklers, i.e. fast response thermal elements and design areas that involve 12 or fewer sprinklers, but are not designated as ESFR. These quick-response storage sprinklers require similar precautions to ESFR sprinklers with respect to not introducing unknowns that were not represented in full-scale fire tests conducted to determine listing parameters. Thereby, it is important to extend the current provisions in Chapters 9 and 32 that are applicable to ESFR sprinklers to include quick-response storage sprinklers.

Cost Impact: The code change proposal will not increase the cost of construction.

F196-13

Public Hearing: Committee: AS AM D
Assembly: ASF AMF DF

910.1-F-SHAPIRO

F197 – 13

910.2.1 (IBC [F] 910.2.1)

Proponent: Randall R. Dahmen, P.E., Wisconsin licensed Commercial Building Inspector, representing self

Revise as follows:

910.2.1 (IBC [F] 910.2.1) Group F-1 or S-1. Buildings and portions thereof used as a Group F-1 or S-1 occupancy having more than 50,000 square feet (4645 m²) in that is undivided area by full height walls having smoke resisting characteristics as required for draft curtains in Section 910.3.5.1.

Reason: The proposed modification of the wording clearly identifies the expectations of the assembly enclosing the Group F-1 or S-1 occupancies.

Cost Impact: The code change proposal will not increase the cost of construction.

F197-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

910.2.1-F-DAHMEN

F198 – 13

910.3.5 (IBC [F] 910.3.5)

Proponent: Stephen DiGiovanni, Clark County, NV Fire Department, representing self

Revise as follows:

910.3.5 (IBC [F] 910.3.5) Draft curtains. Where required by Table 910.3, draft curtains shall be installed only in non-sprinklered buildings on the underside of the roof in accordance with this section.

~~**Exception:** Where areas of the building are equipped with ESFR sprinklers, draft curtains shall not be provided within these areas. Draft curtains shall only be provided at the separation between the ESFR sprinklers and the non-ESFR sprinklers.~~

Reason: The purpose of this amendment is to not require draft curtains in buildings protected with fire sprinklers. The basis of this amendment is from Section 12.1.1 of NFPA 13. Since NFPA 13 does not provide sprinkler design criteria that encompass the use of draft curtains, then the requirement for draft curtains needs to be exempted for buildings protected in accordance with NFPA 13

Cost Impact: The cost impact for this is actual a savings, by not requiring the installation of draft curtains in sprinklered buildings.

F198-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

910.3.5-F-DIGIOVANNI

Acetylene generator room	—	Not Required	Required
Grain processing	—	Not Required	Required
Liquefied petroleum gas-distribution facilities	—	Not Required	Required
Where explosion hazards exist ^f	Detonation	Required	Not Permitted
	Deflagration	Not Required	Required

a. See Section 414.1.3.

b. See the International Fire Code.

c. As generated during manufacturing or processing.

d. Storage or use.

e. In open use or dispensing.

f. Rooms containing dispensing and use of hazardous materials when an explosive environment can occur because of the characteristics or nature of the hazardous materials or as a result of the dispensing or use process.

g. A method of explosion control shall be provided when Class 2 water-reactive materials can form potentially explosive mixtures.

h. Explosion venting is not required for Group H-5 Fabrication Areas complying with Section 415.10.1 and the International Fire Code.

Reason: This proposal is intended to reduce confusion in the application of explosion venting requirements for Group H-5 Occupancies. Currently, IBC and IFC require explosion venting where the MAQs are exceeded per IFC Table 5003.1.1 and IBC Table 307.1. However, fabrication areas of H-5 Occupancies are specifically allowed to exceed these quantities in accordance with IBC 415.10.1.1.1 and IFC 2704.2.2.1 due to the strict controls prescribed for those fabrication areas.

This proposal would clarify that explosion venting is not required in the fabrication areas of H-5 Occupancies. HPM storage rooms and gas rooms are also allowed to exceed the limits of Tables 2704.2.2.1 and IBC 415.10.1.1.1. Explosion venting would still potentially be required in the HPM storage rooms and gas rooms. This is consistent with the current text in IBC 415.10.5.5.

This proposal is consistent with current construction, industry practice and application of explosion venting requirements, as Group H-5 fabrication areas are generally constructed without explosion venting. This proposal simply provides clarification on how the Group H5 requirements correlate with MAQs and explosion venting requirements found elsewhere in code.

Cost Impact: The code change will not increase the cost of construction.

F199-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

911.1T-F-ZUBIA-FCAC

F200 – 13

912.3.1 (IBC [F] 912.3.1)

Proponent: Robert Trotter, MCP., Tennessee Code Development Committee (bobbrotter1023@aol.com)

Revise as follows:

912.3.1 (IBC [F] 912.3.1) Locking fire department connection plugs and caps. ~~The fire code official is authorized to require~~ Approved, locking plugs or caps shall be provided on every fire department connections for water-based *fire protection systems*. Swivels shall be protected from unauthorized removal. Prior to installation, where the responding fire department shall have ~~carries~~ appropriate key wrenches for removal.

Reason: While many jurisdictions are taking advantage of the current authorization that entered the Code in the 2003 edition, other jurisdictions are in need of more stringent requirements. By removing the authorization and mandating that every FDC be protected by locking plugs or caps, the Code would contain the necessary force of law to require building owners to comply. Under the current economy, the theft of brass FDC's is becoming an epidemic, a real problem that puts firefighters at risk. This proposal provides for the latest "plug" technology to protect FDC's. The health, safety and welfare of the public require FDC protection.

Here are some quotes from recently published news articles that should shock the conscience and prove there is a problem that this proposal will correct.

<http://sacramento.cbslocal.com> **Thieves Stripping Parts Out Of Fire Systems**

Metal thieves are stripping small but critical pieces out of fire sprinklers, and fire officials worry the trend could create a bigger fire danger and end up costing lives.

<http://www.pnwlocalnews.com> **Metal thieves stealing fire connections from area business and apartments**

This type of theft has been rampant throughout the Puget Sound area even though a connection, which costs a business between \$400 and \$1,500 to replace, only gets thieves \$15 to \$25 each at a salvage yard. The danger to the public and to a business is during a fire. If the FDC is missing, firefighters will not be able to supplement the sprinkler system or get water to firefighting crews inside the building of multistory businesses. This endangers not only the firefighters, but anyone inside the building. Increased damage to the building itself and higher rebuilding costs are also possible.

<http://www.beavertonvalleytimes.com> **The dark side of recycling**

...Portland Police Bureau that a band of metal thieves had found a lucrative new target: fire department connections (FDCs), the chunky brass fittings used by firefighters to connect their hoses to the internal sprinkler systems of commercial buildings. Detective Mike Malanaphy of the Portland Police Bureau now believes that Sharrow and Guild were responsible for the disappearance of more than 100 FDCs from buildings across the metro area — including the Oregon Humane Society, Legacy Salmon Creek Hospital, and the SmartPark on Southwest 10th Avenue". "It's difficult to assess the damage caused by the thefts, but Malanaphy reckons that \$30,000 would be a lowball estimate — and it doesn't take into account the possibility that a missing FDC could cripple firefighters in the event of a blaze. The pair's profit from reselling the brass? About \$3,000.

Cost Impact: The code change proposal will increase the cost of construction. The cost depends on the type of protection but is not expected to exceed \$375 per individual FDC.

F200-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

912.3.1-F-TROTTER

F201 – 13

912.4 (IBC [F] 912.4)

Proponent: Joshua D Smith, representing NYS Office of Fire Prevention and Control
(Joshua.smith@dhses.ny.gov)

Revise as follows:

912.4 (IBC [F] 912.4) Signs. A metal sign with raised letters at least 1 inch (25 mm) in size shall be mounted on at all fire department connections serving automatic sprinklers, standpipes or fire pump connections to indicate the system being supplied. ~~Such signs shall read: AUTOMATIC SPRINKLERS or STANDPIPES or TEST CONNECTION or a combination thereof as applicable. The signs and the caps of the connections shall be marked as follows:~~

1. For a connection serving only a standpipe the sign shall read STANDPIPE and the cap shall be colored red.
2. For a connection serving a combination automatic sprinkler and standpipe system the sign shall read COMBINATION STANDPIPE AND SPRINKLER and the cap shall be colored yellow.
3. For a connection serving an automatic sprinkler system only the sign shall read SPRINKLER or AUTOMATIC SPRINKLER and the cap shall be colored green.
4. For a connection serving a non-automatic sprinkler system the sign shall read NON-AUTOMATIC SPRINKLER and the cap shall be colored silver.
5. Test connections shall have signs that read TEST CONNECTION and the caps shall be colored black.

Where the fire department connection does not serve the entire building, a sign shall be provided indicating the portions of the building served.

Reason: There are often signs installed for fire department connections that are often a single color, such as chrome or brass signs, that are not easily read from the point where a fire apparatus will be able to first see the connection. The color coding of the caps will make identifying the function of the fire department connection more easily discernible from a greater distance for fire apparatus fire fighters. The more common use of mutual aid agreements between jurisdictions, and the push to standardize equipment and terminology for NIMS compliance would be of benefit from a standardized color coding system. With this in mind, no matter where a fire department or personnel may be from when they have to respond to a call when covering another jurisdiction's response area the markings of a FDC will all mean the same and the mutual aid departments can still operate efficiently.

Cost Impact:

F201-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

912.4-F-SMITH

F202 – 13

912.4 (IBC [F] 912.4)

Proponent: Joshua D Smith, representing NYS Office of Fire Prevention and Control
(Joshua.smith@dhses.ny.gov)

Revise as follows:

912.4 (IBC [F] 912.4) Signs. Signs shall be provided for fire department connections in accordance with Sections 912.4.1 through 912.4.3.

912.4.1 (IBC [F] 912.4.1) Fire department Connection Identification. A metal sign with raised letters at least 1 inch (25 mm) in size shall be mounted on all fire department connections serving automatic sprinklers, standpipes or fire pump connections. Such signs shall read: AUTOMATIC SPRINKLERS or STANDPIPES or TEST CONNECTION or a combination thereof as applicable.

912.4.2 (IBC [F] 912.4.2) Partial coverage signage. Where the fire department connection does not serve the entire building, a sign shall be provided indicating the portions of the building served.

912.4.3 (IBC [F] 912.4.3) Operating pressure. A metal sign with letters at least 1 inch (25 mm) in size shall be mounted above all fire department connections to indicate the pressure needed to supply the system being connected to.

Reason: By having a sign indicating the proper operating pressure for the system being supplied by the FDC the ability for the fire department to operate more efficiently is increased as well as the level of fire fighter safety is also increased. By knowing the proper operating pressures the system will not be under supplied, ensuring proper fire fighting operations, but the system will also not be over pressurized which can cause harm to the fire fighters but can also cause damage to the system.

Cost Impact: This will increase the cost of construction

F202-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

912.4.1 (NEW)-F-SMITH

F203 – 13

913.2.2 (New) [IBC [F] 913.2.2 (New)]

Proponent: Robert J Davidson, Davidson Code Concepts, LLC, representing self
(rjd@davidsoncodeconcepts.com)

Revise as follows:

913.2.2 (IBC [F] 913.2.2) Fuel line piping protection. Fuel lines supplying diesel engine driven fire pumps shall be protected by an approved fuel line protective system with a fire-resistance rating equivalent to the fire resistance rating of the construction enclosing the fire pump room where such piping is located in areas outside the fire pump room.

Reason: When electric powered fire pumps are installed Section [F] 913.2 and the referenced standards, (NFPA 20 and NFPA 70), require protection against exposure from fire for the fire pump, the components and the wiring supplying the electric powered fire pump.

NFPA 20 INSTALLATION OF STATIONARY PUMPS FOR FIRE PROTECTION

Chapter 9 Electric Drive for Pumps

9.1.4* All power supplies shall be located and arranged to protect against damage by fire from within the premises and exposing hazards.

NFPA 70 ARTICLE 695 Fire Pumps

(E) Arrangement. All power supplies shall be located and arranged to protect against damage by fire from within the premises and exposing hazards. [20:9.1.4]

Multiple power sources shall be arranged so that a fire at one source does not cause an interruption at the other source.

913.2-F-DAVIDSON

913.2-F-DAVIDSON

Additional NFPA 20 protection language

4.12* Equipment Protection.

4.12.1* General Requirements. The fire pump, driver, controller, water supply, and power supply shall be protected against possible interruption of service through damage caused by explosion, fire, flood, earthquake, rodents, insects, windstorm, freezing, vandalism, and other adverse conditions.

4.12.1.1* Indoor Fire Pump Units.

4.12.1.1.1 Fire pump units serving high-rise buildings shall be protected from surrounding occupancies by a minimum of 2-hour fire-rated construction or physically separated from the protected building by a minimum of 50 ft (15.3 m).

4.12.1.1.2 Indoor fire pump rooms in non-high-rise buildings or in separate fire pump buildings shall be physically separated or protected by fire-rated construction in accordance with Table 4.12.1.1.2.

4.12.1.1.3 The location of and access to the fire pump room shall be preplanned with the fire department.

However, the same protection against fire exposure is not provided for fuel lines serving diesel engine powered fire pumps, a component just as important to ensure availability of fire flows as the other fire pump components.

NFPA 20 INSTALLATION OF STATIONARY PUMPS FOR FIRE PROTECTION

11.4.4* Fuel Piping.

11.4.4.1 Flame-resistant reinforced flexible hose listed for this service with threaded connections shall be provided at the engine for connection to fuel system piping.

11.4.4.2 Fuel piping shall not be galvanized steel or copper.

11.4.4.3 The fuel return line shall be installed according to the engine manufacturer's recommendation.

11.4.4.4 There shall be no shutoff valve in the fuel return line to the tank.

11.4.4.5* Fuel Line Protection. A guard, pipe protection, or approved double-walled pipe shall be provided for all exposed fuel lines.

11.4.4.6 Fuel Solenoid Valve. Where an electric solenoid valve is used to control the engine fuel supply, it shall be capable of manual mechanical operation or of being manually bypassed in the event of a control circuit failure.

This proposal adds a new Section "913.2.2 / [F] 913.2.3 Fuel line piping protection" that provides for a level of fire resistance protection equal to the fire-resistance rating of the fire pump room enclosing construction for those portions of the fuel oil piping that are installed outside of the fire pump room where they may be exposed to a fire in the occupancy protected.

The IBC language is shown here for visualization of how the added language would appear in that document.

[F] 913.2 Protection against interruption of service. The fire pump, driver and controller shall be protected in accordance with NFPA 20 against possible interruption of service through damage caused by explosion, fire, flood, earthquake, rodents, insects, windstorm, freezing, vandalism and other adverse conditions.

913.2.1 Protection of fire pump rooms. Fire pumps shall be located in rooms that are separated from all other areas of the building by 2-hour fire barriers constructed in accordance with Section 707 or 2-hour horizontal assemblies constructed in accordance with Section 711, or both.

Exceptions:

1. In other than high-rise buildings, separation by 1-hour fire barriers constructed in accordance with Section 707 or 1-hour horizontal assemblies constructed in accordance with Section 711, or both, shall be permitted in buildings equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 or 903.3.1.2.
2. Separation is not required for fire pumps physically separated in accordance with NFPA 20.

[F] 913.2.2 Fuel line piping protection: In addition to complying the requirements of NFPA 20, Fuel lines supplying diesel powered fire pumps shall be protected against fire by an approved fuel line protective system with a fire-resistance rating equivalent to the rating of the construction enclosing the fire pump room where portions of the fuel line piping are located in areas outside the room the fire pump is located in.

Cost Impact: The code change proposal will increase the cost of construction.

F203-13

	Assembly:	ASF	AMF	DF

913.2-F-DAVIDSON

F204 – 13

913.2.2 (IBC [F] 913.2.2 (New)), Chapter 80 (IBC Chapter 35)

Proponent: Bob Eugene, representing Underwriters Laboratories (Robert.Eugene@ul.com)

Add new text as follows:

913.2.2 (IBC [F] 913.2.2) Circuits supplying fire pumps. Cables used for survivability of circuits supplying fire pumps shall be listed in accordance with UL 2196. Electrical circuit protective systems shall be installed in accordance with their listing requirements.

Add new standard to Chapter 80 (IBC Chapter 35) as follows:

UL

2196-2001 Tests for Fire Resistive Cables, with revisions through December 7, 2003.....913.2.2

Reason: UL 2196 is the ANSI approved standard for tests of fire resistive cables. NFPA 20 (fire pumps) includes selective survivability requirements to assure integrity of certain critical circuits. NFPA 70 does not specify the applicable standard within the mandatory provisions of the code, but recognizes electrical circuit protective systems as an alternate to listed cables. An electrical circuit protective system is a field assembly of components that must be installed according to the listing requirements and manufacturer's instructions in order to maintain the listing for the system. There are more than two dozen electrical circuit protective systems listed in the UL Fire Resistance Directory.

Cost Impact: None.

Analysis: A review of the standard proposed for inclusion in the code, UL 2196-2001, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28), will be posted on the ICC website on or before April 1, 2013.

F204-13

	Assembly:	ASF	AMF	DF

913.2.2 (NEW)-F-EUGENE

F205 – 13

913.3 (New) [IBC [F] 913.3(New)]

Proponent: Jeffrey M. Hugo, CBO, representing the National Fire Sprinkler Association
(hugo@nfsa.org)

Add new text as follows:

913.3 (IBC [F] 913.3) Fire Pump rooms egress and access. Fire pump rooms located on levels other than the level of exit discharge shall discharge into an exit passageway constructed in accordance with Section 1023 or directly into a interior exit stairway in accordance with Section 1022.

Reason: New sections are necessary as NFPA 20 permits fire pump rooms to be located on floors that are not always on the same floor as the level of exit discharge. While the fire pump is operating, NFPA 20 requires building personnel to be in the room for testing and during a fire event and requires the exit of the fire pump room to go into an exit passageway.

During a fire, the person being sent to the pump room on an upper or lower floor than the level of exit discharge needs to be able to safely get from the stairwell to the pump room without encountering the fire. Therefore, the exit stairwell or an exit passageway needs to lead to the pump room.

Cost Impact: Will not increase the cost of construction

F205-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

913.2.1.2 (NEW)-FS-HUGO

F206 – 13

914.8.2 (New)

Proponent: Eric R. Rosenbaum, Hughes Associates, Inc. representing the Air Traffic Control Tower Fire Life Safety Task Group (erosenbaum@haifire.com+)

Revise as follows:

914.8.2 Fire suppression for new airport traffic control towers. Where an occupied floor is located more than 35 feet (10668 mm) above the lowest level of fire department vehicle access, new airport traffic control towers shall be equipped with an *automatic sprinkler system* in accordance with Section 903.3.1.

914.8.2 914.8.3 Fire suppression for aircraft hangars Aircraft hangars shall be provided with a fire suppression system designed in accordance with NFPA 409, based upon the classification for the hangar given in Table 914.8.2.

Exception: When a fixed base operator has separate repair facilities on site, Group II hangars operated by a fixed base operator used for storage of transient aircraft only shall have a fire suppression system, but the system shall be exempt from foam requirements.

Reason: The proposed change reflects changes accepted in Section 412.3 of the IBC regarding new airport traffic control towers. The accepted change in the IBC requires an automatic sprinkler system in all new air traffic control towers with an occupiable floor 35 ft or more above the lowest level of fire department vehicle access. This change clarifies the application of the criteria in Section 914.8 Aircraft-related occupancies. A copy of the accepted change in the IBC is as follows:

412.3 Airport traffic control towers. The provisions of Sections 412.3.1 through 412.3.11 shall apply to airport traffic control towers occupied only for the following uses:

1. Airport traffic control cab.
2. Electrical and mechanical equipment rooms.
3. Airport terminal radar and electronics rooms.
4. Office spaces incidental to the tower operation.
5. Lounges for employees, including sanitary facilities.

412.3.1 Type of construction. Airport traffic control towers shall be constructed to comply with the height limitations of Table 412.3.2.

TABLE 412.3.2
HEIGHT LIMITATIONS FOR AIRPORT TRAFFIC CONTROL TOWERS

TYPE OF CONSTRUCTION	HEIGHT ^a (feet)
IA	Unlimited
IB	240
IIA	100
IIB	85
IIIA	65

a. Height to be measured from grade plane to cab floor

412.3.2 Stairway Stairways in Airport traffic control towers shall conform to the requirements of Section 1009. Such *stairways* shall be a smokeproof enclosure in accordance with Section 909.20. The stair pressurization alternative in accordance with Section 909.20.5 shall be permitted to be used. *Stairways* shall not be required to extend to the roof as specified in Section 1009.11.

412.3.3 Exit access. From observation levels, airport traffic control towers shall be permitted to have a single means of exit access for a distance of travel not exceeding 100 ft (30 m). This means of egress shall be permitted to include exit access utilizing an unenclosed stair at the observation level.

412.3.4 Single means of egress. Not less than one *exit stairway* shall be permitted for airport traffic controls towers of any height provided that the *occupant load* per floor is not greater than 15 and the area per floor does not exceed 1,500 square feet (140 m²).

412.3.4.1 Arrangement of single means of egress. Airport traffic control towers permitted a single exit and located above another building shall be provided with one of the following:

1. Exit enclosure separated from the other building with no door openings to or from the other building

2. Exit enclosure leading directly to an exit enclosure serving the other building, with walls and door separating the exit enclosures from each other, and another door allowing access to the top floor of the building that provides access to a second exit serving that floor.

412.3.4.2 Interior Finish. Airport traffic control towers permitted a single exit in accordance with Section 412.3.4 shall be restricted to interior wall and ceiling finishes of Class A or Class B.

412.3.5 Automatic fire detection systems. Airport traffic control towers shall be provided with an automatic fire detection system installed in accordance with Section 907.2.

412.3.6 Automatic sprinkler system. Airport traffic control towers shall be equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1.

412.3.7 Standby power. A standby power system that conforms to Chapter 27 shall be provided in airport traffic control towers more than 65 feet (19 812 mm) in height. Power shall be provided to the following equipment:

1. Pressurization equipment, mechanical equipment and lighting.
2. Elevator operating equipment.
3. Fire alarm and smoke detection systems.

412.3.8 Elevator Protection. Wires or cables that provide normal and standby power, control signals, communication with the car, lighting, heating, air conditioning, ventilation and fire-detecting systems to elevators shall be protected by construction having a minimum 1-hour *fire resistance rating* or shall be circuit integrity cable having a minimum 1-hour *fire-resistance rating*.

412.3.9 Accessibility. Airport traffic control towers need not be *accessible* as specified in the provisions of Chapter 11.

Cost Impact: This code change will increase the cost of construction from the current code requirements in some instances; however, reflects current building practices of the FAA.

Analysis: The accepted code change mentioned in the proposal is G86-12 (AMPC).

F206-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

914.8.2 (NEW)-F-ROSENBAUM

F207 – 13

IBC 1001.2, IBC [F] 1001.3

Proponent: Robert Rice, Josephine County, OR, representing Oregon Building Officials Association (structdesigner@yahoo.com)

Revise as follows:

IBC 1001.2 ~~Minimum requirements.~~ Alterations to existing means of egress. It shall be unlawful to alter a building or structure in a manner that will reduce the number of *exits*, or the capacity of the *means of egress* to less than required by this code. **~~[F] 1001.3 Maintenance.~~ Means of egress shall be maintained in accordance with the *International Fire Code* and a permit is required prior to construction, alteration or addition in accordance with Section 105.1.**

(Renumber remaining section.)

Reason: This proposal is to rename the title of Section 1001.2. This section states that it is unlawful to alter the means of egress system. The title "Minimum requirements" does not fit with the content of the section. The existing code-designed means of egress may or may not be the minimum requirements but, that's not what this section is addressing. Technically speaking, it could further be argued that this section of code is totally unnecessary and pointless. Any time the structure is altered, including the means of egress, Section 105.1 requires a permit to do the alteration(s) as stated,

[A] 105.1 Required. *Any owner or authorized agent who intends to construct, enlarge, alter, repair, move, demolish, or change the occupancy of a building or structure, or to erect, install, enlarge, alter, repair, remove, convert or replace any electrical, gas, mechanical or plumbing system, the installation of which is regulated by this code, or to cause any such work to be done, shall first make application to the building official and obtain the required permit.*

Cost Impact: None. This proposal does not add any new requirement or limitation to the code. It is intended to make the section title consistent with the contents of the section.

Analysis: If this code change is approved, the future maintenance scoping of the revised section will be determined by the ICC Code Correlation Committee.

F207-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

1001.2-F-RICE

F208 – 13

1030.2.1

Proponents: John Williams, CBO, Chair, ICC Ad Hoc Committee on Health Care (john.williams@doh.wa.gov) and Carl Baldassarra, P.E., FSFPE, Chair, ICC Code Technology Committee (cbaldassarra@RJAGroup.com); John Woestman, Kellen Company, representing Builders Hardware Manufacturers Association (BHMA) (jwoestman@kellencompany.com)

Revise as follows:

1030.2.1 Security devices and egress locks. Security devices affecting *means of egress* shall be subject to approval of the *fire code official*. ~~Special Security devices and locking arrangements in the means of egress including, but not limited to access-controlled egress doors, security grills, locks and latches, and delayed egress locks that restrict, control, or delay egress shall be installed and maintained as required by this chapter.~~

Reason:

Williams/Baldassarra: Revisions approved in the 2012 ICC code development cycle for Chapter 10 of the 2015 IBC, and corresponding sections of Chapter 10 of the 2015 IFC, regarding “shall be permitted” locking systems should be coordinated in this section of the IFC.

The proposed modification deletes the “including, but not limited to” clause and clarifies that any security device or locking arrangement that restricts, controls, or delays egress is to be maintained as required by this chapter of the IFC. The table below lists the expected titles of these extensively revised sections, and the code change proposals affecting these sections.

2012 IBC and 2012 IFC	2015 IBC and 2015 IFC	Code Change Proposals
1008.1.9.6 Special locking arrangements in Group I-2.	1008.1.9.6 Controlled egress doors in Group I-1 and I-2.	E66-12 AMPC E67-12 AM E69-12 AMPC
1008.1.9.7 Delayed egress locks.	1008.1.9.7 Delayed egress.	E70-12 AM E72-12 AM E74-12 AMPC
1008.1.9.8 Access-controlled egress doors.	1008.1.9.8 Sensor release of electrically locked egress doors.	E77-12 AS E78-12 AM E80-12 AS
1008.1.9.9 Electromagnetically locked egress doors.	1008.1.9.9 Electromagnetically locked egress doors.	E77-12 AS E81-12 AS E82-12 AM

This proposal is submitted by the ICC Ad Hoc Committee for Healthcare (AHC). The AHC was established by the ICC Board of Directors to evaluate and assess contemporary code issues relating to hospitals and ambulatory healthcare facilities. The AHC is composed of building code officials, fire code officials, hospital facility engineers, and state healthcare enforcement representatives. The goals of the committee are to ensure that the ICC family of codes appropriately addresses the fire and life safety concerns of a highly specialized and rapidly evolving healthcare delivery system. This process is part of a joint effort between ICC and the American Society for Healthcare Engineering, a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. Since its inception in April 2011, the AHC has held 8 open meetings and over 150 workgroup calls which included members of the AHC as well as any interested party to discuss and debate the proposed changes. All meeting materials and reports are posted on the AHC website at: <http://www.iccsafe.org/cs/AHC/Pages/default.aspx>.

This proposal is being co-sponsored by the ICC Code Technology Committee. The ICC Board established the ICC Code Technology Committee (CTC) as the venue to discuss contemporary code issues in a committee setting which provides the necessary time and flexibility to allow for full participation and input by any interested party. The code issues are assigned to the CTC by the ICC Board as “areas of study”. Information on the CTC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CTC effort can be downloaded from the following website: <http://www.iccsafe.org/cs/CTC/Pages/default.aspx>. Since its inception in April/2005, the CTC has held twenty five meetings - all open to the public.

Woestman: Revisions approved in the 2012 ICC code development cycle for Chapter 10 of the 2015 IBC, and corresponding sections of Chapter 10 of the 2015 IFC, regarding “shall be permitted” locking systems should be coordinated in this section of the IFC.

The proposed modification deletes the “including, but not limited to” clause and clarifies that any security device or locking arrangement that restricts, controls, or delays egress is to be maintained as required by this chapter of the IFC.

The table below lists the expected titles of these extensively revised sections, and the code change proposals affecting these sections.

2012 IBC and 2012 IFC	2015 IBC and 2015 IFC	Code Change Proposals
1008.1.9.6 Special locking arrangements in Group I-2.	1008.1.9.6 Controlled egress doors in Group I-1 and I-2.	E66-12 AMPC E67-12 AM E69-12 AMPC

Cost Impact: None

F208-13

Public Hearing: Committee: AS AM D
Assembly: ASF AMF DF

1030.2.1-F-WOESTMAN

F209 – 13

1030.3.1 (New)

Proponent: John Williams, CBO, Chair, ICC Ad Hoc Committee on Health Care (john.williams@doh.wa.gov) and Carl Baldassarra, P.E., FSFPE, Chair, ICC Code Technology Committee (cbaldassarra@RJAGroup.com)

Add new text as follows:

1030.3.1 Group I-2. In Group I-2, the required clear width for aisles, corridors and ramps that are part of the required means of egress shall comply with Section 1018.2. The facility shall have a plan to maintain the required clear width during emergency situations.

Exception: In areas required for bed movement, equipment shall be permitted in the required width where all the following provisions are met:

1. The equipment is low hazard and wheeled.
2. The equipment does not reduce the effective clear width for the means of egress to less than 5 feet (1525 mm).
3. The equipment is limited to:
 - 3.1 Equipment and carts in use;
 - 3.2 Medical emergency equipment;
 - 3.3 Infection control carts; and
 - 3.4 Patient lift and transportation equipment.
4. Medical emergency equipment and patient lift and transportation equipment, when not in use, is required to be located on one side of the corridor.
5. The equipment is limited in number to a maximum of one per patient sleeping room or patient care room within each smoke compartment.

Reason: The new language in Section 1030.3.1 is to be placed in the International Fire Code as a procedural requirement. It is recognized that the 8'-0" wide corridor in an Group I-2 occupancy where beds are moved is to remain at 8'-0" in width. The language recognizes and identifies the fact that certain movable pieces of equipment will be present in the corridor during normal operations of the patient care units and seeks to restrict the types and number of such pieces of equipment and the restrictions the equipment may impose on the means of egress.

The language also recognizes that during emergencies facilities must have an emergency management plan that address the steps that must be taken by the facility and responding staff to ensure that the required 8'-0" wide corridor is kept clear of movable obstructions.

The terminology is consistent with NFPA 101.

This proposal is submitted by the ICC Ad Hoc Committee for Healthcare (AHC). The AHC was established by the ICC Board of Directors to evaluate and assess contemporary code issues relating to hospitals and ambulatory healthcare facilities. The AHC is composed of building code officials, fire code officials, hospital facility engineers, and state healthcare enforcement representatives. The goals of the committee are to ensure that the ICC family of codes appropriately addresses the fire and life safety concerns of a highly specialized and rapidly evolving healthcare delivery system. This process is part of a joint effort between ICC and the American Society for Healthcare Engineering, a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. Since its inception in April 2011, the AHC has held 8 open meetings and over 150 workgroup calls which included members of the AHC as well as any interested party to discuss and debate the proposed changes. All meeting materials and reports are posted on the AHC website at: <http://www.iccsafe.org/cs/AHC/Pages/default.aspx>.

This proposal is being co-sponsored by the ICC Code Technology Committee. The ICC Board established the ICC Code Technology Committee (CTC) as the venue to discuss contemporary code issues in a committee setting which provides the necessary time and flexibility to allow for full participation and input by any interested party. The code issues are assigned to the CTC by the ICC Board as "areas of study". 	Assembly:	ASF	AMF	DF

1030.3.1 (NEW)-F-BALDASSARRA-WILLIAMS-ADHOC

F210 – 13

1101.3

Proponent: David S. Collins, FAIA, The Preview Group, Inc., representing The American Institute of Architects (dcollins@preview-group.com); Robert J Davidson, Davidson Code Concepts, LLC

Revise as follows:

1101.3 Permits. Permits for alterations necessary to comply with this section shall be required as set forth in Sections ~~105.6 and 105.7 and the International Building Code~~ 105.1 of the *International Existing Building Code*.

Reason: This change will direct the code user to the correct reference section for obtaining a permit to make any alterations necessary to conform to this section of the IFC. Sections 105.6 and 105.7 are for operational permits for various operations or the installation of certain systems, not alterations to an existing building. With the deletion of Chapter 34 from the IBC, the only provisions in the ICC family of codes for permits for existing buildings are found in the IEBC.

Cost Impact: There is no cost impact of this change.

F210-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

1101.3 (NEW)-F-COLLINS

F211 – 13

1103.1

Proponent: David S. Collins, FAIA, The Preview Group, Inc., representing The American Institute of Architects (dcollins@preview-group.com); Robert J Davidson, Davidson Code Concepts, LLC

Revise as follows:

1103.1 Required construction. Existing buildings shall comply with not less than the minimum provisions specified in Table 1103.1 and as further enumerated in Sections 1103.2 through 1103.9.

The provisions of this chapter shall not be construed to allow the elimination of fire protection systems or a reduction in the level of fire safety provided in buildings constructed in accordance with previously adopted codes.

Exceptions:

1. Group U occupancies.
2. Work performed under a permit in accordance with Section 105.1 of the International Existing Building Code.

Reason: The language in this section has been interpreted to mean that once a building is built, none of the features in a fire protection systems may be removed, or the fire safety elements modified based on newer code provisions. Doing so under the system of permits required to modify or remove such a system should be permitted by the code.

Many codes required fire safety features such as rated partitions and opening protection that is not required in modern building codes. If such features or protections are allowed to be removed by the code in effect for such facilities, those changes should be allowed.

Cost Impact: This proposal will not increase the cost of construction.

F211-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

1103.1-F-COLLINS

F212 – 13

1103.1, 1104.1; IEBC 804.2.2.2 (NEW)

THIS IS A 2 PART CODE CHANGE. PART I WILL BE HEARD BY THE IFC CODE DEVELOPMENT COMMITTEE AND PART II WILL BE HEARD BY THE IEBC CODE DEVELOPMENT COMMITTEE AS SEPARATE CODE CHANGES. SEE THE TENTATIVE HEARING ORDER FOR THESE COMMITTEES.

Proponent: John Williams, CBO, Chair, ICC Ad Hoc Committee on Health Care
(john.williams@doh.wa.gov)

PART I – INTERNATIONAL FIRE CODE

Revise as follows:

SECTION 1103 FIRE SAFETY REQUIREMENTS FOR EXISTING BUILDING

1103.1 Required construction. Existing buildings shall comply with not less than the minimum provisions specified in Table 1103.1 and as further enumerated in Sections 1103.2 through 1103.9.

The provisions of this chapter shall not be construed to allow the elimination of fire protection systems or a reduction in the level of fire safety provided in buildings constructed in accordance with previously adopted codes.

Exceptions:

1. Where approved in accordance with Section 102.4, in Group I-2 Condition 2 buildings where an automatic sprinkler system installed in accordance with Section 903.3.1.1 has been added and the building is now sprinklered throughout, the existing fire resistance ratings, opening protectives, penetrations and joints in assemblies are not required to be maintained where such fire resistance ratings, opening protectives, penetrations and joints are not required in new construction for sprinklered buildings.
2. Group U occupancies.

SECTION 1104 MEANS OF EGRESS FOR EXISTING BUILDINGS

1104.1 General. *Means of egress* in existing buildings shall comply with the minimum egress requirements when specified in Table 1103.1 as further enumerated in Sections 1104.2 through 1104.23, and the building code that applied at the time of construction. Where the provisions of this chapter conflict with the building code that applied at the time of construction, the most restrictive provision shall apply. Existing buildings that were not required to comply with a building code at the time of construction shall comply with the minimum egress requirements when specified in Table 1103.1 as further enumerated in Sections 1104.2 through 1104.24.

Exception: Where approved in accordance with Section 102.4, in Group I-2 Condition 2 buildings where an automatic sprinkler system installed in accordance with Section 903.3.1.1 has been added and the building is now sprinklered throughout, the existing fire resistance ratings, opening protectives, penetrations and joints in assemblies are not required to be maintained where such fire resistance ratings, opening protectives, penetrations and joints are not required in new construction for sprinklered buildings.

PART II – INTERNATIONAL EXISTING BUILDING CODE

Add new text as follows:

804.2.2.2 Group I-2. Where approved, in Group I-2 Condition 2 buildings where an automatic sprinkler system installed in accordance with Section 903.3.1.1 of the *International Building Code* has been added and the building is now equipped throughout with an automatic sprinkler system, the existing fire resistance ratings, opening protectives, penetrations and joints in assemblies are not required to be maintained where such fire resistance ratings, opening protectives, penetrations and joints are not required in new construction for buildings equipped throughout with an automatic sprinkler system.

Reason: The changes provide tradeoffs for installation of automatic sprinkler systems consistent with those allowed for new construction and also with those allowed by CMS. In many editions of the legacy codes and the ICC Codes dating from the 1980s and even before, the same or similar tradeoffs were allowed when a facility elected to provide sprinkler protection. The AD Hoc Committee on Health Care is proposing requiring retrofit of sprinklers in Hospitals that we feel provide the best protection available and feel because of this the tradeoffs are justified in existing facilities as has been vetted and justified in new construction for many years. These requirements are part of a package of retrofit requirements that provide a minimum level of safety considered necessary for patients, staff and first responders in an environment in which patients are in many instances not capable of self preservation and must be protected in place. Automatic sprinkler protection is key to any plan for protecting residents in place and for the safety of those responding to emergencies by providing the extra time needed to respond. The requirements are also consistent with current CMS standards that apply to all hospitals nationwide receiving Medicare/Medicaid funding and would not add additional requirements to those facilities beyond current nationwide Federal requirements but would allow the facilities to better meet those requirements without possible costly conflicts in other codes.

If this proposal is successful and the proposal for a new Section 1105 is also approved, the Adhoc Health Care committee will bring forward a corresponding exception to be applicable for the new Section 1105.1 as follows:

SECTION 1105 CONSTRUCTION REQUIREMENTS FOR EXISTING GROUP I-2

1105.1 General. Existing Group I-2 shall meet the following requirements:

1. The minimum fire safety requirements in Section 1103, and
2. The minimum egress requirements in Section 1104, and
3. The additional egress and construction requirements in Sections 1105.2 through 1105.7.5.2.

Where the provisions of this chapter conflict with the construction requirements that applied at the time of construction, the most restrictive provision shall apply.

Exception: Where approved in accordance with Section 102.4, in Group I-2 Condition 2 buildings where a sprinkler system installed in accordance with Section 903.3.1.1 has been added and the building is now sprinklered throughout, the existing fire resistance ratings, opening protectives, penetrations and joints in assemblies are not required to be maintained where such fire resistance ratings, opening protective, penetrations and joints are not required in new construction for sprinklered buildings.

This proposal is submitted by the ICC Ad Hoc Committee for Healthcare (AHC). The AHC was established by the ICC Board of Directors to evaluate and assess contemporary code issues relating to hospitals and ambulatory healthcare facilities. The AHC is composed of building code officials, fire code officials, hospital facility engineers, and state healthcare enforcement representatives. The goals of the committee are to ensure that the ICC family of codes appropriately addresses the fire and life safety concerns of a highly specialized and rapidly evolving healthcare delivery system. This process is part of a joint effort between ICC and the American Society for Healthcare Engineering, a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. Since its inception in April 2011, the AHC has held 8 open meetings and over 150 workgroup calls which included members of the AHC as well as any interested party to discuss and debate the proposed changes. All meeting materials and reports are posted on the AHC website at: <http://www.iccsafe.org/cs/AHC/Pages/default.aspx>.

Cost Impact: None

F212-13

PART I – INTERNATIONAL FIRE CODE

Public Hearing:	Committee:	AS	AM	D

PART II – INTERNATIONAL EXISTING BUILDING CODE

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

1103.1-F-WILLIAMS-ADHOC

F213 – 13

1103.1.1 (New), [A] 102.6, Chapter 80

Proponent: Adolf Zubia. Chairman, IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azubiamia@yahoo.com)

Add new next as follows:

1103.1.1 Historic Buildings. Facilities designated as *historic buildings* shall develop a fire protection plan in accordance with Chapter 10 and 11 of NFPA 914. The fire protection plans shall comply with the maintenance and availability provisions in Section 404.4 and 404.5.

Revise as follows:

[A] 102.6 Historic buildings. The provisions of this code relating to the construction, *alteration*, repair, enlargement, restoration, relocation or moving of buildings or structures shall not be mandatory for existing buildings or structures identified and classified by the state or local jurisdiction as historic buildings when such buildings or structures do not constitute a distinct hazard to life or property. Fire protection in designated historic buildings ~~and structures~~ shall be provided ~~in accordance~~ with an approved fire protection plan as required in Section 1103.1.1.

Add new standard Chapter 80 as follows:

NFPA

914—2010 Code for Fire Protection of Historic Structures.1103.1.1

Reason: The intent of this code change is to clarify the requirements in the IFC with respect to the fire protection plan for historic buildings. This proposal does not change the current requirements for fire protection system, but only provides clarity.

IFC Section 102.6 currently requires an “approved fire protection plan.” But then the code provides no guidance as to what the plan needs to address, or what needs to be in the “approved fire protection plan.” This proposal adds a reference to NFPA 914 in Chapter 11 (new section 1103.1.1) which now establishes specific criteria to evaluate the historic building in accordance with NFPA 914 and requires maintenance and availability of the plan in accordance with current requirements for Fire Safety Plans as per Section 404 . This change will provide more specific guidance to code officials, design professionals and building owners as to the provisions that are applicable to fire protection plans for historic buildings in order to provide a reasonable level of building and life safety provisions.

Cost Impact: The code change will not increase the cost of construction.

Analysis: A review of the standard proposed for inclusion in the code, NFPA 914 with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 1, 2013.

F213-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

1103.1.1-F-ZUBIA-FCAC

F214 – 13

1103.3

Proponent: Ron Burton, PTW Advisors, LLC, representing BOMA international (ronburton@ptwadvisors.com)

Revise as follows:

1103.3 Elevator operation. Existing elevators with a travel distance of 25 feet (7620 mm) or more above or below the main floor or other level of a building and intended to serve the needs of emergency personnel for fire-fighting or rescue purposes shall be provided with emergency operation in accordance with ASME A17.3.

Exception: Buildings without occupied floors located more than 75 feet above the lowest level of fire department vehicle access where provided with automatic sprinkler systems installed in accordance with Section 903.3.1.1 or 903.3.1.2.

Reason: The purpose of this proposed change is to:

- Clearly identify the fire code as the scoping document for the requirement of retroactive fire safety building features;
- Clarify the intent of the code with respect to which elevators must be retrofitted with Phase I emergency recall operation and

Phase II emergency in-car operation; and,

- Provide the opportunity to substitute fire sprinkler installation for Phase I emergency recall operation and Phase II emergency in-car operation retrofits in low and mid-rise buildings.

These changes are needed because of the exceeding expense of compliance for many of these retrofits. It is not unknown for application of the mandatory Phase I and Phase II retrofits required by the A17.3 Safety Code for Existing Elevators and Escalators to trigger complete replacement of the elevator machinery at costs running into the hundreds of thousands of dollars. What is a relatively inexpensive fire safety feature in a new elevator installation is unreasonably onerous when applied to existing elevators. It's therefore reasonable to codify alternate methods for building owners to meet the intent of the codes.

It's important to note that the 25 foot travel threshold for ASME A17.3 emergency operation retrofit is not mitigated by occupant load; number of stories; elevator use; building fire or smoke compartment conditions; the presence of sprinklers; or any building specific operational firefighting considerations. For elevators installed prior to the adoption of newer elevator emergency operations features, many existing 3 story buildings require retrofit; elevators in non-atmospherically segregated spaces like low-rise atriums require retrofits; vintage freight elevators, regardless of maintenance condition or the ability of building occupants to access them, require retrofits. The problem of inflexible compliance options is magnified by the usual division of professional jurisdictions because elevator authorities typically do not have the expertise to assess fire risk on a total building basis; hence the need for the fire code to scope retroactive fire safety provisions.

By allowing for more affordable or effective alternatives to the Phase I and Phase II retrofits, less opposition should exist to adoption of ASME A17.3 and its other safety requirements such as safety bulkheads for hydraulic elevators and door restrictors, thereby enhancing overall elevator safety.

Status of State Adoptions of ASME A17.3 Phase I and Phase II FF Service Retroactive Requirements	
22	States adopt ASME A17.3
1	State modifies ASME A17.3 to trigger FF service retrofit at 70 feet of travel.
1	State amends away FF service retrofit for existing elevators.
1	State only requires FF service retrofit where triggered by other alterations; no blanket retroactivity.
1	State adopts ASME A17.3 "for regulatory guidance only for elevators classified as remodeled."
1	State amends ASME A17.3 to change 25 foot travel trigger to 3 stories.
1	State adopts ASME A17.3 but has a 5 year (until mid-2015) moratorium on required PH II retrofits.
28	States Do Not Adopt ASME A17.3

Intents of the Code

The intents of Phase I emergency recall are to prevent elevator users from being discharged at a floor that is engaged in a fire; from accessing an elevator during a fire; and, in a detected fire condition, to return the elevator car to a designated floor for firefighter access for operations and rescue.

The intent of Phase II emergency in-car operation is to provide firefighters the ability to operate the elevator for firefighting operations and rescue.

The proposed exception recognizes that there is no documentation of civilian or firefighter life loss while in an elevator during a structural fire in a building protected with automatic fire sprinklers. It is reasonable that if an owner has already provided superior fire safety features in an existing building that they not be required to retrofit expensive fire safety features of limited value.

Additionally, the most recent comprehensive professional review of sprinkler system reliability concluded that "when sprinklers are present in the fire area of a fire large enough to activate sprinklers in a building not under construction, sprinklers operate 91% of the

time. When they operate, they are effective 96% of the time, resulting in a combined performance of operating effectively in 88% of reported fires where sprinklers were present in the fire area and fire was large enough to activate sprinklers.”¹ This is contrasted with an eight-year study of 178 high-rise fires in New York City in which elevators with Phase I and Phase II “firefighter service” were used revealed the following disturbing findings:

- 59 elevators failed either on arrival of the firefighters or during the fire. (33 percent)
- 37 percent of the 59 failures were the result of fire or water damage to the elevator electrical system.²

There is no record of elevator occupant fire fatalities in a sprinklered building.

For buildings within the scope of the exception, which are not already sprinklered, the exception provides an incentive to provide fire sprinklers.

The references to Sections 903.3.1.1 and 903.3.1.2 mean that only a fire sprinkler system installed in accordance with the appropriate technical standard will permit relaxation of the Phase I and Phase II emergency operations requirements.

The codification of these substitutions is consistent with Section 1.3, Purpose and Exceptions, of ASME A17.3 which states:

“The purpose of this Code is to provide for the safety of life and limb, and to promote the public welfare.

Where a requirement, because of practical difficulty, cannot be complied with literally or where its literal application would cause undue hardship, the authority having jurisdiction may, upon proper application, grant exceptions, but only when it is clearly evident that reasonable safety is assured.

The authority having jurisdiction may also grant exceptions or permit alternate methods where it is assured that equivalent objectives can be achieved by establishing and maintaining effective safety.”

No suggestion is being made that new elevator systems should not be required to comply.

Finally, a corresponding request for a revision to ASME A17.3 will be submitted to clarify that the requirement for retrofitting the fire safety features of Phase I emergency recall operation and Phase II emergency in-car operation is triggered by the fire code.

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

1103.3-F-BURTON

F215 – 13

1103.3

Proponent: Greg Johnson, Johnson Consulting Services, representing self
(gjohnsonconsulting@gmail.com)

Revise as follows:

1103.3 Elevator operation. Existing elevators with a travel distance of 25 feet (7620 mm) or more above or below the main floor or other level of a building and intended to serve the needs of emergency personnel for fire-fighting or rescue purposes shall be provided with emergency operation in accordance with ASME A17.3.

Exceptions:

1. Buildings without occupied floors located more than 55 feet above the lowest level of fire department vehicle access where protected at the elevator shaft openings with additional fire doors in accordance with Section 716.5 of the *International Building Code* and where all of the following conditions are met:
 - 1.1 The doors shall be provided with vision panels of approved fire-protection-rated glazing so located as to furnish clear vision of the approach to the elevator. Such glazing shall not exceed 100 square inches in area.
 - 1.2 The doors shall be held open but be automatic-closing by activation of a fire alarm initiating device installed in accordance with the requirements of NFPA 72 as for Phase I Emergency Recall Operation, and shall be located at each floor served by the elevator; in the associated elevator machine room, control space, or control room; and in the elevator hoistway, when sprinklers are located in those hoistways.
 - 1.3 The doors, when closed, shall have signs visible from the approach area stating: WHEN THESE DOORS ARE CLOSED OR IN FIRE EMERGENCY, DO NOT USE ELEVATOR. USE EXIT STAIRS.
2. Buildings without occupied floors located more than 55 feet above the lowest level of fire department vehicle access when provided with automatic sprinkler systems installed in accordance with Section 903.3.1.1 or 903.3.1.2.
3. Freight elevators in buildings provided with both automatic sprinkler systems installed in accordance with Section 903.3.1.1 or 903.3.1.2 and at least one ASME 17.3 compliant elevator serving the same floors.

The provisions of this section shall not be construed to allow the elimination of previously installed Phase I emergency recall or Phase II emergency in-car systems.

Reason: Rule 211.3 of ASME A17.3, Firefighters' Service — Automatic Elevators, requires that: "*All automatic (nondesignated attendant) operation elevators having a travel of 25 ft (7.62 m) or more above or below the designated level shall conform to the requirements of this Rule.*"

The purpose of this proposed change is to:

- Clearly identify the fire code as the scoping document for the requirement of retroactive fire safety building features;
- Clarify the intent of the code with respect to which elevators must be retrofitted with Phase I emergency recall operation and Phase II emergency in-car operation;
- Provide the opportunity in existing low-rise buildings to substitute additional opening protectives at elevator shaft openings for Phase I emergency recall operation and Phase II emergency in-car operation retrofits; and,
- Provide the opportunity to substitute fire sprinkler installation for Phase I emergency recall operation and Phase II emergency in-car operation retrofits in low-rise buildings.

These changes are needed because of the exceeding expense of compliance for many of these retrofits. It is not unknown for application of the mandatory Phase I and Phase II retrofits required by the A17.3 Safety Code for Existing Elevators and Escalators to trigger complete replacement of the elevator machinery at costs running into the hundreds of thousands of dollars. What is a relatively inexpensive fire safety feature in a new elevator installation is unreasonably onerous when applied to existing elevators. It's therefore reasonable to codify alternate methods for building owners to meet the intent of the codes.

It's important to note that the 25 foot travel thresh-hold for ASME A17.3 emergency operation retrofit is not mitigated by occupant load; number of stories; elevator use; building fire or smoke compartment conditions; the presence of sprinklers; or any building specific operational firefighting considerations. For elevators installed prior to the adoption of newer elevator emergency operations features, many existing 3 story buildings require retrofit; elevators in non-atmospherically segregated spaces like low-rise atriums require retrofits; vintage freight elevators, regardless of maintenance condition or the ability of building occupants to access them, require retrofits. The problem of inflexible compliance options is magnified by the usual division of professional jurisdictions because elevator authorities typically do not have the expertise to assess fire risk on a total building basis; hence the need for the fire code to scope retroactive fire safety provisions.

By allowing for more affordable or effective alternatives to the Phase I and Phase II retrofits, less opposition should exist to adoption of ASME A17.3 and its other retroactive safety requirements such as safety bulkheads for hydraulic elevators and door restrictors, thereby enhancing overall elevator safety.

Status of State Adoptions of ASME A17.3 Phase I and Phase II FF Service Retroactive Requirements	
22	States adopt ASME A17.3
1	State modifies ASME A17.3 to trigger FF service retrofit at 70 feet of travel.
1	State amends away FF service retrofit for existing elevators.
1	State only requires FF service retrofit where triggered by other alterations; no blanket retroactivity.
1	State adopts ASME A17.3 <i>"for regulatory guidance only for elevators classified as remodeled."</i>
1	State amends ASME A17.3 to change 25 foot travel trigger to 3 stories.
1	State adopts ASME A17.3 but has a 5 year (until mid-2015) moratorium on required PH II retrofits.
28	States Do Not Adopt ASME A17.3

Intents of the Code

The intents of Phase I emergency recall are to prevent elevator users from being discharged at a floor that is engaged in a fire; from occupants accessing an elevator during a fire; and, in a detected fire condition, to return the elevator car to a designated floor for firefighter access for operations and rescue.

The intent of Phase II emergency in-car operation is to provide firefighters the ability to operate the elevator for firefighting operations.

Proposed Exception 1 meets the intent of the code by:

- Providing an additional fire door, with a vision panel, between elevator occupants and a fire engaged floor. This protects occupants from car and hoistway doors automatically opening directly to a fire event. The vision panel lets occupants view fire risk and select another floor to travel to for egress. This door provides an additional barrier to smoke and water contamination of the hoistway and improves building compartmentation.
- Providing additional signs on the added door immediately at the elevator opening telling building occupants to not use the elevator when the door is closed. In other words, if you can read the sign you shouldn't use the elevator.
- Recognizing that common firefighting operations policy requires firefighters to use the stairs to address any fire on the 6th floor or lower in a building; meaning that in low rise buildings immediate firefighter access to the elevators is not as critical. The 6th floor of a building typically corresponds to the building and fire codes' definition of a high-rise building as one with *"an occupied floor located more than 75 feet (22 860 mm) above the lowest level of fire department vehicle access."* This is broadly recognized as the elevation at which a compromise is achieved between the inherent hazard of using an elevator in a structural fire response and the need to respond in a timely way to the fire.

Exception 1 also tacitly acknowledges that these are not elevators that were ever *"intended to serve the needs of emergency personnel for fire-fighting or rescue purposes"* as the charging section states.

Locations of fire alarm initiating devices used to initiate door closing are identical to those used to initiate Phase I operations via reference to NFPA 72 by ASME A17.3.

Proposed Exception 2 recognizes that there is no documentation of civilian or firefighter life loss while in an elevator during a structural fire in a building protected with automatic fire sprinklers. It is reasonable that if an owner has already provided superior fire safety features in an existing building that they not be required to retrofit expensive fire safety features of limited value. For buildings within the scope of the exception, which are not already sprinklered, Exception 2 provides an incentive to provide fire sprinklers.

The references to Sections 903.3.1.1 and 903.3.1.2 mean that only a fire sprinkler system installed in accordance with the appropriate technical standard will permit relaxation of the Phase I and Phase II emergency operations requirements.

55 feet was selected as the upper limit for the floor height of buildings within the scope of the proposed change after soliciting the advice of the Fire Code Action Committee at its November 2012 meeting. Committee members suggested a height limit of around four stories would be preferable when considering response factors associated with ascertaining elevator occupant locations and conditions. Since 55 feet is the elevation at which automatic sprinkler protection is triggered, and since it roughly corresponds to 4 stories, it is offered as a suitable threshold.

Proposed Exception 3 recognizes that buildings which already have an elevator equipped with Phase I and Phase II emergency operations already meet the intent of Phase II firefighter operations provisions. The fire sprinkler requirement and the limited passenger use of freight elevators means that the likelihood of life loss in the freight elevator is virtually nil. For buildings without fire sprinklers this provision provides an incentive to install fire sprinkler systems.

The codification of these substitutions is consistent with Section 1.3, Purpose and Exceptions, of ASME A17.3 which states: *"The purpose of this Code is to provide for the safety of life and limb, and to promote the public welfare."*

Where a requirement, because of practical difficulty, cannot be complied with literally or where its literal application would cause undue hardship, the authority having jurisdiction may, upon proper application, grant exceptions, but only when it is clearly evident that reasonable safety is assured.

The authority having jurisdiction may also grant exceptions or permit alternate methods where it is assured that equivalent objectives can be achieved by establishing and maintaining effective safety."

No suggestion is being made that new elevator systems should not be required to comply.

Finally, a corresponding request for a revision to ASME A17.3 will be submitted to clarify that the requirement for retrofitting the fire safety features of Phase I emergency recall operation and Phase II emergency in-car operation is triggered by the fire code.

Cost Impact: The change should reduce the cost of compliance by providing more flexibility for owners to comply.

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

1103.3-F-JOHNSON

F216 – 13

1103.3 (New), 1103.3.1 (New)

Proponent: John Williams, CBO, Chair, ICC Ad Hoc Committee on Health Care
(john.williams@doh.wa.gov)

Revise as follows:

1103.3 Existing elevators. Existing elevators, escalators and moving walks shall comply with the requirements of Sections 1103.3.1 and 1103.3.2.

1103.3.1 Elevators, escalators and moving walks. Existing elevators, escalators and moving walks in Group I-2 Condition 2 occupancies shall comply with ASME A17.3.

1103.3.2 Elevator emergency operation. Existing elevators with a travel distance of 25 feet (7620 mm) or more above or below the main floor or other level of a building and intended to serve the needs of emergency personnel for fire-fighting or rescue purposes shall be provided with emergency operation in accordance with ASME A17.3.

Reason: The healthcare industry has historically been required to comply with regulations set forth by accreditation and certification agencies, such as The Joint Commission. Because the ICC family of codes does not currently have an existing elevator standard, ASME A17.3 *Safety Code for Existing Elevators and Escalators* is proposed for compliance of existing elevators in Group I-2 Condition 2 occupancies. ASME A17.3 has been referenced by guidelines adopted by The Joint Commission for over a decade and this code change will provide correlation of the IFC with the mandated healthcare industry standard.

Adding a reference to ASME A17.3 will require that existing elevators escalators and moving walks and their related operating equipment in Group I-2 Condition 2 occupancies comply with a minimum level of safety. Because the occupants of these types of facilities are often incapable of self-preservation, it will also provide important features essential for occupant safety including escalator and moving walk emergency stop buttons and automatic skirt obstruction stop features. A new Section 1103.3 is included editorially to conform to established code style for multiple requirement sections.

This proposal is submitted by the ICC Ad Hoc Committee for Healthcare (AHC). The AHC was established by the ICC Board of Directors to evaluate and assess contemporary code issues relating to hospitals and ambulatory healthcare facilities. The AHC is composed of building code officials, fire code officials, hospital facility engineers, and state healthcare enforcement representatives. The goals of the committee are to ensure that the ICC family of codes appropriately addresses the fire and life safety concerns of a highly specialized and rapidly evolving healthcare delivery system. This process is part of a joint effort between ICC and the American Society for Healthcare Engineering (ASHE), a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. Since its inception in April, 2011, the AHC has held 8 open meetings and over 150 workgroup calls which included members of the AHC as well as any interested party to discuss and debate the proposed changes. All meeting materials and reports are posted on the AHC website at: <http://www.iccsafe.org/cs/AHC/Pages/default.aspx>

Cost Impact: The code change proposal should not increase the cost of construction because compliance with similar requirements is already mandated by facility licensure requirements.

F216-13

	Assembly:	ASF	AMF	DF

1103.3 (NEW)-F-WILLIAMS-ADHOC

F217 – 13

1103.4, 1103.4.1, 1103.4.2, 1103.4.3, 1103.4.4, 1103.4.8 (New)

Proponent: Carl Baldassarra, P.E., FSFPE, Chair, ICC Code Technology Committee
(cbaldassarra@RJAGroup.com)

Revise as follows:

SECTION 1103 FIRE SAFETY REQUIREMENTS FOR EXISTING BUILDINGS

1103.4 Vertical openings. Interior vertical ~~shafts~~ openings, including but not limited to *stairways*, elevator hoistways, service and utility shafts, that connect two or more stories of a building, shall be enclosed or protected as specified in Sections 1103.4.1 through 1103.4.7.

1103.4.1 Group ~~I-2~~ and ~~I-3~~ occupancies. In Group ~~I-2~~ and ~~I-3~~ occupancies, interior vertical openings connecting two or more stories shall be protected with 1-hour fire-resistance-rated construction.

Exception: In Group I-3 occupancies, exit stairways or ramps and exit access stairways or ramps constructed in accordance with Section 408 in the *International Building Code*.

1103.4.2 Three to five stories. In other than Group ~~I-2~~ and ~~I-3~~ occupancies, interior vertical openings connecting three to five stories shall be protected by either 1-hour fire-resistance-rated construction or an *automatic sprinkler system* shall be installed throughout the building in accordance with Section 903.3.1.1 or 903.3.1.2.

Exceptions:

1. Vertical opening protection is not required for Group R-3 occupancies.
2. Vertical opening protection is not required for open parking garages ~~and ramps~~.
3. Vertical opening protection for escalators shall be in accordance with Section 1103.4.5, 1103.4.6 or 1103.4.7.
4. Exit access stairways and ramps shall be in accordance with Section 1103.4.8.

1103.4.3 More than five stories. In other than Group ~~I-2~~ and ~~I-3~~ occupancies, interior vertical openings connecting more than five stories shall be protected by 1-hour fire-resistance-rated construction.

Exceptions:

1. Vertical opening protection is not required for Group R-3 occupancies.
2. Vertical opening protection is not required for open parking garages ~~and ramps~~.
3. Vertical opening protection for escalators shall be in accordance with Section 1103.4.5, 1103.4.6 or 1103.4.7.
4. Exit access stairways and ramps shall be in accordance with Section 1103.4.8.

1103.4.4 Atriums and covered malls. In other than Group ~~I-2~~ and ~~I-3~~ occupancies, interior vertical openings in a covered mall building or a building with an atrium shall be protected by either 1-hour fire-resistance-rated construction or an *automatic sprinkler system* shall be installed throughout the building in accordance with Section 903.3.1.1 or 903.3.1.2.

Exceptions:

1. Vertical opening protection is not required for Group R-3 occupancies.
2. Vertical opening protection is not required for open parking garages ~~and ramps~~.

3. Exit access stairways and ramps shall be in accordance with Section 1103.4.8.

1103.4.5 Escalators in Group B and M occupancies. Escalators creating vertical openings connecting any number of stories shall be protected by either 1-hour fire-resistance-rated construction or an *automatic sprinkler system* in accordance with Section 903.3.1.1 installed throughout the building, with a draft curtain and closely spaced sprinklers around the escalator opening.

1103.4.6 Escalators connecting four or fewer stories. In other than Group B and M occupancies, escalators creating vertical openings connecting four or fewer stories shall be protected by either 1-hour fire-resistance-rated construction or an *automatic sprinkler system* in accordance with Section 903.3.1.1 or 903.3.1.2 shall be installed throughout the building, and a draft curtain with closely spaced sprinklers shall be installed around the escalator opening.

1103.4.7 Escalators connecting more than four stories. In other than Group B and M occupancies, escalators creating vertical openings connecting five or more stories shall be protected by 1-hour fire-resistance-rated construction.

1103.4.8 Occupancies other than Group I-2 and I-3. In other than Group I-2 and I-3 occupancies, floor openings containing exit access stairways or ramps that do not comply with one of the conditions listed in this section shall be protected by 1-hour fire-resistance-rated construction.

1. Exit access stairways and ramps that serve, or atmospherically communicate between, only two stories. Such interconnected stories shall not be open to other stories.
2. In Group R-1, R-2 or R-3 occupancies, exit access stairways and ramps connecting four stories or less serving and contained within an individual dwelling unit or sleeping unit or live/work unit.
3. Exit access stairways and ramps in buildings equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1, where the area of the vertical opening between stories does not exceed twice the horizontal projected area of the stairway or ramp, and the opening is protected by a draft curtain and closely spaced sprinklers in accordance with NFPA 13. In other than Groups B and M occupancies, this provision is limited to openings that do not connect more than four stories.
4. Exit access stairways and ramps within an atrium complying with the provisions of Section 404 of the International Building Code.
5. Exit access stairways and ramps in open parking garages that serve only the parking garage.
6. Exit access stairways and ramps serving open-air seating complying with the exit access travel distance requirements of Section 1028.7 of the International Building Code.
7. Exit access stairways and ramps serving the balcony, gallery or press box and the main assembly floor in occupancies such as theaters, places of religious worship, auditoriums and sports facilities.

Reason: The intent of this code change is to resolve conflicts between the means of egress requirements in chapter 10 of both the IBC and IFC, and chapter 11 of the IFC regarding open exit access stairway and ramp construction. There are a number of building code provisions for new construction in current IBC/IFC chapter 10 Means of Egress that permit exit access stair floor openings without a fire rated enclosure. Many of these permitted floor openings are required to be fire rated by IFC chapter 11 Construction Requirements for Existing Buildings. This sets up a direct conflict not just between the IBC and IFC but between two chapters in the IFC. A building constructed under the 2012 IBC/IFC and in full compliance with chapter 10 of both codes is in violation of IFC sections 1103.4 through 1104.3.7 as soon as the certificate of occupancy issued. Clearly it was not the intent of IFC chapter 11 to contradict chapter 10 of the IFC or IBC. This code change takes the conditions that permit exit access stair and ramp floor openings and places them in IFC chapter 11 so that the requirements of IFC chapter 11 are consistent with IFC chapter 10 and IBC chapter 10.

Specific section changes:

Section 1103.4.1 was modified to specifically address groups I-2 and I-3 and 1103.4.2 through 1103.4.4 was modified to include I-1 and I-4 occupancies. This was done because the specific conditions that allow unenclosed exit access stairs in IBC and IFC chapter 10 differ based on that distinction. In addition the group I-3 exception was added to 1103.4.1 to be consistent with the current exception #10 to IFC/IBC section 1009.3 and the current single exception to IFC/IBC section 1022.2.

Sections 1103.4.2 through 1103.4.4 each had an exception added to refer to new section 1103.4.3 for conditions that allow unenclosed exit access stairs.

Section 1103.4.3 was added to provide all of the current conditions that allow an un-enclosed exit access stair or ramp. All of these conditions are existing from IFC/IBC chapter 10 section 1009.3. Note that in the 2015 IBC and IFC these conditions will be in new IFC/IBC section 1018. It is very important to note that this section and these conditions only apply to exit access stairs and ramps. This new section does not apply to exit stairs. Exit stairs are not exempted from enclosure.

The ICC Board established the ICC Code Technology Committee (CTC) as the venue to discuss contemporary code issues in a committee setting which provides the necessary time and flexibility to allow for full participation and input by any interested party. The code issues are assigned to the CTC by the ICC Board as "areas of study". Information on the CTC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CTC effort can be downloaded from the following website: <http://www.iccsafe.org/cs/CTC/Pages/default.aspx>. Since its inception in April/2005, the CTC has held twenty five meetings - all open to the public.

Cost Impact: None

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

1103.4-F-BALDASSARRA-CTC

F218 – 13

1103.4.1

Proponent: John Williams, CBO, Chair, ICC Ad Hoc Committee on Health Care
(john.williams@doh.wa.gov)

Revise as follows:

IFC 1103.4.1 Group I occupancies. In Group I occupancies, interior vertical openings connecting two or more stories shall be protected with 1-hour fire-resistance-rated construction.

Exceptions:

1. In Group I-2 Condition 2 equipped throughout with an automatic sprinkler system, vertical opening connecting two or more stories need not be protected with 1-hour fire-resistance-rated construction where both of the following conditions are met:
 - 1.1. The atrium volume is accounted for in the design of a smoke control system in accordance with Section 909.
 - 1.2 The floor levels within the vertical opening shall contain only low or ordinary fire hazard uses.
2. In Group I-2 Condition 2, where an automatic sprinkler system is installed in accordance with Section 404.6 of the *International Building Code*, glass walls shall be considered to be equivalent to 1-hour fire-resistance-rated construction for purposes of this section. Where glass doors are provided in the glass wall, they shall be either self-closing or automatic-closing.
3. In Group I-2 Condition 2, 1-hour fire-resistance-rated construction is not required where a glass-block wall assembly complying with Section 2110 of the *International Building Code* and having a ¾-hour fire protection rating is provided.

Reason: The intent of this code change is to make the IFC consistent with federal standards that are in place for the maintenance of Group I-2 Condition 2 (hospitals) and to clarify the allowable use and construction of atria in hospitals. This adds language to clarify the fire hazard class allowed in the existing atrium (no higher than ordinary), as opposed to only low hazard class in new. A smoke control system is also acknowledged as a factor when it comes to separation of the atrium, and clarifies that the smoke control system's engineering analysis must account for any spaces open to it.

Glass walls points back to the language in IBC Section 404.6 in an attempt to set that as a minimum, retroactive standard. It is far simpler to address a potential deficiency with addition of a smoke control system or properly installed sprinklers at the glass, rather than reconstructing the walls themselves.

This proposal is submitted by the ICC Ad Hoc Committee for Healthcare (AHC). The AHC was established by the ICC Board of Directors to evaluate and assess contemporary code issues relating to hospitals and ambulatory healthcare facilities. The AHC is composed of building code officials, fire code officials, hospital facility engineers, and state healthcare enforcement representatives. The goals of the committee are to ensure that the ICC family of codes appropriately addresses the fire and life safety concerns of a highly specialized and rapidly evolving healthcare delivery system. This process is part of a joint effort between ICC and the American Society for Healthcare Engineering (ASHE), a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. Since its inception in April, 2011, the AHC has held 5 open meetings and over 150 workgroup calls which included members of the AHC as well as any interested party to discuss and debate the proposed changes. All meeting materials and reports are posted on the AHC website at: <http://www.iccsafe.org/cs/AHC/Pages/default.aspx>

Cost impact: This proposal would make the IFC consistent with federal standards that are in place for the maintenance of hospitals, and therefore would not represent an increase in cost.

F219 – 13

1103.4.1

Proponent: Robert J Davidson, Davidson Code Concepts, LLC, representing self (BFICOCS)
(rjd@davidsoncodeconcepts.com)

Revise as follows:

1103.4.1 Group I-3 occupancies. In Group I-3 occupancies, interior vertical openings connecting two or more stories shall be protected with 1-hour fire-resistance-rated construction.

Exceptions:

1. In Group I-3 equipped throughout with an automatic sprinkler system, vertical opening connecting two or more stories need not be protected with 1-hour fire-resistance-rated construction where both of the following conditions are met:
 - 1.1. The atrium and connecting stories are accounted for in the design of a smoke control system in accordance with Section 909.
 - 1.2. The floor levels within the vertical opening shall contain only low or ordinary fire hazard uses.
2. In Group I-3 where an automatic sprinkler system is installed throughout the building and in accordance with Section 404.6 of the *International Building Code*, glass walls shall be considered to be equivalent to 1-hour fire-resistance-rated construction for purposes of this section. Where glass doors are provided in the glass wall, they shall be either self-closing or automatic-closing.
3. In Group I-3, 1-hour fire-resistance-rated construction is not required where a glass- block wall assembly complying with Section 2110 of the *International Building Code* and having a $\frac{3}{4}$ -hour fire protection rating is provided.

Reason: The intent of this code change is to clarify the allowable use and construction of atria in jail. This adds language to clarify the fire hazard class allowed in the existing atrium (no higher than ordinary), as opposed to only low hazard class in new. A smoke control system is also acknowledged as a factor when it comes to separation of the atrium, and clarifies that the smoke control systems engineering analysis must account for any spaces open to it.

Glass walls points back to the language in the IBC in an attempt to set that as a minimum, retroactive standard. It is far simpler to address a potential deficiency with addition of a smoke control system or properly installed sprinklers at glass, rather than reconstructing the walls themselves.

This is intended to coordinate with the Group I-2 provisions.

Cost impact:

F219-13

1103.4.8 (New), 1103.4.9 (New), 603.8.6 (New), 603.8.7 (New)

Proponent: John Williams, CBO, Chair, ICC Ad Hoc Committee on Health Care (john.williams@doh.wa.gov) and Carl Baldassarra, P.E., FSFPE, Chair, ICC Code Technology Committee (cbaldassarra@RJAGroup.com)

Add new text as follows:

1103.4.8 Waste and linen chutes. In Group I-2 occupancies, existing waste and linen chutes shall comply with Sections 1103.4.8.1 through 1103.4.8.5.

1103.4.8.1 Enclosure. Chutes shall be enclosed with 1-hour fire-resistance-rated construction. Opening protectives shall be in accordance with Section 716 of the *International Building Code* and have a fire protection rating of not less than 1-hour.

1103.4.8.2 Chute intakes. Chute intakes shall comply with Section 1103.4.8.2.1 or 1103.4.8.2.2.

1103.4.8.2.1 Chute intake direct from corridor. Where intake to chutes is direct from a corridor, the intake opening shall be equipped with a chute intake door in accordance with Section 716 of the *International Building Code* and having a fire protection rating of not less than 1-hour.

1103.4.8.2.2 Chute intake via a chute intake room. Where the intake to chutes is accessed through a chute intake room, the room shall be enclosed with 1-hour fire-resistance rated construction. Opening protectives for the intake room shall be in accordance with Section 716 of the *International Building Code* and have a fire protection rating of not less than ¾ hour. Opening protective for the chute enclosure shall be in accordance with Section 1103.4.8.1.

1103.4.8.3 Automatic sprinkler system. Chutes shall be equipped with an *approved automatic sprinkler system* in accordance with Section 903.2.11.2.

1103.4.8.4 Chute discharge rooms. Chutes shall terminate in a dedicated chute discharge room. Such rooms shall be separated from the remainder of the building by a minimum of 1-hour fire-resistance-rated construction. Opening protectives shall be in accordance with Section 716 of the *International Building Code* and have a fire protection rating of not less than 1-hour.

1103.4.8.5 Chute discharge protection. Chute discharges shall be equipped with a self-closing or automatic-closing opening protective in accordance with Section 716 of the *International Building Code* and having a fire protection rating of not less than 1-hour.

1103.4.9 Flue-fed incinerators. Existing flue-fed incinerator rooms and associated flue shafts shall be protected with 1-hour fire-resistance-rated construction and have no other vertical openings connected with the space other than the associated flue. Opening protectives shall be in accordance with Section 716 of the *International Building Code* and have a fire protection rating of not less than 1-hour.

Add new text as follows:

603.8.6 Flue-fed incinerators in Group I-2. In Group I-2 occupancies, the continued use of existing flue-fed incinerators is prohibited.

603.8.7 Incinerator inspections in Group I-2. Incinerators in Group I-2 occupancies shall be inspected at least annually in accordance with the manufacturer's instructions. Inspection records shall be maintained on the premises and made available to the fire code official upon request.

Reason: The intent of this code change is to clarify the allowable use and construction of chutes and incinerators in Group I-2 occupancies. These items are still used as an integral part of the operation of a healthcare facility, especially the waste or linen chutes. Some incinerators are still in use, but this proposed requirement seeks to separate them from other vertical openings, especially a trash chute, by requiring a separate discharge room from the incinerator. Although newer incinerators are designed to contemporary codes, standards and regulations, most older incinerators are not in use or are otherwise abandoned in existing facilities because of other regulation from entities such as the EPA, this requirement seeks to separate and protect any potential hazard of inactive incinerator systems from the rest of the building.

Also, in older facilities that pre-date current requirements, there is the occasion that the chute door opens into a corridor. It was not prohibited at the time of construction, so it is not practical to reconstruct the chute to meet modern standards. Therefore, this section aims to directly address that situation by defining requirements for which it should be safely maintained.

This proposal would make the IFC consistent with federal standards that are in place to maintain hospitals, and therefore would not represent an increase in cost.

This proposal is submitted by the ICC Ad Hoc Committee on Healthcare (AHC). The AHC was established by the ICC Board of Directors to evaluate and assess contemporary code issues relating to hospitals and ambulatory healthcare facilities. The AHC is composed of building code officials, fire code officials, hospital facility engineers, and state healthcare enforcement representatives. The goals of the committee are to ensure that the ICC family of codes appropriately addresses the fire and life safety concerns of a highly specialized and rapidly evolving healthcare delivery system. This process is part of a joint effort between ICC and the American Society for Healthcare Engineering (ASHE), a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. Since its inception in April, 2011, the AHC has held 8 open meetings and over 150 workgroup calls which included members of the AHC as well as any interested party to discuss and debate the proposed changes. All meeting materials and reports are posted on the AHC website at: <http://www.iccsafe.org/cs/AHC/Pages/default.aspx>

This proposal is being co-sponsored by the ICC Code Technology Committee. The ICC Board established the ICC Code Technology Committee (CTC) as the venue to discuss contemporary code issues in a committee setting which provides the necessary time and flexibility to allow for full participation and input by any interested party. The code issues are assigned to the CTC by the ICC Board as "areas of study". Information on the CTC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CTC effort can be downloaded from the following website: <http://www.iccsafe.org/cs/CTC/Pages/default.aspx>. Since its inception in April/2005, the CTC has held twenty five meetings - all open to the public. In 2012, three of the 25 face-to-face meetings were held. In addition to the CTC meetings, the CTC established Study Groups (SG) of interested parties for each of the areas of study. These SG's are responsible for reviewing the available information and making recommendations to the CTC. All totaled, the SG's held over 70 conference calls in 2012.

Cost Impact: No increase in the cost of construction is associated with this code change. This change is consistent with existing federal certification requirements.

Proponent: Anthony C. Apfelbeck, City of Altamonte Springs Building/Fire Safety Division, representing self (ACApfelbeck@Altamonte.org)

Revise as follows:

1103.5.3 Group A-2. An automatic sprinkler system shall be provided throughout Group A-2 fire areas where the occupant load exceeds 300. The automatic sprinkler system shall be provided throughout the floor where the Group A-2 occupancy is located, and in all floors between the Group A-2 occupancy and the level of exit discharge.

**Table 1103.1
OCCUPANCY AND USE REQUIREMENTS**

Section	Use			Occupancy Classification																		
				A	B	E	F	H-1	H-2	H-3	H-4	H-5	I-1	I-2	I-3	I-4	M	R-1	R-2	R-3	R-4	S
1103.5.3	-	-	-	R ^a	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

(Portions of table not shown remain unchanged)

a. Only applies to Group A-2 occupancies

Reason: Recommendation #2 of the "Report of the Technical Investigation of the Station Nightclub Fire" recommends that fire sprinklers be provided "for existing nightclubs with an occupancy limit greater than 100." An extract of this recommendation is listed below:

"Recommendation 2

The results of the investigation clearly demonstrated the value of an NFPA 13 compliant automatic fire sprinkler system in extending the time the nightclub remained tenable. Recommendation 2 mirrors the action already taken by NFPA to strengthen the requirement for sprinklers in new and existing nightclubs and festival seating venues.

NIST recommends that model codes require sprinkler systems, and that state and local authorities adopt and aggressively enforce this provision:

a) for all new nightclubs regardless of size, and

b) for existing nightclubs with an occupancy limit greater than 100 people."

As indicated in the NIST report, this recommendation has already been implemented in NFPA 101. However, not all jurisdictions adopt NFPA 101. In many jurisdictions, the IFC is the only adopted document that regulates life safety in existing buildings. Therefore, for existing occupancies in IFC only states, there is no current requirement for fire sprinklers in existing assembly occupancies. The lack of a requirement addressing this issue presents the adopting jurisdiction with a false perception that a reasonable level of life safety protection is provided in existing unsprinklered nightclubs with a high-occupant load. If an adopting jurisdiction chooses to remove this code provision during the adoption process, that is their local prerogative. However, it is the burden of the ICC process to promulgate codes based on technical merit and not a potential political implication at the local level. The NIST report clearly recommends that a reasonable level of life safety is only provided when an existing nightclub is protected by a fire sprinkler system. A copy of the NIST report justifying this code change recommendation is available on-line at: http://www.nist.gov/public_affairs/releases/Vol_I_NCSTAR2.pdf

While the NIST report recommends a 100 person threshold, the committee may not be comfortable with that stringent of a number considering the 100 threshold would apply to all A-2 occupancies. This code change takes into consideration that impact and utilizes a 300 person threshold rather than a 100 person threshold. This threshold will exempt out many existing small restaurants and other A-2 occupancies that outside of the scope anticipated by NIST in the "Report of the Technical investigation of the Station Nightclub Fire."

Cost Impact: This code change will not increase the cost of construction but will have a financial impact on existing A-2 occupancies that are currently not fire sprinkler protected and exceed an occupant load of 300.

1103.5.3 (New), Table 1103.1

Proponent: Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azubiamia@yahoo.com)

Revise as follows:

1103.5.3 Group A-2. An automatic sprinkler system shall be installed in accordance with Section 903.3.1.1 throughout existing buildings or portions thereof used as Group A-2 occupancies with an occupant load of 300 or more.

Table 1103.1
OCCUPANCY AND USE REQUIREMENTS

Section	Use			Occupancy Classification																		
				A	B	E	F	H-1	H-2	H-3	H-4	H-5	I-1	I-2	I-3	I-4	M	R-1	R-2	R-3	R-4	S
1103.5.3	-	-	-	R ^a	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

(Portions of table not shown remain unchanged)

a. Only applies to Group A-2 occupancies

Reason: This requirement implements the Recommendation #1 included in the NIST Report of the Technical Investigation of The Station Nightclub Fire (NIST NCSTAR 2: Vol. I). *Recommendation 1* of the NIST report states:

"Model codes should require sprinkler systems for all new and existing nightclubs regardless of size."

There is a list of fires in Group A-2 occupancies. This list includes the Station Nightclub, Beverly Hill Supper Club, the Coconut Grove and others. Each of these fires have resulted in a significant loss of life.

Group A-2 occupancies involve conditions such as large occupant loads, high occupant density, significant fuel loading and moveable furnishings and decorations. Group A-2 occupancies also include the potential for reduced lighting levels, high noise levels, combustible decorations, strobe and flashing lights, alcohol consumption, and confusing egress paths. Each of these alone can be a significant issue, but when combined they lead to the inability of the occupants to promptly and safely exit the building under fire conditions.

This proposal considers the arrangement of the IBC occupancy classifications and the inclusion of other uses in addition to nightclubs within the Group A-2 classification. Therefore, this proposal does not reach as far as the recommendation from NIST. While the NIST proposal recommends fire sprinklers in ALL facilities, this proposal will require existing Group A-2 occupancies to be retrofitted with a fire sprinkler system only if the occupant load exceeds 300. Setting the threshold at 300 occupants will place the requirement where the higher potential for loss of life exists.

The proposed section only requires that the Group A-2 occupancy is provided with a fire sprinkler system. The section does not require the entire fire area to be protected, nor does it require the entire floor to be protected. The fire sprinkler system would be installed in the portion of the building which contains the Group A-2 occupancy.

This proposal is submitted by the ICC Fire Code Action Committee (FCAC). This ICC committee was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portions thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the Fire-CAC has held 6 open meetings and numerous Regional Work Group and Task Group meetings and conference calls which included members of the committees as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the FAC website at: <http://www.iccsafe.org/cs/CAC/Pages/default.aspx>.

Cost Impact: The code change will not increase the cost of new construction, but it will create a cost for existing unsprinklered buildings classified as Group A-2.

1103.5.3 (New), 1103.5.3.1 (New), 1103.5.3.2 (New)

Proponent: Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azubiamia@yahoo.com)

Add new text as follows:

1103.5.3 High-Rise Buildings. An automatic sprinkler system installed in accordance with Section 903.3.1.1 shall be provided throughout existing high-rise buildings.

Exceptions:

1. Airport traffic control towers.
2. Open parking structures.
3. Group U Occupancies.
4. Occupancies in Group F-2.
5. Buildings with an engineered fire protection plan in accordance with Section 1103.5.3.2

1103.5.3.1 Compliance Schedule. Building owners shall file a compliance schedule with the fire code official no later than 180 days after the first effective date of this code. The compliance schedule shall not exceed 12 years for an automatic sprinkler system retrofit and 5 years for an approved engineered fire protection plan.

1103.5.3.2 Engineered Fire Protection Plan. An approved engineered fire protection plan shall be developed by a design professional with experience in fire protection engineering. The engineered fire protection plan shall address the following fire protection and life safety goals:

1. The building is designed and equipped with safeguards against the spread of fire and products of combustion so that no person not directly adjacent to or involved in the ignition of a fire shall suffer serious injury or death from a fire and;
2. The building is designed and equipped with safeguards against the spread of fire so that the property losses are limited to the compartment of origin and;
3. The building is designed and constructed with fire protection features so that fire fighters can appropriately perform rescue operations, protect property, and utilize fire-fighting equipment and controls without unreasonable risk exposure and;
4. Other fire protection and life safety goals as specified by the fire code official based on the unique occupancy, size, construction and features of the building.

Reason: Modern fire and building codes require complete automatic fire sprinkler protection and a variety of other safety features in new high-rise construction. Many older high-rise buildings lack automatic fire sprinkler protection and other basic fire protection features necessary to protect the occupants, emergency responders, and the structure itself. Without complete automatic fire sprinkler protection, fire departments cannot provide the level of protection that high-rise buildings demand. Existing high-rise buildings that are not protected with fire sprinklers represent a significant hazard to the occupants and firefighters. Additionally, High-Rise fires can significantly impact a communities' infrastructure and the economic viability.

Between 2003 and 2006, there was an average of 13,400 reported structure fires in high-rise buildings annually. These incidents resulted in 62 civilian deaths, 490 civilian injuries, and \$179 million in direct property damage per year. Furthermore, from 1977 to 2009, 25 firefighters died from non-stress related cardiac death during fire suppression operations in high-rise buildings. By their very nature, high-rise fires present unique firefighting challenges that are extremely difficult for firefighters to mitigate without the presence of fire sprinkler systems. Some of these challenges include:

High-rise structure fires require significantly more resources, such as personnel and equipment, to extinguish than do fires in other types of occupancies. This further strains the responding fire department and firefighters.

Due to their height, smoke movement in high-rise structures is very different from that of other structures. Temperature gradients result in varying pressures throughout the structure, which can allow for the rapid, uncontrolled movement of smoke and flame (known as the "stack effect").

By design, exits from high-rise structures are limited. In an emergency, the movement of people out of a building is particularly difficult. A prime example of this hazard is the One Meridian Plaza fire. This fire occurred on the 22nd floor of the 38-story Meridian Bank Building and was reported to the Philadelphia Fire Department on February 23, 1991 at approximately 2040 hours and burned for more than 19 hours. The fire caused three firefighter fatalities and injuries to 24 firefighters. The 12-alarms brought 51 engine

companies, 15 ladder companies, 11 specialized units, and over 300 firefighters to the scene. It was the largest high-rise office building fire in modern American history, completely consuming eight floors of the building, and was only controlled only when it reached a floor that was protected by automatic sprinklers. In 1999 the building was torn down amidst a storm of litigation. The HVAC and other utilities in some high-rises service multiple levels and can facilitate the spread of smoke and flame through a building due to the height of the building, response times for the fire department to reach the actual fire itself are extended, contributing to larger fire growth thereby attributing to extensive smoke spread throughout the building.

This proposal is submitted by the ICC Fire Code Action Committee (FCAC). This ICC committee was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portions thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the Fire-CAC has held 6 open meetings and numerous Regional Work Group and Task Group meetings and conference calls which included members of the committees as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the FAC website at: <http://www.iccsafe.org/cs/CAC/Pages/default.aspx>.

Cost Impact: This change will increase the cost of operating an existing High-Rise building.

1103.5.3 (New), Table 1103.1

Proponent: Anthony C. Apfelbeck, City of Altamonte Springs Building/Fire Safety Division, representing self (ACApfelbeck@Altamonte.org)

Revise as follows:

1103.5.3 High-Rise Buildings. Existing high-rise buildings shall be equipped with either:

1. An automatic sprinkler system installed throughout the building in accordance with Section 903.3.1.1 or;
2. An approved engineered fire protection plan in accordance with Section 1103.5.3.1.

Exception: The provisions of this section shall not apply to the following:

1. Airport traffic control towers.
2. Open parking structures.
3. Group U Occupancies.
4. Occupancies in Group F-2.
5. Open air portions of Group A-5 Occupancies.

1103.5.3.1 Engineered Fire Protection Plan. Where required by Section 1103.5.3, an approved engineered fire protection plan shall be developed by a licensed design professional with experience in fire protection engineering. The fire protection plan shall address the following fire protection and life safety goals:

1. The building shall be designed, equipped and maintained with safeguards against the spread of fire and products of combustion so that no person not directly adjacent to or involved in the ignition of a fire shall suffer serious injury or death from a fire and;
2. The building shall be designed, equipped and maintained with safeguards that restrict the spread of fire through the building and;
3. The building shall be designed, equipped and maintained with fire protection features so that fire fighters can perform rescue operations, protect property, and utilize fire-fighting equipment and controls without being unduly hindered in suppression or rescue operations and;
4. Other fire protection and life safety goals based on the unique occupancy, size, construction and features of the building.

1103.5.3.2 Compliance Schedule. Building owners shall file a compliance schedule with the fire code official no later than 180 days after the first effective date of Section 1103.5.3. The compliance schedule shall not exceed 12 years for an automatic sprinkler system retrofit in accordance with Section 1103.5.1 (1) or 6 years for an engineered fire protection plan in accordance with Section 1103.5.3 (2).

1103.5.3.2.1 Compliance Extensions. The fire code official is authorized to approve up to two one year extensions to the compliance schedule specified in Section 1103.5.3.2 where the building owner has demonstrated to the fire code official that the compliance schedule has been pursued with due diligence.

**Table 1103.1
OCCUPANCY AND USE REQUIREMENTS**

Section	Use	Occupancy Classification																		
	High rise	A	B	E	F	H-1	H-2	H-3	H-4	H-5	I-1	I-2	I-3	I-4	M	R-1	R-2	R-3	R-4	S
1103.5.3	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R

(Portions of table not shown remain unchanged)

Reason: Existing unsprinklered high-rise buildings continue to be a hazard to occupants, firefighters and their ability to mitigate damage from fires. As an example:

1. 1988 First Interstate Bank: \$200 million in direct property damage, 64 fire companies, gutted 12th-16th floor.
2. 1991 One Meridian Plaza: \$100 million in direct property damage, 18 hour fire gutting 22 floors.
3. 1996 Rockefeller Center: Fires in 5 separate electrical rooms, 300+ firefighters responded, television broadcasts interrupted.
4. 2003 Cook County Office Building: Six civilian deaths.
5. 2004 Caracas Tower: Fire spread to 26 floor and burned for 17 hours, 40 firefighters injured.
6. 2005 Madrid Windsor: 32 Story totally destroyed by fire.

The concern with existing high-rise buildings is best summed up in the Cook County Administration Fire Report, authored by James Lee Witt Associates, in major finding number 1: "Lack of an automatic fire sprinkler system. The building was not equipped with an automatic fire sprinkler system that would have controlled or extinguished the fire in the incipient stage." The recommendations in the Cook County Administration Fire Report further state, "The State of Illinois and City of Chicago should amend their codes to include provisions for the mandatory retrofit installation of complete automatic fire sprinkler systems in all existing-high rise structures." It is important to note that Mr. Witt brings significant credibility to this finding and recommendation as he is also the past CEO of the ICC.

If this finding and recommendation is valid for the City of Chicago and the State of Illinois for the protection of their citizens and firefighters, then this finding and recommendation is also valid as a base level of building and life safety protection within the IFC.

In addition, the NIST Final Report of the Collapse of the World Trade Center Tower states in recommendation 26: "NIST recommends that state and local jurisdictions adopt and aggressively enforce available provisions in building codes to ensure that egress and sprinkler requirements are met by existing buildings."

The NFPA 101 Life Safety Code requires a similar level of protection as this proposal in requiring existing high-rise buildings to be equipped with fire sprinkler protection or an Engineered Life Safety System. This language has been in place within the Life Safety Code for numerous cycles. It is unclear why NFPA 101 specifies this level of protection but the IFC fails to provide a similar level of protection for the occupants and emergency responders.

This proposal attempts to mitigate some of the obvious economic impact by allowing for the use of a fire protection plan prepared by a design professional. While this fire protection plan will not provide an equivalent level of protection to a complete automatic fire sprinkler system, it will assist in addressing, and mitigating, a significant number of the risk factors to high-rise occupants and fire fighters who must confront these extremely hazardous fire conditions. The broad goals of the fire protection plan contained in 1103.5.2.1 are specifically derived from the goals contained in the ICC Code for Performance Based Design. These broad goals provide the designer with maximum flexibility in developing a reasonable code compliant approach.

Unfortunately, this and other fire sprinkler retrofit issues have been discussed as an issue of politics rather than as a technical code issue in past code change cycles. As an example: "The retroactive requiring of sprinklers in buildings should be left as a local decision due to the economic and political impact of such requirements." (F116-04/05) By taking this type of response on a code issue, the committee removes itself from the making a technical decision based on the technical merit code change and inserts itself as a local political policy making body. The two roles are distinctly different. It is the responsibility of the code promulgation body to determine if there is sufficient technical justification to warrant the code change and if the code change is within the scope of the document. The scope of the IFC states:

102.1 Construction and design provisions.

The construction and design provisions of this code shall apply to:

1. Structures, facilities and conditions arising after the adoption of this code.
2. Existing structures, facilities and conditions not legally in existence at the time of adoption of this code.
3. Existing structures, facilities and conditions when required in Chapter 11.
4. Existing structures, facilities and conditions which, in the opinion of the fire code official, constitute a distinct hazard to life or property.

This code change, and all retrofit code changes, are clearly within the scope of the IFC. The only question for the committee to answer is: Does an existing unsprinklered high-rise building provide a reasonable level of property protection, civilian life safety protection and firefighter protection? The technical evidence indicates that this is clearly not the case. By ignoring the technical need and deflecting responsibility for retrofit of existing high-rise as a political issue, a message is sent via this code to state and local government, that an unsprinklered existing high-rise building does provide a reasonable level of building and life safety protection. This is clearly not the case.

Cost Impact: This proposal will increase the code of construction. The impact of this change will be on existing high-rise buildings.

F224-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

1103.5.3 (NEW) #1-F-APFELBECK

F225 – 13

1103.5.3 (New)

Proponent: John Williams, CBO, Chair, ICC Ad Hoc Committee on Health Care
(john.williams@doh.wa.gov)

Add new text as follows:

1103.5.3 Group I-2 Condition 2. In addition to the requirements of Section 1103.5.2, existing buildings of Group I-2 Condition 2 occupancy shall be equipped throughout with an approved automatic sprinkler system in accordance with Section 903.3.1.1. The automatic sprinkler system shall be installed by [DATE TO BE INSERTED BY THE JURISDICTION].

Reason: The intent of this code change is to make mandatory the use of an approved automatic sprinkler system throughout existing hospital (Group I-2 Condition 2) occupancies. The healthcare industry recognizes sprinkler systems are a vital component of the safety of the overall building systems and components. The current mandatory sprinkler retrofit requirement in Section 1103.5.2 first entered the Fire Code in the 2009 version, but does not require sprinklering the entire building throughout. The Ad Hoc for Healthcare, which is made up of representatives from both regulated facilities and enforcement, believe that it is time to take the requirement a step further and require the ENTIRE building to be sprinklered within a reasonable time frame.

To ensure continuous operation in healthcare facilities, the installation of sprinklers systems needs to be carefully planned so as to not adversely affect patient health. Accessing and exposing ceiling spaces can create conditions that will lead to infection and possibility death to patients with compromised or suppressed immune systems. In many situations, hospitals may not be able to appropriately retrofit the installation of a fire suppression system; in those situations, a time frame is needed to replace facilities. . The period for adoption of this proposed requirement has been left to the local authority having jurisdiction. Coordinating the timeframe for adoption with federal requirements is recommended. It is currently anticipated that the Centers for Medicaid and Medicare (the federal authority having jurisdiction) will require retroactive sprinklering of hospitals by the year 2021. However, the exact timeframe is uncertain at the time of development of this change.

Regardless, the federal government is considering the reasons noted above. This is an important next step in ensuring the safety of fragile population. Facilities need some time to accomplish this safety, without adversely affected the health of patients and disrupting patient care. These are the same factors that a jurisdiction should consider when choosing a date for adoption. It should be also clear that this change is a separate measure that must be taken in addition to the current requirement. It is not intended to allow a facility to have a timeframe for installing the current requirement (although jurisdictions may choose to do this). Nor is it intended to imply that the entire building containing a hospital should be sprinklered immediately. At a minimum, a three year timeframe is recommended for implementation of this requirement. This considers the process planning, capital approval, regulatory approval, design and installation of the sprinkler system. The capital planning piece of a large scale initiative, such as a building-wide sprinkler system, normally spans multiple fiscal years, and more can be considered if the regulatory environment allows.

This proposal is submitted by the ICC Ad Hoc Committee for Healthcare (AHC). The AHC was established by the ICC Board of Directors to evaluate and assess contemporary code issues relating to hospitals and ambulatory healthcare facilities. The AHC is composed of building code officials, fire code officials, hospital facility engineers, and state healthcare enforcement representatives. The goals of the committee are to ensure that the ICC family of codes appropriately addresses the fire and life safety concerns of a highly specialized and rapidly evolving healthcare delivery system. This process is part of a joint effort between ICC and the American Society for Healthcare Engineering (ASHE), a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. Since its inception in April, 2011, the AHC has held 8 open meetings and over 150 workgroup calls which included members of the AHC as well as any interested party to discuss and debate the proposed changes. All meeting materials and reports are posted on the AHC website at: <http://www.iccsafe.org/cs/AHC/Pages/default.aspx>

Cost impact: This proposal would make the IFC consistent with the direction that federal standards are taking to maintain hospitals and therefore would not represent an increase in cost.

Analysis: The "Group I-2 Condition 2" terminology used in this proposal in lieu of "Group I-2 hospital" is the result of approved Group A code change G257-12.

F225-13

	Assembly:	ASF	AMF	DF

1103.5.3 (NEW)-F-WILLIAMS-ADHOC

F226 – 13

1103.5.3 (New)

Proponent: Thomas G. Daly representing The Hospitality Security Consulting Group, LLC

Add new text as follows:

1103.5.3 Group R-1 hotels and motels. *An automatic sprinkler system shall be provided throughout existing Group R-1 hotels and motels.*

Exception: Group R-1 hotels and motels of one story in height where all individual guestrooms and contiguous attic and crawl spaces are separated from each other and public and common areas by at least 1-hour fire partitions and each individual guestroom has an exit directly to a public exit court or yard.

Reason:

- A. Background: In the United States civilian fire deaths in Group R-1 hotels and motels over the past two decades have occurred exclusively in non-sprinklered and multi-story low-rise hotels/motels as predicted by the hotel industry. Notable National Fire Protection Association (NFPA) *and/or* media reported multiple loss of life low-rise hotel/motel fires include:
1. Fontana Hotel - Miami Beach, FL - three stories - 9 civilian fire deaths - 4/6/1990
 2. Paxton Hotel- Chicago, IL - four stories - 21 civilian fire deaths - 3/23/1993
 3. Howard Johnson Hotel - Bowling Green, KY - two stories - 4 civilian deaths - 1/6/1996
 4. Comfort Inn Hotel- Greenville, SC - three stories - 6 civilian deaths - 1/25/2004
 5. Mason Hotel- San Diego, CA - three stories - 2 civilian deaths - 12/17/2004
 6. Mitzpah Hotel- Reno, NV - three stories -12 civilian deaths -10/31/2006
 7. Zanzibar Motel- Reno, NV - two stories - 2 civilian deaths -12/10/2007
 8. Days Inn Hotel- Hoover, AL - two stories - 4 civilian deaths - 1/16/2010
- Civilian fire deaths in hotels/motels averaged 7.7 per 1000 fires with no automatic suppression system present for the 1994-1998 timeframe. Civilian fire deaths in hotel/motel fires averaged 11 each year from 2003-2007"- Civilian fire injuries in hotel/motel fires averaged 151 per year for the period 2003-2007.4
- B. Code provisions remain inadequate to address hazard. Despite firesafety improvements for existing buildings mandated by the IFC starting in 20005 those changes have not resulted in a reduction in the annual civilian fire death statistics in nonsprinklered hotels/motels. Comparatively, no fire civilian fire deaths have been reported in sprinklered Group R-1 hotels/motels. After a decade of these codes changes fire deaths and injuries continue to occur in low-rise non-sprinklered Group R-1 hotels/motels. Without further code enhancements for existing hotels/motels, this carnage will continue. As such, a 'distinct hazard' continues to be present to occupants of non-sprinklered Group R-1 hotels and motels with regard to fires therein.
- C. Cost/benefits: The U.S. lodging industry has largely completed the mostly voluntary sprinkler retrofitting of existing high-rise hotels, an effort which resulted in zero fire fatalities over the past two decades in such hotels? Leading lodging operators and franchisors including Hilton, Marriott and Starwood have also completed the sprinkler retrofitting of their low-rise hotels, dispelling the myth that such retrofit costs are prohibitive. Those costs are no more expensive than the routinely scheduled replacement of furnishings, fixtures and equipment (FF&E) including mattresses, case goods, carpeting, draperies and wall covering done by the industry. A hotel/motel sprinkler retrofit project is a one-time capital cost whereas the replacement of FF&E is a continuing periodic capital cost which the industry routinely bears. A hotel/motel sprinkler retrofit provides for a reduction in property insurance premiums and reduces the risk to firefighters engaged in fire suppression activities therein. As a result of these sprinkler system retrofits none of those cited hotel chains has experienced a civilian fire fatality in any of their hotels in the last two decades. Nonetheless, some lodging chains and many independent low-rise hotel owners/operators have not taken the same proactive action to protect their guests. The cost of such retrofits for commercial buildings including hotels and motels has been mitigated significantly by the permitted use of NFPA 13R as the installation standard for residential occupancies of 4 stories and less, the use of listed CPVC pipe in lieu of steel pipe or copper tube, the use of extended coverage sprinklers, the lack of the need in most cases for a fire pump in low rise Group R-1 buildings and through tax incentives in the forms of grants, tax credits, tax deductions and/or low interest loans for doing so see, for examples, state statutes in Alaska, South Carolina 10 and California 11 as well as numerous local ordinances.

Summary: Existing IFC provisions have failed to prevent hotel/motel fire fatalities and thus a 'distinct hazard' to Group R-1 hotel and motel occupants continues to exist. The code change proposed herein, if adopted, will eliminate the 'distinct hazard' to life for such occupants.

	Assembly:	ASF	AMF	DF

1103.5.3 (NEW)-F-DALY

F227 – 13

1103.7.2

Proponent: Carl Baldassarra, P.E., FSFPE, Chair, ICC Code Technology Committee
(cbaldassarra@RJAGroup.com)

Revise as follows:

1103.7.2 Group I-1. An automatic ~~fire alarm~~ smoke detection system shall be installed in existing Group I-1 ~~residential care/assisted living~~ facilities in accordance with Section 907.2.6.1.

Exceptions:

1. Manual fire alarm boxes in resident or patient sleeping areas shall not be required at *exits* if located at all nurses' control stations or other constantly attended staff locations, provided such stations are visible and continuously accessible and that travel distances required in Section 907.5.2 are not exceeded.
2. Where each sleeping room has a *means of egress* door opening directly to an exterior egress balcony that leads directly to the *exits* in accordance with Section 1019, and the building is not more than three stories in height.

Reason: The deletion after Group I-1 is for consistency with the terminology established in G31-12. The change of terminology is for consistency with Section 907.2.6.1. See below.

907.2.6.1 Group I-1. An automatic smoke detection system shall be installed in *corridors*, waiting areas open to *corridors* and *habitable spaces* other than *sleeping units* and kitchens. The system shall be activated in accordance with Section 907.5.

Exceptions:

1. Smoke detection in *habitable spaces* is not required where the facility is equipped throughout with an *automatic sprinkler system* installed in accordance with Section 903.3.1.1.
2. Smoke detection is not required for exterior balconies.

This will not change the single-station smoke detector requirements in Section 1103.8.

The ICC Board established the ICC Code Technology Committee (CTC) as the venue to discuss contemporary code issues in a committee setting which provides the necessary time and flexibility to allow for full participation and input by any interested party. The code issues are assigned to the CTC by the ICC Board as "areas of study". Information on the CTC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CTC effort can be downloaded from the following website: <http://www.iccsafe.org/cs/CTC/Pages/default.aspx>. Since its inception in April/2005, the CTC has held twenty five meetings - all open to the public.

Cost Impact: None

F227-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

1103.7.2-F-BALDASSARRA-CTC

F228 – 13

1103.7.6

Proponent: Jeffrey M. Shapiro, International Institute of Ammonia Refrigeration
(jeff.shapiro@intlcodeconsultants.com)

Revise as follows:

1103.7.6 Group R-2. A manual fire alarm system that activates the occupant notification system in accordance with Section 907.6 shall be installed in existing Group R-2 occupancies more than three stories in height or with more than 16 *dwelling* or *sleeping units*.

Exceptions:

1. Where each living unit is separated from other contiguous living units by *fire barriers* having a *fire-resistance rating* of not less than 0.75 hour, and where each living unit has either its own independent *exit* or its own independent stairway or ramp discharging at grade.
2. A separate fire alarm system is not required in buildings that are equipped throughout with an *approved supervised automatic sprinkler system* installed in accordance with Section 903.3.1.1 or 903.3.1.2 and having a local alarm to notify all occupants.
3. A fire alarm system is not required in buildings that do not have interior *corridors* serving *dwelling units* and are protected by an *approved automatic sprinkler system* installed in accordance with Section 903.3.1.1 or 903.3.1.2, provided that *dwelling units* either have a *means of egress* door opening directly to an exterior *exit access* that leads directly to the *exits* or are served by open ended *corridors* designed in accordance with Section 1026.6, Exception 4.
4. A fire alarm system is not required in buildings that do not have interior *corridors* serving *dwelling units*, do not exceed 3 stories in height and comply with all of the following:
 - 4.1 Each *dwelling unit* is separated from other contiguous *dwelling units* by *fire barriers* having a *fire-resistance rating* of not less than $\frac{3}{4}$ hour
 - 4.2 Each *dwelling unit* is provided with interconnected smoke alarms complying with Section 907.2.11 in all sleeping rooms, plus not less than one hardwired smoke alarm in the common area of each floor or mezzanine level. Interconnection shall be permitted to be hardwired or by listed smoke alarms with wireless interconnect capability

Reason: The proposal provides a reasonable alternative to retrofitting a manual fire alarm system in existing Group R-2 occupancy buildings not exceeding three stories in height and having exits that lead directly to the outside. Fire risk in apartments tends to be greatest for occupants inside the dwelling unit where a fire originates, and money spent to retrofit firesafety equipment in apartments is better spent within dwelling units, as opposed to common areas.

Countless existing apartment buildings have only a single smoke alarm in the common area, and the IFC does not require retrofitting of smoke alarms in sleeping rooms when such alarms weren't required at the time of construction. The lack of smoke alarms in bedrooms, and particularly the lack of interconnecting alarm signals, increases the risk of injury or death in a unit of fire origin and other units that experience smoke infiltration. An additional consequence may be delayed recognition of a fire event, which increases the risk of harm to other building occupants and may delay notification of the fire department.

The alternative of a manual fire alarm system is less beneficial from a safety perspective because it requires an occupant to detect a fire event (which may take more time with fewer smoke alarms) and then find and activate a pull stations. Occupants must then respond to the alarm signal, and with the history of false alarms associated with manual fire alarm systems in apartment buildings, a response without other indications of a fire is questionable.

Cost Impact: The code change proposal will not increase the cost of construction.

F228-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

1103.7.6-F-SHAPIRO

F229 – 13

1103.8.1

Proponent: David S. Collins, FAIA, The Preview Group, Inc., representing The American Institute of Architects (dcollins@preview-group.com); Robert J Davidson, Davidson Code Concepts, LLC

Revise as follows:

1103.8.1 Where required. Existing Group I-1 and R occupancies shall be provided with single-station smoke alarms in accordance with Section 907.2.11 of the *International Building Code*, except as ~~provided~~ required in Sections 1103.8.2. ~~and or~~ 1103.8.3.

Reason: The provisions of 1103.8.2 and 1103.8.3 aren't exceptions, but additional requirements for interconnection and power source for specific applications. Each of these two sections can be applied independently without connection to one another.

Cost Impact: The proposal will not increase the cost of construction.

F229-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

1103.8.1-F-COLLINS-DAVIDSON

F230 – 13

1103.10 (New)

Proponent: John Williams, CBO, Chair, ICC Ad Hoc Committee on Health Care

Add new text as follows:

1103.10 Medical gases. Medical gases stored and transferred in healthcare related facilities shall be in accordance with Chapter 53.

Reason: This proposal adds a retroactive requirement in Chapter 11 that requires compliance with Chapter 53 compressed gases when medical gases are stored and transferred in healthcare related facilities. It was felt necessary to make sure that all existing facilities comply with these requirements to meet CMS guidelines. A general reference was made since it would not simply be compliance with Section 5306 that is necessary but with the compressed gas requirements in general. The medical gas requirements are only one aspect of the regulation of compressed gases.

This proposal is submitted by the ICC Ad Hoc Committee for Healthcare (AHC). The AHC was established by the ICC Board of Directors to evaluate and assess contemporary code issues relating to hospitals and ambulatory healthcare facilities. The AHC is composed of building code officials, fire code officials, hospital facility engineers, and state healthcare enforcement representatives. The goals of the committee are to ensure that the ICC family of codes appropriately addresses the fire and life safety concerns of a highly specialized and rapidly evolving healthcare delivery system. This process is part of a joint effort between ICC and the American Society for Healthcare Engineering (ASHE), a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. Since its inception in April, 2011, the AHC has held 8 open meetings and over 150 workgroup calls which included members of the AHC as well as any interested party to discuss and debate the proposed changes. All meeting materials and reports are posted on the AHC website at: <http://www.iccsafe.org/cs/AHC/Pages/default.aspx>

Cost impact: The code change proposal should not increase the cost of construction because compliance is already required by facility licensure requirements.

F230-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

1103.10 (NEW)-F-WILLIAMS-ADHOC

F231 – 13

1104.2

Proponent: David S. Collins, FAIA, The Preview Group, Inc., representing The American Institute of Architects (dcollins@preview-group.com); Robert J Davidson, Davidson Code Concepts, LLC

Revise as follows:

1104.2 Elevators, escalators and moving walks. Elevators, escalators and moving walks shall not be used as a component of a required means of egress.

Exceptions:

1. Elevators used as an accessible means of egress where allowed by Section 1007.4 of the *International Building Code*.
2. Previously approved elevators, escalators and moving walks in existing buildings.

Reason: Chapters 4 and 30 of the IBC include occupant evacuation elevators for use in lieu of a third egress stair from high rise buildings of Group R-2 over 420 feet in height. If such elevators are “previously approved” the IFC should not prohibit their use.

Cost Impact: This will decrease the cost of construction by the elimination of conflicts within code enforcement documents.

F231-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

1104.2-F-COLLINS

F232 – 13

1104.5

Proponent: David S. Collins, FAIA, The Preview Group, Inc., representing The American Institute of Architects (dcollins@preview-group.com); Robert J Davidson, Davidson Code Concepts, LLC

Revise as follows:

1104.5 Illumination emergency power. ~~Where means of egress illumination is provided, the power~~ supply shall normally be provided by the premises' electrical supply. In the event of power supply failure, illumination shall be automatically provided from an emergency system for the following occupancies where such occupancies require two or more means of egress:

Reason: It isn't clear in the current wording when the power must be provided and for what purpose.

Cost Impact: There will be no cost impact with this change.

F232-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

1104.5-F-COLLINS

F233 – 13

1104.7

Proponent: John Williams, CBO, Chair, ICC Ad Hoc Committee on Health Care
(john.williams@doh.wa.gov)

Revise as follows:

1104.7 Size of doors. The minimum width of each door opening shall be sufficient for the *occupant load* thereof and shall provide a clear width of not less than 28 inches (711 mm). Where this section requires a minimum clear width of 28 inches (711 mm) and a door opening includes two door leaves without a mullion, one leaf shall provide a clear opening width of 28 inches (711 mm). The maximum width of a swinging door leaf shall be 48 inches (1219 mm) nominal. In ambulatory care facilities, doors serving as means of egress from patient treatment rooms or patient sleeping rooms shall provide a clear width of not less than 32 inches (813 mm). ~~Means of egress doors in an occupancy~~ In Group I-2, doors serving as means of egress and used for the movement of beds shall provide a clear width not less than 41.5 inches (1054 mm). The maximum width of a swinging door leaf shall be 48 inches (1219 mm) nominal. The height of doors openings shall not be less than 80 inches (2032 mm).

Exceptions:

1. The minimum and maximum width shall not apply to door openings that are not part of the required *means of egress* in occupancies in Groups R-2 and R-3.
2. Door openings to storage closets less than 10 square feet (0.93 m²) in area shall not be limited by the minimum width.
3. Width of door leaves in revolving doors that comply with Section 1008.1.4.1 shall not be limited.
4. Door openings within a *dwelling unit* shall not be less than 78 inches (1981 mm) in height.
5. Exterior door openings in *dwelling units*, other than the required *exit* door, shall not be less than 76 inches (1930 mm) in height.
6. *Exit access* doors serving a room not larger than 70 square feet (6.5 m²) shall be not less than 24 inches (610 mm) in door width.
7. Door closers and door stops shall be permitted to be 78 inches (1980 mm) minimum above the door.

Reason: Most of this proposal is an editorial coordination with IBC Section 1008.1.1. The addition of the 32" inch clear width for Ambulatory Care Facilities is based on the nature of the activities within the space. This will also coordinate with the federal requirements for accessibility in the 1994 ADAAG and 2010 ADA Standard for Accessible Design for these necessary facilities.

This proposal is submitted by the ICC Ad Hoc Committee on Healthcare (AHC). The AHC was established by the ICC Board of Directors to evaluate and assess contemporary code issues relating to hospitals and ambulatory healthcare facilities. The AHC is composed of building code officials, fire code officials, hospital facility engineers, and state healthcare enforcement representatives. The goals of the committee are to ensure that the ICC family of codes appropriately addresses the fire and life safety concerns of a highly specialized and rapidly evolving healthcare delivery system. This process is part of a joint effort between ICC and the American Society for Healthcare Engineering (ASHE), a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. Since its inception in April, 2011, the AHC has held 5 open meetings and over 80 workgroup calls which included members of the AHC as well as any interested party to discuss and debate the proposed changes. All meeting materials and reports are posted on the AHC website at: <http://www.iccsafe.org/cs/AHC/Pages/default.aspx>.

Cost Impact: None

F233-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

1104.7-F-WILLIAMS-ADHOC

F234 – 13

1104.8

Proponent: John Woestman, Kellen Company, representing Builders Hardware Manufacturers Association (BHMA) (jwoestman@kellencompany.com)

Revise as follows:

1104.8 Opening force for doors. The opening force for interior side-swinging doors without closers shall not exceed a 5 pound (22 N) force. These forces do not apply to the force required to retract latch bolts or disengage other devices that hold the door in a closed position. For other side-swinging, sliding and folding doors, the door latch shall release when subjected to a force of not more than 15 pounds (66 N). The door shall be set in motion when subjected to a force not exceeding 30 pounds (133 N). The door shall swing to a full-open position when subjected to a force of not more than 50 pounds (222 N). Forces shall be applied to the latch side.

Reason: Revisions approved in the 2012 ICC code development cycle for the 2015 IBC should be coordinated in this section of the IFC. The proposed revisions to this section of the IFC is consistent with the revisions to section 1008.1.3 of the 2015 IBC and section 1008.1.3 of the 2015 IFC, resulting from code change proposal E62-12 which was approved "as modified" in 2012.

Cost Impact: None

F234-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

1104.8-F-WOESTMAN

F235 – 13

1104.22

Proponent: Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azubiamia@yahoo.com)

Revise as follows:

1104.22 Minimum aisle width. The minimum clear width of *aisles* shall be:

1. Forty-two inches (1067 mm) for stepped aisles ~~aisle stairs~~ having seating on each side.

Exception: Thirty-six inches (914 mm) where the *aisle* serves less than 50 seats.

2. Thirty-six inches (914 mm) for stepped *aisles* having seating on only one side.

Exceptions:

1. Thirty inches (760 mm) for catchment areas serving not more than 60 seats.
2. Twenty-three inches (584 mm) between a stepped aisle handrail and seating where an aisle does not serve more than five rows on one side.

3. Twenty inches (508 mm) between a stepped *aisle* handrail or guard and seating when the *aisle* is subdivided by the *handrail*.
4. Forty-two inches (1067 mm) for level or ramped *aisles* having seating on both sides.

Exception: Thirty-six inches (914 mm) where the *aisle* serves less than 50 seats.

5. Thirty-six inches (914 mm) for level or ramped *aisles* having seating on only one side.

Exception: Thirty inches (760 mm) for catchment areas serving not more than 60 seats.

- ~~6. Twenty-three inches (584 mm) between a stepped stair handrail and seating where an aisle does not serve more than five rows on one side.~~

Reason: This proposal is submitted by the ICC Fire Code Action Committee (FCAC). This ICC committee was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portions thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the Fire-CAC has held 6 open meetings and numerous Regional Work Group and Task Group meetings and conference calls which included members of the committees as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the FAC website at: <http://www.iccsafe.org/cs/CAC/Pages/default.aspx>.

The language for aisles has been revised in IFC/IBC Section 1028.9.1 to relocate Item 6 to Exception 2 under Item 2 by E143-09/10. This section should be coordinated. The current section is inconsistent when using the term "stepped aisle" and "aisle stair". E86-12 has changed the term to "stepped aisles" throughout the IBC. Below is the revised IBC text for clarity:.

1028.9.1 Minimum aisle width. The minimum clear width for *aisles* shall be as shown:

1. Forty-eight inches (1219 mm) for *stepped aisles* having seating on each side.

Exception: Thirty-six inches (914 mm) where the *aisle* serves less than 50 seats.

2. Thirty-six inches (914 mm) for *aisle stairs* having seating on only one side.

Exception: Twenty-three inches (584 mm) between an *aisle stair handrail* and seating where an *aisle* does not serve more than five rows on one side

3. Twenty-three inches (584 mm) between an *aisle stair handrail* or *guard* and seating where the aisle is subdivided by a handrail.
4. Forty-two inches (1067 mm) for level or ramped *aisles* having seating on both sides.

Exceptions:

1. Thirty-six inches (914 mm) where the *aisle* serves less than 50 seats.
2. Thirty inches (762 mm) where the *aisle* does not serve more than 14 seats.
5. Thirty-six inches (914 mm) for level or ramped *aisles* having seating on only one side.

Exception: Thirty inches (762 mm) where the *aisle* does not serve more than 14 seats.

Cost Impact: This change will not increase the cost of construction

F235-13

1105 (New)

Proponent: John Williams, CBO, Chair, ICC Ad Hoc Committee on Health Care (john.williams@doh.wa.gov) and Carl Baldassarra, P.E., FSFPE, Chair, ICC Code Technology Committee (cbaldassarra@RJAGroup.com)

Add new text as follows:

SECTION 1105 **INCIDENTAL USES IN EXISTING GROUP I-2**

1105.1 General. Incidental uses associated with and located within existing single occupancy or mixed occupancy Group I-2 buildings and that generally pose a greater level of risk to such occupancies shall comply with the provisions of Sections 1105.2 through 1105.4.2.1. Incidental uses in Group I-2 occupancies are limited to those listed in Table 1105.1.

1105.2 Occupancy classification. Incidental uses shall not be individually classified in accordance with Section 302.1 of the *International Building Code*. Incidental uses shall be included in the building occupancies within which they are located.

1105.3 Area limitations. Incidental uses shall not occupy more than 10 percent of the *building area* of the *story* in which they are located.

1105.4 Separation and protection. The incidental uses listed in Table 1105.1 shall be separated from the remainder of the building or equipped with an *automatic sprinkler system*, or both, in accordance with the provisions of that table.

1105.4.1 Separation. Where Table 1105.1 specifies a fire-resistance-rated separation, the incidental uses shall be separated from the remainder of the *building* in accordance with Section 509.4.1 of the *International Building Code*.

1105.4.2 Protection. Where Table 1105.1 permits an *automatic sprinkler system* without a fire-resistance-rated separation, the incidental uses shall be separated from the remainder of the building by construction capable of resisting the passage of smoke in accordance with Section 509.4.2 of the *International Building Code*.

1105.4.2.1 Protection limitation. Except as otherwise specified in Table 1105.1 for certain incidental uses, where an *automatic sprinkler system* is provided in accordance with Table 1105.1, only the space occupied by the incidental use need be equipped with such a system.

TABLE 1105.1
INCIDENTAL USES IN EXISTING GROUP I-2 OCCUPANCIES

<u>ROOM OR AREA</u>	<u>SEPARATION AND/OR PROTECTION</u>
<u>Furnace room where any piece of equipment is over 400,000 Btu per hour input.</u>	<u>1 hour or provide automatic sprinkler system</u>
<u>Rooms with boilers where the largest piece of equipment is over 15 psi and 10 horsepower</u>	<u>1 hour or provide automatic sprinkler system</u>
<u>Refrigerant machinery room</u>	<u>1 hour or provide automatic sprinkler system</u>
<u>Hydrogen cutoff rooms, not classified as Group H</u>	<u>2 hours</u>
<u>Incinerator rooms</u>	<u>2 hours and provide automatic sprinkler system</u>
<u>Paint shops not classified as Group H</u>	<u>2 hours; or 1 hour and provide automatic sprinkler</u>

<u>ROOM OR AREA</u>	<u>SEPARATION AND/OR PROTECTION</u>
	<u>system</u>
<u>Laboratories and vocational shops, not classified as Group H</u>	<u>1 hour or provide automatic sprinkler system</u>
<u>Laundry rooms over 100 square feet</u>	<u>1 hour or provide automatic sprinkler system</u>
<u>Patient rooms equipped with padded surfaces</u>	<u>1 hour or provide automatic sprinkler system</u>
<u>Physical plant maintenance shops.</u>	<u>1 hour or provide automatic sprinkler system</u>
<u>Waste and linen collection rooms with containers with total volume of 10 cubic feet or greater.</u>	<u>1 hour or provide automatic sprinkler system</u>
<u>Storage rooms greater than 100 square feet</u>	<u>1 hour or provide automatic sprinkler system</u>
<u>Stationary storage battery systems having a liquid electrolyte capacity of more than 50 gallons for flooded lead-acid, nickel cadmium or VRLA, or more than 1,000 pounds for lithium-ion and lithium metal polymer used for facility standby power, emergency power or uninterruptable power supplies</u>	<u>2 hours</u>

For SI: 1 square foot = 0.0929 m², 1 pound per square inch (psi) = 6.9 kPa, 1 British thermal unit (Btu) per hour = 0.293 watts, 1 horsepower = 746 watts, 1 gallon = 3.785 L.

(Renumber subsequent sections)

Reason: This proposal is submitted by the ICC Ad Hoc Committee for Healthcare (AHC). The AHC was established by the ICC Board of Directors to evaluate and assess contemporary code issues relating to hospitals and ambulatory healthcare facilities. The AHC is composed of building code officials, fire code officials, hospital facility engineers, and state healthcare enforcement representatives. The goals of the committee are to ensure that the ICC family of codes appropriately addresses the fire and life safety concerns of a highly specialized and rapidly evolving healthcare delivery system. This process is part of a joint effort between ICC and the American Society for Healthcare Engineering (ASHE), a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. Since its inception in April, 2011, the AHC has held 8 open meetings and over 150 workgroup calls which included members of the AHC as well as any interested party to discuss and debate the proposed changes. All meeting materials and reports are posted on the AHC website at: <http://www.iccsafe.org/cs/AHC/Pages/default.aspx>

This proposal is being co-sponsored by the ICC Code Technology Committee. The ICC Board established the ICC Code Technology Committee (CTC) as the venue to discuss contemporary code issues in a committee setting which provides the necessary time and flexibility to allow for full participation and input by any interested party. The code issues are assigned to the CTC by the ICC Board as "areas of study". Information on the CTC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CTC effort can be downloaded from the following website: <http://www.iccsafe.org/cs/CTC/Pages/default.aspx>. Since its inception in April/2005, the CTC has held twenty five meetings - all open to the public. In 2012, three of the 25 face-to face meetings were held. In addition to the CTC meetings, the CTC established Study Groups (SG) of interested parties for each of the areas of study. These SG's are responsible for reviewing the available information and making recommendations to the CTC. All totaled, the SG's held over 70 conference calls in 2012.

The provisions of this code change are being proposed for the IFC to establish requirements for the protection of incidental use areas in existing Group I-2 occupancies. Incidental use area provisions are applicable to new construction in Section 509 of the IBC, however similar provisions are needed for existing Group I-2 occupancies since the hazards posed by such rooms or spaces are no different for existing buildings than for new. Proposed Section and Table 1105.1 are very similar to and based upon IBC Section and Table 509, except that references to occupancies other than Group I-2 are not included. The basic requirements proposed for incidental uses in existing healthcare occupancies rely upon the provisions of the IBC for the specifics of construction and protection. Proposed Sections 1105.2 through 1105.4.2.1 are based on IBC Sections 509.2 through 509.4.2.1, editorially corrected for the IFC and for correlation. These proposed provisions will provide correlation with not only the IBC but also with the current operational and CMS program standards for existing Group I-2 occupancies. A section-by-section summary follows:

1105.1: This proposed section establishes the scope of Section 1105 and its applicability to Group I-2 occupancies. Incidental uses are rooms or areas that constitute special hazards or risks to life safety that are not typically addressed by the provisions for the occupancy group in which they occur even though such rooms or areas may functionally be an extension of the primary use. Only those rooms or areas indicated in Table 1105 are to be regulated as incidental uses. Incidental uses can be located within both single-occupancy and mixed-occupancy buildings. The concern is that those areas designated as incidental uses pose a risk to the remainder of the building, and as such, some degree of protection is required. In general, the nature of these incidental uses is such that they are small areas that are not frequented by the building occupants very often in which a fire could get underway and go unnoticed for a longer time than in a part of the building that is constantly occupied.

1105.2: Consistent with the IBC, this proposed section expressly states that incidental uses are not considered as separate and distinct occupancy classifications but, rather, are classified the same as the occupancies in which they are located. As an example, a waste and linen collection room in a hospital would be classified as a portion of the Group I-2 occupancy even though it may present a level of hazard more akin to a Group S-1 occupancy if it were to be classified separately.

1105.3: The proposed floor area limitation of 10 percent for incidental uses emphasizes the ancillary nature of such rooms and areas and correlates with the IBC. Each incidental use would be limited to a maximum floor area of 10 percent of the floor area of the story in which it is located. Where there are two or more tenants located on the same story, the 10 percent limitation is based upon the floor area of each individual tenant space rather than that of the entire story. The application of the limit on a tenant-by-tenant basis is consistent with the concept of incidental uses typically being ancillary only to a portion of the building, i.e., the specific tenant occupancy.

1105.4: In addition to identifying those rooms or areas that warrant regulation as incidental uses, proposed Table 1105.1 will also indicate the required degree of protection or separation. The requirements identified in Table 1105.1 vary depending on the incidental use. In some cases, a specific type of separation and/or protection is required, while in others there is an option.

1105.4.1: Where a fire-resistance rated separation would be required, the incidental use would need to be separated from other portions of the building in accordance with assemblies complying with the IBC.

1105.4.2: In this proposed section, where Table 1105.1 would allow protection by an automatic sprinkler system without a fire-resistance-rated separation, the construction enclosing the incidental use would still need to resist the passage of smoke. Construction details for resisting the passage of smoke are provided in the IBC.

1105.4.2.1: This proposed section makes it clear that the sprinkler systems stipulated in Table 1105 would be required for the incidental use area only.

TABLE 1105.1: Proposed Table 1105.1 identifies the incidental uses and the required separation or other protection that would need to be provided in all Group I-2 occupancies.

Information note: IBC Table 509 was revised by approved Group A code change G130-12, also submitted by the AHC, which is reproduced here below for reference purposes only:

G130 – 12
Table 509

Proponent: John Williams, CBO, Chair, ICC Ad Hoc Committee on Health Care

Revise as follows:

TABLE 509
INCIDENTAL USES

ROOM OR AREA	SEPARATION AND/OR PROTECTION
Furnace room where any piece of equipment is over 400,000 Btu per hour input.	1 hour or provide automatic sprinkler system
Rooms with boilers where the largest piece of equipment is over 15 psi and 10 horsepower	1 hour or provide automatic sprinkler system
Refrigerant machinery room	1 hour or provide automatic sprinkler system
Hydrogen cutoff rooms, not classified as Group H	1 hour in Group B, F, M, S and U occupancies; 2 hours in Group A, E, I and R occupancies.
Incinerator rooms	2 hours and provide automatic sprinkler system
Paint shops, not classified as Group H, located in occupancies other than Group F	2 hours; or 1 hour and provide automatic sprinkler system
<u>In Group E occupancies, laboratories and vocational shops; not classified as Group H, located in Group E or I-2 occupancy</u>	1 hour or provide automatic sprinkler system
<u>In Group I-2 occupancies, laboratories not classified as Group H</u>	<u>1 hour and provide automatic sprinkler system</u>
<u>In ambulatory care facilities, laboratories not classified as Group H</u>	<u>1 hour or provide automatic sprinkler system</u>
Laundry rooms over 100 square feet	1 hour or provide automatic sprinkler system
<u>In Group I-2, laundry rooms over 100 square feet</u>	<u>1 hour</u>
Group I-3 cells and <u>Group I-2 patient rooms</u> equipped with padded surfaces	1 hour
<u>In Group I-2, physical plant maintenance shops.</u>	<u>1 hour</u>
<u>In ambulatory care facilities or Group I-2 occupancies, waste and linen collection rooms located in either Group I-2 occupancies or ambulatory care facilities with containers that have an aggregate volume of 10 cubic feet or greater</u>	1 hour
<u>In other than ambulatory care facilities and Group I-2 occupancies, waste and linen collection rooms over 100 square feet</u>	1 hour or provide automatic sprinkler system
<u>In ambulatory care facilities or Group I-2 occupancies, storage rooms greater than 100 square feet</u>	<u>1 hour</u>
Stationary storage battery systems having a liquid electrolyte capacity of more than 50 gallons for flooded lead-acid, nickel cadmium or	1 hour in Group B, F, M, S and U occupancies; 2 hours in Group A, E, I and R occupancies.

VRLA, or more than 1,000 pounds for lithium-ion and lithium metal polymer used for facility standby power, emergency power or uninterruptable power supplies	
--	--

For SI: 1 square foot = 0.0929 m², 1 pound per square inch (psi) = 6.9 kPa, 1 British thermal unit (Btu) per hour = 0.293 watts, 1 horsepower = 746 watts, 1 gallon = 3.785 L.

Reason: This proposal is submitted by the ICC Ad Hoc Committee for Healthcare (AHC). The AHC was established by the ICC Board of Directors to evaluate and assess contemporary code issues relating to hospitals and ambulatory healthcare facilities. The AHC is composed of building code officials, fire code officials, hospital facility engineers, and state healthcare enforcement representatives. The goals of the committee are to ensure that the ICC family of codes appropriately addresses the fire and life safety concerns of a highly specialized and rapidly evolving healthcare delivery system. This process is part of a joint effort between ICC and the American Society for Healthcare Engineering (ASHE), a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. Since its inception in April, 2011, the AHC has held 5 open meetings and over 80 workgroup calls which included members of the AHC as well as any interested party to discuss and debate the proposed changes. All meeting materials and reports are posted on the AHC website at: <http://www.iccsafe.org/cs/AHC/Pages/default.aspx>

Currently, more detail is needed in the Incidental Use table to add spaces currently being maintained in healthcare and ambulatory care occupancies. The above chart makes the noted tables consistent with current operational and programmatic standards in the Group I-2 occupancy.

The current version of the table does not address the occasion when materials in a laboratory increases, most notably in the aggregate of larger histology / cytology laboratories. Materials such as xylene, hydrochloric acid, ethanol and fixatives (among others) are present in these areas. Although they are stored in gallon and liter quantities, and not bulk storage, the quantities add up over the larger lab control areas when they are in use at the benches.

The distinction between smaller stat labs, largely found in ambulatory care facilities, and larger clinical labs, found in hospitals, is being proposed. Ambulatory care facilities has been added to the current laboratory category to address those support spaces such as stat labs that are set up for a specific time-sensitive purpose, such as blood draw and chemotherapy, to save time in the Group B occupancy setting. Larger scale or non-critical lab operations are typically sent out to proprietary labs from ambulatory facilities. When addressing labs crossing the threshold into one hour rated construction, these labs are typically constructed as stand-alone operations and commonly appear in Group B occupancies, and are subject to the current occupancy separation requirements.

Volume thresholds are being considered in waste and linen collection rooms because basic exam spaces contain some level of waste containers and linen hampers without rising to the level of storage. The 10 cubic foot threshold represents essentially two medium sized linen hampers and/or trash receptacles. Larger linen and waste receptacle containers, and not the smaller containers typically found in an exam room or patient sleeping room, are subject to volume rather than square footage of the room because a relatively small space, with the 10 cubic foot threshold crossed in a space well below, for example, 100 square feet.

Group I-2 is also being added to the requirement for one hour rating with rooms equipped with padded surfaces. The instance of these rooms existing in a hospital is rare. It is prudent, however, to add the requirement where there is the occasion that such rooms are used in areas such as emergency departments, inpatient psychiatric units, or similar areas.

Physical plant and maintenance shops are a very specific function in a hospital building, and are being added to the table to ensure protection due to the stored materials related to the physical plant operation.

Addition of storage rooms as an area requiring 1 hour rated protection is a key functional aspect of a Group I-2 healthcare building. Areas that become unused become storage areas very quickly. Specifically calling out storage areas helps define and control the storage of combustibles, and avoid creating random storage in otherwise unmonitored or unprotected areas.

Areas addressed in the past, but are no longer included in the table, are addressed in the International Fire Code (IFC). For example, storage of combustible gases is addressed in IFC Section 5306.2 and has specific references to the Group I-2 occupancy. Gift shops, formerly listed as an incidental area requiring protection, have largely been eliminated from these requirements in the I-Codes and other model codes, and are addressed in the context of being open to the corridor. In consideration of ambulatory care facilities, where not otherwise specifically called out, categories that are required for both Group B and I occupancies are assumed to cover Group I-2 and ambulatory care facilities. Examples of this interpretation are hydrogen cut-off rooms and stationary battery storage.

Cost Impact: None

Cost Impact: The code change proposal should not increase the cost of construction because compliance with similar requirements is already required by facility licensure requirements.

Add new text as follows:

SECTION 1105 CONSTRUCTION REQUIREMENTS FOR EXISTING GROUP I-2

IFC 1105.1 General. Existing Group I-2 shall meet the following requirements:

1. The minimum fire safety requirements in Section 1103, and
2. The minimum mean of egress requirements in Section 1104, and
3. The additional egress and construction requirements in Sections 1105.

Where the provisions of this chapter conflict with the construction requirements that applied at the time of construction, the most restrictive provision shall apply.

1105.7 Group I-2 automatic sprinkler system. An automatic sprinkler system installed in accordance with Section 903.3.1 shall be provided throughout existing Group I-2 fire areas. The sprinkler system shall be provided throughout the floor where the Group I-2 occupancy is located, and in all floors between the Group I-2 occupancy and the level of exit discharge.

1105.8 Group I-2 automatic fire alarm system. An automatic fire alarm system shall be installed in existing Group I-2 occupancies in accordance with Section 907.2.6.2.

Exception: Manual fire alarm boxes in patient sleeping areas shall not be required at exits if located at all nurses' control stations or other constantly attended staff locations, provided such stations are visible and continuously accessible and that travel distances required in Section 907.5.2.1 are not exceeded.

Revise as follows:

**TABLE 1103.1
OCCUPANCY AND USE REQUIREMENTS^a**

Section n	Use			Occupancy Classification																		
	High rise	Atrium or covered mall	Under- ground building	A	B	E	F	H -1	H -2	H -3	H -4	H -5	I- 1	I- 2	I- 3	I- 4	M	R -1	R -2	R -3	R -4	S
1104	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R	R
1105	⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮	R	⋮	⋮	⋮	⋮	⋮	⋮	⋮	⋮

(Portions of table not shown remain unchanged)

R = The building is required to comply.

- a. Existing buildings shall comply with the sections identified as "Required" (R) based on occupancy classification or use, or both, whichever is applicable.

1103.5.2 Group I-2. ~~An automatic sprinkler system shall be provided throughout existing Group I-2 fire areas. The sprinkler system shall be provided throughout the floor where the Group I-2 occupancy is located, and in all floors between the Group I-2 occupancy and the level of exit discharge. In Group I-2, an automatic sprinkler system shall be provided in accordance with Section 1105.7.~~

1103.7.3 Group I-2. ~~An automatic fire alarm system shall be installed in existing Group I-2 occupancies in accordance with Section 907.2.6.2. In Group I-2, an automatic fire alarm system shall be installed in accordance with Section 1105.8.~~

Exception: ~~Manual fire alarm boxes in resident or patient sleeping areas shall not be required at exits if located at all nurses' control stations or other constantly attended staff locations, provided such stations are visible and continuously accessible and that travel distances required in Section 907.5.2.1 are not exceeded.~~

Reason: This change adds minimum requirements for existing Group I-2 into Chapter 11. The intent is to increase the bare minimum safety requirements due to the fragile and sensitive populations within these facilities. These requirements are meant to be applied retroactively. This is not a new concept for these facilities – it aligns with the current approach by the Center for Medicaid and Medicare Services (CMS), the federal authority having jurisdiction. Hospitals are now required by CMS to have a life safety survey on a regular basis. If the facility does not meet certain life safety minimums, they are required to upgrade their existing facility. This code change will align the Fire Code with those CMS minimum requirements and will hopefully lead to industry consolidation. These retroactive requirements are added to assist code officials and surveyors during the ongoing regular inspection of hospital facilities and are consistent with the inspections required by federal laws for certification and reimbursement. The requirements consider the minimum previously approved construction methods. These requirements will provide jurisdictions the ability to adopt minimum retroactive provisions that have been vetted by the industry as well as code officials and that are consistent with current national standards used by the Federal Government providing a more uniform level of safety and eliminating many of the current code conflicts for existing facilities.

We looked at several sources to determine what the appropriate minimum bar should be, including the current building and fire code, current CMS guidelines, and previous versions of the ICC and model codes. On all issues, enforcement agencies and the regulated facilities weighed in to ensure that these changes are both necessary and achievable.

The intent of this proposal is to create a new Section 1105, to have a section for Group I-2 specific and unique requirements. Section 1105.1 General, provides a general scoping for this section. Areas in the hospital and nursing homes not in patient care areas will use the general provisions in Section 1103 and 1104. Where there are more restrictive provisions for hospitals or nursing homes, they will be listed in Section 1105.

Current provisions that were relocated to this section (1105.7 – automatic sprinkler system; 1105.8 – automatic fire alarm system) will remain applicable to all Group I-2. Section 1105.7, sprinkler requirements is relocated from 1103.5.2. Section 1105.8, automatic fire alarm system is relocated from 1103.7.3.

There is a package of proposal that are intended to be incorporated into this section. Below is how a new Section 1105 will look if all the proposals are accepted.

IFC SECTION 1105 CONSTRUCTION REQUIREMENTS FOR EXISTING GROUP I-2

IFC 1105.1 General. Existing Group I-2 shall meet the following requirements:

1. The minimum fire safety requirements in Section 1103, and
2. The minimum mean of egress requirements in Section 1104, and
3. The additional egress and construction requirements in Sections 1105.

Where the provisions of this chapter conflict with the construction requirements that applied at the time of construction, the most restrictive provision shall apply.

1105.2 Construction. Group I-2 Condition 2 shall not be located on a floor level higher than the floor level limitation in Table 1105.2 based on the type of construction.

**Table 1105.2
FLOOR LEVEL LIMITATIONS FOR GROUP I-2 Condition 2**

VA	Note b	P	P	NP	NP
	Note c	NP	NP	NP	NP
VB	Note b	P	NP	NP	NP
	Note c	NP	NP	NP	NP

P = Permitted; NP = Not Permitted

- Floors level shall be counted based on the number of stories above grade.
- The building is equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1.
- The building is equipped with an automatic sprinkler system in accordance with Section 1105.7.

1105.3 Corridor construction. In Group I-2, in areas housing patient sleeping or care rooms, corridor walls and the opening protectives therein shall provide a barrier designed to resist the passage of smoke in accordance with Sections 1105.3.1 through 1105.3.7.

1105.3.1 Materials. The walls shall be of materials permitted by the building type of construction.

1105.3.2 Fire-resistance rating. Unless required elsewhere in the code, corridor walls are not required to have a fire-resistance rating.

1105.3.3 Corridor Walls Continuity. Corridor walls shall extend from the top of the foundation or floor below to one of the following:

- The underside of the floor or roof sheathing, deck or slab above.
- The underside of a ceiling above where the ceiling membrane is constructed to limit the passage of smoke.
- The underside of a lay-in ceiling system where the ceiling tiles weigh at least one pound per square foot of tile.

1105.3.4 Openings in corridor walls. Openings in corridor walls shall provide protection in accordance with 1105.3.4.1 through 1105.3.4.3.

1105.3.4.1 Windows. Windows in corridor walls shall be sealed to limit the passage of smoke, or the window shall be automatic closing upon detection of smoke, or the window opening shall be protected by an automatic closing device that closes upon detection of smoke.

Exception: In smoke compartments not containing patient sleeping rooms, pass-through windows or similar openings shall be permitted in accordance with Section 1105.3.4.3.

1105.3.4.2 Doors. Doors in corridor walls shall comply with Sections 1105.3.4.2.1 through 1105.3.4.2.3.

1105.3.4.2.1 Louvers. Doors in corridor walls shall not include louvers, transfer grills or similar openings.

Exception: Doors shall be permitted to have louvers, transfer grills or similar openings at toilet rooms or bathrooms; storage rooms that do not contain storage of flammable or combustible material; and storage rooms that are not required to be separated as incidental uses.

1105.3.4.2.2 Corridor doors. Doors in corridor walls shall limit the transfer of smoke by complying with the following:

1. Doors shall be constructed of not less than 1-3/4 inch (44 mm) thick solid bonded core wood or capable of resisting fire for a minimum of 1/3 hours.

Exception: Corridor doors in buildings equipped throughout with an automatic sprinkler system.

2. Frames for side hinged swinging doors shall have stops on the sides and top to limit transfer of smoke.
3. Where provided, vision panels in doors shall be a fixed glass window assembly installed to limit the passage of smoke. Existing wired glass panels with steel frames shall be permitted to remain in place.
4. Doors undercuts shall not exceed 1 inch (25 mm).
5. Doors shall be positive latching with devices that resist not less than 5 pounds (22.2 N). Roller latches are prohibited.
6. Mail slots or similar openings shall be permitted in accordance with Section 1105.3.4.3.

1105.3.4.2.3 Dutch doors. Where provided, dutch doors shall comply with Section 1105.3.4.2.2. In addition, dutch doors shall be equipped with latching devices on either the top or bottom leaf to allow leaves to latch together. The space between the leaves shall be protected with devices such as astragals to limit the passage of smoke.

1105.3.4.2.4 Self- or automatic-closing doors. Where self- or automatic-closing doors are required, closers shall be maintained in operational condition.

1105.3.4.3 Openings in corridor walls and doors. Mail slots, pass through windows or similar openings shall not be required to be protected where the aggregate area of the openings between the corridor and a room are not greater than 80 square inches (51 613 mm²) and are located with the top edge of any opening no higher than 48 inches above the floor.

1105.3.5 Penetrations. The space around penetrating items shall be filled with an *approved* material to limit the passage of smoke.

1105.3.6 Joints. Joints shall be filled with an *approved* material to limit the passage of smoke.

1105.3.7 Ducts and air transfer openings. The space around a duct penetrating a smoke partition shall be filled with an *approved* material to limit the passage of smoke. Air transfer openings in smoke partitions shall be provided with a *smoke damper* complying with Section 717.3.2.2 of the International Building Code.

Exception: Where the installation of a *smoke damper* will interfere with the operation of a required smoke control system in accordance with Section 909, *approved* alternative protection shall be utilized.

1105.4 Means of egress. In addition to the means of egress requirements in Section 1104, Group I-2 facilities shall meet the means of egress requirements in Section 1105.4.1 through 1105.4.7.

1105.4.1 Exit signs and emergency illumination. The power system for exit signs and emergency illumination for the means of egress shall provide power for not less than 90 minutes and consist of storage batteries, unit equipment or an on-site generator.

1105.4.2 Emergency power for operational needs. The essential electrical system shall be capable of supplying services in accordance with NFPA 99.

1105.4.3 Size of Door. Means of egress doors used for the movement of patients in beds shall provide a minimum clear width of 41.5 inches (1054 mm). The height of door opening shall not be less than 80 inches (2032 mm).

Exception: Door closers and door stops shall be permitted to be 78 inches minimum above the floor.

1105.4.4 Ramps. In areas where ramps are used for movement of patients in beds, the clear width of the ramp shall not be less than 48 inches (1219 mm).

1105.4.5 Corridor width. In areas where corridors are used for movement of patients in beds, the clear width of the corridor shall not be less than 48 inches (1219 mm).

1105.4.6 Dead end corridors. In smoke compartments containing patient sleeping rooms and treatment rooms, dead end corridors shall not exceed 30 feet unless approved by the fire official.

1105.4.7 Aisles. In areas where aisles are used for movement of patients in beds, the clear width of the aisle shall not be less than 48 inches (1219 mm).

1105.5 Smoke compartments. Smoke compartments shall be provided in existing Group I-2 Condition 2, in accordance with Sections 1105.5.1 through 1105.5.4.

1105.5.1 Design. Smoke barriers shall be provided to subdivide each story used for patients sleeping with an occupant load of more than 30 patients into no fewer than two smoke compartments.

1105.5.1.1 Refuge areas. Refuge areas shall be provided within each smoke compartment. The size of the refuge area shall accommodate the occupants and care recipients from the adjoining smoke compartment. Where a smoke compartment is adjoined

by two or more smoke compartments, the minimum area of the refuge area shall accommodate the largest occupant load of the adjoining compartments.

The size of the refuge area shall provide the following:

1. Not less than 30 net square feet (2.8 m²) for each care recipient confined to bed or stretcher.
2. Not less than 15 square feet (1.4 m²) for each resident in a Group I-2 using mobility assistance devices.
3. Not less than 6 square feet (0.56 m²) for each occupant not addressed in Items 1 and 2.

Areas of spaces permitted to be included in the calculation of the refuge area of corridors, sleeping areas, treatment rooms, lounge or dining areas and other low-hazard areas.

1105.5.2 Smoke barriers. Smoke barriers shall be constructed in accordance with Section 709 of the *International Building Code*.

Exceptions:

1. Existing smoke barriers with a minimum of 1/2 –hour fire-resistance rating are permitted to remain.
2. Smoke barriers shall be permitted to terminate at an atrium enclosure in accordance with Section 404.6 of the *International Building Code*.

1105.5.3 Opening protectives. Openings in smoke barriers shall be protected in accordance with Section 716 of the *International Building Code*. Opening protectives shall have a minimum fire-protection-rating of 1/3 hours.

Exception: Wired glass vision panels in doors shall be permitted to remain.

1105.5.4 Duct and air transfer openings. Penetrations in a smoke barrier by duct and air transfer openings shall comply with Section 717 of the *International Building Code*.

Exception: Where existing duct and air transfer openings in smoke barriers exist without smoke dampers, they shall be permitted to remain. Any changes to existing smoke dampers shall be submitted for review and approved in accordance with IBC Section 717 of the *International Building Code*.

1105.6 Group I-2 care suites. Care suites in existing Group I-2 Condition 2 occupancies shall comply with Section 407.4.3 through 407.4.3.6.2 of the *International Building Code*.

1105.7 Group I-2 automatic sprinkler system. An automatic sprinkler system installed in accordance with Section 903.3.1 shall be provided throughout existing Group I-2 fire areas. The sprinkler system shall be provided throughout the floor where the Group I-2 occupancy is located, and in all floors between the Group I-2 occupancy and the level of exit discharge.

1105.8 Group I-2 automatic fire alarm system. An automatic fire alarm system shall be installed in existing Group I-2 occupancies in accordance with Section 907.2.6.2.

Exception: Manual fire alarm boxes in patient sleeping areas shall not be required at exits if located at all nurses' control stations or other constantly attended staff locations, provided such stations are visible and continuously accessible and that travel distances required in Section 907.5.2.1 are not exceeded.

This proposal is submitted by the ICC Ad Hoc Committee for Healthcare (AHC). The AHC was established by the ICC Board of Directors to evaluate and assess contemporary code issues relating to hospitals and ambulatory healthcare facilities. The AHC is composed of building code officials, fire code officials, hospital facility engineers, and state healthcare enforcement representatives. The goals of the committee are to ensure that the ICC family of codes appropriately addresses the fire and life safety concerns of a highly specialized and rapidly evolving healthcare delivery system. This process is part of a joint effort between ICC and the American Society for Healthcare Engineering, a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. Since its inception in April 2011, the AHC has held 8 open meetings and over 150 workgroup calls which included members of the AHC as well as any interested party to discuss and debate the proposed changes. All meeting materials and reports are posted on the AHC website at: <http://www.iccsafe.org/cs/AHC/Pages/default.aspx>.

This proposal is being co-sponsored by the ICC Code Technology Committee. The ICC Board established the ICC Code Technology Committee (CTC) as the venue to discuss contemporary code issues in a committee setting which provides the necessary time and flexibility to allow for full participation and input by any interested party. The code issues are assigned to the CTC by the ICC Board as "areas of study". Information on the CTC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CTC effort can be downloaded from the following website: <http://www.iccsafe.org/cs/CTC/Pages/default.aspx>. Since its inception in April/2005, the CTC has held twenty five meetings - all open to the public.

P = Permitted; NP = Not Permitted

a. Floors level shall be counted based on the number of stories above grade.

b. The building is equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1.

c. The building is equipped with an automatic sprinkler system in accordance with Section 1105.7.

Reason: This change adds minimum requirements for existing hospitals (Group I-2, Condition 2) into Chapter 11. The intent is to increase the bare minimum safety requirements due to the fragile and sensitive populations within these facilities. These requirements are meant to be applied retroactively. This is not a new concept for these facilities – it aligns with the current approach by the Center for Medicaid and Medicare Services (CMS), the federal authority having jurisdiction. Hospitals are now required by CMS to have a life safety survey on a regular basis. If the facility does not meet certain life safety minimums, they are required to upgrade their existing facility. This code change will align the Fire Code with those CMS minimum requirements and will hopefully lead to industry consolidation. These retroactive requirements are added to assist code officials and surveyors during the ongoing regular inspection of hospital facilities and are consistent with the inspections required by federal laws for certification and reimbursement. The requirements consider the minimum previously approved construction methods. These requirements will

provide jurisdictions the ability to adopt minimum retroactive provisions that have been vetted by the industry as well as code officials and that are consistent with current national standards used by the Federal Government providing a more uniform level of safety and eliminating many of the current code conflicts for existing facilities.

We looked at several sources to determine what the appropriate minimum bar should be, including the current building and fire code, current CMS guidelines, and previous versions of the ICC and model codes. On all issues, enforcement agencies and the regulated facilities weighed in to ensure that these changes are both necessary and achievable.

These provisions are written specifically for hospitals (Group I-2, Condition 2). These retroactive requirements are added to assist code officials and surveyors during the ongoing regular inspection of hospital facilities. These inspections are required by federal laws for certification and reimbursement. This requirement considers the minimum previously approved construction methods. This is consistent with the federal requirements that these facilities are currently held too.

The revision to Section 1105.2 is proposed this retroactive limitation requirement for the allowable height based upon construction type because it is a key component of the regulatory approval for a health care facility, and so that surveying and licensing requirements can be documented and provided for in the IFC. Without these limitations provided for in the IFC, to which the healthcare industry is required to comply and support, the implementation and use of the IFC as a compliance document could not be possible. While most if not all existing hospitals were constructed to comply with these minimum construction requirements, many were constructed using methods that pre-dated the current construction type matrix, and were comprised of an "assembly" (i.e. minimum thickness concrete slab with a metal lath and plaster ceiling below) which provided the necessary fire rating. This section will allow all hospitals to be evaluated on an ongoing basis to verify the system/assembly used to obtain the required fire rating will be maintained or replaced with an equivalent system/assembly.

The existing allowance for the occupancies as stipulated in the proposed table, are less than that for new construction and do not increase the cost of construction and operations beyond what is currently mandated for healthcare facilities.

This proposal is submitted by the ICC Ad Hoc Committee for Healthcare (AHC). The AHC was established by the ICC Board of Directors to evaluate and assess contemporary code issues relating to hospitals and ambulatory healthcare facilities. The AHC is composed of building code officials, fire code officials, hospital facility engineers, and state healthcare enforcement representatives. The goals of the committee are to ensure that the ICC family of codes appropriately addresses the fire and life safety concerns of a highly specialized and rapidly evolving healthcare delivery system. This process is part of a joint effort between ICC and the American Society for Healthcare Engineering, a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. Since its inception in April 2011, the AHC has held 8 open meetings and over 150 workgroup calls which included members of the AHC as well as any interested party to discuss and debate the proposed changes. All meeting materials and reports are posted on the AHC website at: <http://www.iccsafe.org/cs/AHC/Pages/default.aspx>.

Add new text as follows:

IFC SECTION 1105 **CONSTRUCTION REQUIREMENTS FOR EXISTING GROUP I-2**

1105.3 Corridor construction. In Group I-2, in areas housing patient sleeping or care rooms, corridor walls and the opening protectives therein shall provide a barrier designed to resist the passage of smoke in accordance with Sections 1105.3.1 through 1105.3.7.

1105.3.1 Materials. The walls shall be of materials permitted by the building type of construction.

1105.3.2 Fire-resistance rating. Unless required elsewhere in the code, corridor walls are not required to have a fire-resistance rating.

1105.3.3 Corridor Walls Continuity. Corridor walls shall extend from the top of the foundation or floor below to one of the following:

1. The underside of the floor or roof sheathing, deck or slab above.
2. The underside of a ceiling above where the ceiling membrane is constructed to limit the passage of smoke.
3. The underside of a lay-in ceiling system where the ceiling tiles weigh at least one pound per square foot of tile.

1105.3.4 Openings in corridor walls. Openings in corridor walls shall provide protection in accordance with 1105.3.4.1 through 1105.3.4.3.

1105.3.4.1 Windows. Windows in corridor walls shall be sealed to limit the passage of smoke, or the window shall be automatic closing upon detection of smoke, or the window opening shall be protected by an automatic closing device that closes upon detection of smoke.

Exception: In smoke compartments not containing patient sleeping rooms, pass-through windows or similar openings shall be permitted in accordance with Section 1105.3.4.3.

1105.3.4.2 Doors. Doors in corridor walls shall comply with Sections 1105.3.4.2.1 through 1105.3.4.2.3.

1105.3.4.2.1 Louvers. Doors in corridor walls shall not include louvers, transfer grills or similar openings.
Exception: Doors shall be permitted to have louvers, transfer grills or similar openings at toilet rooms or bathrooms; storage rooms that do not contain storage of flammable or combustible material; and storage rooms that are not required to be separated as incidental uses.

1105.3.4.2.2 Corridor doors. Doors in corridor walls shall limit the transfer of smoke by complying with the following:

1. Doors shall be constructed of not less than 1-3/4 inch (44 mm) thick solid bonded core wood or capable of resisting fire for a minimum of 1/3 hours.

Exception: Corridor doors in buildings equipped throughout with an automatic sprinkler system.

2. Frames for side hinged swinging doors shall have stops on the sides and top to limit transfer of smoke.
3. Where provided, vision panels in doors shall be a fixed glass window assembly installed to limit the passage of smoke. Existing wired glass panels with steel frames shall be permitted to remain in place.
4. Doors undercuts shall not exceed 1 inch (25 mm).
5. Doors shall be positive latching with devices that resist not less than 5 pounds (22.2 N). Roller latches are prohibited.
6. Mail slots or similar openings shall be permitted in accordance with Section 1105.3.4.3.

1105.3.4.2.3 Dutch doors. Where provided, dutch doors shall comply with Section 1105.3.4.2.2. In addition, dutch doors shall be equipped with latching devices on either the top or bottom leaf to allow leaves to latch together. The space between the leaves shall be protected with devices such as astragals to limit the passage of smoke.

1105.3.4.2.4 Self- or automatic-closing doors. Where self- or automatic-closing doors are required, closers shall be maintained in operational condition.

1105.3.4.3 Openings in corridor walls and doors. Mail slots, pass through windows or similar openings shall not be required to be protected where the aggregate area of the openings between the corridor and a room are not greater than 80 square inches (51 613 mm²) and are located with the top edge of any opening no higher than 48 inches above the floor.

1105.3.5 Penetrations. The space around penetrating items shall be filled with an *approved* material to limit the passage of smoke.

1105.3.6 Joints. Joints shall be filled with an *approved* material to limit the passage of smoke.

1105.3.7 Ducts and air transfer openings. The space around a duct penetrating a smoke partition shall be filled with an *approved* material to limit the passage of smoke. Air transfer openings in smoke partitions shall be provided with a *smoke damper* complying with Section 717.3.2.2 of the International Building Code.

Exception: Where the installation of a *smoke damper* will interfere with the operation of a required smoke control system in accordance with Section 909, *approved* alternative protection shall be utilized.

1104.17 Corridors construction. Corridors serving an occupant load greater than 30 and the openings therein shall provide an effective barrier to resist the movement of smoke. Transoms, louvers, doors and other openings shall be kept closed or be self closing. In Group I-2, corridors in areas housing patient sleeping or care rooms shall comply with Section 1105.3.

Exceptions:

1. Corridors in occupancies other than in Group H ~~and I-2~~, which are equipped throughout with an approved automatic sprinkler system.
2. ~~Patient room doors in corridors in occupancies in Group I-2 where smoke barriers are provided in accordance with the International Building Code.~~
32. Corridors in occupancies in Group E where each room utilized for instruction or assembly has at least one-half of the required means of egress doors opening directly to the exterior of the building at ground level.
43. Corridors that are in accordance with the *International Building Code*.

SECTION 202 **GENERAL DEFINITIONS**

Dutch door. A door divided horizontally so that the top can be operated independently from the bottom.

Reason: This change adds minimum requirements for existing Group I-2 into Chapter 11 by adding specific retrofit requirements. This change will move the existing retrofit requirements for corridors in I-2 occupancies to proposed new section 1105.3 and add more detailed specific requirements. The intent is to increase the bare minimum safety requirements due to the fragile and sensitive populations within these facilities. These requirements are meant to be applied retroactively. This is not a new concept for these facilities as it aligns with the current approach by the Center for Medicaid and Medicare Services (CMS), the federal authority having jurisdiction. Hospitals are now required by CMS to have a life safety survey on a regular basis. If the facility does not meet certain life safety minimums, they are required to upgrade their existing facility. These retroactive requirements are added to assist code officials and surveyors during the ongoing regular inspection of hospital facilities and are consistent with the inspections required by federal laws for certification and reimbursement. The requirements consider the minimum previously approved construction methods. These requirements will provide jurisdictions the ability to adopt minimum retroactive provisions that provide a more uniform level of safety and eliminate many of the current code conflicts for existing facilities.

We looked at several sources to determine what the appropriate minimum bar should be, including the current building and fire code, current CMS guidelines, and previous versions of the ICC and model codes. On all issues, enforcement agencies and the regulated facilities weighed in to ensure that these changes are both necessary and achievable.

These provisions are written specifically for hospitals (Group I-2, Condition 2). These are retrofit requirements that provide a minimum level of safety considered necessary for patients, staff and first responders in an environment in which patients are in many instances not capable of self preservation and must be protected in place. The changes also provide tradeoffs for automatic sprinkler systems consistent with those allowed for new construction and also with those allowed by CMS. In no way does this affect the existing requirement that existing, approved construction must be maintained in the manner that it was approved. It simply provides a tool for evaluating historical construction techniques.

Specific points include:

- Existing corridor construction should primarily be evaluated for its ability to resist or limit the transfer of smoke, regardless of the code at the time of construction.. Corridor walls, even if they were built 60 years ago, should be regularly assessed confirm that they minimize the transfer of smoke. This section describes some criteria by which this can be assessed.
- The requirements clearly indicate that portions of corridor walls required to have a fire resistance ratings by other code provisions must meet those provisions. This addresses where a corridor wall also happens to be a smoke barrier, incidental use area separation, etc.
- The Ad Hoc Committee added a specific section on dutch doors. Dutch doors have been used in health care facilities for many years for various necessary operational reasons. While existing language in the IBC does not specifically speak of dutch doors, their use is not prohibited but if used must meet the requirements contained in Section 407.3 including positive latching and limiting the transfer of smoke. This change will provide clarity for existing installations by giving specific guidance on the minimum acceptable requirements including positive latching and smoke transfer for their use in corridor walls. A definition is provided for additional clarity.
- The Ad Hoc committee also proposes similar detail for doors, windows, louvers and other potential penetrations or openings in corridor walls in an attempt to add clarity to the intent of the code on limiting the transfer of smoke. These proposals are consistent with current CMS standards.
- There are exceptions that deal with existing mail slot, pass-through and similar openings that are commonly found in hospitals. These are needed for privacy, medication security and other operational needs. Our proposal places restrictions on these existing openings similar to the current federal requirements.

This proposal is submitted by the ICC Ad Hoc Committee for Healthcare (AHC). The AHC was established by the ICC Board of Directors to evaluate and assess contemporary code issues relating to hospitals and ambulatory healthcare facilities. The AHC is composed of building code officials, fire code officials, hospital facility engineers, and state healthcare enforcement representatives. The goals of the committee are to ensure that the ICC family of codes appropriately addresses the fire and life safety concerns of a highly specialized and rapidly evolving healthcare delivery system. This process is part of a joint effort between ICC and the American Society for Healthcare Engineering, a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. Since its inception in April 2011, the AHC has held 8 open meetings and over 150 workgroup calls which included members of the AHC as well as any interested party to discuss and debate the proposed changes. All meeting materials and reports are posted on the AHC website at: <http://www.iccsafe.org/cs/AHC/Pages/default.aspx>.

This proposal is being co-sponsored by the ICC Code Technology Committee. The ICC Board established the ICC Code Technology Committee (CTC) as the venue to discuss contemporary code issues in a committee setting which provides the necessary time and flexibility to allow for full participation and input by any interested party. The code issues are assigned to the CTC by the ICC Board as "areas of study". Information on the CTC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CTC effort can be downloaded from the following website: <http://www.iccsafe.org/cs/CTC/Pages/default.aspx>. Since its inception in April/2005, the CTC has held twenty five meetings - all open to the public.

	Assembly:	ASF	AMF	DF

1105.3 (NEW)-F-BALDASSARRA-WILLIAMS-ADHOC

F240 – 13

1105.4 (New), 1104.5.1, 1104.7, 1104.15, 1104.17.2, Table 1104.17.2, 1104.22

Proponent: John Williams, CBO, Chair, ICC Ad Hoc Committee on Health Care (john.williams@doh.wa.gov) and Carl Baldassarra, P.E., FSFPE, Chair, ICC Code Technology Committee (cbaldassarra@RJAGroup.com)

Revise as follows:

SECTION 1105 **CONSTRUCTION REQUIREMENTS FOR EXISTING GROUP I-2**

1105.4 Means of egress. In addition to the means of egress requirements in Section 1104, Group I-2 facilities shall meet the means of egress requirements in Section 1105.4.1 through 1105.4.7.

1105.4.1 Exit signs and emergency illumination. The power system for exit signs and emergency illumination for the means of egress shall provide power for not less than 90 minutes and consist of storage batteries, unit equipment or an on-site generator.

1105.4.2 Emergency power for operational needs. The essential electrical system shall be capable of supplying services in accordance with NFPA 99.

1105.4.3 Size of Door. Means of egress doors used for the movement of patients in beds shall provide a minimum clear width of 41.5 inches (1054 mm). The height of door opening shall not be less than 80 inches (2032 mm).

Exception: Door closers and door stops shall be permitted to be 78 inches minimum above the floor.

1105.4.4 Ramps. In areas where ramps are used for movement of patients in beds, the clear width of the ramp shall not be less than 48 inches (1219 mm).

1105.4.5 Corridor width. In areas where corridors are used for movement of patients in beds, the clear width of the corridor shall not be less than 48 inches (1219 mm).

1105.4.6 Dead end corridors. In smoke compartments containing patient sleeping rooms and treatment rooms, dead end corridors shall not exceed 30 feet unless approved by the fire official.

1105.4.7 Separation of exit access doors. Any patient sleeping room, or any suite that includes patient sleeping rooms, of more than 1,000 square feet shall have at least two exit access doors placed a distance apart equal to not less than one-third of the length of the maximum overall diagonal dimension of the patient sleeping room or suite to be served, measured in a straight line between exit access doors.

1105.4.8 Aisles. In areas where aisles are used for movement of patients in beds, the clear width of the aisle shall not be less than 48 inches (1219 mm).

1104.5.1 Emergency power duration and installation. In other than Group I-2, ~~systems requiring the emergency power system~~ shall provide power for not less than 60 minutes and consist of storage batteries, unit equipment or an on-site generator. In Group I-2, ~~the emergency power essential electrical systems shall comply with Sections 1105.4.1 and 1105.4.2 provide power for not less than 90 minutes and consist of storage batteries, unit equipment or an on-site generator.~~ The installation of the emergency power system shall be in accordance with Section 604.

1104.7 Size of doors. The minimum width of each door opening shall be sufficient for the occupant load thereof and shall provide a clear width of not less than 28 inches (711 mm). Where this section requires a minimum clear width of 28 inches (711 mm) and a door opening includes two door leaves without a

mullion, one leaf shall provide a clear opening width of 28 inches (711 mm). ~~The maximum width of a swinging door leaf shall be 48 inches (1219 mm) nominal. In Group I-2, doors serving as means of egress doors in an occupancy in Group I-2 and used for the movement of patients in beds shall comply with Section 1105.4.3. provide a clear width not less than 41.5 inches (1054 mm). The maximum width of a swinging door leaf shall be 48 inches (1219 mm) nominal.~~ The height of doors openings shall not be less than 80 inches (2032 mm).

Exceptions:

1. The minimum and maximum width shall not apply to door openings that are not part of the required means of egress in occupancies in Groups R-2 and R-3.
2. Door openings to storage closets less than 10 square feet (0.93 m²) in area shall not be limited by the minimum width.
3. Width of door leaves in revolving doors that comply with Section 1008.1.4.1 shall not be limited.
4. Door openings within a dwelling unit shall not be less than 78 inches (1981 mm) in height.
5. Exterior door openings in dwelling units, other than the required exit door, shall not be less than 76 inches (1930 mm) in height.
6. Exit access doors serving a room not larger than 70 square feet (6.5 m²) shall be not less than 24 inches (610 mm) in door width.
7. Door closers and door stops shall be permitted to be 78 inches (1980 mm) minimum above the door.

1104.15 Width of ramps. ~~Existing~~ Ramps are permitted to have a minimum width of 30 inches (762 mm) but not less than the width required for the number of occupants served as determined by Section 1005.1. In Group I-2, ramps serving as a means of egress and used for the movement of patients in beds shall comply with Section 1105.8.

~~1104.17.2~~ 1104.18 Dead ends end corridors. Where more than one exit or exit access doorway is required, the exit access shall be arranged such that dead ends do not exceed the limits specified in Table 1104.47-2 18. In Group I-2, in smoke compartments containing patient sleeping rooms and treatment rooms, dead end corridors shall be comply with Section 1105.7.

Exception: A dead-end passageway or corridor shall not be limited in length where the length of the dead end passageway or corridor is less than 2.5 times the least width of the dead-end passageway or corridor.

**TABLE 1104.17.2 1104.18
COMMON PATH, DEAD-END AND TRAVEL DISTANCE LIMITS (by occupancy)**

OCCUPANCY	COMMON PATH LIMIT		DEAD-END LIMIT		TRAVEL DISTANCE LIMIT	
	Unsprinklered (feet)	Sprinklered (feet)	Unsprinklered (feet)	Sprinklered (feet)	Unsprinklered (feet)	Sprinklered (feet)
Group I-1	75	75	20	50	200	250
Group I-2 (Health care)	NR ^e	NR ^e	NR- <u>Note f</u>	NR- <u>Note f</u>	150	200 ^c
Group I-3 (Detention and correctional — Use Conditions II, III, IV, V)	100	100	NR	NR	150 ^c	200 ^c
Group I-4 (Day Care Centers)	NR	NR	20	20	200	250

(Portions of table not shown remain unchanged)

NR = No requirements.

For SI: 1 foot = 304.8 mm, 1 square foot = 0.0929 m².

- a. 20 feet for common path serving 50 or more persons; 75 feet for common path serving less than 50 persons.
- b. See Section 1028.9.5 for dead-end aisles in Group A occupancies.
- c. This dimension is for the total travel distance, assuming incremental portions have fully utilized their allowable maximums. For travel distance within the room, and from the room exit access door to the exit, see the appropriate occupancy chapter.
- d. See the *International Building Code* for special requirements on spacing of doors in aircraft hangars.
- e. In Group I-2, separation of exit access doors within a Any patient sleeping room, or any suite that includes patient sleeping rooms, of more than 1,000 square feet shall have at least two exit access doors placed a distance apart equal to not less than one-third of the length of the maximum overall diagonal dimension of the patient sleeping room or suite to be served, measured in a straight line between exit access doors shall comply with Section 1105.4.7.
- f. In Group I-2, in smoke compartments containing patient sleeping rooms and treatment rooms, dead end corridors shall comply with Section 1105.4.6.
- g.f. Where a tenant space in Group B, S and U occupancies has an occupant load of not more than 30, the length of a common path of egress travel shall not be more than 100 feet.

1104.22 Minimum aisle width. The minimum clear width of aisles shall be:

1. Forty-two inches (1067 mm) for aisle stairs having seating on each side.

Exception: Thirty-six inches (914 mm) where the aisle serves less than 50 seats.

2. Thirty-six inches (914 mm) for stepped aisles having seating on only one side.

Exception: Thirty inches (760 mm) for catchment areas serving not more than 60 seats.

3. Twenty inches (508 mm) between a stepped aisle handrail or guard and seating when the aisle is subdivided by the handrail.
4. Forty-two inches (1067 mm) for level or ramped aisles having seating on both sides.

Exception: Thirty-six inches (914 mm) where the aisle serves less than 50 seats.

5. Thirty-six inches (914 mm) for level or ramped aisles having seating on only one side.

Exception: Thirty inches (760 mm) for catchment areas serving not more than 60 seats.

6. Twenty-three inches (584 mm) between a stepped stair handrail and seating where an aisle does not serve more than five rows on one side.

7. In Group I-2, where aisles are used for movement of patients in beds aisles shall comply with 1105.4.8.

Reason: This change adds minimum requirements for existing Group I-2 into Chapter 11. The intent is to increase the bare minimum safety requirements due to the fragile and sensitive populations within these facilities. These requirements are meant to be applied retroactively. This is not a new concept for these facilities – it aligns with the current approach by the Center for Medicaid and Medicare Services (CMS), the federal authority having jurisdiction. Hospitals are now required by CMS to have a life safety survey on a regular basis. If the facility does not meet certain life safety minimums, they are required to upgrade their existing facility. This code change will align the Fire Code with those CMS minimum requirements and will hopefully lead to industry consolidation. These retroactive requirements are added to assist code officials and surveyors during the ongoing regular inspection of hospital facilities and are consistent with the inspections required by federal laws for certification and reimbursement. The requirements consider the minimum previously approved construction methods. These requirements will provide jurisdictions the ability to adopt minimum retroactive provisions that have been vetted by the industry as well as code officials and that are consistent with current national standards used by the Federal Government providing a more uniform level of safety and eliminating many of the current code conflicts for existing facilities.

We looked at several sources to determine what the appropriate minimum bar should be, including the current building and fire code, current CMS guidelines, and previous versions of the ICC and model codes. On all issues, enforcement agencies and the regulated facilities weighed in to ensure that these changes are both necessary and achievable.

These retroactive requirements are added to assist code officials and surveyors during the ongoing regular inspection of hospital facilities. These inspections are required by federal laws for certification and reimbursement, and is designed to assist those that are already tasked with performing those inspections. It is not the intention to add responsibility to the fire official to perform additional inspections. Rather, it is the intention to better define the minimum previously approved construction methods as it relates to the healthcare building type, and are consistent with the federal requirements that these facilities are currently held too.

This newly proposed section has been formatted to consolidate requirements, and is mostly just a move of existing fire code provisions. Since the current provisions are applicable to all Group I-2, this section is written addressing all Group I-2 where

applicable. Means of egress in areas where there are movement of patients in stretchers or beds has been reordered to be consistent with IFC 1104. It is noted that many areas of nursing homes do not include movement of patients in beds.

The following is a synopsis of the provisions listed above that have been relocated from other sections:

- 1105.4 Means of egress - Means of egress in areas where there are movement of patients in beds. The order is consistent with IFC 1104.
- 1105.4.1 Exit signs and emergency illumination – existing facilities can continue to use battery packs for exits signs and emergency lighting
- 1105.4.2 Emergency power for operational needs – extending section 1104.5.1 by adding requirements from and references to NFPA 99. Similar to IFC 604.3, requires the facility to analyze the hazards in their particular region and prepare accordingly.
- 1105.4.3 Size of door – Existing language that has been transferred from IFC 1104.7; follows format of IBC 1008.1.1.
- 1105.4.4 Ramps – References from IFC 1104.15 to the healthcare specific requirements.
- 1105.4.5 Corridor width – Follows current federal guidance for existing buildings.
- 1105.4.6 Dead end corridors – References from IFC 1104.15 to the healthcare specific requirements.
- 1105.4.7 Separation of exit access doors – Moved a healthcare specific requirement from footnote e in Table 1014.7.2 into Section 1105.
- 1105.4.8 Aisles – Provides a reference from IFC 1104.22 to more specific healthcare requirements.

Finally, in no way does this change affect the current requirement that existing, approved construction must be maintained in the manner that it was approved. The fire code clearly states that existing, approved safety feature must be maintained to the code at the time of construction. Most hospitals have been around for many decades and have several vintages of construction. This change simply provides a tool for evaluating historical conditions.

This proposal is submitted by the ICC Ad Hoc Committee for Healthcare (AHC). The AHC was established by the ICC Board of Directors to evaluate and assess contemporary code issues relating to hospitals and ambulatory healthcare facilities. The AHC is composed of building code officials, fire code officials, hospital facility engineers, and state healthcare enforcement representatives. The goals of the committee are to ensure that the ICC family of codes appropriately addresses the fire and life safety concerns of a highly specialized and rapidly evolving healthcare delivery system. This process is part of a joint effort between ICC and the American Society for Healthcare Engineering, a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. Since its inception in April 2011, the AHC has held 8 open meetings and over 150 workgroup calls which included members of the AHC as well as any interested party to discuss and debate the proposed changes. All meeting materials and reports are posted on the AHC website at: <http://www.iccsafe.org/cs/AHC/Pages/default.aspx>.

This proposal is being co-sponsored by the ICC Code Technology Committee. The ICC Board established the ICC Code Technology Committee (CTC) as the venue to discuss contemporary code issues in a committee setting which provides the necessary time and flexibility to allow for full participation and input by any interested party. The code issues are assigned to the CTC by the ICC Board as “areas of study”. Information on the CTC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CTC effort can be downloaded from the following website: <http://www.iccsafe.org/cs/CTC/Pages/default.aspx>. Since its inception in April/2005, the CTC has held twenty five meetings - all open to the public.

1105.4 (NEW)-F-BALDASSARRA-WILLIAMS-ADHOC

F241 – 13

1105.5 (New)

Proponent: John Williams, CBO, Chair, ICC Ad Hoc Committee on Health Care
(john.williams@doh.wa.gov)

Add new text as follows:

SECTION 1105

CONSTRUCTION REQUIREMENTS FOR EXISTING GROUP I-2

1105.5 Smoke compartments. Smoke compartments shall be provided in existing Group I-2 Condition 2, in accordance with Sections 1105.5.1 through 1105.5.4.

1105.5.1 Design. Smoke barriers shall be provided to subdivide each story used for patients sleeping with an occupant load of more than 30 patients into no fewer than two smoke compartments.

1105.5.1.1 Refuge areas. Refuge areas shall be provided within each smoke compartment. The size of the refuge area shall accommodate the occupants and care recipients from the adjoining smoke compartment. Where a smoke compartment is adjoined by two or more smoke compartments, the minimum area of the refuge area shall accommodate the largest occupant load of the adjoining compartments.

The size of the refuge area shall provide the following:

1. Not less than 30 net square feet (2.8 m²) for each care recipient confined to bed or stretcher.
2. Not less than 15 square feet (1.4 m²) for each resident in a Group I-2 using mobility assistance devices.
3. Not less than 6 square feet (0.56 m²) for each occupant not addressed in Items 1 and 2.

Areas of spaces permitted to be included in the calculation of the refuge area of corridors, sleeping areas, treatment rooms, lounge or dining areas and other low-hazard areas.

1105.5.2 Smoke barriers. Smoke barriers shall be constructed in accordance with Section 709 of the *International Building Code*.

Exceptions:

1. Existing smoke barriers with a minimum of 1/2 –hour fire-resistance rating are permitted to remain.
2. Smoke barriers shall be permitted to terminate at an atrium enclosure in accordance with Section 404.6 of the *International Building Code*.

1105.5.3 Opening protectives. Openings in smoke barriers shall be protected in accordance with Section 716 of the *International Building Code*. Opening protectives shall have a with a minimum fire-protection-rating of 1/3 hours.

Exception: Wired glass vision panels in doors shall be permitted to remain.

1105.5.4 Duct and air transfer openings. Penetrations in a smoke barrier by duct and air transfer openings shall comply with Section 717 of the *International Building Code*.

Exception: Where existing duct and air transfer openings in smoke barriers exist without smoke dampers, they shall be permitted to remain. Any changes to existing smoke dampers shall be

submitted for review and approved in accordance with IBC Section 717 of the *International Building Code*.

Reason: This change adds minimum requirements for existing hospitals (Group I-2, Condition 2) into Chapter 11. The intent is to increase the bare minimum safety requirements due to the fragile and sensitive populations within these facilities. These requirements are meant to be applied retroactively. This is not a new concept for these facilities – it aligns with the current approach by the Center for Medicaid and Medicare Services (CMS), the federal authority having jurisdiction. Hospitals are now required by CMS to have a life safety survey on a regular basis. If the facility does not meet certain life safety minimums, they are required to upgrade their existing facility. This code change will align the Fire Code with those CMS minimum requirements and will hopefully lead to industry consolidation. These retroactive requirements are added to assist code officials and surveyors during the ongoing regular inspection of hospital facilities and are consistent with the inspections required by federal laws for certification and reimbursement. The requirements consider the minimum previously approved construction methods. These requirements will provide jurisdictions the ability to adopt minimum retroactive provisions that have been vetted by the industry as well as code officials and that are consistent with current national standards used by the Federal Government providing a more uniform level of safety and eliminating many of the current code conflicts for existing facilities.

We looked at several sources to determine what the appropriate minimum bar should be, including the current building and fire code, current CMS guidelines, and previous versions of the ICC and model codes. On all issues, enforcement agencies and the regulated facilities weighed in to ensure that these changes are both necessary and achievable.

This provision is written in regard to the design, construction and application of smoke compartments for Group I-2 hospital facilities. Smoke compartments are a key component of the defend in place strategy, a strategy where victims are protected from fire without relocation, used in healthcare facilities to limit the movement of smoke. These compartments act as safe locations for patients by preventing the spread of smoke. Through compartmentalization, patients may remain safely in their rooms as fire suppression systems and fire responders extinguish the fire. Under severe fire conditions that threaten the immediate compartment area, patients may be evacuated horizontally to the safety of an adjacent compartment on the same floor. Being able to do this is critical since due to the health status of many patients their evacuation from the building might put them in grave danger. The proper design, construction and application of smoke compartments will provide added protection, buy valuable time and save lives of critically ill patients before a total evacuation may become necessary.

These retroactive requirements are added to assist code officials and surveyors during the ongoing regular inspection of hospital facilities. These inspections are required by federal laws for certification and reimbursement. This requirement considers the minimum previously approved construction methods. This is consistent with the federal requirements that these facilities are currently held too. Specific concepts include:

- 1105.5 Smoke compartments – The defend-in-place concept is a basic minimum level of safety for these facilities. Every facility should be equipped at least two smoke compartments for temporary relocation of patients.
- 1105.5.1 Design - This section addresses existing acceptable configuration of smoke barrier walls and smoke barriers for existing hospitals in areas with sleeping rooms.
- 1105.5.1.1 Refuge area – Addresses adequate sizing of refuge areas. IBC 407.5.1 also includes requirements for independent egress and horizontal assemblies.
- 1105.5.2 Smoke barriers – The intent is to bring noncompliant smoke barriers to at least ½ hour fire resistance rating. Previously approved smoke barriers are not intended to be reduced to ½. Chapter 7 of the IFC would require maintenance of approved construction.
- 1105.5.3 Opening protectives - Address doors in smoke barriers in existing Group I-2 occupancies. Reference to 716 is so you that don't lose other requirements.
- 1105.5.4, Guides the inspector of existing facilities on how they would look at opening protectives. Smoke dampers have not always been required in hospitals, and the 2015 IBC would not require them. Therefore, in those hospitals that were originally approved without smoke dampers required, that condition is allowed to remain in place. Any modification of existing smoke dampers would have to go through the normal process for making an alteration to existing construction.

This proposal is submitted by the ICC Ad Hoc Committee for Healthcare (AHC). The AHC was established by the ICC Board of Directors to evaluate and assess contemporary code issues relating to hospitals and ambulatory healthcare facilities. The AHC is composed of building code officials, fire code officials, hospital facility engineers, and state healthcare enforcement representatives. The goals of the committee are to ensure that the ICC family of codes appropriately addresses the fire and life safety concerns of a highly specialized and rapidly evolving healthcare delivery system. This process is part of a joint effort between ICC and the American Society for Healthcare Engineering, a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. Since its inception in April 2011, the AHC has held 8 open meetings and over 150 workgroup calls which included members of the AHC as well as any interested party to discuss and debate the proposed changes. All meeting materials and reports are posted on the AHC website at: <http://www.iccsafe.org/cs/AHC/Pages/default.aspx>.

F242 – 13

1105.6 (New), Table 1104.17.2

Proponent: John Williams, CBO, Chair, ICC Ad Hoc Committee on Health Care

Revise as follows:

IFC SECTION 1105 CONSTRUCTION REQUIREMENTS FOR EXISTING GROUP I-2

1105.6 Group I-2 care suites. Care suites in existing Group I-2 Condition 2 occupancies shall comply with Section 407.4.3 through 407.4.3.6.2 of the *International Building Code*.

**TABLE 1104.17.2 1104.18
COMMON PATH, DEAD-END AND TRAVEL DISTANCE LIMITS (by occupancy)**

OCCUPANCY	COMMON PATH LIMIT		DEAD-END LIMIT		TRAVEL DISTANCE LIMIT	
	Unsprinklered (feet)	Sprinklered (feet)	Unsprinklered (feet)	Sprinklered (feet)	Unsprinklered (feet)	Sprinklered (feet)
Group I-1	75	75	20	50	200	250
Group I-2 (Health care)	NR-Note e	NR-Note e	NR	NR	150	200 ^c
Group I-3 (Detention and correctional Use Conditions II, III, IV, V)	100	100	NR	NR	150 ^c	200 ^c
Group I-4 (Day Care Centers)	NR	NR	20	20	200	250

(Portions of table not shown remain unchanged)

NR = No requirements.

For SI: 1 foot = 304.8 mm, 1 square foot = 0.0929 m².

- 20 feet for common path serving 50 or more persons; 75 feet for common path serving less than 50 persons.
- See Section 1028.9.5 for dead-end aisles in Group A occupancies.
- This dimension is for the total travel distance, assuming incremental portions have fully utilized their allowable maximums. For travel distance within the room, and from the room exit access door to the exit, see the appropriate occupancy chapter.
- See the *International Building Code* for special requirements on spacing of doors in aircraft hangars.
- In Group I-2 Condition 2, Any patient care recipient sleeping room, or any suite that includes patient sleeping rooms, of more than 1,000 square feet shall have at least two exit access doors placed a distance apart equal to not less than one-third of the length of the maximum overall diagonal dimension of the patient sleeping room or suite to be served, measured in a straight line between exit access doors shall comply with Section 1105.6.
- Where a tenant space in Group B, S and U occupancies has an occupant load of not more than 30, the length of a common path of egress travel shall not be more than 100 feet.

Reason: This change adds minimum requirements for existing hospitals (Group I-2, Condition 2) into Chapter 11. The intent is to increase the bare minimum safety requirements due to the fragile and sensitive populations within these facilities. These requirements are meant to be applied retroactively. This is not a new concept for these facilities – it aligns with the current approach by the Center for Medicaid and Medicare Services (CMS), the federal authority having jurisdiction. Hospitals are now required by CMS to have a life safety survey on a regular basis. If the facility does not meet certain life safety minimums, they are required to upgrade their existing facility. This code change will align the Fire Code with those CMS minimum requirements and will hopefully lead to industry consolidation. These retroactive requirements are added to assist code officials and surveyors during the ongoing regular inspection of hospital facilities and are consistent with the inspections required by federal laws for certification and reimbursement. The requirements consider the minimum previously approved construction methods. These requirements will provide jurisdictions the ability to adopt minimum retroactive provisions that have been vetted by the industry as well as code officials and that are consistent with current national standards used by the Federal Government providing a more uniform level of safety and eliminating many of the current code conflicts for existing facilities.

We looked at several sources to determine what the appropriate minimum bar should be, including the current building and fire code, current CMS guidelines, and previous versions of the ICC and model codes. On all issues, enforcement agencies and the regulated facilities weighed in to ensure that these changes are both necessary and achievable.

This proposal defines the requirements for care suites (both sleeping and non-sleeping) which are an integral design concept for many areas within a hospital. Typical uses include ICU's, Operating Rooms, Emergency Departments and Imaging Departments. The suites allow for better and safer care than non-suite options. The new provisions deal with common path of travel, separation of exit access doors, and number of doors passed through (i.e. previously intervening rooms) in suites. This is much more complete than the current text.

This proposal is submitted by the ICC Ad Hoc Committee for Healthcare (AHC). The AHC was established by the ICC Board of Directors to evaluate and assess contemporary code issues relating to hospitals and ambulatory healthcare facilities. The AHC is composed of building code officials, fire code officials, hospital facility engineers, and state healthcare enforcement representatives. The goals of the committee are to ensure that the ICC family of codes appropriately addresses the fire and life safety concerns of a highly specialized and rapidly evolving healthcare delivery system. This process is part of a joint effort between ICC and the American Society for Healthcare Engineering, a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. Since its inception in April 2011, the AHC has held 8 open meetings and over 150 workgroup calls which included members of the AHC as well as any interested party to discuss and debate the proposed changes. All meeting materials and reports are posted on the AHC website at: <http://www.iccsafe.org/cs/AHC/Pages/default.aspx>.

Cost Impact: None

F242-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

1105.6-F-WILLIAMS-ADHOC

F243 – 13

1105.9 (New)

Proponent: John Williams, CBO, Chair, ICC Ad Hoc Committee on Health Care
(john.williams@doh.wa.gov)

Section 1105.9 Essential electrical systems. Essential electrical systems in Group I-2 Condition 2 occupancies shall be in accordance with Sections 1105.9.1 and 1105.9.2.

1105.9.1 Where required. In Group I-2 Condition 2 occupancies where life support is being provided, an essential electrical system shall be provided in accordance with NFPA 99.

1105.9.2 Installation and duration. In Group I-2, Condition 2 Occupancies, the installation and duration of operation of existing essential electrical systems shall be based upon a hazard vulnerability analysis conducted in accordance with NFPA 99.

Reason: This proposal addresses CMS Ktag K146 for existing buildings. The proposal does two things. First, it requires that existing I-2 Condition 2 occupancies provide essential electrical systems where life support is being provided. Second it requires in Group I-2 Condition 2 occupancies that the existing installations and duration of operation of the essential electrical system be assessed based upon a hazard vulnerability analysis in accordance with NFPA 99.

Both of these elements are important. New Section 1105.9.1 requires any buildings that would not be addressed by CMS but have similar risks to provide the necessary power resources. The other requires a reassessment of the essential electrical systems based upon a hazard vulnerability analysis to make sure that the systems meet the needs of the facilities for emergencies. A specific requirement was not provided for the IEBC with regard to ASCE 24 since the IEBC would require compliance with ASCE 24 anytime there are substantial improvements made to a building. The term Substantial improvement is a specifically defined term as follows as excerpted from the IEBC.

SUBSTANTIAL IMPROVEMENT. For the purpose of determining compliance with the flood provisions of this code, any *repair, alteration, addition*, or improvement of a building or structure, the cost of which equals or exceeds 50 percent of the market value of the structure, before the improvement or *repair* is started. If the structure has sustained *substantial damage*, any repairs are considered *substantial improvement* regardless of the actual *repair* work performed. The term does not, however, include either:

1. Any project for improvement of a building required to correct existing health, sanitary, or safety code violations identified by the *code official* and that is the minimum necessary to ensure safe living conditions; or
2. Any *alteration* of a historic structure, provided that the *alteration* will not preclude the structure's continued designation as a historic structure.

This proposal is submitted by the ICC Ad Hoc Committee for Healthcare (AHC). The AHC was established by the ICC Board of Directors to evaluate and assess contemporary code issues relating to hospitals and ambulatory healthcare facilities. The AHC is composed of building code officials, fire code officials, hospital facility engineers, and state healthcare enforcement representatives. The goals of the committee are to ensure that the ICC family of codes appropriately addresses the fire and life safety concerns of a highly specialized and rapidly evolving healthcare delivery system. This process is part of a joint effort between ICC and the American Society for Healthcare Engineering (ASHE), a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. Since its inception in April, 2011, the AHC has held 8 open meetings and over 150 workgroup calls which included members of the AHC as well as any interested party to discuss and debate the proposed changes. All meeting materials and reports are posted on the AHC website at: <http://www.iccsafe.org/cs/AHC/Pages/default.aspx>

Cost impact: The code change proposal should not increase the cost of construction because compliance is already required by facility licensure requirements.

F244 – 13

2004.7 (New), Chapter 80

Proponent: Christopher M Wanka, College Park Volunteer Fire Department, representing self

Add new text as follows:

2004.7 Other Aircraft Maintenance. All maintenance, repairs, modifications, or construction performed upon aircraft not addressed elsewhere in this code shall be conducted in accordance with NFPA 410.

Add new standard to Chapter 80 as follows:

NFPA 410-10 Standard on Aircraft Maintenance.....2004.7

Reason: Aircraft maintenance is often a hazardous procedure due to the inherent hazards of aircraft. NFP 410 is a consensus document created that specifies minimum safety requirements to be performed during specified maintenance operations such as fuel or oxygen system maintenance, cleaning of aircraft, and hazardous operations such as defueling aircraft. It provides additional fire safety requirements to these procedures as well as additional fire protection requirements be in place for other specified procedures.

NFPA 410: Standard for Aircraft Maintenance would be a newly referenced standard in the IFC

Cost Impact: This will not affect any construction cost. It may impact business operation cost due to increased work times due to following additional safety precautions.

Analysis: A review of the standard proposed for inclusion in the code, NFPA 410-10, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28), will be posted on the ICC website on or before April 1, 2013.

2204.1

Proponent: Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azubiamia@yahoo.com)

Revise as follows:

2204.1 Standards. ~~The fire code official is authorized to enforce applicable provisions of the c-Codes and standards listed in Table 2204.1 to prevent and control dust explosions shall apply to operations involving combustible dust.~~

Reason: This change is based on a recommendation from the Chemical Safety Board (CSB) following their investigation of the dust explosions at the Hoeganaes Corporation in Gallatin, Tennessee. The CSB determined that the state of Tennessee considered the language in this code section to be a discretionary (not mandatory) code requirements; the state of Tennessee did not adopt this section of the IFC because it considered the requirement as not mandatory. This code change is intended to clarify the intent of this code section as to when the applicable dust standards must be enforced to prevent dust accumulations that could lead to dust explosions.

This proposal is submitted by the ICC Fire Code Action Committee (FCAC). This ICC committee was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portions thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the Fire-CAC has held 6 open meetings and numerous Regional Work Group and Task Group meetings and conference calls which included members of the committees as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the FAC website at: <http://www.iccsafe.org/cs/CAC/Pages/default.aspx>.

Cost Impact: This code change will not increase the cost of construction

F246 – 13

2306.8.1, 2306.8.2 (New), Chapter 80

Proponent: Bob Eugene, representing UL LLC

Revise as follows:

2306.8 Alcohol-blended fuel-dispensing operations. The design, fabrication and installation of alcohol-blended fuel dispensing systems shall also be in accordance with Section 2306.7 and Sections 2306.8.1 through 2306.8.5.

2306.8.1 ~~Listed Approval of equipment.~~ Dispensers ~~shall be listed~~ in accordance with UL 87A. Hoses, nozzles, breakaway fittings, swivels, flexible connectors or dispenser emergency shutoff valves, vapor recovery systems, leak detection devices and pumps used in alcohol-blended fuel-dispensing systems shall be listed ~~or approved~~ for the specific purpose.

2306.8.2 Compatibility. Dispensers shall only be used with the fuels for which they have been listed, which are marked on the product. Field installed components including hose assemblies, breakaway couplings, swivel connectors and hose nozzle valves shall be provided in accordance with the listing and the marking on the unit.

(Renumber subsequent sections)

Add a new standard to Chapter 80 as follows:

UL

87A – 12 Outline of Investigation for Power-Operated Dispensing Devices for Gasoline and Gasoline/ethanol Blends with Nominal Ethanol Concentrations up to 85 Percent

Reason: In 2007 UL submitted proposal F230 07/08 which added the section on alcohol-blended fuel-dispensing operations. This was done to address the growing number of E-85 installations. Part of that proposal allowed alcohol-blended fuel-dispensers and components to be listed or approved, where normal gasoline dispensers were required to be listed. This was done in recognition that standards and listings for these dispensers did not exist at the time.

The UL 87A Outline of Investigation for Power-Operated Dispensing Devices for Gasoline and Gasoline/ethanol Blends with Nominal Ethanol Concentrations up to 85 Percent was subsequently developed to cover dispensers intended for use with high concentration ethanol blends. Listed dispensers and the related hanging hardware are now listed for high concentration ethanol blends, and are being installed across the U.S. This proposal recognizes the current E-85 dispensing practices and accomplishes the following:

1. Reintroduces the requirements for these dispensers and related hardware to be listed, rather than listed or approved.
2. Includes reference to the UL 87A Outline of Investigation used to investigate these products.

Cost Impact: None

Analysis: A review of the standard proposed for inclusion in the code, UL 87A-12, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28), will be posted on the ICC website on or before April 1, 2013.

2306.8.3-F-EUGENE

F248 – 13

2307.2 (IFGC [F] 412.2), 2307.2.2 (IFGC [F] 412.4); 2307.2.3 (IFGC [F] 412.5) (New)

Proponent: Bruce Swiecicki representing National Propane Gas Association (bswiecicki@npga.org)

Revise as follows:

2307.2 (IFGC [F] 412.2) Approvals. Storage vessels and equipment used for the storage or dispensing of LP-gas shall be *approved* or *listed* in accordance with Sections 2307.2.1 ~~and 2307.2.2~~ through 2307.2.3.

2307.2.1 (IFGC [F] 412.3) Approved equipment. Containers, pressure relief devices (including pressure relief valves), pressure regulators, and piping for LP-gas shall be *approved*.

2307.2.2 (IFGC [F] 412.4) Listed equipment. Hoses, hose connections, vehicle fuel connections, ~~dispensers~~, LP-gas pumps and electrical equipment used for LP-gas shall be *listed*.

2307.2.3 (IFGC [F] 412.5) LP-Gas dispensers. Where installed at facilities that are not intended for public refueling of vehicles, LP-gas dispensing equipment shall be approved. Where installed at facilities that are intended for public refueling of vehicles, LP-gas dispensers shall be listed.

Reason: The vast majority of LP-gas motor fuel dispensers in use today are not listed units. However, these dispensers are not available to the general public to refuel its vehicles. They are installed at private companies for use with fleet vehicles or for filling portable motor fuel cylinders used with forklift trucks, lawn mowers and other motorized applications. Requiring these dispensers to be “approved” rather than “listed” allows for their continued installation and use. The code official is able to approve the installation whether the “packaged” dispenser system itself is listed or not, using the requirements in Section 2307 and Chapter 61 of the IFC, as well as referenced standard NFPA 58 “LP-Gas Code.” These references provide all the necessary requirements for approving the installation of a dispenser. The individuals that use these dispensers are properly trained on the hazards of LP-gas and the safe use of the filling equipment.

Dispensers may also be located at public refueling stations (gasoline stations) along with other fuels. We are proposing in paragraph 2307.2.3 that for these applications, propane dispenser systems must be listed units to make them equivalent to the units that are being installed for self-service gasoline and diesel applications. These units would be factory-assembled with a storage container, pump, meter and dispenser hose and hose end valve on a common base or skid and shipped to the site for installation as a packaged unit. Or, they may be assembled at a factory and fully contained within a cabinet, shipped to the site for installation on an island and served by a remote LP-gas tank, similar to gasoline dispensers,

Cost Impact: This proposal will not increase the cost of construction.

2307.2.2-F-SWIECICKI

F250 – 13

2307.4 (IFGC [F] 412.6)

Proponent: Bruce Swiecicki representing National Propane Gas Association (bswiecicki@npga.org)

Revise as follows:

2307.4 (IFGC [F] 412.6) Location of dispensing operations and equipment. ~~In addition to the requirements of Section 2306.7, the point of transfer for LP-gas dispensing operations shall be 25 feet (7620 mm) or more from buildings having combustible exterior wall surfaces, buildings having noncombustible exterior wall surfaces that are not part of a 1-hour fire-resistance-rated assembly, or buildings having combustible overhangs, lot lines of property which could be built on, public streets, or sidewalks and railroads; and at least 10 feet (3048 mm) from driveways and buildings having noncombustible exterior wall surfaces that are part of a fire-resistance-rated assembly having a rating of 1-hour or more. The point of transfer for LP-Gas dispensing operations shall be separated from buildings and other exposures in accordance with the following:~~

1. Not less than 25 feet from buildings in which the exterior wall is not part of a fire-resistance-rated assembly having a rating of 1 hour or greater.
2. Not less than 25 feet from combustible overhangs on buildings, measured from a vertical line dropped from the face of the overhang at a point nearest the point of transfer.
3. Not less than 25 feet from the lot line of property that can be built upon.
4. Not less than 25 feet from mainline railroad track centers.
5. Not less than 10 feet from public streets, highways, thoroughfares, sidewalks and driveways.
6. Not less than 10 feet from buildings in which the exterior wall is part of a fire resistance rated assembly having a rating of 1 hour or greater.

Exception: The point of transfer for LP-gas dispensing operations need not be separated from canopies that are constructed in accordance with the *International Building Code* and that provide weather protection for the dispensing equipment. LP-gas containers shall be located in accordance with Chapter 61. LP-gas storage and dispensing equipment shall be located outdoors ~~and in accordance with Section 2306.7.~~

Reason: The changes to section 2307.4 are necessary in order to make the paragraph easier to understand and to eliminate reference to Section 2306.7, which addresses dispenser installations for gasoline and diesel fuels, neither of which are similar to LP-gas. Therefore, Section 2306.7 contains many requirements that do not make sense when applied to LP-gas installations. We are therefore proposing a new section (2307.5) that will contain just those requirements from 2306.7 that are applicable to LP-gas dispensers.

Also included in the new formatting are proposed changes that will bring the IFC into agreement with NFPA 58 "LP-Gas Code" with respect to separation distances.

Cost Impact: This proposal will not increase the cost of construction.

F250-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

2307.4-F-SWIECICKI

F251 – 13

2307.5 (IFGC [F] 412.7.6) (New), 2307.6 (IFGC [F] 412.7), 2307.6.1 (IFGC [F] 412.7) (New), 2307.6.3 (IFGC [F] 412.7.4) (New)

Proponent: Bruce Swiecicki representing National Propane Gas Association (bswiecicki@npga.org)

Revise as follows:

2307.5 (IFGC [F] 412.7.6) Additional Requirements for LP-Gas Dispensers and Equipment. LP-gas dispensers and related equipment shall comply with the following provisions.

1. Pumps shall be fixed and shall be designed to allow control of the flow and to prevent leakage or accidental discharge.
2. Dispensing devices installed within 10 feet of where vehicle traffic occurs, shall be protected against physical damage by mounting on a concrete island 6 inches or more in height, or shall be protected in accordance with Section 312.
3. Dispensing devices shall be securely fastened to their mounting surface in accordance with the dispenser manufacturer's instructions.

2307.5-2307.6 (IFGC [F] 412.7) Installation of LP-gas dispensing devices and equipment. The installation and operation of LP-gas dispensing systems shall be in accordance with Sections ~~2307.5.1~~ 2307.6.1 through ~~2307.5.3~~ 2307.6.4 and Chapter 61. LP-gas dispensers and dispensing stations shall be installed in accordance with the manufacturer's specifications and their listing.

~~**2307.5.1 (IFGC [F] 412.7.1) Valves** A manual shutoff valve and an excess flow-control check valve shall be located in the liquid line between the pump and the dispenser inlet where the dispensing device is installed at a remote location and is not part of a complete storage and dispensing unit mounted on a common base. An excess flow-control check valve or an emergency shutoff valve shall be installed in or on the dispenser at the point at which the dispenser hose is connected to the liquid piping. A differential backpressure valve shall be considered equivalent protection. A listed shutoff valve shall be located at the discharge end of the transfer hose.~~

2307.6.1 (IFGC [F] 412.7) Product Control Valves. The dispenser system piping shall be protected from uncontrolled discharge in accordance with the following:

1. Where mounted on a concrete base, a means shall be provided and installed within ½-inch of the top of the concrete base that will prevent flow from the supply piping in the event that the dispenser is displaced from its mounting.
2. A manual shutoff valve and an excess flow-control check valve shall be located in the liquid line between the pump and the dispenser inlet where the dispensing device is installed at a remote location and is not part of a complete storage and dispensing unit mounted on a common base.
3. An excess flow-control check valve or an emergency shutoff valve shall be installed in or on the dispenser at the point at which the dispenser hose is connected to the liquid piping.
4. A listed automatic-closing type hose nozzle valve with or without a latch-open device shall be provided on island-type dispensers.

~~**2307.5.2- 2307.6.2 (IFGC [F] 412.7.2) Hoses.**~~ Hoses and piping for the dispensing of LP-gas shall be provided with hydrostatic relief valves. The hose length shall not exceed 18 feet (5486 mm). An *approved* method shall be provided to protect the hose against mechanical damage.

2307.6.3 (IFGC [F] 412.7.4) Breakaway Protection. Dispenser hoses shall be equipped with a listed emergency breakaway device designed to retain liquid on both sides of the breakaway point. Where hoses are attached to hose-retrieving mechanisms, the emergency breakaway device shall be located such that the breakaway device activates to protect the dispenser from being displaced.

2307.5.3 (IFGC [F] 412.7.3) 2307.6.4 (IFGC [F] 412.7.5) Vehicle impact protection. ~~Vehicle impact protection for LP-gas storage containers, pumps and dispensers shall be provided in accordance with Section 2306.4. Where installed within 10 feet of vehicle traffic, LP-gas storage containers, pumps and dispensers shall be protected in accordance with Section 2307.5 (2).~~

Reason: This proposal is a companion change to revisions proposed to Section 2307.4, which eliminated reference to Section 2306.7. Because Section 2306.7 addresses dispenser installations for gasoline and diesel fuels, neither of which are similar to LP-gas, it therefore contains many requirements that do not make sense when applied to LP-gas installations.

New 2307.5 contains three requirements extracted from current Section 2306.7 that would be applicable to LP-gas dispensers. Proposed #1 is based on current 2306.7.2 and proposed #2 and #3 are based on 2306.7.3.

New 2307.6 has been revised editorially to reflect the changed section numbers.

Paragraph 2307.6.1 has moved the requirements from 2306.7 that are applicable to LP-gas dispensers into the more appropriate location. Requirement #1 is based on current code section 2306.7.4 but since the hardware performance requirements in that section for gasoline and diesel dispensers differ from what is available for LP-gas dispenser systems, the text more closely resembles the requirements currently appearing in NFPA 30A *Motor Fuel Dispensing Facilities and Repair Garages*, with the exception that the inch location for the protective means must be within ½-inches of the top of the concrete, as required in 2306.7.4. Requirement #2 is based on NFPA 58 *LP-Gas Code* and provides protection for the piping system where the storage container is located remotely from the dispenser. Requirements #3 is based on requirements in NFPA 58. Requirement #4 is pulled from current section 2306.7.6.

New Section 2307.6.3 is based on current Section 2306.7.5.1, but provides a performance requirement rather than a specified protection point where a hose retrieval mechanism is installed.

Section 2307.6.4 specifies where protection from vehicle impact is required, which is consistent with what will appear in the 2014 edition of NFPA 58.

Cost Impact: This proposal will not increase the cost of construction.

	Assembly:	ASF	AMF	DF

2307.5 (NEW)-F-SWIECICKI

F252 – 13

2307.6 (IFGC [F] 412.8), 2307.7

Proponent: Bruce Swiecicki representing National Propane Gas Association (bswiecicki@npga.org)

Revise as follows:

2307.6 (IFGC [F] 412.8) ~~Private~~ Public fueling of motor vehicles. ~~Self-service LP-gas dispensing systems, including key, code and card lock dispensing systems, shall not be open to the public and shall be limited to the filling of permanently mounted fuel containers on LP-gas powered vehicles. Self-service LP-Gas dispensing systems, including key, code and card lock dispensing systems, shall be limited to the filling of containers providing fuel to the LP-Gas powered vehicle.~~

~~In addition to the requirements of Sections 2305 and 2306.7, The requirements for self-service LP-gas dispensing systems shall be in accordance with the following:~~

- ~~1. The arrangement and operation of the transfer of product into a vehicle shall be in accordance with this section and Chapter 61.~~
- ~~2. The system shall be provided with an emergency shutoff switch located within 100 feet (30 480 mm) of, but not less than 20 feet (6096 mm) from, dispensers.~~
- ~~23. The owner of the LP-gas motor fuel-dispensing facility or the owner's designee shall provide for the safe operation of the system and the training of users.~~
- ~~4. The dispenser and hose-end valve shall release not more than 4cc of liquid to the atmosphere upon breaking the connection with the fill valve on the vehicle.~~
- ~~5. Fire extinguishers shall be provided in accordance with Section 2305.4.~~
- ~~6. Warning signs shall be provided in accordance with Section 2305.6.~~
- ~~7. The area around the dispenser shall be maintained in accordance with Section 2305.7.~~

2307.7 Overfilling. LP-gas containers shall not be filled with LP-gas in excess of the volume determined using the fixed maximum liquid level gauge installed on the container, the volume determined by the overfilling prevention device installed on the container, outage installed by the manufacturer or the weight determined by the required percentage of the water capacity marked on the container stamped on the tank.

Reason: Propane is recognized as an alternative motor vehicle fuel by the U.S. government. In order for the public to take full advantage of the benefits of its reduced emissions and cleaner burning properties, the code must be changed to recognize the technologies that are available to ensure the safe refueling of LP-gas vehicles, which in turn will result in increasing acceptance of this smart alternative fuel.

The current provisions in Section 2307.6, which prohibit public access to self-service equipment, are too restrictive and without any basis in safety or technical experience. There are no reasons to prohibit anyone who has been properly trained to perform the refueling operation from refueling their LP-gas vehicle at a public refueling facility. Propane (LP-Gas) refueling technology provides the following features:

- Liquid product will not flow out of the hose end valve unless the valve is completely connected and securely in place on the fill valve of the vehicle.
- Propane hose end valves will mate with the fill valve on the vehicle and upon disconnect will release no more than 4 cubic centimeters of liquid to the atmosphere.
- The propane refueling system is a closed system, which means that there is no opportunity for air, water or any other contaminant to enter the system.
- Individuals must be trained in order to use the filling equipment. This requirement is ensured by the use of key, code and card lock dispensing systems. Only trained individuals are issued the necessary security devices to enable the refueling of the vehicle.

Regarding the proposed changes to 2307.6, the deletion of references to Sections 2305 and 2306.7 are necessary because those sections are mostly intended to be used for the installation of Class I or Class II liquids. Since propane is a liquefied petroleum gas, many of the provisions in those sections are not applicable to propane installations. The applicable requirements from those two sections have been relocated to 2307.6. In addition, proposed requirement #4 is based on NFPA 30A *Motor Fuel Dispensing Facilities and Repair Garages*.

The proposed change to 2307.7 is necessary in order to incorporate the correct terminology and also recognize that sometimes, the fixed maximum liquid level gauge is installed by a trained service technician. This is especially the case if repairs are being made to the container or the valve. In addition, some vehicles rely upon an overfilling prevention device and the fixed maximum liquid level gauge is not used. Therefore, it is necessary to list that device as an approved means for filling the container.

Cost Impact: This proposal will not increase the cost of construction.

	Assembly:	ASF	AMF	DF

2307.6-F-SWIECICKI

F253 – 13

2308.4 (IFGC [F] 413.5)

Proponent: James Ranfone, American Gas Association (jranfone@aga.org)

Revise as follows:

2308.4 (IFGC [F] 413.5) Private fueling of motor vehicles. Self-service CNG-dispensing systems, including key, code and card lock dispensing systems, shall be limited to the filling of permanently mounted fuel containers on CNG-powered vehicles. Self-service CNG-dispensing systems shall be installed in accordance with Section 2304 (IFGC: the *International Fire Code*).

~~In addition to the requirements in Section 2305, the owner of a self-service CNG motor fuel-dispensing facility shall ensure the safe operation of the system and the training of users.~~

Reason: The requirement that the owners ensures the safe operation and provide training is unenforceable.

Cost Impact: None.

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

2308.4-F-RANFONE

F254 – 13

2309.3.1.1, 2309.3.1.2, Chapter 80

Proponent: Robert J Davidson, Davidson Code Concepts, LLC, representing the National Renewable Energy Laboratory (NREL) (rjd@davidsoncodeconcepts.com)

Revise as follows:

2309.3.1.1 Outdoors. Generation, compression, or storage equipment shall be allowed outdoors in accordance with Chapter 58 and NFPA 2.

2309.3.1.2 Indoors. Generation, compression, storage and dispensing equipment shall be located in indoor rooms or areas constructed in accordance with the requirements of the *International Building Code*, the *International Fuel Gas Code* and, the *International Mechanical Code* and ~~one of the following:~~ NFPA 2.

- ~~1. Inside a building in a hydrogen cutoff room designed and constructed in accordance with Section 421 of the *International Building Code*.~~
- ~~2. Inside a building not in a hydrogen cutoff room where the gaseous hydrogen system is listed and labeled for indoor installation and installed in accordance with the manufacturer's installation instructions.~~
- ~~3. Inside a building in a dedicated hydrogen fuel dispensing area having an aggregate hydrogen delivery capacity no greater than 12 standard cubic feet per minute (SCFM) and designed and constructed in accordance with Section 703.1 of the *International Fuel Gas Code*.~~

Add new standard to Chapter 80 as follows:

NFPA

2-11 Hydrogen Technologies Code 2309.3.1.1, 2309.3.1.2

Reason: This proposal adds a reference to NFPA 2 "Hydrogen Technologies Code" in Section 2309.3.1.1 and to Section 2309.3.1.2, along with a deletion of the three methods currently in the code.

NFPA 2 has been formed to provide a source document for the storage, use and handling of hydrogen and much work has gone into refining terms and requirements. For increased safety and consistency in the application of hydrogen technologies, the addition of NFPA 2 as a reference for outdoor installations of motor fueling and for the requirements for indoor fueling in conjunction with the other requirements contained within the relevant I-Codes is an appropriate step to take.

From the 2011 edition of NFPA 2:

Origin and Development of NFPA 2

"With the increased interest in hydrogen being used as a fuel source, the National Fire Protection Association was petitioned to develop an all-encompassing document that establishes the necessary requirements for hydrogen technologies. In 2006, the Technical Committee on Hydrogen Technology was formed and tasked to develop a document that addresses all aspects of hydrogen storage, use, and handling, that draws from existing NFPA codes and standards, and that identifies and fills technical gaps for a complete functional set of requirements for code users and enforcers. This document is also structured so that it works seamlessly with building and fire codes."

Extensive requirements have been developed and are located within NFPA 2 (see Sections 10.3.2.2 Indoor Public Fueling and 10.3.3.2 Indoor Nonpublic Fueling of that standard), and the practical method to utilize the extensive requirements is through adding references to that document. A review of the requirements identifies that trying to add the actual technical requirements to the IFC would require extensive work and then might not get around copyright issues.

As part of the proposal is to add NFPA 2 to Chapter 80 as a referenced standard.

NFPA 2-2011 can be viewed at this location: <http://www.nfpa.org/aboutthecodes/AboutTheCodes.asp?DocNum=2>

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: A review of the standard proposed for inclusion in the code, NFPA 2-11, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28), will be posted on the ICC website on or before April 1, 2013.

F254-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

2309.3.1.1-F-DAVIDSON

F255 – 13

2309.4.1

Proponent: Robert Boyd, Boyd Hydrogen, LLC, representing self (Bob@BoydH2.com)

Revise as follows:

2309.4.1 Dispensing Systems. Dispensing systems shall be equipped with an overpressure protection device set at not greater than 140 percent of the service pressure of the fueling nozzle it supplies.

Reason: There is no technical or system safety reason why the overpressure protecting device in a H2 dispenser must be set at 140 percent of the service pressure of the fueling nozzle.

SAE and NFPA-52 and NFPA-2 requirements for the overpressure protection are that the device is to be **set at no greater** than 140 times the service pressure (1.1 x 1.25 x Service pressure).

Some dispenser manufactures may want to provide systems that have a lower set point for the overpressure protection device. For example some dispensers may want to set the maximum fill pressure to 110% of service pressure and set the overpressure device to 125% of service pressure. This would have no impact on the relative safety of the dispensing system and should be allowed.

The proposed revised language will allow for more dispenser options without any additional risks.

Cost Impact: None

F255-13

2309.4.1-F-BOYD

F256 – 13

2309.6 (New), 2311.8

Proponent: Robert J Davidson, Davidson Code Concepts, LLC, representing the National Renewable Energy Laboratory (NREL) (rjd@davidsoncodeconcepts.com)

Revise as follows:

~~2311.8~~ 2309.6 Defueling of hydrogen from ~~motor vehicle~~ fuel storage containers. The discharge or defueling of hydrogen from ~~motor vehicle~~ fuel storage tanks for the purpose of maintenance, cylinder certification, calibration of dispensers or other activities shall be in accordance with Sections ~~2311.8.1~~ 2309.6.1 through ~~2311.8.1.2.4~~ 2309.6.1.2.4.

~~2311.8.1~~ 2309.6.1 Methods of discharge. The discharge of hydrogen from ~~motor vehicle~~ fuel storage tanks shall be accomplished through a closed transfer system in accordance with Section ~~2311.8.1.1~~ 2309.6.1.1 or an approved method of atmospheric venting in accordance with Section ~~2311.8.1.2~~ 2309.6.1.2.

~~2311.8.1.1~~ 2309.6.1.1 Closed transfer system. *(No change to current text)*

~~2311.8.1.2~~ 2309.6.1.2 Atmospheric venting of hydrogen from ~~motor vehicle~~ fuel storage containers. When atmospheric venting is used for the discharge of hydrogen from ~~motor vehicle~~ fuel storage tanks, such venting shall be in accordance with Sections ~~2311.8.1.2.1~~ 2309.6.1.2.1 through ~~2311.8.1.2.4~~ 2309.6.1.2.1.4.

~~2311.8.1.2.1~~ 2309.6.1.2.1 Defueling equipment required at vehicle maintenance and repair facilities. All facilities for repairing hydrogen systems on hydrogen fueled vehicles shall have equipment to defuel ~~vehicle storage tanks~~. Equipment used for defueling shall be listed and labeled or approved for the intended use.

~~2311.8.1.2.1.1~~ 2309.6.1.2.1.1 Manufacturer's equipment required. Equipment supplied by the ~~vehicle~~ manufacturer shall be used to connect the ~~vehicle~~ storage tanks to be defueled to the vent pipe system.

~~2311.8.1.2.1.2~~ 2309.6.1.2.1.2 Vent pipe maximum diameter. *(No change to current text)*

~~2311.8.1.2.1.3~~ 2309.6.1.2.1.3 Maximum flow rate. *(No change to current text)*

~~2311.8.1.2.1.4~~ 2309.6.1.2.1.4 Isolated use. *(No change to current text)*

~~2311.8.1.2.2~~ 2309.6.1.2.2 Construction documents. *(No change to current text)*

~~2311.8.1.2.3~~ 2309.6.1.2.3 Stability of cylinders, containers and tanks. *(No change to current text)*

~~2311.8.1.2.4~~ 2309.6.1.2.4 Grounding and bonding. *(No change to current text)*

~~2311.8.2~~ 2309.6.2 Repair of hydrogen piping. Piping systems containing hydrogen shall not be opened to the atmosphere for repair without first purging the piping with an inert gas to achieve 1 percent hydrogen or less by volume. Defueling operations and exiting purge flow shall be vented in accordance with Section ~~2311.8.1.2~~ 2309.6.1.2.

~~2311.8.3~~ 2309.6.3 Purging. *(No change to current text)*

~~2311.8.3.1~~ 2309.6.3.1 System purge required. *(No change to current text)*

SECTION 2311 REPAIR GARAGES

2311.5 Preparation of vehicles for repair. For vehicles powered by gaseous fuels, the fuel shutoff valves shall be closed prior to repairing any portion of the vehicle fuel system.

Vehicles powered by gaseous fuels in which the fuel system has been damaged shall be inspected and evaluated for fuel system integrity prior to being brought into the repair garage. The inspection shall include testing of the entire fuel delivery system for leakage.

2311.8 Defueling equipment required at vehicle maintenance and repair facilities. Facilities for repairing hydrogen fuel systems on hydrogen-fueled vehicles shall have equipment to defuel vehicle storage tanks. Where work must be performed on a vehicle's fuel storage tank for the purpose of maintenance, repair or cylinder certification, defueling and purging shall be conducted in accordance with Section 2309.6 .

Reason: The primary reason for moving the language is to eliminate some confusion in applying the code. There are some in the industry and code enforcement world that mistakenly believe defueling is required every time a hydrogen fueled vehicle is repaired. That is not true, see Section 2311.5.

If you view Section 2308.8 for CNG fueling activities you will find similar language directly within the dedicated CNG section of the code, the same concept which is being proposed here for hydrogen with the movement of the language.

An additional benefit is that the ability to defuel hydrogen is needed for repair and servicing of the fixed hydrogen fuel compression, storage and dispensing equipment located at these facilities.

By moving the language to new Section 2909.6 and modifying the language to apply to "fuel storage", instead of "motor vehicle fuel storage", the language is more generic and applicable.

At Section 2311.8.1.2.1, (New 2309.6.1.2.1), the stricken language is left at 2311.8 with a pointer to this location to direct motor vehicle fuel storage cylinder defueling operations to these requirements. In addition, the word "approved" is added for the acceptance of the equipment. as this is still an emerging technology and there needs to be an option for "approved" by the code official.

In Section 2311, New Section 2311.8 is inserted. By taking out the defueling language it eliminates some confusion and by pointing to the relocated the language at Section 2309.6 we make sure it is applied only in those cases where defueling of the motor vehicle fuel cylinder is necessary.

There is no loss in current code requirements. There is an enhancement by providing for the defueling of fixed site equipment and eliminating a misapplication of the defueling requirements.

Cost Impact: The code change proposal will not increase the cost of construction.

F256-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

2311.8-F-DAVIDSON

F257 – 13

2310.5.3

Proponent: Marcelo M Hirschler, GBH International (gbhint@aol.com)

Revise as follows:

2310.5.3 Rubbish containers. ~~Metal containers with tight-fitting or self-closing lids shall be provided for the temporary storage of combustible trash or rubbish.~~ Containers with tight-fitting or self-closing lids shall be provided for temporary storage of combustible debris, rubbish and waste material. The rubbish containers shall be constructed entirely of materials that comply with any one of the following:

1. Noncombustible materials.
2. Materials that meet a peak rate of heat release not exceeding 300 kW/m² when tested in accordance with ASTM E 1354 at an incident heat flux of 50 kW/m² in the horizontal orientation.

Reason: Rubbish containers need not be constructed of metal but can be constructed of other noncombustible materials, including materials that have been shown to be safe by meeting a very severe fire test, just like those required by section 808 for I1, I2 and I3 occupancies. The key requirement that the lids be tight fitting or self closing is retained in the proposal. Note that the requirement covers all type of rubbish and is not intended to address spills of combustible or flammable liquids (or Class I, II or IIIA liquids), covered by 2310.5.2. The use of the phrase “combustible debris, rubbish and waste” makes this section consistent with other sections of the IFC.

Cost Impact: This should lower costs by offering more alternatives.

F257-12

Public Hearing:	Committee:	AS	AM	D

2310.5.3-F-HIRSCHLER

F258 – 13

2311.7

Proponent: Spencer Quong, Quong & Associates, Inc. representing Toyota Technical Center (squong@squong.com)

Revise as follows:

2311.7 Repair garages for vehicles fueled by lighter-than air fuels. Repair garages for the conversion and repair of vehicles which use CNG, liquefied natural gas (LNG), hydrogen or other lighter-than-air motor fuels shall be in accordance with Sections 2311.7 through 2311.7.2.3 in addition to the other requirements of Section 2311.

Exceptions:

1. Repair garages where work is not performed on the fuel system and is limited to exchange of parts and maintenance requiring no open flame or welding.
2. Repair garages where all of the following conditions exist:
 - 2.1 Work is not performed on the hydrogen storage tank and is limited to exchange of parts and maintenance requiring no open flame or welding.
 - 2.2 Where work is performed on the hydrogen fuel system, the hydrogen fuel storage container shall be securely sealed such that it is a closed system during maintenance using manufacturer approved procedures.
 - 2.3 The entire fuel system shall be defueled in accordance with Section 2311.8 to a quantity that is less than 200 cubic feet (5.6 m³).

Reason: This proposal is requesting to modify exception to Section 2311.7 to allow work on the fuel system, except for the hydrogen storage tank without having to install additional ventilation and gas detection systems in the repair garage. If work is performed on the fuel system, the vehicle's shutoff valve must be securely closed on the fuel storage container so that it is a closed system and no gas can escape during maintenance operations. In addition, the proposal also requires that entire vehicle fuel system, including the storage container, be defueled to less than 200 cubic feet (NTP).

Although each hydrogen passenger vehicle is different, typically their storage containers hold between 5000-50000 cubic feet (NTP) of hydrogen at high pressure (5000-10000 psi). However, the hydrogen leaving the storage container is regulated to a lower pressure, typically less than 250 psi and less than 10 cubic feet (NTP) of hydrogen.

Any release of hazardous material can pose a problem. However, this proposal addresses the issues in two ways. First, it requires that the shutoff valve on the fuel storage container to be securely closed. Hydrogen vehicles are required to have a manual valve that can be shut off for maintenance¹. In most vehicles, the shutoff valve fails shut, so the standard operating procedure to ensure that the valve is closed is to disconnect the 12V battery. For manual valves, it can be tagged and locked in the off position. Since almost all of the hydrogen is in the fuel storage container, this requirement will ensure only a minimal amount of hydrogen is left in the remainder of the fuel system.

Second, in the event that the fuel storage container is opened during repairs and all of the hydrogen is allowed to escape, this proposal requires that the entire fuel system be defueled to less than 200 cubic feet (NTP). **This is less than 20% of the Maximum Allowable Quantity (MAQ) per control area** listed in Table 5003.1.1(1) through 5003.1.1(4). In addition, Section 5308.1.1 allows for the indoor storage and use of cylinders of non-liquefied compressed, flammable gases not exceeding a capacity of 250 cubic feet NTP used for maintenance purposes without any ventilation and gas detection systems. Finally, according to Table 105.6.8, an operational permit is not required for less than 200 cubic feet (NTP) of flammable, compressed gases.

With more and more hydrogen vehicles on the road, there is a need to be able to work on the low pressure side of the fuel system at any repair garage without adding additional ventilation and gas detection systems. This proposal allows for this work as long as two requirements are met: the fuel storage container is closed and amount of hydrogen is less than **the existing IFC limitations for hazardous materials, and flammable and compressed gases**. Already, repair garages have industrial cylinders of acetylene and other flammable gases without additional ventilation and detection equipment. Even if the repair garages meet the requirements in this exception, they will still need to be in accordance with Sections 5001 and 5003.

¹ Section 4.1.1.3 of SAEJ2579 "Standard for Fuel Systems in Fuel Cell and Other Hydrogen Vehicles"

Cost Impact: The code change proposal will not increase the cost of construction.

2311.7-F-QUONG

F259 – 13

2311.7, 2311.7.1 (IMC [F] 502.16), 2311.7.1.1 (IMC [F] 502.16.1), 2311.7.1.1 (New), 2311.7.1.2 (New)

Proponent: James Ranfone, American Gas Association (jranfone@aga.org)

Revise as follows:

2311.7 Repair garages for vehicles fueled by lighter-than-air fuels. Repair garages for the conversion and repair of vehicles which use CNG, liquefied natural gas (LNG), hydrogen or other lighter-than-air motor fuels shall be in accordance with Sections 2311.7 through 2311.7.3 in addition to the other requirements of Section 2311.

Exception: Repair garages where work is not performed on the fuel system and is limited to minor repairs such as the exchange of parts and maintenance requiring no open flame or welding.

2311.7.1 (IMC [F] 502.16) Ventilation. Repair garages used for the major repair such as engine overhauls, painting, body and fender work, and repairs that require draining of the motor vehicle fuel tank are performed on, of natural gas- or hydrogen-fueled vehicles shall be provided with an approved mechanical ventilation system. ~~The mechanical ventilation system shall be in accordance with the International Mechanical Code and Sections 2311.7.1.1 and 2311.7.1.2 meet the requirements in 2311.7.1.1 or 2311.7.1.2.~~

2311.7.1.1 Electrical systems and equipment located within 18 inches (46 cm) of the ceiling shall be listed for installation in a flammable gas location.

2311.7.1.2. The area within 18 in. (46 cm) of the ceiling shall be provided with ventilation of at least 1 ft³/min/ft² of floor area taken from a point within 18 in. (46 cm) of the highest point in the ceiling.

Exception: ~~Repair garage with natural ventilation when approved.~~

2311.7.1.1 (IMC [F] 502.16.1) Design. Indoor locations shall be ventilated utilizing air supply inlets and exhaust outlets arranged to provide uniform air movement to the extent practical. Inlets shall be uniformly arranged on exterior walls near floor level. ~~Outlets shall be located at the high point of the room in exterior walls or the roof.~~

Ventilation shall be by a continuous mechanical ventilation system or by a mechanical ventilation system activated by a continuously monitoring natural gas detection system or, for hydrogen, a continuously monitoring flammable gas detection system, each activating at a gas concentration of not more than 25 percent of the lower flammable limit (LFL). In all cases, the system shall ~~shut down the fueling system alarm~~ in the event of failure of the ventilation system.

~~The ventilation rate shall be at least 1 cubic foot per minute per 12 cubic feet [0.00139 m³ x (s x m³)] of room volume.~~

Reason: The industry standard for repair garages is NFPA 30A, Code for Motor Fuel Dispensing Facilities and Repair Garages. NFPA 30A does not require general mechanical ventilation for repair garages that service either liquid or lighter-than-air odorized fuels. For odorized gases fuels NFPA30A does require that the area within 18 inches below the roof either be classified as a hazardous location (therefore requiring the installation of electrical equipment listed for hazardous locations) or be provided with mechanical ventilation (and therefore that area is no longer considered a hazardous location). This type of site-specific requirement is consistent with IFC section 2311.4.3 for liquid fuels, requiring mechanical ventilation for below grade locations to prevent the accumulation of flammable vapors. There is no technical justification to require general mechanical or natural ventilation for an entire repair garage that services either liquid or gaseous fueled vehicles.

Proposed revisions would:

- Make the IFC ventilation requirements consistent with NFPA 30A.
- Introduce the concept of minor and major repairs as means to clarify when code requirements are to be installed. This is consistent with NFPA 30A.
- The requirement that the fueling system be shut down in the event of a mechanical ventilation failure makes no sense since fueling operations are not occurring in the repair garage. The failure of such system should sound an alarm.

- The 1 ft³/m/12 ft³ room volume is being deleted in favor of 4 air changes per hour to be consistent with NFPA 30A.

Cost Impact: None.

2311.7-F-RANFONE

F260 – 13

2404.6.1.2.1

Proponent: Geoff Raifsnider, P.E., Global Finishing Solutions representing self
(graifsnider@globalfinishing.com)

Revise as follows:

2404.6.1.2.1 Interlocks. The spraying apparatus, drying apparatus and ventilating system for the spray booth or spray room shall be equipped with interlocks arranged to:

1. Prevent operation of the spraying apparatus while drying operations are in progress.
2. Where the drying apparatus is located in the spray booth or spray room, prevent operation of the drying apparatus until a timed purge of spray vapors from the spray booth or spray room is complete. This purge time shall be based upon completing not less than 4 air changes of spray booth or spray room volume. Purge spray vapors from the spray booth or spray room for a period of not less than 3 minutes before the drying apparatus is rendered operable.
3. Have the ventilating system maintain a safe atmosphere within the spray booth or spray room during the drying process and automatically shut off drying apparatus in the event of a failure of the ventilating system.
4. Shut off the drying apparatus automatically if the air temperature within the booth exceeds 200°F (93°C).

Reason: The current language does not state how the value is calculated. The proposed language clarifies how to calculate the purge time and bases it upon the amount of fresh air introduced in the same manner that is used for purging an oven. This is appropriate since the drying operation has turned the spray booth into an oven.

As mentioned this proposal is based upon the language in NFPA 86 Standard for Ovens and Furnaces 2011 Edition. The idea is to replace the air in the booth at least four times (4 ft³ of air/ft³ of booth) to ensure that the concentration at the end of the purge interval is less than 25% of the lower flammable limit.

The IFC (2406.1.2) currently requires compliance with Chapter 30 when utilizing drying in a spray booth. Section 3007.2 states that a nameplate shall be provided that, among other information, indicates the required purge time (2107.2(3)). The code official can initially verify that the purge timer is set to this value. If there is cause to doubt this information the calculations mentioned can be performed to verify the minimum purge time.

The purge interval is a function of the spray booth size (cubic feet) and the ventilation rate (cubic feet per minute). Both of these values are documented and measurable for a given spray booth.

To verify that the purge time is sufficient to meet the code, multiply the volume of the booth by four (4) and divide by the exhaust flow rate. An example would be a spray booth that measures 10 ft wide x 10 ft high x 14 ft long (volume = 1,400 ft³). If this booth was designed for 100 feet per minute downdraft the exhaust flow rate would be 14,000 ft³/min (10 ft x 14 ft x 100 fpm). To calculate the minimum purge time you would multiply 1400 ft³ by four (4) and divide by 14,000 ft³/min. The resulting minimum purge time would be 0.4 minutes (1400x4/14000=0.4).

For booths that elevate the air temperature for curing via the same supply air unit used for tempering the air for painting, there is no need for a post paint purge of spray vapors. One type of spray/cure booth elevates the incoming (outside) air temperature and does not recirculate. This type poses no risk of bringing spray vapors back around and through the heating source. The other type of spray/cure booth switches to a recirculation mode during cure. In this mode, the spray/cure booth functions just like an oven and since other sections of the code require the concentration in the exhaust air stream to be less than 25% of the LFL the concentration that could be seen at the burner is not flammable. However if the drying apparatus is in the spray area and could be directly exposed to spray vapors, it makes sense to purge that space prior to energizing the drying apparatus.

There are many paint finishing operations, typically in the automotive refinish industry, that are negatively affected by the delay between painting and curing at an elevated temperature. By allowing the proposed changes, the spray booth designer can take into account the importance the purge interval may have on the process. By designing for the correct air flow, both a safe environment for energizing the drying apparatus and a minimum time between spray and cure can be achieved.

Cost Impact: This code change proposal will not increase the cost of construction

2404.6.1.2.1-F-RAIFSNIDER

F261 – 13

2404.7.3 (IMC [F] 502.7.3.3)

Proponent: Geoff Raifsnider, P.E., Global Finishing Solutions representing self (graifsnider@globalfinishing.com)

Revise as follows:

2404.7.3 (IMC [F] 502.7.3.3) Air velocity. ~~Ventilation systems shall be designed, installed and maintained such that the average air velocity over the open face of the booth, or booth cross section in the direction of airflow during spraying operations, shall not be less than 100 feet per minute (0.51 m/s). Each spray area shall be provided with mechanical ventilation in accordance with Sections 2404.7.3.1 through 2404.7.3.3 (IMC 502.7.3.3.1 through 502.7.3.3.3).~~

2404.7.3.1 (IMC [F] 502.7.3.3.1) Open face or open front spray booth. For spray application operations conducted in an open face or open front spray booth, the ventilation system shall be designed, installed and maintained such that the average air velocity into the spray booth through all openings shall be not less than 100 feet per minute (0.51 m/s).

Exception: For fixed or automated electrostatic spray application equipment the average air velocity into the spray booth through all openings shall be not less than 50 feet per minute (0.25 m/s).

2404.7.3.2 (IMC [F] 502.7.3.3.2) Enclosed spray booth or spray room. For spray application operations conducted in an enclosed spray booth or spray room, the ventilation system shall be designed, installed and maintained so that the flammable contaminants are diluted in noncontaminated air to maintain concentrations in the exhaust air flow below 25 percent of the contaminant's lower flammable limit (LFL).

2404.7.3.3 (IMC [F] 502.7.3.3.3) Enclosed spray booth or spray room with openings for product conveyance. In addition to the requirements of 2404.7.3.2, the ventilation system shall be designed, installed and maintained so that the average air velocity into the spray booth through openings shall be not less than 100 feet per minute (0.51 m/s).

Exception: Where methods are used to reduce cross drafts that can draw vapors and overspray through openings from the spray booth or spray room, the average air velocity into the spray booth or spray room shall be capable of capturing and confining vapors and overspray to the spray booth or spray room.

Reason: For spray application using flammable and combustible materials, the industry standards are OSHA 1910.107 and 1910.94, Chapter 24 of the International Fire Code (IFC), and NFPA 33.

With regards to ventilating spray booths and spray rooms, NFPA 33 and the IFC have similar language stating that the concentration of flammable materials in the exhaust system must be kept below 25 percent of the lower flammable limit (LFL).^{1,2} From this requirement alone the minimum ventilation rate of a spray booth or spray room could be calculated. And by dividing this ventilation rate by the cross sectional area of the booth in the direction of air flow a minimum average velocity can be calculated. OSHA requirements for average air velocity were based upon the 1969 edition of NFPA 33 and were intended to provide a measureable that could be used to check the effectiveness of maintaining the booth exhaust below 25% of the LFL.⁵ OSHA has recognized that the requirements for average air velocity were not intended for totally enclosed booths.⁶

Current language in the IFC specifies 100 feet per minute minimum air velocity and offers explanation in their commentary that the objective is containment within a designated spraying space and limiting the overspray.^{3,4} It goes on to explain that 100 FPM is the minimum capture velocity for particulate spray material. In an open face booth, it may be necessary to have a face velocity of 100 FPM or higher to provide the capture needed; but in an enclosed booth the enclosure provides the containment.

The following ventilation design basis for paint spray booths is common in the industry and has been effective in providing clean, safe and reliable painting environments which are in compliance with the intent of the International Fire Code, OSHA, and NFPA 33.

1. The total exhaust ventilation rate shall be based upon the minimum amount of air required to maintain the concentration of flammable vapors in the exhaust below 25%
2. Where appropriate the exhaust rate shall be increased by the amount of air needed to:

- maintain a minimum average velocity through all openings which prevent the escape of overspray from the spray booth
- achieve the desired collection of overspray toward the exhaust filters
- achieve the desired paint transfer efficiency

There are many types of booths and rooms in which the 100 fpm value would be detrimental to the quality of the product and based upon the amount of paint used is well in excess of the minimum dilution air needed to keep the exhaust below 25% of the LFL. This extra air also increases the operating costs. The air velocities for a specific spray booth or spray room should be specific to the individual design that accomplishes the desired performance (i.e. 25% LFL or containment of overspray at openings). Chapter 13.75 of Industrial Ventilation – A Manual of Recommended Practice 26th Edition Published by ACGIH, lists many recommended air velocity ranges for various painting operations, some above and some below 100 fpm. This publication could be referenced in the standard or commentary.

This proposal does not require additional knowledge or tools for the AHJ. The designer or owner of the spray booth or room can provide calculations showing the minimum ventilation rate based upon the type and amount of paint being sprayed. The ventilation rate can be converted into an average velocity in the spray area. The AHJ can ask for balancing information to confirm the installation meets the code requirements or can independently measure the design velocity in the same manner as currently used by the AHJ to confirm 100 FPM.

The following are the references indicated above:

1. Chapter 7.2, NFPA 33, Standard for Spray Application Using Flammable or Combustible Materials 2007 Edition
"Each spray area shall be provided with mechanical ventilation that is capable of confining and removing vapors and mists to a safe location and is capable of confining and controlling combustible residues, dusts, and deposits. The concentration of the vapors and mists in the exhaust stream of the ventilation system shall not exceed 25 percent of the lower flammable limit."
2. Chapter 510.3, 2012 International Mechanical Code® 2012 Edition
"The design and operation of the exhaust system shall be such that flammable contaminants are diluted in noncontaminated air to maintain concentrations in the exhaust flow below 25 percent of the contaminant's lower flammability limit."
3. Chapter 2404.7.3, 2012 International Fire Code® 2012 Edition
"Air velocity. Ventilation systems shall be designed, installed and maintained such that the average air velocity over the open face of the booth, or booth cross section in the direction of airflow during spraying operations, shall not be less than 100 feet per minute (0.51 m/s)."
4. Chapter 1504.7.3, 2006 International Fire Code® Commentary

"To facilitate the keeping of flammable vapors within a designated spraying space and limiting the amount of overspray, the code requires that the exhaust system be adequately sized to maintain an average velocity over the open face of the booth or booth cross section of no less than 100 feet per minute (0.51 m/s), which is the minimum velocity to capture particulate spray material. Velocities exceeding 200 lineal feet per minute (1.01 m/s) have been determined to be too great for this purpose. To determine the minimum ventilation/exhaust capacity in cubic feet per minute (cfm), multiply the booth width (feet) by booth height (feet) by 100 (lineal per feet)."

1. OSHA Directive STD 01-05-010 - STD 1-5.10 - Clarification of 29 CFR 1910.107(b)(5)(i) Average Air Velocity of Spray Booths, June 1, 1973
"The average air velocity requirements over the open face of the booth stated in this paragraph for spray finishing operations using flammable and combustible liquids were taken from NFPA-33-1969 and pertain to those hazards associated with fire protection or the removal of flammable vapor accumulation from the interior of the booth during spraying operations. This paragraph applies to maintaining the concentration of flammable vapors below the lower explosive limit (LEL) in a spray booth but does not apply to maintaining operator exposures to within the permissible exposure limits (PEL)."
2. OSHA Standard Interpretations 10/22/2001 - Clarification of minimum face velocity requirements for spray booths, October 22, 2001

Question: 29 CFR 1910.107(b)(5) only refers to a dry filter spray booth. What is the minimum air velocity requirement for a waterwash spray booth or an enclosed booth with no openings?

Reply: OSHA currently does not have specific standards addressing velocity requirements for a waterwash spray booth or an enclosed booth with no openings. However, 1910.94(c)(6)(ii) requires that the vapor concentration in all area of the booth remain at a level below 25 percent of the lower explosive limit (LEL). This requirement corresponds to the requirements of NFPA 33, section 5.2, Ventilation, performance requirements (2000 edition)."

Cost Impact: This code change proposal will not increase the cost of construction.

2404.7.3-F-RAIFSNIDER

F262 – 13

2703.15.3 (IBC [F] 415.10.10.3) (New)

Proponent: Patrick A. McLaughlin McLaughlin & Associates, representing the Semiconductor Industry Association (pmclaughma@aol.com)

Add new text as follows:

2703.15.3 (IBC [F] 415.10.10.3) Emergency power protection level. Where emergency power is required, the system shall meet the requirements for a Protection Level 2, Class 2 system in accordance with NFPA 110.

Reason: : Some jurisdictions have interpreted NFPA 110 classification level for semiconductor facilities to be Level 1 when it should be Level 2. Level 1 requires 96 hour of fuel and applies to hospitals and similar occupancies. The rationale is supported by the following:

- This would align H5 occupancies with NFPA 55 – Compressed Gases and Cryogenic Fluids Code
 - 6.6.2 Emergency Power. When emergency power is required, the system shall meet the requirements for a Protection **Level 2** system in accordance with NFPA 110, *Standard for Emergency and Standby Power Systems*.
- Semiconductor facilities meet the definition of Level 2 systems: “shall be installed when failure of the EPSS to perform is **less critical to human life and safety** and where the authority having jurisdiction shall permit a higher degree of flexibility than that provided by a Level 1 system”. Failure of the EPSS in a H5 occupancy would not “result in loss of human life or serious injuries” as defined by NFPA 110. Level 1 systems are intended for facilities such as hospitals “when failure of the equipment to perform could **result in loss of human life or serious injuries**”.
- Existing H5 facilities worldwide have Level 2 EPSS.
- EPSS manufacturers suggest that a H5 is not Level 1.
- Due to the large energy usage and backup systems in an H5 occupancy, fuel handling/storage for 96 hours poses increased environmental/public safety/security risks. A typical H5 occupancie utilizes 10 hours of EPSS. A comparison of the fuel storage between 10 hrs and 96 hrs is provided below:
 - 10hr: = 41,790 gallons
 - 96hr = 401,184 gallon

Cost Impact: The code change proposal will not increase the cost of construction.

F262-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

2703.15.3 (NEW)-F-MCLAUGHLIN

F263 – 13

2705.2.3.1, 202 (IBC 202)

Proponent: Patrick A. McLaughlin, McLaughlin & Associates, representing The Semiconductor Industry Association (pmclaugma@aol.com)

Revise as follows:

2705.2.3.1 Construction. Workstations in *fabrication areas* shall be constructed of materials compatible with the materials used and stored at the workstation. The portion of the workstation that serves as a cabinet for HPM gases, ~~and HPM Class I flammable liquids, Class II or Class IIIA combustible liquid~~ shall be noncombustible and, if of metal, shall be not less than 0.0478-inch (18 gage) (1.2 mm) steel.

SECTION 202 (IBC [F] 202) GENERAL DEFINITIONS

~~**HPM FLAMMABLE LIQUID.** An HPM liquid that is defined as either a Class I flammable liquid or a Class II or Class IIIA combustible liquid.~~

Reason: HPM flammable liquids, which include Class I, II and IIIA liquid, are mentioned only once in the Codes in IFC Section 2705.2.3.1. This change deletes the definition of HPM flammable liquids and replaces it in Section 2705.2.3.1 with the text from the HPM flammable liquids definition. The result will be that Section 2705.2.3.1 will still apply to the same materials, and the requirements in the Code that apply to other HPMs, will not be misapplied to Class II and IIIA combustible liquids. There is no justification to treat Class II and IIIA combustible liquids the same as flammable liquids in H5 occupancies. No other occupancy does so. The corresponding IBC definition is also deleted.

Cost Impact: The code change proposal will not increase the cost of construction.

F263-13

	Assembly:	ASF	AMF	DF

2705.2.3.1-F-MCLAUGHLIN

F264 – 13

2808.3

Proponent: Robert J Davidson, Davidson Code Concepts, LLC, representing the Biomass Feedstock Industry Committee on Codes and Standards (BFICOCs) (rjd@davidsoncodeconcepts.com)

Revise as follows:

2808.3 Size of piles. Piles shall not exceed 25 feet (7620 mm) in height, 150 feet (45 720 mm) in width and 250 feet (76 200 mm) in length.

Exception: The *fire code official* is authorized to allow the pile size to be increased when a fire protection plan is provided for approval that includes, but is not limited to the following:

1. Storage yard areas and materials-handling equipment selection, design, and arrangement shall be based upon sound fire prevention and protection principles.
2. Factors that lead to spontaneous heating shall be identified in the plan and control of the various factors shall be identified and implemented, including provisions for monitoring the internal condition of the pile.
3. The plan shall include means for early fire detection, reporting to the public fire department; and facilities needed by the fire department for fire extinguishment including a water supply and fire hydrants.
4. Fire apparatus access roads around the piles and access roads to the top of the piles shall be established, identified and maintained.
5. Regular yard inspections by trained personnel shall be included as part of an effective fire prevention maintenance program.

Additional fire protection called for in the plan ~~is~~ shall be provided and shall be installed in accordance with ~~Chapter 9 this code~~. The increase of the pile size shall be based upon the capabilities of the ~~system~~ installed fire protection systems and features.

Reason: The purpose of this proposal is to provide better tools and guidance for fire code officials when proposals to increase pile size are submitted. The current language for the exception to Section 2808.3 is:

Exception: The fire code official is authorized to allow the pile size to be increased when additional fire protection is provided in accordance with Chapter 9. The increase shall be based upon the capabilities of the system installed.

The language provides no actual guidance other than a statement that the pile size is based upon the systems installed in accordance with Chapter 9. A review of Chapter 9 provides no additional guidance.

In reality, the protection needed for increased pile size include fire flows through a hydrant system, fire apparatus access roads, means for monitoring pile temperatures, a means of notifying the fire department and a sound fire prevention maintenance program. The language added to modify the existing exception provides for these features to be addressed in a fire protection plan submittal to the fire code official for approval. Because the systems installed may be covered by various portions of the code such as fire apparatus access roads covered by Chapter 5, the reference to Chapter 9 was changed to "this code".

The basis of this language should not be new to experienced fire code officials, it can be found in the discontinued standard NFPA 46 which was referenced by some legacy fire code editions and it was located in NFPA 230 which was referenced by the 2003 edition of the IFC. When NFPA eliminated NFPA 230 and put some of the requirements in NFPA 13 with the bulk going to NFPA 1, no work was done to add language to the later editions of the IFC to replace language relied upon from the referenced standard.

Extract from NFPA 230-2003 PROTECTION OF STORAGE OF FOREST PRODUCTS

11.6.2 General.

11.6.2.1* *The fire hazard potential inherent in storage piles shall be controlled by a positive fire prevention program under the direct supervision of upper level management that shall include the following:*

- (1) *Selection, design, and arrangement of storage yard areas and materials-handling equipment based upon sound fire prevention and protection principles*
- (2) *Establishment of control over the various factors that lead to spontaneous heating, including provisions for monitoring the internal condition of the pile*
- (3) *Means for early fire detection and extinguishment*

- (4) *Driveways around the piles and access roads to the top of the piles for effective fire-fighting operations*
- (5) *Facilities for calling the public fire department and facilities needed by the fire department for fire extinguishment*
- (6) *Effective fire prevention maintenance program, including regular yard inspections by trained personnel*

The Biomass Feedstock Industry Committee on Codes and Standards (BFICOCS), led by Oak Ridge National Laboratory (ORNL), is an initiative of the Department of Energy Biomass Technologies Office (BTO). As part of the BTO integrated biorefinery efforts, the BFICOCS was assembled to conduct analysis of existing fire and building codes and to prepare proposed code changes designed to facilitate the development of the commercial-scale biomass industry while maintaining a focus on safety. The committee is made up of managers, engineers and code officials from industry, government laboratories, consulting firms, and the American Society of Agricultural and Biological Engineers.

Fire codes related to storage, handling, and preprocessing of biomass are based on industries that operate in a significantly different manner than the growing biomass-based energy industry. Applying current research on biomass properties and knowledge of conventional and emerging storage, handling, and preprocessing technologies, the BFICOCS has identified changes in the IFC that benefit industry and the public.

Cost Impact: The code change proposal will not increase the cost of construction.

2808.3-F-DAVIDSON

F265 – 13

2810 (New), 2801.1

Proponent: Robert J Davidson, Davidson Code Concepts, LLC, representing self
(rjd@davidsoncodeconcepts.com)

Add new text as follows:

SECTION 2810

WOOD AND PLASTIC PALLET STORAGE AND REHABILITATION

2810.1 General. All facilities with either storage or rehabilitation of pallets shall be in accordance with Sections 2810.2 through 2810.5.2 and Section 2803.

2810.2 Fire Flow. The minimum required fire flow in pallet storage yards exceeding 3200 sq feet of pallet storage areas shall be not less than 2,000 gpm (7571 L/m). For storage yards with stable piles greater than 6,200 sq. ft. (576 m²) the required fire flow shall be not less than 3,000 gpm (8516 L/m). Pallet storage yards shall not exceed the available fire hydrant flow and spacing.

2810.3 Fire Hydrants. Fire hydrants required for fire flow purposes for pallet storage arrays shall be installed in accordance with Section 507 within three hundred (300) feet (152.4m) of pallet locations measured along unobstructed access paths.

2810.4 Fire Department Access. Fire apparatus access roads in accordance with Section 503 shall be located within one hundred fifty (150) feet (45,720mm) of all portions of the pallet storage array(s). Permanent delineation of on-site fire apparatus access roads shall be provided as required by the fire code official.

2810.5 Idle Pallet Storage. Pallet storage shall be in compliance with Sections 2810.5.1 or 2810.5.2 as applicable.

2810.5.1 Exterior pallet repair and storage areas greater than 3,200 sq ft. Exterior pallet storage arrays greater than 3200 square feet shall comply with all of the following:

1. Stacks shall not exceed a height of fifteen (15) ft. (4.57 m).
2. Stacks shall be no closer than eight (8) ft. (2.44 m) to any property line or a distance equal to the stack height, whichever is greater.
3. Stacks shall be no closer than eight (8) ft. (2.44 m) to any other on-site storage area.
4. Stacks shall be no closer than fifteen (15) ft. (4.57 m) to any on-site structure.
5. Stacks shall be arranged to form stable piles.
6. Piles shall not contain more than six thousand (6,000) cu. ft. (170 m³) of pallets.
7. Piles shall be separated from other piles by a minimum distance of eight (8) ft. (2.44 m).
8. Piles shall be arranged in a grid system to form pallet storage arrays with a maximum dimension of fifty (50) ft. by fifty (50) ft. (15.25 m by 15.25 m).
9. Pallet storage arrays shall be separated by a minimum distance of twenty four (24) ft. (7.32 m).

2810.5.2 Exterior storage not greater than 3200 sq ft in area. Exterior pallet storage not greater than 3200 square feet shall comply with all of the following:

1. Stacks shall be no closer than eight (8) ft. (2.44 m) to any property line or a distance equal to the stack height, whichever is greater.
2. Stacks shall be no closer than eight (8) ft. (2.44 m) to any other on-site storage.
3. Stacks shall be no closer than fifteen (15) ft. (4.57 m) to any on-site structure.

Exception: Where approved by the fire code official, stacks located closer than fifteen (15) ft. to an on-site structure shall maintain minimum horizontal clearances based on the quantity of pallets and the level of protection provided by the building construction as follows:

1. The minimum horizontal clearance for 50 pallets or less adjacent to a masonry wall without openings located within twenty (20) ft. (6 m) horizontally of the pallet stacks, or adjacent to a masonry wall with 2 hour fire-resistance rated protected openings shall be zero (0) feet (0 m).
2. The minimum horizontal clearance for 51 to 200 pallets adjacent to a masonry wall without openings located within twenty (20) ft. (6 m) horizontally of the pallet stacks, or a masonry wall with 2 hour fire-resistance rated protected openings shall be eight (8) feet (2.44 m).
3. The minimum horizontal clearance for 50 pallets or less adjacent to a wood or metal building equipped throughout with an approved automatic sprinkler system shall be eight (8) ft. (2.44 m).
4. Stacks located less than fifteen (15) ft. (4.57 m) from an exterior building wall shall not exceed a height equal to thirty (30) inches below the roof line elevation, or fifteen (15) feet (4.57 m), whichever is less.
5. Stacks shall be arranged to form stable piles.

Revise as follows:

SECTION 2801 GENERAL

2801.1 Scope. The storage, manufacturing and processing of timber, lumber, plywood, non-metallic pallets, veneers and byproducts shall be in accordance with this chapter.

Reason: There have been an increasing number of large scale fires involving the repair and outdoor storage of combustible pallets. Numerous local jurisdictions have been adding local requirements to their fire code adoptions to deal with this increased fire threat. These new requirements are to provide code language in the IFC addressing the high challenge fire protection issues involving large amounts of idle pallets. The concepts for the technical language in this proposal were taken from the Clark County, Nevada fire code amendments, a county that has dealt with large scale fires and developed the requirements in response to those conflagrations.

Section 2810.2 specifies that the requirements apply to facilities that store or rehabilitate wood or plastic pallets. The rehabilitation activities include storage along with additional hazards introduced by the rehabilitation activities.

Fires in pallet storage areas are fast growing and spreading requiring an adequate fire flow. Threshold of 2,000 GPM for greater than 3,200 sq. ft. of storage will provide for up to 4 - 500 GPM master stream appliances to be utilized when required, increasing to 3,000 GPM when piles larger than 6,200 sq. ft. exist.

Referring to IFC Table B105.1 for required fire flows the 2,000 GPM requirement is for Type V-B buildings of 4,401 - 6,200 sq. ft., since the open array of the pallets provide for a faster fire spread and greater need for master stream appliances than a completed building typically would, the 2,000 GPM is appropriate for the minimum flow required. Since pile size and separation from individual piles is provided for in Section 2810.5 a fire flow 3,000 GPM was utilized for areas of storage over 6,200 sq. ft.

Fire department access roads are required in section 2810.4.

Section 2810.5 provides for the storage arrangement of piles and stacks addressing height, maximum pile size and distances from exposures. A stack is an individual stack of pallets, a pile is a group of 2 or more stacks of pallets grouped together.

Cost Impact: The code change proposal will increase the cost of construction.

2801.1-F-DAVIDSON

F266 – 13

3101.1, 3103.1

Proponent: Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azubiamia@yahoo.com)

Revise as follows:

3101.1 Scope. Tents and membrane structures shall comply with this chapter. The provisions of Section 3103 are applicable only to temporary tents and membrane structures. The provisions of Section 3104 are applicable to temporary and permanent tents and membrane structures. Other temporary structures shall comply with the *International Building Code*.

3103.1 General. ~~All temporary tents~~ Tents and membrane structures used for temporary periods shall comply with this section. Other temporary structures erected for a period of 180 days or less shall comply with the *International Building Code*.

Reason: This proposal is submitted by the ICC Fire Code Action Committee (FCAC). This ICC committee was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portions thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the Fire-CAC has held 6 open meetings and numerous Regional Work Group and Task Group meetings and conference calls which included members of the committees as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the FAC website at: <http://www.iccsafe.org/cs/CAC/Pages/default.aspx>.

Background – There has been confusion with attempting to apply the IFC requirements in Chapter 31 to temporary structures. Typically this occurs because the fire code official is already involved with the temporary event regarding other operational permits required by the IFC.

For example, a weekend concert is planned at the fair. The fire code official is already involved with various IFC operational permits for Place of Assembly, Carnival/Fair, and Temporary Membrane Structures and Tents. However, when a stage, platform or other temporary structure is erected the IBC regulates the construction.

The proposal adds a sentence to IFC 3101.1 to send the code user to the IBC for temporary structures. IBC 108.2 and 3103 clearly address the design requirements for temporary structures. IBC 3103.1 has a similar reference back to the IFC to temporary membrane structures and temporary tents. Clearly, the IFC is designed to address 'temporary tents' and 'temporary membrane structures', while IBC 3103 is intended to address 'temporary structures'.

This reference to the IBC is repeated in IFC 3103.1. Normally a redundant sentence is not needed in the code, but since this has been an area of confusion, it is warranted to repeat the reference again.

See link for incident at Indiana State Fair - <http://www.youtube.com/watch?v=4jEmtxnrVCI>

Cost Impact: The code change will not increase the cost of construction.

F266-13

3101.1-F-ZUBIA-FCAC

F267 – 13

3103.3.1 (New)

Proponent: Brad Emerick, Denver Fire Department representing the Fire Marshal's Association of Colorado (FMAC) and the Colorado Chapter of the ICC (CCICC) (brad.emerick@denvergov.org)

Add new text as follows:

3103.3.1 Special Amusement. Tents and other membrane structures erected for the purpose of a special amusement building shall comply with the provisions of Section 411 of the *International Building Code*.

Reason: The scoping language in Section 3101 doesn't leave much room for stepping outside Chapter 31 for proposed uses other than those contemplated in Chapter 31. However, temporary membrane structures are being used for an increasingly wider variety of occupancies. One of the more hazardous is special amusement buildings.

The growing popularity of haunted houses usually erected within a month of Halloween and dismantled shortly thereafter, has enticed producers to (try to) utilize temporary membrane structures for these events. Due to the intentionally disorienting nature of these occupancies, additional life-safety measures beyond those prescribed in Chapter 31 (which really only contemplates large, open, usually seated assembly occupancies) are required. The section cited in the IBC addresses temporary special amusement buildings as well as permanent, and provides established life-safety measures.

Cost Impact: This change will not affect the cost of construction.

F267-13

	Assembly:	ASF	AMF	DF

3103.3.1-F-EMERICK

F268 – 13

3103.9; 3103.9.1 (New), 3103.9.2 (New)

Proponent: Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azubiamia@yahoo.com)

Revise as follows:

3103.9 Anchorage required. Tents or membrane structures and their appurtenances shall be adequately roped, braced and anchored to withstand the elements of weather and prevent against collapsing. ~~Documentation of structural stability shall be furnished to the fire code official on request.~~

3103.9.1 Structural design. Tents and membrane structures shall be designed and constructed to comply with Chapter 16 of the *International Building Code* where any of the following conditions occur:

1. The occupant load of the tent or membrane structure exceeds 100.
2. The tent or membrane structure is classified as a Group A, E, or I.
3. The tent or membrane structure is classified as a Group R Occupancy with an occupant load exceeding 50, or
4. The tent or membrane structure exceeds one story.

3103.9.2 Documentation. Documentation of structural stability shall be furnished to the fire code official upon request.

Reason: There has been confusion with attempting to apply the IFC requirements in Chapter 31 to temporary tents and membrane structures relative to structural stability.

These structures can be seen at concerts, outdoor functions, fairs, etc. Even though the provision of 'temporary' limits the usability of these structures to less than 180 days, improper structural design can still lead to problems.

Many of these temporary tents and temporary membrane structures have multiple floors, and over 30 feet in height. As the height increases, the impact of collapse increases and typically these structures are surrounded by hundreds of people.

This proposal revises IFC Section 3103.9 to include requirements for temporary tents and membrane structures to comply with IBC Chapter 16 structural requirements when there is a significant life hazard within the structure, as reflected in Section 3103.9.1. The relative significance is based on the occupancy classification, the occupant load, or the number of levels within the tent or membrane structure.

The requirement for documentation is relocated from 3103.9 to 3103.9.2.

This proposal is submitted by the ICC Fire Code Action Committee (FCAC). This ICC committee was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portions thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the Fire-CAC has held 6 open meetings and numerous Regional Work Group and Task Group meetings and conference calls which included members of the committees as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the FAC website at: <http://www.iccsafe.org/cs/CAC/Pages/default.aspx>.

Cost Impact: This code change may increase the cost of construction

Proponent: Anne vonWeller, representing Witt Associates; Karl Ruling, Technical Standards Manager, Professional Lighting and Sound Association representing self; Scott Adams, Deputy Chief Park City Fire District, representing self

Add new text as follows:

SECTION 3105 **TEMPORARY STAGE CANOPIES**

3105.1 General. Temporary stage canopies shall comply with Section 3104, Sections 3105.2 through 3105.8 and ANSI E1.21.

3105.2 Approval. Temporary stage canopies in excess of 400 square feet shall not be erected operated or maintained for any purpose without first obtaining approval and a permit from the fire code official.

3105.3 Permits. Permits shall be required as set forth in Sections 105.6 and 105.7.

3105.4 Use period. Temporary stage canopies shall not be erected for a period of more than 45 days.

3105.5 Required documents. All of the following documents shall be submitted to the fire code official for review before a permit is approved:

1. Construction documents: Construction documents shall be prepared by a registered design professional in accordance with the *International Building Code*. Construction documents shall include:
 - 1.1. A summary sheet showing design criteria, loads and support reactions.
 - 1.2. Detailed construction and installation drawings.
 - 1.3. Design calculations.
 - 1.4. Operating limits of the structure explicitly outlined by the design professional including environmental conditions and physical forces.
 - 1.5. Effects of additive elements such as video walls, supported scenery, audio equipment, vertical and horizontal coverings.
 - 1.6. Means for adequate stability including specific requirements for guying and cross-bracing, ground anchors or ballast for different ground conditions.
2. Designation of responsible party: The owner of the temporary stage canopy shall designate in writing a person to have responsibility for the temporary stage canopy on the site. The designated person shall have sufficient knowledge of the construction documents, manufacturer's recommendations and operations plan to make judgments regarding the structure's safety and to coordinate with the fire code official.
3. Operations plan: The operations plan shall reflect manufacturer's operational guidelines, procedures for environmental monitoring and actions to be taken under specified conditions consistent with the construction documents.

3105.6 Inspections. Inspections shall comply with Section 106 and Sections 3105.6.1 and 3106.6.2.

3105.6.1 Independent inspector. The owner of a temporary stage canopy shall employ a qualified, independent approved agency or individual to inspect the installation of a temporary stage canopy.

3105.6.2 Inspection report. The inspecting agency or individual shall furnish an inspection report to the fire code official. The inspection report shall indicate that the temporary stage canopy was inspected and was or was not installed in accordance with the approved construction documents. Discrepancies shall be

brought to the immediate attention of the installer for correction. Where any discrepancy is not corrected, it shall be brought to the attention of the fire code official and the designated responsible party.

3105.7 Means of egress. The means of egress for temporary stage canopies shall comply with Chapter 10.

3105.8 Location. Temporary stage canopies shall be located a distance from property lines and buildings to accommodate distances indicated in the construction drawings for guy wires, cross-bracing, ground anchors or ballast. Location shall not interfere with egress from a building or encroach on fire apparatus access roads.

SECTION 202 GENERAL DEFINITIONS

TEMPORARY STAGE CANOPY. A temporary stage canopy is a temporary ground-supported structure used to cover stage areas and support equipment in the production of outdoor entertainment events.

Revise as follows:

SECTION 3101 GENERAL

3101.1 Scope. Tents, canopies, temporary stage canopies and membrane structures shall comply with this chapter. The provisions of Section 3103 are applicable only to temporary membrane structures. The provisions of Section 3104 are applicable to temporary and permanent membrane structures.

SECTION 3102 DEFINITIONS

3102.1 Definitions. The following terms are defined in Chapter 2:

AIR-INFLATED STRUCTURE.
AIR-SUPPORTED STRUCTURE.
MEMBRANE STRUCTURE.
TEMPORARY STAGE CANOPY.
TENT.

[A] 105.6.43 Temporary membrane structures and tents. An operational permit is required to operate an air-supported temporary membrane structure, a temporary stage canopy or a tent having an area in excess of 400 square feet (37 m2).

Exceptions: 1. and 2. (No change to current text.)

[A] 105.7.16 Temporary membrane structures and tents. A construction permit is required to erect an air-supported temporary membrane structure, a temporary stage canopy or a tent having an area in excess of 400 square feet (37 m2).

Exceptions: 1. through 3. (No change to current text.)

Add new standard to Chapter 80 as follows:

ANSI

E1.21-2006 Entertainment Technology: Temporary Ground Supported Overhead Structures Used to Cover the Stage Areas and Support Equipment in the Production of Outdoor Entertainment Events.

Reason: There were four high-profile temporary stage canopy collapses during the 2011 summer concert season: one on August 7th at Brady District Block Party, Tulsa Oklahoma; one on July 17th at the Cisco Ottawa Blues Festival in Ottawa, Canada; one on August 13, 2011, at the Indiana State Fairgrounds which resulted in the loss of seven lives and the injury of fifty more; and another on August 18th at the Pukkelpop Festival in Kiewit, Belgium. Again, in the summer of 2012 an additional life was lost at a Radiohead concert in Toronto. All resulted in tremendous property damage and two in multiple fatalities. The obvious concern is for the safety of the performers and audiences, stage-hands, lighting technicians, security personnel and every other profession or individual that necessitates proximity to a temporary stage.

Temporary stage canopies are very specialized and complex. The nature of the structures must accommodate a wide variety of changing components such as audio equipment, video walls and scenery. The entertainment industry is continually evolving with new ways to improve shows creating larger and more complex spectacles.

Due to the nearly unique design of temporary stage canopies, it is difficult for most fire inspectors to find adequate guidance in current code language to satisfactorily regulate these specialized structures.

Witt Associates contracted with the Indiana State Fair Commission to complete a comprehensive assessment of the 2011 State Fair collapse incident. The assessment included a review of applicable laws and model codes as well as a nationwide survey of best practices. A major recommendation of the assessment was:

“National model building and fire codes should adopt more specific standards for temporary membrane stage structures reflecting the increasing complexity of these structures”

The complete report may be reviewed at www.wittassociates.com/clients-projects/project-list/indiana-state-fair-collapse-independent-assessment. This proposal addresses the report recommendation, incorporates a reasonable industry standard and best practices.

- 3105.1 - An ANSI standard exists which is specifically targeted to temporary stage canopies. ANSI E1.21-2006 was produced by the Entertainment Services and Technology Association (ESTA). ESTA recently merged with an international organization, Professional Lighting and Sound Association (PLASA). Fire and building code officials may download the standard at no charge provided they register at www.plasa.org.
- 3105.2 - The trigger starting regulation at 400 square feet is consistent with the current International Fire Code.
- 3104.4 - The 45 day duration is consistent with ANSI E1.21.
- 3105.5 - This section is a summary of the relevant requirements of ANSI E1.21 necessary to provide guidance to regulating authorities. Stage canopies are subject to more diverse loads than most permanent structures. Because of the variable weights of equipment for different shows, the need to monitor changing weather conditions and the requirement to be able to raise and lower the roof to install equipment, there is a necessity for a design professional to fully analyze the structure and a need to designate a responsible person on site who understands this complexity of considerations.
- 3105.6 - It is unlikely many fire inspectors will be familiar with the specialized nature of these structures. That is the reason we are recommending a qualified specialized inspector be employed by the owner to inspect and report to the authority having jurisdiction and the designated responsible person. An Entertainment Technician Certification Program (ETCP) certification exists which would demonstrate competence to inspect the majority of temporary stage canopies. For large, unusually complex canopies there is latitude for the fire official to require inspection by structural engineer familiar with these types of temporary structures.
- 3105.7 and
- 3105.8 - This language is for general safety and is consistent with the International Fire Code.
- 3102 - Definitions were added to describe the specialized structure to be regulated.

Cost Impact: The code change proposal will increase the cost of construction

3203

Proponent: Jeffrey M. Hugo, CBO, representing the National Fire Sprinkler Association
(hugo@nfsa.org)

Revise as follows:

3203.1 Classification of commodities. Commodities shall be classified as Class I, II, III, IV in accordance with NFPA 13. ~~or high hazard in accordance with this section.~~ High hazard commodities shall be classified in accordance with Section 3203.3. Materials listed within each commodity classification are assumed to be unmodified for improved combustibility characteristics. Use of flame-retarding modifiers or the physical form of the material could change the classification. ~~See Section 3203.7 for classification of Group A, B and C plastics.~~

3203.2. Plastics. Plastics shall be designated as Group A, B or C in accordance with NFPA 13.

3203.2 Class I commodities. ~~Class I commodities are essentially noncombustible products on wooden or nonexpanded polyethylene solid deck pallets, in ordinary corrugated cartons with or without single-thickness dividers, or in ordinary paper wrappings with or without pallets. Class I commodities are allowed to contain a limited amount of Group A plastics in accordance with Section 3203.7.4. Examples of Class I commodities include, but are not limited to, the following:~~

- ~~Alcoholic beverages not exceeding 20 percent alcohol~~
- ~~Appliances noncombustible, electrical~~
- ~~Cement in bags~~
- ~~Ceramics~~
- ~~Dairy products in nonwax-coated containers (excluding bottles)~~
- ~~Dry insecticides~~
- ~~Foods in noncombustible containers~~
- ~~Fresh fruits and vegetables in nonplastic trays or containers~~
- ~~Frozen foods~~
- ~~Glass~~
- ~~Glycol in metal cans~~
- ~~Gypsum board~~
- ~~Inert materials, bagged~~
- ~~Insulation, noncombustible~~
- ~~Noncombustible liquids in plastic containers having less than a 5-gallon (19 L) capacity~~
- ~~Noncombustible metal products~~

3203.3 Class II commodities. ~~Class II commodities are Class I products in slatted wooden crates, solid wooden boxes, multiple-thickness paperboard cartons or equivalent combustible packaging material with or without pallets. Class II commodities are allowed to contain a limited amount of Group A plastics in accordance with Section 3203.7.4. Examples of Class II commodities include, but are not limited to, the following:~~

- ~~Alcoholic beverages not exceeding 20 percent alcohol, in combustible containers~~
- ~~Foods in combustible containers~~
- ~~Incandescent or fluorescent light bulbs in cartons~~
- ~~Thinly coated fine wire on reels or in cartons~~

3203.4 Class III commodities. ~~Class III commodities are commodities of wood, paper, natural fiber cloth, or Group C plastics or products thereof, with or without pallets. Products are allowed to contain limited amounts of Group A or B plastics, such as metal bicycles with plastic handles, pedals, seats and tires.~~

Group A plastics shall be limited in accordance with Section 3203.7.4. Examples of Class III commodities include, but are not limited to, the following:

- Aerosol, Level 1 (see Chapter 28)
- Combustible fiberboard
- Cork, baled
- Feed, bagged
- Fertilizers, bagged
- Food in plastic containers
- Furniture: wood, natural fiber, upholstered, nonplastic, wood or metal with plastic-padded and covered armrests
- Glycol in combustible containers not exceeding 25 percent
- Lubricating or hydraulic fluid in metal cans
- Lumber
- Mattresses, excluding foam rubber and foam plastics
- Noncombustible liquids in plastic containers having a capacity of more than 5 gallons (19 L)
- Paints, oil base, in metal cans
- Paper, waste, baled
- Paper and pulp, horizontal storage, or vertical storage that is banded or protected with *approved wrap*
- Paper in cardboard boxes
- Pillows, excluding foam rubber and foam plastics
- Plastic-coated paper food containers
- Plywood
- Rags, baled
- Rugs, without foam backing
- Sugar, bagged
- Wood, baled
- Wood doors, frames and cabinets
- Yarns of natural fiber and viscose

3203.5 Class IV commodities. Class IV commodities are Class I, II or III products containing Group A plastics in ordinary corrugated cartons and Class I, II and III products with Group A plastic packaging, with or without pallets. Group B plastics and free-flowing Group A plastics are also included in this class. The total amount of nonfree-flowing Group A plastics shall be in accordance with Section 3203.7.4. Examples of Class IV commodities include, but are not limited to, the following:

- Aerosol, Level 2 (see Chapter 51)
- Alcoholic beverages, exceeding 20 percent but less than 80 percent alcohol, in cans or bottles in cartons
- Clothing, synthetic or nonviscose
- Combustible metal products (solid)
- Furniture, plastic upholstered
- Furniture, wood or metal with plastic covering and padding
- Glycol in combustible containers (greater than 25 percent and less than 50 percent)
- Linoleum products
- Paints, oil base in combustible containers
- Pharmaceutical, alcoholic elixirs, tonics, etc.
- Rugs, foam back
- Shingles, asphalt
- Thread or yarn, synthetic or nonviscose

3203.6 3203.3 High-hazard commodities. High-hazard commodities are high-hazard products presenting special fire hazards beyond those of Class I, II, III or IV. Group A plastics not otherwise classified are included in this class.

Examples of high-hazard commodities include, but are not limited to, the following:

Aerosol, Level 3 (see Chapter 51)
Alcoholic beverages, exceeding 80-percent alcohol, in bottles or cartons
Commodities of any class in plastic containers in carousel storage
Flammable solids (except solid combustible metals)
Glycol in combustible containers (50 percent or greater)
Lacquers, which dry by solvent evaporation, in metal cans or cartons
Lubricating or hydraulic fluid in plastic containers
Mattresses, foam rubber or foam plastics
Pallets and flats which are idle combustible
Paper and pulp, rolled, in vertical storage which is unbanded or not protected with an approved wrap
Paper, asphalt, rolled, horizontal storage
Paper, asphalt, rolled, vertical storage
Pillows, foam rubber and foam plastics
Pyroxylin
Rubber tires
Vegetable oil and butter in plastic containers

3203.7 Classification of plastics. Plastics shall be designated as Group A, B or C in accordance with Sections 3203.7.1 through 3203.7.4.

3203.7.1 Group A plastics. Group A plastics are plastic materials having a heat of combustion that is much higher than that of ordinary combustibles, and a burning rate higher than that of Group B plastics. Examples of Group A plastics include, but are not limited to, the following:

ABS (acrylonitrile-butadiene-styrene copolymer)
Acetal (polyformaldehyde)
Acrylic (polymethyl methacrylate)
Butyl rubber
EPDM (ethylene-propylene rubber)
FRP (fiberglass-reinforced polyester)
Natural rubber (expanded)
Nitrile rubber (acrylonitrile-butadiene rubber)
PET or PETE (polyethylene terephthalate)
Polybutadiene
Polycarbonate
Polyester elastomer
Polyethylene
Polypropylene
Polystyrene (expanded and unexpanded)
Polyurethane (expanded and unexpanded)
PVC (polyvinyl chloride greater than 15-percent plasticized, e.g., coated fabric unsupported film)
SAN (styrene acrylonitrile)
SBR (styrene-butadiene rubber)

3203.7.2 Group B plastics. Group B plastics are plastic materials having a heat of combustion and a burning rate higher than that of ordinary combustibles, but not as high as those of Group A plastics. Examples of Group B plastics include, but are not limited to, the following:

Cellulosics (cellulose acetate, cellulose acetate butyrate, ethyl cellulose)
Chloroprene rubber
Fluoroplastics (ECTFE, ethylene-chlorotrifluoroethylene copolymer; ETFE, ethylene-tetrafluoroethylene copolymer; FEP, fluorinated ethylene-propylene

~~copolymer)~~
~~Natural rubber (nonexpanded)~~
~~Nylon (Nylon 6, Nylon 6/6)~~
~~PVC (polyvinyl chloride greater than 5 percent, but not exceeding 15 percent plasticized)~~
~~Silicone rubber~~

~~3203.7.3 Group C plastics.~~ ~~Group C plastics are plastic materials having a heat of combustion and a burning rate similar to those of ordinary combustibles. Examples of Group C plastics include, but are not limited to, the following:~~

~~Fluoroplastics (PCTFE, polychlorotrifluoroethylene;
PTFE, polytetrafluoroethylene)
Melamine (melamine formaldehyde)
Phenol
PVC (polyvinyl chloride, rigid or plasticized less than 5 percent, e.g., pipe, pipe fittings)
PVDC (polyvinylidene chloride)
PVDF (polyvinylidene fluoride)

Urea (urea formaldehyde)~~

~~3203.4 3203.7.4 Limited quantities of Group A plastics in mixed commodities.~~ ~~Figure 3203.4 3203.7.4 shall be used to determine the quantity of Group A plastics allowed to be stored in a package or carton or on a pallet without increasing the commodity classification.~~

Figure 3203.4 3203.7.4 Mixed Commodities^{a,b}

Shade in new area starting at 5% by weight and 5 % by volume instead of 10% by weight and 10% by volume.

- This figure is intended to determine the commodity classification of a mixed commodity in a package, carton or on a pallet where plastics are involved.
- The following is an example of how to apply the figure: A package containing a Class III commodity has 12-percent Group A expanded plastic by volume. The weight of the unexpanded Group A plastic is 10 percent. This commodity is classified as a Class IV

commodity. If the weight of the unexpanded plastic is increased to 14 percent, the classification changes to a high-hazard commodity.

$$\text{c. Percent by volume} = \frac{\text{Volume of plastic in pallet load}}{\text{Total volume of pallet load, including pallet}}$$

$$\text{d. Percent by weight} = \frac{\text{Volume of plastic in pallet load}}{\text{Total volume of pallet load, including pallet}}$$

Reason: The majority of these examples are in sync with the commodities of NFPA 13, however, there are several that conflict with the current and soon to be referenced edition of NFPA 13. These conflicts can cause significant problems for designers and incorrect storage protection for owners and communities. Removing the examples does not change the technical requirements of this chapter, but only directs the user to NFPA 13 to get the appropriate design commodity.

Cost Impact: Will not increase the cost of construction

F270-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

3203.2-F-HUGO

F271 – 13

3203.2

Proponent: Elley Klausbruckner representing Klausbruckner & Associates Inc (ek@klausbruckner.com)

Revise as follows:

3203.2 Class I commodities. Class I commodities are essentially noncombustible products on wooden or ~~nonexpanded polyethylene solid deck pallets~~, in ordinary corrugated cartons with or without single-thickness dividers, or in ordinary paper wrappings with or without pallets. Class I commodities are allowed to contain a limited amount of Group A plastics in accordance with Section 3203.7.4. Examples of Class I commodities include, but are not limited to, the following:

- Alcoholic beverages not exceeding 20-percent alcohol
- Appliances noncombustible, electrical
- Cement in bags
- Ceramics
- Dairy products in nonwax-coated containers (excluding bottles)
- Dry insecticides
- Foods in noncombustible containers
- Fresh fruits and vegetables in nonplastic trays or containers
- Frozen foods
- Glass
- Glycol in metal cans
- Gypsum board
- Inert materials, bagged
- Insulation, noncombustible
- Noncombustible liquids in plastic containers having less than a 5-gallon (19 L) capacity
- Noncombustible metal products

Reason: Nonexpanded Polyethylene Solid Deck Pallets increase the fuel load of pallet considerably. In NFPA 13, the commodity classification of products stored on plastic pallets are increased by 1-2 classes depending on the type of plastic pallets. In some cases [depending on the weights], it can even be classified as High Hazard Commodity when using Figure 3203.7.4.

Based on research of databases etc., there is no substantiation for classifying products stored on these types of pallets as Class I. However, there are major incidences such as the Post and Paddock Fire prepared by Scott Stookey [former ICC Senior Staff] which point to the possibility of sprinkler failure if the protection of noncombustible materials on nonexpanded polyethylene solid deck is based on Class I Commodity.

Additionally with the rampant use of non-listed plastic pallets [mainly shipped from overseas], these products are a major concern to fire fighter safety.

Cost Impact: The code change proposal will not increase the cost of construction.

F271-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

3203.2-F-KLAUSBRUCKNER

F272 – 13

3206.4.1 (New), 3208.2.1

Proponent: Robert J Davidson, Davidson Code Concepts, LLC, representing self
(rjd@davidsoncodeconcepts.com)

Revise as follows:

3206.4.1 Pallets. Automatic sprinkler system requirements based upon the presence of pallets shall be in accordance with NFPA 13.

3208.2.1 Plastic pallets and shelves. Storage on plastic pallets or plastic shelves shall be protected by approved specially engineered fire protection systems.

Exception: Plastic pallets listed and labeled in accordance with UL 2335 shall be treated as wood pallets for determining required sprinkler protection.

Reason: As currently written, Chapter 32 gives the impression that pallets are only a factor when involving rack storage. This is not the case, NFPA 13 has extensive requirements for pallet use and storage based upon the type of pallet that must be designed for and maintained during occupancy.

This proposal deletes references to plastic pallets and adds a section pointing the user of the code to NFPA 13 for design and installations requirements relative to the presence of pallets.

Example language from NFPA 13-2010

<http://www.nfpa.org/aboutthecodes/AboutTheCodes.asp?DocNum=13>

- 3.9.1.11*** Conventional Pallets. A material-handling aid designed to support a unit load with openings to provide access for material-handling devices. (See Figure A.3.9.1.11.)
- 3.9.1.21** Plastic Pallet. A pallet having any portion of its construction consisting of a plastic material.
- 3.9.1.22*** Reinforced Plastic Pallet. A plastic pallet incorporating a secondary reinforcing material (such as steel or fiberglass) within the pallet.
- 3.9.1.27** Wood Pallet. A pallet constructed entirely of wood with metal fasteners.

5.6.2 Pallet Types.

- 5.6.2.1** **General.** When loads are palletized, the use of wood or metal pallets, or listed pallets equivalent to wood, shall be assumed in the classification of commodities.
- 5.6.2.2*** **Unreinforced Plastic Pallets.** For Class I through Class IV commodities, when unreinforced polypropylene or unreinforced high-density polyethylene plastic pallets are used, the classification of the commodity unit shall be increased one class.
- 5.6.2.2.1** Unreinforced polypropylene or unreinforced high-density polyethylene plastic pallets shall be marked with a permanent symbol to indicate that the pallet is unreinforced.
- 5.6.2.3*** For Class I through Class IV commodities, when reinforced polypropylene or reinforced high-density polyethylene plastic pallets are used, the classification of the commodity unit shall be increased two classes except for Class IV commodity, which shall be increased to a cartoned unexpanded Group A plastic commodity.
- 5.6.2.3.1** Pallets shall be assumed to be reinforced if no permanent marking or manufacturer's certification of nonreinforcement is provided.
- 5.6.2.4** No increase in the commodity classification shall be required for Group A plastic commodities stored on plastic pallets.
- 5.6.2.5** For ceiling-only sprinkler protection, the requirements of 5.6.2.2 and 5.6.2.3 shall not apply where plastic pallets are used and where the sprinkler system uses spray sprinklers with a minimum K-factor of K-16.8 (240).
- 5.6.2.6** The requirements of 5.6.2.2 through 5.6.2.7 shall not apply to nonwood pallets that have demonstrated a fire hazard that is equal to or less than wood pallets and are listed as such.
- 5.6.2.7** For Class I through Class IV commodities stored on plastic pallets when other than wood, metal, or polypropylene or high-density polyethylene plastic pallets are used, the classification of the commodity unit shall be determined by specific testing conducted by a national testing laboratory or shall be increased two classes.

12.12* Protection of Idle Pallets.

12.12.1 Wood Pallets.

- 12.12.1.1*** Wood pallets shall be permitted to be stored in the following arrangements:

- (1) Stored outside
- (2) Stored in a detached structure
- (3) Stored indoors where arranged and protected in accordance with 12.12.1.2

Table 12.12.1.2(a) Control Mode Density/Area Sprinkler Protection for Indoor Storage of Idle Wood Pallets

12.12.2 Plastic Pallets.

12.12.2.1 Plastic pallets shall be permitted to be stored in the following manners:

- (1) Plastic pallets shall be permitted to be stored outside.
- (2) Plastic pallets shall be permitted to be stored in a detached structure.
- (3) Plastic pallets shall be permitted to be stored indoors where arranged and protected in accordance with the requirements of 12.12.2.2.

Cost Impact: The code change proposal will not increase the cost of construction.

F272-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

3206.4.1 (NEW)-F-DAVIDSON

F273 – 13

3206.6.1.1

Proponent: Elley Klausbruckner representing Klausbruckner & Associates Inc (ek@klausbruckner.com)

Revise as follows:

3206.6.1.1 Number of doors required. A minimum of one access door shall be provided in each 100 lineal feet (30 480 mm), or fraction thereof, of the exterior walls that face required fire apparatus access roads. The required access doors shall be distributed such that the lineal distance between adjacent access doors does not exceed 100 feet (30 480 mm).

Exception: The lineal distance between adjacent access doors can exceed 100 feet (30 480 mm) in existing building where no change in occupancy is proposed. Final number and distribution of access doors in existing building shall be approved.

Reason: Many existing buildings do not meet the requirements of 100 foot distribution required in the second sentence of 3206.6.1.1. The section stating "The required access doors shall be distributed such that the lineal distance between adjacent access doors does not exceed 100 feet (30 480 mm)" was proposed and first appeared in the 2009 Edition of the Fire Code. Existing warehouses where one tenant moves out and a new tenant moves in will require a new high piled storage permit. As part of the permit, the current/adopted edition of Chapter 32 is applied which would result in many cases cutting holes in [in many cases concrete] exterior walls and/or restriction in business as a result of adding doors where currently roll up doors exist. This would allow a small amount of flexibility for building owners of existing buildings and the fire code official when adding doors appears costly and/or impractical.

Cost Impact: The code change proposal will not increase the cost of construction.

F273-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

3206.6.1.1-F-KLAUSBRUCKNER

F274 – 13

3206.9.3

Proponent: Elley Klausbruckner representing Klausbruckner & Associates Inc (ek@klausbruckner.com)

Revise as follows:

3206.9.3 Dead ends. Dead-end aisles shall ~~be in accordance with Chapter 10~~ not exceed 50 feet (15240 mm).

Reason: There are no dead-end requirements for aisles for storage warehouses in Chapter 10. The only dead end requirements in Chapter 10 apply to corridors [Section 1018.4] and in assembly occupancies.[Section 1028.9.5], as well as in existing occupancies [Section and Table 1104.17.2]. There are no requirements applicable to a warehouse and/or high piled storage area.

Cost Impact: The code change proposal may increase the cost of construction.

F274-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

3206.9.3-F-KLAUSBRUCKNER

F275 – 13

3208.2.1, Chapter 80

Proponent: Jesse J. Beitel, Hughes Associates, Inc, representing United Technologies Corporation
(jbeitel@haifire.com)

Revise as follows:

3208.2.1 Plastic pallets and shelves. Storage on plastic pallets or plastic shelves shall be protected by approved specially engineered fire protection systems.

Exception: Plastic pallets listed and labeled in accordance with UL 2335 or FM 4996 shall be treated as wood pallets for determining required sprinkler protection.

Add new standard to Chapter 80 as follows:

FM

ANSI/FM 4996-13 Approval Standard for Classification of Pallets and Other Material Handling Products as Equivalent to Wood Pallets

Reason: This Code proposal adds an alternative test method for the purpose of determining if a plastic pallet is equivalent to a wood pallet. This test method is used by FM Approvals.

The test method requires that a plastic pallet be subjected to a series of fire tests. Upon successful completion of the required tests, a plastic pallet can be determined to be equivalent to a wood pallet.

The proposed test method, FM 4496 is currently being revised and is undergoing ANSI balloting. It is anticipated that the standard will be completed within the timeframe required by ICC.

Cost Impact: None

Analysis: A review of the standard proposed for inclusion in the code, FM 4996-13, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28), will be posted on the ICC website on or before April 1, 2013.

F275-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

3208.2.1-F-BEITEL

F276 – 13

3208.2.2

Proponent: William Fletcher, P.E., Fletcher Fire Protection Engineering

Revise as follows:

3208.2.2 Racks with solid shelving. Racks with solid shelving having an area greater than ~~32~~ 20 square feet (~~3-1.9~~ m^2), measured between *approved* flue spaces at all four edges of the shelf, shall be in accordance with this section.

Exceptions:

1. Racks with mesh, grated, slatted or similar shelves having uniform openings not more than 6 inches (152 mm) apart, comprised of at least 50 percent of the overall shelf area, and with *approved* flue spaces are allowed to be treated as racks without solid shelves.
2. Racks used for the storage of combustible paper records, with solid shelving, shall be in accordance with NFPA 13.

Reason: This proposal provides consistency with NFPA 13. Section 3.9.3.7.7 notes “shelves within racks with a surface area ≤ 20 sq ft, or 50% open slats is considered an open rack, and thus ESFR ceiling only protection is appropriate. This maximum 20 sq ft shelf rule is the usual standard most consultants follow when determining if the rack shelving can be considered open, and thus appropriate for ESFR protection.

Cost Impact: The change will not increase the cost of construction.

F276-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

3208.2.2-F-FLETCHER

F277 – 13

Table 3208.3

Proponent: William Fletcher, P.E., Fletcher Fire Protection Engineering

Revise as follows:

**TABLE 3208.3
REQUIRED FLUE SPACES FOR RACK STORAGE**

RACK CONFIGURATION	AUTOMATIC SPRINKLER PROTECTION		SPRINKLER AT THE CEILING WITH OR WITHOUT MINIMUM IN-RACK SPRINKLERS			IN-RACK SPRINKLERS AT EVERY TIER	NONSPRINKLERED
			≤ 25 feet		> 25 feet	Any height	Any height
	Storage height		Option 1	Option 2			
Single-row rack	Transverse flue space	Size ^{ba}	3 inches	Not Applicable	3 inches	Not Required	Not Required
		Vertically aligned	Not Required	Not Applicable	Yes	Not Applicable	Not Required
	Longitudinal flue space		Not Required	Not Applicable	Not Required	Not Required	Not Required
Double-row rack	Transverse flue space	Size ^{ba}	6 inches ^a	3 inches	3 inches	Not Required	Not Required
		Vertically aligned	Not Required	Not Required	Yes	Not Applicable	Not Required
	Longitudinal flue space		Not Required	6 inches	6 inches	Not Required	Not Required
Multi-row rack	Transverse flue space	Size ^{ba}	6 inches	Not Applicable	6 inches	Not Required	Not Required
		Vertically aligned	Not Required	Not Applicable	Yes	Not Applicable	Not Required
	Longitudinal flue space		Not Required	Not Applicable	Not Required	Not Required	Not Required

For 1 inch = 25.4 mm, 1 foot = 304.8 mm. SI:

a. ~~Three-inch transverse flue spaces shall be provided at least every 10 feet where ESFR sprinkler protection is provided.~~

b.a. Random variations are allowed, provided that the configuration does not obstruct water penetration.

Reason: I would like to start by noting that I see a lot of people in our industry (consultants, insurance, ahj's) not adhering to the guidelines of open shelving within racks, when using ceiling only, ESFR sprinkler systems. If a fire occurs with ESFR protection, and solid shelves are present within the racks, the fire may not be controlled/suppressed. Large areas of shelving, whether created by pallets, hand stacking of boxes and parts, or even plywood sheets will defeat the key mechanisms needed for suppression of a rack storage fire when ceiling only, ESFR heads are used. The solid shelves will block the heat from rising and quickly fusing the heads, horizontal fire spread occurs, and the water from the heads cannot travel down in to the racks, to achieve suppression. This has been demonstrated by full scale fire testing at FM Global's research lab, and other nationally recognized testing labs as well.

Supporting Information

My concern is with how the 2012, IFC, and 2010, CFC Sec. is written.

The maximum allowable area for shelving within racks to be considered "open" is <32 sq ft. per 3208.2.2.

Table 3208.3 then defines various transverse and longitudinal flue space options, for different rack configurations. For Double Row Racks, Table 3208.3 has Foot note "a" that says: 3 in. transverse flues required every 10 ft. when ESFR used. And, no longitudinal flues are needed.

If this code section is followed, a warehouse operator can have a 3 in transverse flue space every 10 ft. For a typical double row rack using 40 x 48 in. pallets, the depth of one side of the double row rack (1/2 H, in Fig A.3.9.3. 7 "b" drawing below from NFPA 13) could be at least 4 ft or more. The total shelf area would then be 10 x 4 = 40 sq. ft. (unless open wire mesh shelving, or equivalent was used). This 40 sq. ft. helve area exceeds 32 sq. ft., and could theoretically be even larger than that.

- | | |
|------------------|---------------------------|
| A Load depth | G Pallet |
| B Load width | H Rack depth |
| E Storage height | L Longitudinal flue space |
| F Commodity | T Transverse flue space |

FIGURE A.3.9.3.7(b)
Double-Row Racks Without Solid or Slatted Shelves.

The racks would then look more like Figure A.3.9.3.7© below.

- | | |
|------------------|---------------------------|
| A Shelf depth | H Rack depth |
| B Shelf height | L Longitudinal flue space |
| E Storage height | T Transverse flue space |
| F Commodity | |

FIGURE A.3.9.3.7(c)
Double-Row Racks with Solid Shelves.

In referring to NFPA 13 (I am using the 2010 Version, which is similar to the 2012 version in this area), Section 3.9.3.7.7 notes "shelves within racks with a surface area ≤ 20 sq ft, or 50% open slats is considered an open rack, and thus ESFR ceiling only protection is appropriate. This maximum 20 sq ft shelf rule is the usual standard most consultants follow when determining if the rack shelving can be considered open, and thus appropriate for ESFR protection. If the 3 in. transverse flue every 10 ft. rule is applied, it is not even close, because as I noted, I can be well above 32 sq ft shelf area allowed by the IFC/CFC.

3.9.3.7.6 Rack Shelf Area.

The area of the horizontal surface of a shelf in a rack defined by perimeter aisle(s) or nominal 6 in. (152 mm) flue spaces on all four sides, or by the placement of loads that block openings that would otherwise serve as the required flue spaces.

3.9.3.7.7 Open Rack.

Racks without shelving or with shelving in racks that are fixed in place with shelves having a solid surface and a shelf area equal to or less than 20 ft² (1.9 m²) or with shelves having a wire mesh, slatted surface, or other material with openings representing at least 50 percent of the shelf area including the horizontal area of rack members and where the flue spaces are maintained.

3.9.3.7.8 Slatted Shelf Rack.

A rack where shelves are fixed in place with a series of narrow individual solid supports used as the shelf material and spaced apart with regular openings.

3.9.3.7.9 Solid Shelf Rack.

A rack where shelves are fixed in place with a solid, slatted, or wire mesh barrier used as the shelf material and having limited openings in the shelf area.

3.9.3.8 Solid Shelving.

Solid shelving is fixed in place, slatted, wire mesh, or other type of shelves located within racks. The area of a solid shelf is defined by perimeter aisle or flue space on all four sides. Solid shelves having an area equal to or less than 20 ft² (1.9 m²) shall be defined as open racks. Shelves of wire mesh, slats, or other materials more than 50 percent open and where the flue spaces are maintained shall be defined as open racks.

I therefore don't believe the Fire Code adequately addresses this topic, and allows somewhat of a loop hole that can allow ESFR protection with solid shelves. And I can tell you, I am seeing this first hand at many large warehouses I visit in my 24 year career.

Cost Impact: This proposal will not increase the cost of construction.

F277-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

3208.3T-F-FLETCHER

F278 – 13

3304.2, 3304.3 (New), 3304.4

Proponent: Marcelo M Hirschler, GBH International (gbhint@aol.com)

Revise as follows:

~~**3304.2 Waste disposal.** Combustible debris shall not be accumulated within buildings. Combustible debris, rubbish and waste material shall be removed from buildings at the end of each shift of work. Combustible debris, rubbish and waste material shall not be disposed of by burning on the site unless approved.~~

3304.2 Combustible debris, rubbish and waste. Combustible debris, rubbish and waste material shall comply with the requirements of Sections 3304.2.1 through 3304.2.4.

3304.2.1 Combustible debris, rubbish and waste material shall not be accumulated within buildings.

3304.2.2 Combustible debris, rubbish and waste material shall be removed from buildings at the end of each shift of work.

3304.2.3 Rubbish containers. Containers with tight-fitting or self-closing lids shall be provided for temporary storage of combustible debris, rubbish and waste material, until the end of each shift of work. The rubbish containers shall be constructed entirely of materials that comply with any one of the following:

1. Noncombustible materials.
2. Materials that meet a peak rate of heat release not exceeding 300 kW/m^2 when tested in accordance with ASTM E 1354 at an incident heat flux of 50 kW/m^2 in the horizontal orientation.

3304.2.4 Spontaneous ignition. Materials susceptible to spontaneous ignition, such as oily rags, shall be stored in a *listed* disposal container.

3304.3 Burning of combustible debris, rubbish and waste. Combustible debris, rubbish and waste material shall not be disposed of by burning on the site unless *approved*.

3304.3 3304.4 Open burning. *Open burning* shall comply with Section 307.

~~**3304.4 Spontaneous ignition.** Materials susceptible to spontaneous ignition, such as oily rags, shall be stored in a *listed* disposal container.~~

Reason: This section needs to be rewritten in a more logical fashion because 3304.2 needs to address what to do with combustible debris, rubbish and waste but not address prohibitions or *what not to do*, which should be covered in another section (burning of the rubbish). The use of the phrase "combustible debris, rubbish and waste material" makes this section consistent with other sections of the IFC.

When dealing with what needs to be done, the proper sequence is: (a) don't accumulate it, (b) remove it at the end of a work shift and (c) (which is missing) put it in appropriate rubbish containers while you are working. Section 3304.4 addresses a special rubbish container for materials susceptible to spontaneous ignition and should also be covered under 3304.2 and not in a separate section.

With regard to burning of combustible waste, this should have its own section, preceding the section on open burning, and should not be covered under what to do with rubbish.

The added requirement for the rubbish containers (other than those for spontaneous ignition materials) tells inspectors that rubbish containers should be provided for temporary storage of combustible rubbish (until the end of the shift of work). Such containers should be constructed of materials that have been shown to be safe by meeting a very severe fire test, just like those required by section 808 for I1, I2 and I3 occupancies. A key requirement is that the lids be tight fitting or self-closing.

Cost Impact: Minimal.

F278-12

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

3304.2 (NEW)-F-HIRSCHLER

F279 – 13

3304.2.1 (New)

Proponent: Marcelo M Hirschler, GBH International (gbhint@aol.com)

Add new text as follows:

3304.2.1 Rubbish containers. Containers with tight-fitting or self-closing lids shall be provided for temporary storage of combustible debris, rubbish and waste material, until the end of each shift of work. The rubbish containers shall be constructed entirely of materials that comply with either of the following:

1. Noncombustible materials.
2. Materials that meet a peak rate of heat release not exceeding 300 kW/m² when tested in accordance with ASTM E 1354 at an incident heat flux of 50 kW/m² in the horizontal orientation.

Reason: Rubbish containers should be provided for temporary storage of combustible rubbish (until the end of the shift of work). Such containers need not be constructed of metal but can be constructed of other noncombustible materials, including materials that have been shown to be safe by meeting a very severe fire test, just like those required by section 808 for I1, I2 and I3 occupancies. A key requirement is that the lids be tight fitting or self closing. Note that this does not address materials susceptible to spontaneous ignition, such as oily rags, covered by 3304.4. The use of the phrase "combustible debris, rubbish and waste" makes this section consistent with other sections of the IFC.

Cost Impact: Minimal

F279-12

3304.2.1 (NEW)-F-HIRSCHLER

F280 – 13

3306.2 (New), Chapter 80

Proponent: Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azubiamia@yahoo.com)

Revise as follows:

3306.2 Cleaning with flammable gas. Flammable gases shall not be used to clean or remove debris from piping open to the atmosphere.

3306.2.1 Pipe cleaning and purging. The cleaning and purging of flammable gas piping systems, including cleaning new or existing piping systems, purging piping systems into service, and purging piping systems out of service shall comply with NFPA 56.

Exceptions:

1. Compressed gas piping systems other than fuel gas piping systems where in accordance with Chapter 53.
2. Piping systems regulated by the *International Fuel Gas Code*.
3. Liquefied petroleum gas systems in accordance with Chapter 61.

Add a new referenced standard to Chapter 80 as follows:

NFPA

56-12 *Fire and Explosion Prevention During Cleaning and Purging of Flammable Gas Piping Systems*
3306.2.1

Reason: In the past few years two explosions that killed 10 individuals were attributed to workers using natural gas flowing at high velocities to clean/clear fuel gas piping during the commissioning of fuel gas piping at industrial plants. The flammable gas and debris from the piping were subsequently vented to the atmosphere and ignited by sparks, one of which was suspected to be caused by static electricity. For details on the incidents see the U.S. Chemical Safety Board report at: <http://www.csb.gov/assets/document/KleenUrgentRec.pdf>

The practice of using flammable gases to clean or remove debris from fuel piping that is open to the atmosphere is not currently covered by the International Fire Code. This proposal revises Chapter 33 "Fire Safety During Construction and Demolition" requirements to prohibit this practice in piping systems open to the atmosphere.

The NFPA 56 *Provisional Standard for Fire and Explosion Prevention During Cleaning and Purging of Flammable Gas Piping Systems* provides minimum safety requirements for the cleaning and purging of flammable gas piping systems, including cleaning new or existing piping systems, purging piping systems into service, and purging piping systems out of service. It includes the appropriate managerial and operational requirements necessary to ensure safe outcomes. NFPA 56 compliments the proposal and also does not allow flammable gases to be used for internal cleaning of piping open to the atmosphere.

The intent of the proposal is to address fire and explosion hazards with flammable gas piping that is typically found in electric generating plants and in industrial, institutional, and commercial applications.

It is not the intent of this proposal to cover cleaning or purging of (1) compressed gas piping systems other than fuel gas piping systems that comply with Chapter 53, (2) piping systems regulated by the International Fuel Gas Code, (3) liquefied petroleum gas systems that comply with Chapter 61, or (4) piping systems that are not open to the atmosphere.

This proposal is submitted by the ICC Fire Code Action Committee (FCAC). This ICC committee was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portions thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the Fire-CAC has held 6 open meetings and numerous Regional Work Group and Task Group meetings and conference calls which included members of the committees as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the FAC website at: <http://www.iccsafe.org/cs/CAC/Pages/default.aspx>.

Cost Impact: Approval of this change will increase the cost of flammable gas pipe purging because only inert or simple asphyxiant gases will be allowed.

Analysis: A review of the standard proposed for inclusion in the code, NFPA 56-12, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28), will be posted on the ICC website on or before April 1, 2013.

Proponent: Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azubiamia@yahoo.com)

Add new text as follows:

3313.1 (IBC [F] 3311.1, IEBC [F] 1506.1) Where required. In buildings required to have standpipes by Section 905.3.1, not less than one standpipe shall be provided for use during construction. Such standpipes shall be installed prior to construction exceeding ~~when the progress of construction is not more than~~ 40 feet (12 192 mm) in height above the lowest level of fire department vehicle access. Such standpipe shall be provided with fire department hose connections at accessible locations adjacent to usable stairs. Such standpipes shall be extended as construction progresses to within one floor of the highest point of construction having secured decking or flooring.

Reason: This proposal is submitted by the ICC Fire Code Action Committee (FCAC). This ICC committee was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portions thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the Fire-CAC has held 6 open meetings and numerous Regional Work Group and Task Group meetings and conference calls which included members of the committees as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the FAC website at: <http://www.iccsafe.org/cs/CAC/Pages/default.aspx>.

This code change proposal is intended to clarify the requirement for the timing of the installation of a standpipe during construction. The intent of the existing language is to have the standpipe installed by the time construction reaches 40 feet. However, based on the wording of the section, the standpipe could be required as soon as construction exceeds one story.

The current language states that the standpipe shall be installed at the time when the construction is 40 feet or less. This section has been applied to buildings that are only 15 in height.

The intent seems to be that standpipes are installed when the construction extends beyond the reach of firefighting operations utilizing ground level hose streams and ground ladders.

The proposed revision to this section allows construction up to 40 feet in height, but requires the standpipe to be installed before continuing beyond 40 feet.

Cost Impact: This code change will not increase the cost of construction

F281-13

F282 – 13

3510 (New), 202, 3504.1.7, 5704.2.7.6, Chapter 80

Proponent: Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azubiamia@yahoo.com)

Add new text as follows:

SECTION 3510 **HOT WORK ON FLAMMABLE AND COMBUSTIBLE LIQUID STORAGE TANKS**

3510.1 General. Hot work performed on the interior or the exterior of tanks that hold or have held flammable or combustible liquids shall be in accordance with 3510.2.1 through 3510.2.6 and Chapters 4,5,6,7 and 10 of NFPA 326.

3510.2 Prevention. The following steps shall be taken to minimize hazards when hot work must be performed on a flammable or combustible liquid storage container:

1. Use alternative methods to avoid hot work when possible
2. Analyze the hazards prior to performing hot work, identify the potential hazards and the methods of hazard control.
3. Hot work shall conform to the requirements of the code or standard to which the container was originally fabricated.
4. Test the immediate and surrounding work area with a combustible gas detector and provide for a means of continuing monitoring while conducting the hot work.
5. Qualified employees and contractors performing hot work shall use an industry approved hot work permit System to control the work.
6. Personnel shall be properly trained on hot work policies and procedures regarding equipment, safety, hazard controls and job specific requirements.
7. On-site safety supervision shall be present when hot work is in progress to protect the personnel conducting the hot work and provide additional overview of site specific hazards.

SECTION 202 **GENERAL DEFINITIONS**

COMBUSTIBLE GAS DETECTOR. An instrument that samples the local atmosphere and indicates the presence of ignitable vapors or gases within the flammable or explosive range expressed as a volume percent in air.

Revise as follows:

3504.1.7 Precautions in hot work. Hot work shall not be performed on containers or equipment that contains or has contained flammable liquids, gases or solids until the containers and equipment have been thoroughly cleaned, inerted or purged; except that “hot tapping” shall be allowed on tanks and pipe lines when such work is to be conducted by *approved* personnel. Hot work on flammable and combustible liquid storage tanks shall be conducted in accordance with Section 3510.

Revise as follows:

5704.2.7.6 Repair, alteration or reconstruction of tanks and piping. The repair, *alteration* or reconstruction, including ~~welding, cutting and hot tapping~~ of storage tanks and piping that have been placed in service, shall be in accordance with NFPA 30. Hot work, as defined in Section 202, on such tanks shall be conducted in accordance with Section 3510.

Add a new standard to Chapter 80:

NFPA

326- 2010 Standard for the Safeguarding of Tanks and Containers for Entry, Cleaning or Repair,.

Reason: This proposal is submitted by the ICC Fire Code Action Committee (FCAC). This ICC committee was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portions thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the Fire-CAC has held 6 open meetings and numerous Regional Work Group and Task Group meetings and conference calls which included members of the committees as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the FAC website at: <http://www.iccsafe.org/cs/CAC/Pages/default.aspx>.

There are numerous Hot Work permit and policy guidelines for every industry. There have been numerous incidents documented involving loss of life, injury and property damage occurring when hot work has occurred and industry specific precautions were not followed or personnel did not understand the hazard or risk.

This change will improve the general guidelines in the IFC for safely conducting hot work. The only references to hot work on flammable and combustible tanks are in regards to IFC Chapter 3504.1.7 and Chapter 5706 as it pertains to bulk handling and refineries.

This proposal recognizes that API RP 2009, 2002 edition; Safe Welding and Cutting Practices in Refineries, Gas Plants and Petrochemical Plants, is adopted by reference specific to a particular application within industry. Interestingly API 2009 is a recommended practice and not a standard. I propose NFPA 326 be adopted as a viable standard to provide specific safety procedures for hot work on tanks that fall outside of the scope of IFC Chapter 57.

Additionally, the Chemical Safety Board has published general guidelines applicable to most every situation welding or cutting on flammable, combustible or toxic tanks occur and I have included those steps to consider within a new section in IFC chapter 35 so anyone referencing what to do to be safe has some direction and a significant pointer to the standard applicable for the work to be accomplished.

Cost Impact: This code change will not increase the cost of construction

Analysis: A review of the standard proposed for inclusion in the code, NFPA 326-10, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28), will be posted on the ICC website on or before April 1, 2013.

3504.1.7-F-ZUBIA-FCAC

F283 – 13

3603.4

Proponent: Marcelo M Hirschler, GBH International (gbhint@aol.com)

Revise as follows:

3603.4 Rubbish containers. ~~Metal containers with tight-fitting or self-closing lids shall be provided for the temporary storage of combustible trash or rubbish.~~ Containers with tight fitting or self-closing lids shall be provided for temporary storage of combustible debris, rubbish and waste material. The rubbish containers shall be constructed entirely of materials that comply with any one of the following:

1. Noncombustible materials.
2. Materials that meet a peak rate of heat release not exceeding 300 kW/m² when tested in accordance with ASTM E 1354 at an incident heat flux of 50 kW/m² in the horizontal orientation.

Reason: Rubbish containers need not be constructed of metal but can be constructed of other noncombustible materials, including materials that have been shown to be safe by meeting a very severe fire test, just like those required by section 808 for I1, I2 and I3 occupancies. The key requirement that the lids be tight fitting or self closing is retained in the proposal. Note that the requirement covers all type of rubbish and is not intended to address spills of combustible or flammable liquids, covered by 3603.3. The use of the phrase "combustible debris, rubbish and waste material" makes this section consistent with other sections of the IFC.

Cost Impact: This should lower costs by offering more alternatives.

5001.1, Table 5003.1.1(1) [IBC [F] 307.1(1)], Table 5003.1.1(2) [IBC [F] 307.1(2)]; 5701.2

Proponent: Elley Klausbruckner representing Klausbruckner & Associates Inc (ek@klausbruckner.com)

Revise as follows:

5001.1 Scope. Prevention, control and mitigation of dangerous conditions related to storage, dispensing, use and handling of hazardous materials shall be in accordance with this chapter.

This chapter shall apply to all hazardous materials, including those materials regulated elsewhere in this code, except that when specific requirements are provided in other chapters, those specific requirements shall apply in accordance with the applicable chapter. Where a material has multiple hazards, all hazards shall be addressed.

Exceptions:

1. In retail or wholesale sales occupancies, the quantities of medicines, foodstuffs; or consumer ~~or industrial~~ products and cosmetics containing not more than 50 percent by volume of water-miscible liquids and with the remainder of the solutions not being flammable shall not be limited, provided such materials are packaged in individual containers not exceeding 1.3 gallons (5 L).
- 2 through 11 *(No change to current text)*

TABLE 5003.1.1(1) [IBC [F] 307.1(1)] MAXIMUM ALLOWABLE QUANTITY PER CONTROL AREA OF HAZARDOUS MATERIALS POSING A PHYSICAL HAZARD^{a, j, m, n, p}

(No changes to table)

For SI: 1 cubic foot = 0.02832 m³, 1 pound = 0.454 kg, 1 gallon = 3.785 L.

- a. For use of control areas, see Section 5003.8.3.
- b. The aggregate quantity in use and storage shall not exceed the quantity listed for storage.
- c. The quantities of alcoholic beverages in retail and wholesale sales occupancies shall not be limited providing the liquids are packaged in individual containers not exceeding 1.3 gallons. In retail and wholesale sales occupancies, the quantities of medicines, foodstuffs; or consumer ~~or industrial~~ products, and cosmetics containing not more than 50 percent by volume of water-miscible liquids with the remainder of the solutions not being flammable shall not be limited, provided that such materials are packaged in individual containers not exceeding 1.3 gallons.
- d. Maximum allowable quantities shall be increased 100 percent in buildings equipped throughout with an approved automatic sprinkler system in accordance with Section 903.3.1.1. Where Note e also applies, the increase for both notes shall be applied accumulatively.

TABLE 5003.1.1(2) [IBC [F] 307.1(2)] MAXIMUM ALLOWABLE QUANTITY PER CONTROL AREA OF HAZARDOUS MATERIAL POSING A HEALTH HAZARD^{a, b, c, h, i}

(No changes to table)

For SI: 1 cubic foot = 0.02832 m³, 1 pound = 0.454 kg, 1 gallon = 3.785 L.

- a. For use of control areas, see Section 5003.8.3.
- b. In retail and wholesale sales occupancies, the quantities of medicines, foodstuffs; or consumer ~~or industrial~~ products, and cosmetics, containing not more than 50 percent by volume of water-miscible liquids and with the remainder of the solutions not being flammable, shall not be limited, provided that such materials are packaged in individual containers not exceeding 1.3 gallons.
- c through i *(No changes to current text)*

5701.2 Nonapplicability. This chapter shall not apply to liquids as otherwise provided in other laws or regulations or chapters of this code, including:

1. Specific provisions for flammable liquids in motor fuel-dispensing facilities, repair garages, airports and marinas in Chapter 23.
2. Medicines, foodstuffs, cosmetics, and commercial, or institutional and industrial products containing not more than 50 percent by volume of water-miscible liquids and with the remainder of the solution not being flammable, provided that such materials are packaged in individual containers not exceeding 1.3 gallons (5 L).
3. through 10. *(No change to current text.)*

Reason: The term "Industrial products" can apply to anything. A wholesaler of car and truck batteries containing sulfuric acid [e.g. exceeding the MAQs for Toxic and Corrosive liquids] would be exempt by this definition. The original intent of this code section is to exempt materials in smaller containers in occupancies such as supermarkets and pharmacies the small amounts of water-miscible hazardous materials [e.g. household bleach, make up, face toners, etc.] contribute negligible amounts of fuel to a fire.

Cost Impact: The code change proposal will not increase the cost of construction.

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

5003.1.1(1)T-F-KLAUSBRUCKNER

F285 – 13

5001.1, 5004.2.2, 5004.3, 5701.2

Proponent: Brad Emerick, Denver Fire Department representing the Fire Marshal's Association of Colorado (FMAC) and the Colorado Chapter of the ICC (CCICC) (brad.emerick@denvergov.org)

Revise as follows:

5001.1 Scope. Prevention, control and mitigation of dangerous conditions related to storage, dispensing, use and handling of hazardous materials shall be in accordance with this chapter.

This chapter shall apply to all hazardous materials, including those materials regulated elsewhere in this code, except that when specific requirements are provided in other chapters, those specific requirements shall apply in accordance with the applicable chapter. Where a material has multiple hazards, all hazards shall be addressed.

Exceptions:

1 through 9 *(No change to current text)*

~~10. The storage of distilled spirits and wines in wooden barrels and casks.~~

11. *(No change to current text)*

5004.2.2 Secondary containment for hazardous material liquids and solids. Where required by Table 5004.2.2 buildings, rooms or areas used for the storage of hazardous materials liquids or solids shall be provided with secondary containment in accordance with this section when the capacity of an individual vessel or the aggregate capacity of multiple vessels exceeds the following:

1. Liquids: Capacity of an individual vessel exceeds 55 gallons (208 L) or the aggregate capacity of multiple vessels exceeds 1,000 gallons (3785 L); and
2. Solids: Capacity of an individual vessel exceeds 550 pounds (250 kg) or the aggregate capacity of multiple vessels exceeds 10,000 pounds (4540 kg).

Exception: The release of a liquid or solid without secondary containment into a sanitary or storm-water drainage system or onto the ground is allowed when in compliance with federal, state, or local governmental agencies' regulations and permits.

5004.3 Ventilation. Indoor storage areas and storage buildings shall be provided with mechanical exhaust ventilation or natural ventilation where natural ventilation can be shown to be acceptable for the materials stored.

Exception Exceptions:

1. Storage areas for flammable solids complying with Chapter 59.

2. Storage areas for distilled spirits in wooden barrels or casks.

5701.2 Nonapplicability. This chapter shall not apply to liquids as otherwise provided in other laws or regulations or chapters of this code, including:

1 through 9 *(No change to current text)*

~~10. The storage of distilled spirits and wines in wooden barrels and casks.~~

11. The storage of fermented beverages with ethyl alcohol contents of 16% or less.

Reason: There is confusion about the applicability of flammable liquid (Chapter 57) hazardous materials (Chapter 50) provisions to distilled spirits because of the exceptions for distilled spirits and wines stored in wooden barrels and casks in IFC Chapters 50 and 57 (and NFPA 30). The issue arises because of the growing popularity of "boutique" or "craft" distillers locating their operations in urban areas. The proposed language clarifies bulk storage provisions for distilled spirits but does not alter the intent. The proposed language does not affect provisions applicable to use, nor those applicable to liquor storage in retail or wholesale establishments.

First, note distilled spirits are Class 1C and Class 1B flammable liquids. They are primarily comprised of ethyl alcohol (ethanol) and water with concentrations ranging from approximately 19% to 99%. The boiling point of pure ethanol is approximately 178°F so an ethanol mixture with water will boil between 178°F and 212°F. The closed cup flash point for a 19% concentration of ethanol in water is 100°F and for a 58% concentration is 73°F making the mixtures in this range Class 1C flammable liquids (these values are not adjusted for altitude). Ethanol concentrations in water between 58% and 99% are Class 1B flammable liquids.

Second, the Building Code establishes occupancy. If a quantity of a Class 1B or Class 1C flammable liquid exceeding the maximum allowable quantity (MAQ), the room in which it is located is an H3 Occupancy. Please remember this applies to bulk storage (casks, barrels, metal containers, etc. exceeding 1.3 gallon capacities) and not to liquor stores and wholesale distributors for which there are several exceptions.

Third, H occupancies have to be sprinklered. This is the primary provision overlooked because of the confusion noted above. This is not because wood is inherently safer than metal, plastic or glass – it is not. It was probably inserted in the legacy code(s) back when casks were stored in liquid storage warehouses separated by hundreds of feet from one another and urban distilleries weren't contemplated. It was probably held over today because there is not yet an established sprinkler criteria for the storage of Class 1C flammable liquids in wooden barrels and casks. **THIS HOWEVER DOES NOT MEAN THESE ROOMS SHOULD BE EXEMPT FROM SPRINKLERING REQUIREMENTS!** An engineered sprinkler design is required.

Fourth, the applicable code requirements have not been changed. The UBC legacy code excepted distilled spirits stored in wooden barrels and casks from the secondary containment and ventilation requirements normally mandated for flammable liquids. The exception was often misinterpreted even then to extend to the entire range of code provisions. When flammable liquids requirements were brought into the IFC, the exception was moved to the scoping provisions which created the confusion recurring today. The deletion of the exception in Section 5001.1 removes the confusion associated with the applicable requirements. The modifications to Sections 5004.2.2 and 5004.3 reestablish the exceptions to secondary containment and ventilation contained in the legacy code.

The Nonapplicability of Chapter 57 to distilled spirits is retained. The word "wines" is removed from the exception for two reasons:

- a) if the intent to read "distilled wines" then distilled spirits already includes this; and
- b) if the intent is to read "wines and distilled spirits" then wines is included in new item 11 (along with beer).

Cost Impact: This change will not affect the cost of construction.

F285-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

5001.1-F-EMERICK

F286 – 13

5001.1

Proponent: Elley Klausbruckner representing Klausbruckner & Associates Inc (ek@klausbruckner.com)

Revise as follows:

5001.1 Scope. Prevention, control and mitigation of dangerous conditions related to storage, dispensing, use and handling of hazardous materials shall be in accordance with this chapter.

This chapter shall apply to all hazardous materials, including those materials regulated elsewhere in this code, except that when specific requirements are provided in other chapters, those specific requirements shall apply in accordance with the applicable chapter. Where a material has multiple hazards, all hazards shall be addressed.

Exceptions:

1 through 11 *(No change to current text)*

12. Specific provisions for flammable liquids in motor fuel-dispensing facilities, repair garages, airports and marinas in Chapter 23.

Reason: The same exception can be found in Section 5701.2 (Exception 1). The Flammable and Combustible Liquids chapters 57 of the fire code defer to Chapter 23 [Motor Fuel-Dispensing Facilities and Repair Garages] which is very specific and covers the unique use of flammable liquids at motor fuel dispensing facilities, airports and marinas. We believe that it has been the intent to apply Chapter 23 and not Chapters 50 and 57 to these specific operations.

Cost Impact: The code change proposal will not increase the cost of construction.

F286-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

5001.1-F-KLAUSBRUCKNER

F287 – 13

5001.1, 5701.2

Proponent: Elley Klausbruckner representing Klausbruckner & Associates Inc (ek@klausbruckner.com)

Revise as follows:

5001.1 Scope. Prevention, control and mitigation of dangerous conditions related to storage, dispensing, use and handling of hazardous materials shall be in accordance with this chapter.

This chapter shall apply to all hazardous materials, including those materials regulated elsewhere in this code, except that when specific requirements are provided in other chapters, those specific requirements shall apply in accordance with the applicable chapter. Where a material has multiple hazards, all hazards shall be addressed.

Exceptions:

1. through 11. *(No change to current text)*
12. Building and structures occupied for the application of flammable finishes, provided that such buildings or areas comply with the requirements of Chapter 24 of this code and Section 416 of the *International Building Code*.

5701.2 Nonapplicability. This chapter shall not apply to liquids as otherwise provided in other laws or regulations or chapters of this code, including:

1. through 10. *(No change to current text)*
11. Building and structures occupied for the application of flammable finishes, provided that such buildings or areas comply with the requirements of Chapter 24 of this code and Section 416 of the *International Building Code*.

Reason: Per IBC Section 307.1 (Exception 1), an occupancy used for the application of Flammable Finishes cannot be classified as an H Occupancy even if the Maximum Allowable Quantities are exceeded. If the committee believes the intent of IBC is exempt flammable finish operations as long as IBC Section 416 and IFC Chapter 24 are met, then this section helps further clarify the requirements. If the intent of IBC Section 307.1 (Exception 1) is to exempt only the H Occupancy classification [construction, allowable area, egress, etc.], but leave the applicable requirements of IFC Chapters 50 and 57, then this code change proposal should not be approved.

NOTE: Flammable finishes do not just include spray booths, but spray rooms, dipping operations, dual-component coating if applied by brush or roller in quantities exceeding 1 gallon, limited spray spaces, etc. However IBC Section 416 only addresses Spray Rooms and Spray Spaces.

Cost Impact: The code change proposal will decrease the cost of construction.

Combustible fiber ^a	Loose Baled ^o	H-3	(100) (1,000)	Not Applicable	Not Applicable	(100) (1,000)	Not Applicable	Not Applicable	(20) (200)	Not Applicable

(Portions of table not shown remain unchanged)

a. through p. (No change to current text)

q. Where manufactured, generated or used in such a manner that the concentration and conditions create a fire or explosion hazard based on information prepared in accordance with Section 104.7.2 (IBC [F] 414.1.3).

Revise as follows:

IBC [F] 307.5 (IFC 202) High-hazard Group H-3. Buildings and structures containing materials that readily support combustion or that pose a physical hazard shall be classified as Group H-3. Such materials shall include, but not be limited to, the following:

Class I, II or IIIA flammable or combustible liquids that are used or stored in normally closed containers or systems pressurized at 15 pounds per square inch gauge (103.4 kPa) or less

Combustible fibers, other than densely packed baled cotton, where manufactured, generated or used in such a manner that the concentration and conditions create a fire or explosion hazard based on information prepared in accordance with Section 414.1.3

Consumer fireworks, 1.4G (Class C, Common)

Cryogenic fluids, oxidizing

Flammable solids

Organic peroxides, Class II and III

Oxidizers, Class 2

Oxidizers, Class 3, that are used or stored in normally closed containers or systems pressurized at 15 pounds per square inch gauge (103 kPa) or less

Oxidizing gases

Unstable (reactive) materials, Class 2

Water-reactive materials, Class 2

Reason: *"Operations involving combustible fibers are typically associated with salvage, paper milling, recycling, cloth manufacturing, carpet and textile mills and agricultural operations, among others. The primary hazard associated with these operations is the abundance of materials and their ready ignitability. These so-called "Rag Districts," where cloth scrap and clippings are collected and separated for reuse in paper manufacturing, have been associated with catastrophic conflagrations as recently as the 1970s."*

IFC Code Commentary:

The main hazard of combustible fibers is the ignitability of the product with rapid flame spread over exposed material surfaces. There can also be an associated combustible dust hazard depending on how the material is being handled. Currently, Section 5203.5 requires protection against combustible dust hazards by reference to IFC Chapter 22 "Combustible Dust-Producing Operations". The combustible dust hazard can, and in most cases would, present a greater hazard than the fiber ignitability hazard. If a facility complies with IFC Chapter 22 along with referenced standards and the combustible dust hazard is eliminated, "note q" added to Table 5003.1.1(1) / [F] TABLE 307.1(1) in the 2012 edition of the IFC/IBC eliminates the Group H-2 designation for the combustible dust hazard. However, there is no similar provision for the ignitability hazard of the fibers. If the combustible fibers are not manufactured, generated or used in such a manner that the concentration and conditions create a fire or explosion hazard, then there should be a similar provision eliminating the H Group classification for the combustible fibers, a lesser hazard than the combustible dust. In many cases compliance with the reference to IFC Chapter 22 will eliminate the combustible fiber hazard as the combustible dust hazard is controlled.

This proposal adds note q to the entry in the tables for combustible fibers to eliminate the Group H-3 classification where it has been documented that when the fibers are being generated, stored or used, it is not in such a manner that the concentration and conditions create a fire or explosion hazard. The same language is also added to the Combustible fibers subdivision classification at IBC Section [F]307.5 as was done for combustible dust in code change F187-09/10.

The Biomass Feedstock Industry Committee on Codes and Standards (BFICOCS), led by Oak Ridge National Laboratory (ORNL), is an initiative of the Department of Energy Biomass Technologies Office (BTO). As part of the BTO integrated biorefinery efforts, the BFICOCS was assembled to conduct analysis of existing fire and building codes and to prepare proposed code changes designed to facilitate the development of the commercial-scale biomass industry while maintaining a focus on safety. The committee is made up of managers, engineers and code officials from industry, government laboratories, consulting firms, and the American Society of Agricultural and Biological Engineers.

Fire codes related to storage, handling, and preprocessing of biomass are based on industries that operate in a significantly different manner than the growing biomass-based energy industry. Applying current research on biomass properties and knowledge of conventional and emerging storage, handling, and preprocessing technologies, the BFICOCS has identified changes in the IFC that benefit industry and the public.

Cost Impact: The code change proposal will not increase the cost of construction.

F288-13

5003.1.1T-F-DAVIDSON

F289 – 13

Table 5003.1.1(1) [IBC [F] Table 307.1(1)]

Proponent: Glenn A. Dean, Virginia State Fire Marshal's Office (glenn.dean@vdfp.virginia.gov)

Revise as follows:

TABLE 5003.1.1(1) (IBC [F] Table 307.1(1))
MAXIMUM ALLOWABLE QUANTITY PER CONTROL AREA OF HAZARDOUS MATERIALS POSING
A PHYSICAL HAZARD^{a, j, m, n, p}

MATERIAL	CLASS	GROUP WHEN THE MAXIMUM ALLOWABLE QUANTITY IS EXCEEDED	STORAGE ^b			USE-CLOSED SYSTEMS ^b			USE-OPEN SYSTEMS ^b	
			Solid pounds (cubic feet)	Liquid gallons (pounds)	Gas cubic feet at NTP	Solid pounds (cubic feet)	Liquid gallons (pounds)	Gas cubic feet at NTP	Solid pounds (cubic feet)	Liquid gallons (pounds)
Consumer fireworks	1.4G	H-3	125 d, e, l	Not Applicable	Not Applicable	Not Applicable	Not Applicable	Not Applicable	Not Applicable	Not Applicable

(Portions of table not shown remain unchanged)

Reason: Based on an October 2007 report entitled "Fire Safety in Consumer Fireworks Storage and Retail Facilities – Hazard Assessment", the NFPA Standards Council began a lengthy discussion on the amount of consumer fireworks that should be effectively permitted in retail establishments and some the built-in safety requirements that should be associated with that amount. To date the effective allowable amount in the NFPA standards has been 125 pounds net with an available increase to 250 pounds if the building is protected throughout with an approved automatic sprinkler system installed in accordance with NFPA 13. This same provision is mirrored in the IFC in all respects for the maximum allowable quantity of consumer fireworks, including the increase for sprinkler protection, and like the IFC, to allow a building to contain more than that, the NFPA standard would require additional construction requirements akin to those for a Group H-3 building.

Beginning with the October 2007 report, the NFPA Standards Council has since called into question the appropriateness and reasoning of an increase based on sprinkler protection in the absence of test data justifying the increase. Because of the lack of test data to determine at what level or quantity of consumer fireworks above 125 pounds net could or should have the benefit of sprinkler protection, the Standards Council has ordered the issuance of a Tentative Interim Amendment (TIA), in process at the time of this submission, eliminating the option of an increase for sprinkler protection until such time as acceptable test data is submitted to justify an increase and to what level of increase it could be. Therefore, due to the TIA, the maximum amount of consumer fireworks in the NFPA standard for retail establishments is limited to 125 pounds net. There will be no provision for increasing the amount due to sprinkler protection. In addition, with the TIA the maximum size of consumer firework storage buildings will be limited to 12,000ft² in area. Full background information may be found at the document information tab at www.nfpa.org/1124.

For the same reasons, until such time as testing is completed, or if ever completed, this change is to delete the reference to footnote "d" that provided a 100% increase to the amount of consumer fireworks allowed if sprinkler protection is provided, when it has been revealed that the original increase was not based on a credible, verifiable series of tests to determine what the appropriate sprinkler design density should be for what may be typical of the quantities of consumer fireworks present in retail establishments and still not become a Group H-3 building.

Cost Impact: Cost of construction may increase.

Table 5003.1.1(1) [IBC [F] Table 307.1(1)], 5003.8.4

Proponent: Patrick A. McLaughlin McLaughlin & Associates, representing the Lonza Group and PPG Industries, Inc.(pmclaugma@aol.com)

Revise as follows:

TABLE 5003.1.1(1) (IBC [F] Table 307.1(1))
MAXIMUM ALLOWABLE QUANTITY PER CONTROL AREA OF HAZARDOUS MATERIALS POSING
A PHYSICAL HAZARD^{a, j, m, n, p}

MATERIAL	CLASS	GROUP WHEN THE MAXIMUM ALLOWABLE QUANTITY IS EXCEEDED	STORAGE ^b			USE-CLOSED SYSTEMS ^b			USE-OPEN SYSTEMS ^b	
			Solid pounds (cubic feet)	Liquid gallons (pounds)	Gas cubic feet at NTP	Solid pounds (cubic feet)	Liquid gallons (pounds)	Gas cubic feet at NTP	Solid pounds (cubic feet)	Liquid gallons (pounds)
Unstable (reactive)	4	H-1	1 ^{c, g}	(1) ^{c, g}	10 ^{c, g}	0.25 ^g	(0.25) ^g	2 ^{c, g}	0.25 ^g	(0.25) ^g
	3	H-1 or H-2	5 ^{d, e}	(5) ^{d, e}	50 ^{d, e}	1 ^d	(1) ^d	10 ^{d, e}	1 ^d	(1) ^d
	2	H-3	50 ^{d, e}	(50) ^{d, e}	250	50 ^d	(50) ^d	250	10 ^d	(10) ^d
	1	Not Applicable	Not Limited	Not Limited	<u>750</u> ^{d, e} Not Limited	Not Limited	Not Limited	<u>750</u> ^{d, e} Not Limited	Not Limited	Not Limited

(Portions of table not shown remain unchanged.)

a through d (No change to current text)

e. Maximum allowable quantities shall be increased 100 percent when stored in approved storage cabinets, day boxes, gas cabinets, gas rooms, exhausted enclosures, or listed safety cans. Listed safety cans shall be in accordance with Section 5003.9.10. Where Note d also applies, the increase for both notes shall be applied accumulatively.

f through q (No change to current text)

5003.8.4 Gas rooms. Where a gas room is used to increase maximum allowable quantity per control area or provided to comply with the provisions of Chapter 60, the gas room shall be in accordance with Sections 5003.8.4.1 and 5003.8.4.2.

Reason: The 250 cubic feet appears to be a transcription error as it was taken from the Uniform Fire Code which allowed 750 cubic feet. The change will bring the IFC into alignment with NFPA 55, 2010 and 2013 Editions.

Gas rooms are required to be protected by automatic sprinklers, separated based on the occupancy, and have ventilation designed to operate at a negative pressure. These requirements are similar to those that apply to exhausted enclosures which allow the quantity increase. Section 5003.8.4 is modified to insure that the requirements apply if footnote e is used to increase maximum allowable quantities. Accepting this change will bring consistency between the requirements for gas cabinets, exhausted enclosures, and gas rooms with respect to application and MAQ.

Cost Impact: The code change proposal will not increase the cost of construction.

Public Hearing: Committee: AS AM D
Assembly: ASF AMF DF

5003.1.1(1)T-F-MCLAUGHLIN

F291 – 13

Table 5003.1.1(1) [IBC Table [F] 307.1(1)]

Proponent: John Williams, CBO, Chair, ICC Ad Hoc Committee on Health Care (john.williams@doh.wa.gov) and Carl Baldassarra, P.E., FSFPE, Chair, ICC Code Technology Committee (cbaldassarra@RJAGroup.com)

Revise as follows:

TABLE 5003.1.1(1) [IBC Table [F] 307.1(1)]
MAXIMUM ALLOWABLE QUANTITY PER CONTROL AREA OF HAZARDOUS MATERIALS POSING
A PHYSICAL HAZARD^{a, j, m, n, p}

(Portions of table not shown remain unchanged)

a. through o. *(No change to current text)*

p. The following shall not be included in determining the maximum allowable quantities:

1. Liquid or gaseous fuel in fuel tanks on vehicles.
2. Liquid or gaseous fuel in fuel tanks on motorized equipment operated in accordance with this code.
3. Gaseous fuels in piping systems and fixed appliances regulated by the *International Fuel Gas Code*.
4. Liquid fuels in piping systems and fixed appliances regulated by the *International Mechanical Code*.
5. In Group I-2, alcohol based hand rubs classified as Class I or II liquids where installed in accordance with Sections 5705.5 and 5705.5.1. The location of the alcohol based hand rub (ABHR) dispensers shall be provided in the construction documents.

q. *(No change to current text)*

Reason: This proposed change will allow a reasonable amount of Alcohol based Hand Rub for infection control and patient life safety located in Group I-2 occupancies in appropriately sized dispensers to be located in control areas and permits the amounts not to be included in determining the maximum allowable quantities. IFC Section 5705.5 addresses the specifics regarding these amounts and locations.

This proposal is submitted by the ICC Ad Hoc Committee for Healthcare (AHC). The AHC was established by the ICC Board of Directors to evaluate and assess contemporary code issues relating to hospitals and ambulatory healthcare facilities. The AHC is composed of building code officials, fire code officials, hospital facility engineers, and state healthcare enforcement representatives. The goals of the committee are to ensure that the ICC family of codes appropriately addresses the fire and life safety concerns of a highly specialized and rapidly evolving healthcare delivery system. This process is part of a joint effort between ICC and the American Society for Healthcare Engineering (ASHE), a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. Since its inception in April, 2011, the AHC has held 8 open meetings and over 150 workgroup calls which included members of the AHC as well as any interested party to discuss and debate the proposed changes. All meeting materials and reports are posted on the AHC website at: <http://www.iccsafe.org/cs/AHC/Pages/default.aspx>

This proposal is being co-sponsored by the ICC Code Technology Committee. The ICC Board established the ICC Code Technology Committee (CTC) as the venue to discuss contemporary code issues in a committee setting which provides the necessary time and flexibility to allow for full participation and input by any interested party. The code issues are assigned to the CTC by the ICC Board as "areas of study". Information on the CTC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CTC effort can be downloaded from the following website: <http://www.iccsafe.org/cs/CTC/Pages/default.aspx>. Since its inception in April/2005, the CTC has held twenty-five meetings - all open to the public. In 2012, three of the 25 face-to-face meetings were held. In addition to the CTC meetings, the CTC established Study Groups (SG) of interested parties for each of the areas of study. These SG's are responsible for reviewing the available information and making recommendations to the CTC. All totaled, the SG's held over 70 conference calls in 2012.

Cost Impact: This proposal will not increase the cost of construction.

N/A = Not Applicable; NL = Not Limited; UD = Unclassified Detonable

- For use of control areas, see Section 5003.8.3.
- The aggregate quantity in use and storage shall not exceed the quantity listed for storage.
- The quantities of alcoholic beverages in retail and wholesale sales occupancies shall not be limited providing the liquids are packaged in individual containers not exceeding 1.3 gallons. In retail and wholesale sales occupancies, the quantities of medicines, foodstuffs, consumer or industrial products, and cosmetics containing not more than 50 percent by volume of water-miscible liquids with the remainder of the solutions not being flammable shall not be limited, provided that such materials are packaged in individual containers not exceeding 1.3 gallons.
- Maximum allowable quantities shall be increased 100 percent in buildings equipped throughout with an approved automatic sprinkler system in accordance with Section 903.3.1.1. Where Note e also applies, the increase for both notes shall be applied accumulatively.
- Maximum allowable quantities shall be increased 100 percent when stored in approved storage cabinets, day boxes, gas cabinets, exhausted enclosures, or in listed safety cans. ~~Listed safety cans shall be~~ in accordance with Section 5003.9.10. Where Note d also applies, the increase for both notes shall be applied accumulatively.
- Quantities shall not be limited in a building equipped throughout with an approved automatic sprinkler system in accordance with Section 903.3.1.1.
- Allowed only in buildings equipped throughout with an approved automatic sprinkler system.
- Containing not more than the maximum allowable quantity per control area of Class IA, Class IB or Class IC flammable liquids.
- The maximum allowable quantity shall not apply to fuel oil storage complying with Section 603.3.2.
- Quantities in parenthesis indicate quantity units in parenthesis at the head of each column.
- A maximum quantity of 200 pounds of solid or 20 gallons of liquid Class 3 oxidizers is allowed when such materials are necessary for maintenance purposes, operation or sanitation of equipment when the storage containers and the manner of storage are approved.
- Net weight of pyrotechnic composition of the fireworks. Where the net weight of the pyrotechnic composition of the fireworks is not known, 25 percent of the gross weight of the fireworks including packaging shall be used.
- For gallons of liquids, divide the amount in pounds by 10 in accordance with Section 5003.1.2.
- For storage and display quantities in Group M and storage quantities in Group S occupancies complying with Section 5003.11, see Table 5003.11.1.

- o. Densely-packed baled cotton that complies with the packing requirements of ISO 8115 shall not be included in this material class.
- p. The following shall not be included in determining the maximum allowable quantities:
 - 1. Liquid or gaseous fuel in fuel tanks on vehicles.
 - 2. Liquid or gaseous fuel in fuel tanks on motorized equipment operated in accordance with this code.
 - 3. Gaseous fuels in piping systems and fixed appliances regulated by the *International Fuel Gas Code*.
 - 4. Liquid fuels in piping systems and fixed appliances, regulated by the *International Mechanical Code*.
- q. Where manufactured, generated or used in such a manner that the concentration and conditions create a fire or explosion hazard based on information prepared in accordance with Section 104.7.2.

Revise IFC Table 5003.1.1(2) as follows:

- e~~f~~. For storage and display quantities in Group M and storage quantities in Group S occupancies complying with Section 414.2.5, see Tables 414.2.5(1) and 414.2.5(2).
- d~~b~~. The aggregate quantity in use and storage shall not exceed the quantity listed for storage.
- e~~d~~. Maximum allowable quantities shall be increased 100 percent in buildings equipped throughout with an *approved automatic sprinkler system* in accordance with Section 903.3.1.1. Where Note f also applies, the increase for both notes shall be applied cumulatively.
- f~~e~~. Maximum allowable quantities shall be increased 100 percent when stored in approved storage cabinets, gas cabinets or exhausted enclosures as specified in the *International Fire Code*. Where Note e also applies, the increase for both notes shall be applied cumulatively.
- g. Allowed only when stored in approved exhausted gas cabinets or exhausted enclosures as specified in the *International Fire Code*.
- h. Quantities in parenthesis indicate quantity units in parenthesis at the head of each column.
- i. For gallons of liquids, divide the amount in pounds by 10 in accordance with Section 5003.1.2 of the *International Fire Code*.

Reason: Correlation between these sets of tables in the IFC and IBC is critical. There is no reason that the tables need to be formatted differently or contain different wording. This proposal does not change any requirements in the codes. It is editorial in nature and is designed to provide uniformity and consistency for the requirements found in the sets of tables.

Items 1 and 2 are editorial and only simplify the table.

Item 3 is needed to correlate with revisions made in Items 1 and 2.

Item 4 alphabetizes the listings in the table and provides consistency in the header of the table. The revisions in the footnotes provide identical wording to the wording in the IBC.

Item 5 restructures the footnotes to provide consistency for both the Health Hazard table and the Physical Hazard table.

Item 6 duplicates the table from the IFC into the IBC.

Item 7 provides identical wording for the footnotes in the IBC as is found in the IFC.

Item 8 duplicates the table from the IFC into the IBC.

Item 9 provides identical wording for the footnotes in the IBC as is found in the IFC.

Cost Impact: The code change proposal will not increase the cost of construction.

5003.1.1(1)T-F-ZUBIA-FCAC

F293 – 13

Table 5003.1.1(3)

Proponent: Elley Klausbruckner representing Klausbruckner & Associates Inc (ek@klausbruckner.com)

Revise as follows:

TABLE 5003.1.1(3)
MAXIMUM ALLOWABLE QUANTITY PER CONTROL AREA OF HAZARDOUS MATERIALS POSING
A PHYSICAL HAZARD IN AN OUTDOOR CONTROL AREA^{a, b, c, d}

MATERIALS	CLASS	STORAGE ^b			USE-CLOSED SYSTEM ^b			USE-OPEN SYSTEM ^b	
		Solid Pounds (cubic feet)	Liquid gallons (pounds) ^d	Gas cubic feet at NTP	Solid Pounds (cubic feet)	Liquid gallons (pounds) ^d	Gas cubic feet at NTP	Solid Pounds (cubic feet)	Liquid gallons (pounds) ^d
Unstable (reactive)	4	2	(2)	20	1	(1)	2	0.25	(0.25)
	3	20	(20)	200	10	(10)	10	1	4 (1)
	2	200	(200)	1,000	100	(100)	250	10	40 (10)
	1	Not	Not	1,500	Not	Not	Not	Not	Not
		Limited	Limited		Limited	Limited	Limited	Limited	Limited

(Portions of the table not shown remain unchanged)

Reason: The amounts throughout the table are based on a conversion of 10 pounds per 1 gallon. Based on this conversion, effectively 10 times the amounts of water reactive 2 and 3 liquids in open system use are allowed than solids in the current table. Adding the parenthesis is to bring consistency in the requirements.

Cost Impact: The code change proposal will not increase the cost of construction.

5003.1.1(3)T-F-KLAUSBRUCKNER

F294 – 13

5003.2.1

Proponent: Daniel E. Nichols, P.E., New York State Department of State (dan.nichols@dos.ny.gov)

Revise as follows:

5003.2.1 Design and construction of containers, cylinders and tanks. Containers, cylinders and tanks shall be designed and constructed in accordance with *approved* standards. Containers, cylinders, tanks and other means used for containment of hazardous materials shall be of an *approved* type. Pressure vessels not otherwise regulated by this code shall comply with the ASME *Boiler and Pressure Vessel Code*.

Reason: The addition of the reference to the ASME Boiler and Pressure Vessel Code in the 2012 edition has added confusion to the IFC. A 'pressure vessel' is defined as "A closed vessel designed to operate at pressures above 15 psig (103 kPa)." This is not aligned with the requirements in the previous sentence, which states a "cylinder" (which is a closed vessel that has pressures higher than 40 psig and has a circular cross-section) shall be of an approved type. Nowhere in the code does it state that a cylinder is not a pressure vessel.

The proposal adds language to minimize confusion about applicable sections found in the product-specific hazardous materials chapters, such as 5301.2 for compressed gases and 6101.1 for the use of NFPA for liquefied petroleum gases. It is important to keep the allowance for approved types of containers, cylinders, tanks, and other means, even when it comes to pressurized storage components, since ASME is not the only standard for design. US Department of Transportation regulates pressurized storage components that are transported over public roads (The DOT specification). DOT differs from ASME in construction specifications as well as maintenance and testing. A vast majority of cylinders used to store common materials like propane, medical oxygen, carbon dioxide, helium, and compressed air are in DOT cylinders, not ASME.

This proposal is submitted with the endorsement of the New York State Building Officials Conference, the New York State Fire Marshals and Inspectors Association, and the Association of Fire Districts of New York State.

Cost Impact: This change is a clarification and has no cost impact.

F294-13

5003.2.1-F-NICHOLS

F295 – 13

5003.9, 5003.9.11 (New)

Proponent: John Williams, CBO, Chair, ICC Ad Hoc Committee on Health Care
(john.williams@doh.wa.gov)

Revise as follows:

5003.9 General safety precautions. General precautions for the safe storage, handling or care of hazardous materials shall be in accordance with Sections 5003.9.1 through ~~5003.9.10~~ 5003.9.11.

5003.9.11 Emergency showers and eyewash stations. In Group I-2 Condition 2, where the eyes or body of any person are at risk for exposure to injurious corrosive materials, suitable facilities for quick drenching or flushing of the eyes and body shall be provided within the work area for immediate emergency use. The emergency showers and eyewash stations shall be installed in accordance with the International Plumbing Code.

Reason: This proposal addresses KTag K134. The IPC already provides the installation requirements but the requirements are not called up in the IFC. This proposal uses verbiage from OSHA with some minor revisions to remove permissive language. The focus is only on corrosive materials which are defined in the IFC. The scope of this change is limited to Group I-2 condition 2 due to the scoping limitations of the Ad Hoc Healthcare Committee.

Source of verbiage (no copyright issues):

OSHA
1910.151(c)
Where the eyes or body of any person may be exposed to injurious corrosive materials, suitable facilities for quick drenching or flushing of the eyes and body shall be provided within the work area for immediate emergency use.

For Reference:

International Plumbing Code 2012

SECTION 411 EMERGENCY SHOWERS AND EYEWASH STATIONS

411.1 Approval. Emergency showers and eyewash stations shall conform to ISEA Z358.1.

411.2 Waste connection. Waste connections shall not be required for emergency showers and eyewash stations.

This proposal is submitted by the ICC Ad Hoc Committee for Healthcare (AHC). The AHC was established by the ICC Board of Directors to evaluate and assess contemporary code issues relating to hospitals and ambulatory healthcare facilities. The AHC is composed of building code officials, fire code officials, hospital facility engineers, and state healthcare enforcement representatives. The goals of the committee are to ensure that the ICC family of codes appropriately addresses the fire and life safety concerns of a highly specialized and rapidly evolving healthcare delivery system. This process is part of a joint effort between ICC and the American Society for Healthcare Engineering (ASHE), a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. Since its inception in April, 2011, the AHC has held 8 open meetings and over 150 workgroup calls which included members of the AHC as well as any interested party to discuss and debate the proposed changes. All meeting materials and reports are posted on the AHC website at: <http://www.iccsafe.org/cs/AHC/Pages/default.aspx>

Cost impact:

	Assembly:	ASF	AMF	DF

5003.9-F-WILLIAMS-ADHOC

F296 – 13

5003.11

Proponent: Richard C. Ramsey, Director of Engineering, Universal Power Group, representing Universal Power Group.

Revise as follows:

5003.11 Group M storage and display and Group S storage. The aggregate quantity of nonflammable solid and nonflammable or noncombustible liquid hazardous materials stored and displayed within a single *control area* of a Group M occupancy, or an outdoor *control area*, or stored in a single *control area* of a Group S occupancy, is allowed to exceed the *maximum allowable quantity per control area* indicated in Section 5003.1 when in accordance with Sections 5003.11.1 through 5003.11.3.10.

Exception: VRLA, lithium-ion, lithium metal polymer or other types of sealed batteries with immobilized electrolyte shall not require storage and display volumetric limitations.

Reason: IFC 2012 physical limitations on stocking (storage) of corrosive material inventory are too restrictive to allow sufficient VRLA battery inventory volume to do normal business at a large battery distribution center. According to IFC 2012, section 608.5 Spill control and neutralization Exception: VRLA, lithium-ion, lithium metal polymer or other types of sealed batteries with immobilized electrolyte shall not require spill control. Spill control is the majority of control for corrosive/hazardous materials. If there is no possibility of spill, why would there be a stocking limit to the amount of inventory warehoused in one location?

Cost Impact: The code change proposal will not increase the cost of construction.

Table 5003.11.1 [IBC [F] 414.2.5 (1)]

Proponent: Kirk Mitchell, Kirk Mitchell & Associates, LLL, representing Isocyanurates Industry Ad Hoc Committee (IIAHC) (pkmitchell@bellsouth.net)

Revise as follows:

TABLE 5003.11.1 [IBC [F] 414.2.5 (1)]
MAXIMUM ALLOWABLE QUANTITY PER INDOOR AND OUTDOOR CONTROL AREA IN GROUP M AND S OCCUPANCIES – NONFLAMMABLE SOLIDS, NONFLAMMABLE AND NONCOMBUSTIBLE LIQUIDS

CONDITION		MAXIMUM ALLOWABLE QUANTITY PER CONTROL AREA	
Material	Class	Solids pounds	Liquids gallons
A. HEALTH-HAZARD MATERIALS – NONFLAMMABLE AND NONCOMBUSTIBLE SOLIDS AND LIQUIDS			
2. Highly Toxics ^d	Not Applicable	20 ^{b,c}	2 ^{b,c}
3. Toxics ^{b,c,d}	Not Applicable	1,000	100

(Portions of table not shown remain unchanged)

For SI: 1 pounds = 0.454 kg, 1 gallon = 3.785 L, 1 cubic foot = 0.02832 m³

- a. Hazard categories are as specified in Section 5001.2.2
- b. Maximum allowable quantities shall be increased by 100 percent in buildings equipped throughout with an automatic sprinkler in accordance with Section 903.3.1.1. When Note c also applies, the increase for both notes shall be applied accumulatively.
- c. Maximum allowable quantities shall be increased by 100 percent when stored in approved storage cabinets in accordance with Section 5003.8. When Note b also applies, the increase for both notes shall be applied accumulatively.
- d. Toxic or highly toxic solids or liquids displayed in original packaging in Group M or S occupancies and intended for maintenance, operation of equipment, or sanitation when contained in individual packaging not exceeding 100 lb (45.4 kg) shall be limited to an aggregate of 1,200 lb (544.3 kg) or 220 gal (832.8 L). The increases allowed by Notes b and c shall not apply to highly toxic solids and liquids.
- d.e. See Table 5003.8.3.2 for design and number of control areas
- e.f. Maximum allowable quantities for other hazardous material categories shall be in accordance with Section 5003.1.
- f.g. Maximum allowable quantities shall be increased 100 percent in outdoor control areas.
- g.h. Maximum allowable quantities are permitted to be increased to 2,250 pounds when individual packages are in the original sealed containers from the manufacturer or packager and not exceed 10 pounds each.
- h.i. Maximum allowable quantities are permitted to be increased to 4,500 pounds when individual packages are in the original sealed containers from the manufacturer or packager and not exceed 10 pounds each.
- i.j. Quantities are unlimited where protected by an automatic sprinkler system.
- j.k. Quantities are unlimited in an outdoor control area.

Reason: The proposed change provides for a practical degree of storage flexibility for combinations of health hazard materials when intended for the designated use as ascribed. Additionally, the footnoted language is consistent with the updated revised footnoted material found in NFPA 400 Hazardous Materials Code (2013 Edition)

Cost Impact: No anticipated or projected cost impact with this proposal.

	Assembly:	ASF	AMF	DF

5003.11.1T-F-MITCHELL

F298 – 13

IFC: 5004.7; IBC [F] 414.5.3

Proponent: Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azubiamia@yahoo.com)

Revise as follows:

IFC 5004.7 Standby or emergency power. Where mechanical ventilation, treatment systems, temperature control, alarm, detection or other electrically operated systems are required, such systems shall be provided with an emergency or standby power system in accordance with NFPA 70 and Section 604.

Exceptions:

1. Emergency or standby power are not required for the following:
 - ~~4.~~ 1.1. Mechanical ventilation for storage of Class IB and Class IC flammable and combustible liquids in closed containers not exceeding ~~64/2~~ 6.5 gallons (25 L) capacity.
 - ~~2.~~ 1.2. Storage areas for Class 1 and 2 oxidizers.
 - ~~3.~~ 1.3. Storage areas for Class II, III, IV and V organic peroxides.
 - ~~4.~~ 1.4. Storage areas for asphyxiant, irritant and radioactive gases.
- ~~5.~~ For storage areas for highly toxic or toxic materials, see Sections 6004.2.2.8 and 6004.3.4.2.
- ~~6.~~ Standby power for mechanical ventilation, treatment systems and temperature control systems shall not be required where an approved fail-safe engineered system is installed.

For storage and use areas for highly toxic or toxic materials, see Sections 6004.2.2.8 and 6004.3.4.2.

IBC [F] 414.5.3 Emergency or standby power. Where mechanical ventilation, treatment systems, temperature control, alarm, detection or other electrically operated systems are required by the International Fire Code or this code, such systems shall be provided with an emergency or standby power system in accordance with Chapter 27.

Exceptions:

1. Emergency or standby power are not required for the following ~~storage areas~~:
 - 1.1. Mechanical ventilation for storage of Class IB and Class IC flammable and combustible liquids in closed containers not exceeding 6.5 gallons (25 L) capacity.
 - 1.2. Storage areas for Class 1 and 2 oxidizers.
 - 1.3. Storage areas for Class II, III, IV and V organic peroxides.
 - 1.4. Storage, use and handling areas for asphyxiant, irritant and radioactive gases.
 - ~~1.5. For storage, use and handling areas for highly toxic or toxic materials, see Sections 6004.2.2.8 and 6004.3.4.2 of the International Fire Code.~~
2. Standby power for mechanical ventilation, treatment systems and temperature control systems shall not be required where an approved fail-safe engineered system is installed.

For storage and use areas for highly toxic or toxic materials, see Sections 6004.2.2.8 and 6004.3.4.2 of the International Fire Code.

Reason: This proposal is intended to correlate the IBC requirements with the requirements in the IFC. Section 414.5.3 in the IBC should be the same as Section 5004.7 in the IFC. However, there are slight differences. This proposal will correct those differences and provide consistency between the codes.

The revisions in IFC Section 5004.7 and IBC Section 414.5.3 are based on the following:

1. Item 1 is duplicated from the IBC and placed into the IFC. The item is revised so that it is not limited to storage. This is consistent with the following text in Item 1.4 which currently addresses use and handling areas.

2. The items are renumbered as subsections consistent with the IBC format.
3. Item 1.4 is relocated as a second paragraph in the section. This provision is not an exception, it does not eliminate emergency or standby power, but rather it adds additional criteria. This is further confirmed by IFC Section 604.2.11 which states "Emergency power shall be provided for occupancies with highly toxic or toxic materials in accordance with Sections 6004.2.2.8 and 6004.3.4.2."

These two sections are then consistent and correlate with the other requirements found in the IFC and IBC. There is no change in requirements.

Cost Impact: The code change proposal will not increase the cost of construction.

F298-13

	Assembly:	ASF	AMF	DF

5004.7-F-ZUBIA-FCAC

F299 – 13

5104.1, 5104.1.1 (New), 202 (IBC [F] 202)

Proponent: Patrick A. McLaughlin McLaughlin & Associates, representing the Consumer Specialty Products Association (pmclaugma@aol.com)

Revise as follows:

5104.1 General. The inside storage of Level 2 and 3 aerosol products shall comply with Sections 5104.2 through 5104.7 and NFPA 30B. Level 1 aerosol products and those aerosol products covered by Section 5104.1.1 shall be considered equivalent to a Class III commodity and shall comply with the requirements for palletized or rack storage in NFPA 13.

5104.1.1 Aerosol products in plastic containers larger than 118 ml (4 fl. oz.) shall be considered to be equivalent to Class III commodities, as defined in NFPA 13, *Standard for the Installation of Sprinkler Systems*, where any of the following conditions are met:

1. Base product has no fire point when tested in accordance with ASTM D 92, *Standard Test Method for Flash and Fire Points by Cleveland Open Cup Tester*, and nonflammable propellant.
2. Base product has no sustained combustion as tested in accordance with "Method of Testing for Sustained Combustibility", Title 49 Code of Federal Regulations, Part 173, Appendix H, and nonflammable propellant.
3. Base product contains up to 20% by volume (15.8% by weight) of ethanol and/or isopropyl alcohol in an aqueous mix, and nonflammable propellant.
4. Base product contains 4% by weight or less of an emulsified flammable liquefied gas propellant within an aqueous base. The propellant shall remain emulsified for the life of the product. Where such propellant is not permanently emulsified then the propellant shall be nonflammable.

SECTION 202 (IBC [F] 202) GENERAL DEFINITIONS

AEROSOL CONTAINER. A metal can, or a glass or plastic bottle designed to dispense an aerosol. Metal cans or plastic containers shall be limited to a maximum size of 33.8 fluid ounces (1000 ml). Glass ~~or plastic~~ bottles shall be limited to a maximum size of 4 fluid ounces (118 ml).

Reason: A significant amount of new research has been completed on aerosol products in plastic containers that clearly defines a "low hazard" version of the product that can be stored in general purpose warehouses without significantly increasing the fire hazard. The following discussion provides an overview of the work that was done and the conclusions from the effort.

1) Aerosol Products in Plastic Containers – Propellant: Nonflammable; Base: Liquid Content that Does not Support Combustion

The fire hazard created by aerosol products in metal containers is driven by their propellant and the liquid content. An aerosol product that contains a nonflammable propellant and a liquid content that does not support combustion would have a Chemical Heat of Combustion of 0 kJ/g and be classified as a Level 1 aerosol product. Level 1 aerosols are protected using the same protection criteria needed for Class III commodities provided by NFPA 13.

The fire hazard of an aerosol product in a plastic container cannot be directly compared to aerosol products in metal containers. However, using commodity classification information for plastic containers filled with liquids that do not burn supports proposing a protection level for equivalent aerosol products. In this case, the content of the aerosol would not contribute to a fire. Only the primary (plastic container) and secondary (carton) packaging would contribute. If the aerosol was not pressurized, it would directly compare to products listed in NFPA 13 Annex A and FM Global Property Loss Prevention Data Sheet 8-1 as shown below.

NFPA 13 Annex A

Table A.5.6.3

Milk in Plastic – Class I

Bottles, Jars / Filled noncombustible liquids / Plastic, PET – Class I

FM Global Property Loss Prevention Data Sheet 8-1

2.2.2.2 Examples of Class I Commodities

4. Other – Noncombustible liquids in 5 gal (19 l) or smaller plastic containers

Both standards treat a plastic container filled with a liquid that does not burn as a Class I commodity. The addition of a nonflammable propellant to a plastic container will not change the burning properties of the commodity (it may result in a violent rupture with no change in burning rates or severity). The above discussion would point to classifying the aerosol products in plastic containers charged with a nonflammable propellant and liquid that does not burn as a Class I commodity. However, in an effort to provide consistency in the protection of aerosols, the protection proposal targets using the same protection currently recommended for Level 1 aerosols.

2) Aerosol Products in Plastic Containers – Propellant: Nonflammable; Base: Liquid Content Consists of up to 20% Ethanol or Isopropyl Alcohol in Aqueous Solution

An aerosol product in a plastic container that contains a liquid that burns will create a fire hazard at least as severe as the same liquid in an unpressurized plastic container. The fire hazard may increase because the container is pressurized and will definitely increase if it is pressurized with a flammable propellant. As the fire hazard of the aerosol's content increases, the fire hazard of the actual aerosol will increase as well. If on the other hand, the aerosol product in a plastic container was charged with liquid components that can easily be protected in an unpressurized plastic container, similar to the discussion under item 1, there is a good chance that the aerosol products in plastic containers can be protected with a similar level of protection. The only question might be the impact of adding nonflammable propellant.

FM Global has developed protection criteria for several alcohol water mixtures in plastic bottles. The alcohols used in the testing are ethanol and isopropyl alcohol. The mixtures ranged from 100% alcohol (approximate) down to 20% by volume alcohol/80% by volume water. The 20% alcohol/80% water mixture in a plastic bottle in cartons was tested in a full-scale array with the overview of the test presented in Table 1. This alcohol/water mixture does have a definable fire point; however, it produces unstable burning.

Table 1. FM Global Test Summary

Fire Test Summary – Diluted Alcohol Test Series		
Test Number		5
Test Date		1-19-99
Test Parameters	Commodity	20% isopropyl alcohol / 80% water in a 1 pint [470 ml] plastic container in cartons
	Storage Arrangement	Rack
	Storage Height (ft) [m]	Nominal 20 [6.1]
	No. Tiers	4
	Ceiling Height (ft) [m]	30 [9.1]
	Aisle Width (ft) [m]	8 [2.4]
	Sprinkler Type (K factor gpm/psi ^{0.5} [L/min/bar ^{0.5}], Temperature Rating)	K 5.6 [81]/ 286°F [140°C] / Standard Response
	Sprinkler Spacing (ft x ft) [m x m]	10 x 10 [3.0 x 3.0]
Test Results	Discharge Density (gpm/ft ²) [mm/min]	0.30 [12]
	First Sprinkler Operated (min:sec)	21:56
	Total Sprinklers Operated	2
	Peak Gas Temperature (°F) [°C]	585°F [307]
	Peak Steel Temperature (°F) [°C]	189°F [87.2]
Test Concluded (min:sec)		30:00

Based on the results of this test, FM Global has recommended protecting 20%_{vcl} alcohol/80%_{vcl} water mixtures in plastic bottles with the same protection recommended for liquids that do not burn in plastic containers, i.e., Class I commodity. A final question is does pressurizing a plastic container filled with a 20%_{vcl} alcohol/80%_{vcl} water mixture with nonflammable propellant change the burning properties of the product.

Since the propellant will not burn, the only real opportunity to change the burning behavior would be to cause the alcohol/water mixture to burn more severely (e.g., maybe produce fireballs when the mixture is ejected from the container under pressure). To evaluate this potential, a small-scale test series was contracted with Underwriters Laboratories to investigate the impact of pressurizing aerosol products in plastic containers, filled with a 20%_{vol} alcohol/80%_{vol} water mixture, with nonflammable propellants. A summary of 5 tests that were run is provided in Table 2. Two filling methods were investigated, direct fill (liquid and propellant in same space) and bag-on-valve (liquid in one compartment, propellant in outer compartment). UL reported the number of container failures. The overall fire behavior was provided through direct observation. The tests looked at two cases of six containers arranged with a 6 in. (15 cm) flue between them and a point igniter in the flue space. The cases were in a small pan.

Table 2 UL Testing Summary

Test #	Description	Fill Type	Test Results
1	15% ethanol and 85% water	Direct Fill	12 containers ruptured but burned in place No fire balls during rupture No pool fire Bottom of boxes unburned after 6 min
2	15% ethanol and 85% water	Bag on Valve	12 containers ruptured with some ejected away from case 50% of one carton unburned after 4 min No fire balls during rupture No pool fire
3	20% ethanol and 80% water	Direct Fill	12 containers ruptured but burned in place No fire balls during rupture No pool fire Bottom of boxes unburned after 5 min
4	20% ethanol and 80% water Unpressurized Containers	Direct Fill	12 containers ruptured but burned in place No fire balls during rupture No pool fire Bottom of boxes unburned after 10 min
5	20% ethanol and 80% water	Bag on Valve	5 containers ruptured Fire extinguished by rupturing containers

None of the tests produced a pool fire or fireball. In all five tests, portions of the aerosol products in plastic containers and cardboard cases remained unburned. Based on these tests, it appears that the fire properties of alcohol/water mixture remained unchanged when pressurized and that using Class III commodity protection will provide fully adequate protection for the aerosol products in plastic containers.

3) Aerosol Products in Plastic Containers – Propellant: 4% by Weight Nonflammable Propellant or Flammable Propellant that is Emulsified in Liquid Base; Base: Aqueous Base with no Fire Point.

An emulsion, in an aerosol product, would be a mixture of two or more liquids in which one is present as droplets, of microscopic or ultramicroscopic size, distributed throughout the other. Emulsions are formed from the component liquids either spontaneously or, more often, by mechanical means, such as agitation, provided that the liquids that are mixed have no (or a very limited) mutual solubility. Emulsions are stabilized by agents that form films at the surface of the droplets (e.g., soap molecules) or that impart to them a mechanical stability (e.g., colloidal carbon or bentonite). Colloidal distributions or suspension of one or more liquid(s) with another will have a shelf life that varies with the efficiency of the recipe used.

A Level 1 aerosol (metal can) was defined by the fire performance of shave cream. This product had limited amounts of flammable liquefied gas propellant to eject the mixture and to cause foaming of the mixture. In a fire, the hydrocarbon propellant would be ejected and burn, but the large quantities of foam mix and water tended to produce a very limited fire severity. A similar product was evaluated when placed in a plastic aerosol container.

The product consisted of several liquid components that do not support combustion mixed with water and a maximum of 4% by weight flammable liquefied gas propellant. The liquefied gas was held within the liquid mixture as an emulsion. The gas would eject the liquid product and cause the liquid mixture to foam. Since the liquid components do not burn, the main concern centers around the flammable liquefied gas propellant. The evaluation used small, intermediate, and full-scale fire testing to evaluate the fire hazard created by this product. All of the testing was completed at Underwriters Laboratories.

The intermediate and large-scale testing are summarized in Table 3. The large-scale test used the 12-Pallet Aerosol Classification Test protocol. This methodology only applies to metal aerosol products but, lacking any test data, it was considered a good starting point. The 12 pallet load palletized array operated 4 sprinklers in 10 seconds at around a minute and a half after ignition. The fire was quickly knocked down. The test was run for 32 minutes. The liquid product was released during the test and did not contribute. The flammable liquefied gas did create brief flare-ups of the fire when released and continued to create small fireballs throughout the test. The high sprinkler discharge density (0.79 gpm/ft²) (32 mm/min) easily extinguished the majority of the array and limited the fire spread to the ignition flue located in the center of the array. The fire test seemed to demonstrate that the limited amount of flammable liquefied gas in the product would not produce a severe fire; however, the high water density does not permit easy comparison to a Class III commodity fire.

An intermediate-scale test was run under the calorimeter at UL to evaluate the effect of a significantly lower water density (0.25 gpm/ft²) (10 mm/min) on this product. The product was placed in a double row rack with a storage height of 15 ft (4.6 m). Four open sprinklers were located 10 ft (3 m) above the top of the array and arranged to deliver a 0.25 gpm/ft² (10 mm/min). The sprinklers were activated at approximately one minute after ignition. The test was terminated at 4 minutes since the fire was extinguished. The percent damage was not provided in the UL report; however the pictures indicate that the fire was again confined to the ignition flue.

NFPA 13 requires a 0.25 gpm/ft² (10 mm/min) to protect 15 ft (4.6 m) high double row rack storage of Class III commodity in a 25 ft (7.6 m) high building using low temperature ceiling sprinklers [NFPA 13, Table 16.2.1.3.2, Figure 16.2.1.3.2(c) curves E & F, Figure 16.2.1.3.4.1]. The intermediate-scale test indicates that this same protection level easily controlled/extinguished a fire involving the foam shave cream in a plastic aerosol container.

Table 3 UL Test Summary

Shave Cream Intermediate and Large-Scale Fire Test Summaries			
Test Number		1 (Intermediate-Scale)	1 (Large-Scale)
Report Date		12/31/09	10/26/09
Test Parameters	Commodity	Shave Foam in 11 oz (330 ml) Plastic Aerosol	Shave Foam in 11 oz (330 ml) Plastic Aerosol
	Storage Arrangement (pallet loads)	Rack Array under Calorimeter 2 x 2 x 3 high	Palletized Array 2 x 2 x 3 high
	Storage Height (ft) [m]	15 [4.6]	14 [4.3]
	No. Tiers	3	3
	Ceiling Height (ft) [m]	Sprinklers at 25 [7.6] above floor	25 [7.6]
	Aisle Width (ft)	None	None
	Sprinkler Type (K factor gpm/psi ^{0.5} [L/min/bar ^{0.5}], Temperature Rating)	K = 8.0 [120] / Open	11.2 [161] / 155°F [68°C]
	Sprinkler Spacing (ft x ft) [m x m]	10 x 10 [3 x 3]	10 x 10 [3 x 3]
	Discharge Density (gpm/ft ²) [mm/min]	0.25 [10]	0.79 [32]
Test Results	First Sprinkler Operated (min:sec)	1:07 water on	1:23
	Total Sprinklers Operated	4	4
	Peak Gas Temperature (°F) [°C]	3000 kW peak heat release rate	1242 [672]
	Peak Steel Temperature (°F) [°C]	None recorded	165 [74]
	Test Concluded (min:sec)	4:00	32:00

In addition to the intermediate and large-scale fire test, a number of small-scale tests were also done to provide a visual documentation on how a plastic aerosol container with a shave foam type product behaves when exposed to fire without sprinkler protection. These tests consisted of placing two cases of six containers on each side of a standard igniter. The containers were contained in a cardboard box. A shave cream and a hair mousse were tested. A general description of the test results is provided in Table 4. Test 9 used a product that was very similar to what was tested in the intermediate and large-scale testing. It was a shave cream product that had a small percentage of a flammable liquefied gas that was in a stable emulsion with a multi-component liquid mixture. The liquid mixture did not support combustion. The product in Test 10 had a higher weight percent flammable liquefied gas that did not form a stable emulsion in the bottle. A liquefied gas layer formed in the container. It was not clear what the liquid mixture was made up of. In both products, the flammable liquefied gas was used to eject the liquid mixture out of the container and cause the liquid product to create foam.

In Test 9, all but two of the containers failed. The shave foam covered the cases, containers and pan after the test. The product burned weakly and extinguished the igniter used in the test. The product used in Test 10 did appear to burn more vigorously. Container failure produced momentary fireballs. While this limited-scale test cannot predict the behavior of a product in a full-scale arrangement, it did demonstrate that there were differences between the shave cream and the hair mousse, and that the hair mousse produced a more vigorous fire.

Table 4 UL Testing Summary

Test #	Description	Fill Type	Test Results
9	Shave Cream Emulsion (4% by weight hydrocarbon propellant – the emulsion was stable, no propellant layer was noticeable in container)	Direct Fill	Initially flames are about 3 to 4 ft (0.9 to 1.2 m) high. First container ruptures at :50 seconds. Multiple container ruptures follow. The igniter is extinguished by a container rupture at approximately 1:15. The fire goes out at approximately 6 minutes. The two cases are covered in foam shave cream and two containers did not fail. There was no pool fire. The ruptures did not produce noticeable fireballs or increased burning.
10	Mousse and conditioner (6% by weight hydrocarbon propellant – the emulsion was not stable and a propellant layer formed in container)	Direct Fill	Initially flames are about 3 to 4 ft (0.9 to 1.2 m) high. First container ruptures at :48 seconds. Multiple container ruptures follow. The flames increase in intensity with the container ruptures. Eventually all of the containers are breached. A small pool of burning liquid formed but went out quickly. An increase in burning was noticeable with each container failure.

The results of the intermediate-scale testing, the full-scale testing, and the small-scale testing, indicate that an aerosol product in a plastic container filled with a liquid mixture that does not support combustion and no more than 4% by weight flammable liquefied gas in a stable emulsion with the liquid mixture can be protected using criteria recommended for a Class III commodity.

The aerosol container definition was also modified to reflect the current definition in NFPA 30B 2011, edition, that is referenced by the IFC.

Cost Impact: The code change proposal will not increase the cost of construction.

Public Hearing: Committee: AS AM D
Assembly: ASF AMF DF

5104.1-F-MCLAUGHLIN

F300 – 13

5203.7 (New), 5204.1

Proponent: Robert J Davidson, Davidson Code Concepts, LLC, representing the Biomass Feedstock Industry Committee on Codes and Standards (BFICOCS) (rjd@davidsoncodeconcepts.com)

Revise as follows:

5203.7 Sources of ignition. Sources of ignition shall comply with Sections 5203.7.1 through 5203.7.2.

5003.7.1 Smoking. Smoking shall be prohibited and “No Smoking” signs provided as follows:

1. In rooms or areas where materials are stored or dispensed or used in open systems .
2. Within 25 feet (7620 mm) of outdoor storage or open use areas.
3. Facilities or areas within facilities that have been designated as totally “no smoking” shall have “No Smoking” signs placed at all entrances to the facility or area. Designated areas within such facilities where smoking is permitted either permanently or temporarily, shall be identified with signs designating that smoking is permitted in these areas only.

Signs required by this section shall be in English as a primary language or in symbols allowed by this code and shall comply with Section 310.

5203.7.2 Open flames. Open flames and high-temperature devices shall not be used in a manner which creates a hazardous condition and shall be listed for use with the materials stored or used.

5204.1 General. Loose combustible fibers, not in suitable bales or packages and ~~whether housed or stored outdoors~~ in the open, shall ~~not be stored within 100 feet (30 480 mm) any structure, except as indicated in this chapter~~ comply with Section 2808 of this code. Occupancies involving the indoor storage of loose combustible fibers in amounts exceeding the maximum allowable quantity per control area as set forth in Section 5003.1 shall comply with Sections 5204.2 through 5204.6.

Reason: This proposal is part of a package of proposals concerning Chapter 52 Combustible Fibers. An issue identified in review of the current code language and structure is that though Chapter 52 Combustible Fibers is located in the "Hazardous Materials" portion of the code, combustibles fibers are not defined as a hazardous material.

5001.2 Material classification. Hazardous materials are those chemicals or substances defined as such in this code. Definitions of hazardous materials shall apply to all hazardous materials, including those materials regulated elsewhere in this code.

5001.2.1 Mixtures. Mixtures shall be classified in accordance with hazards of the mixture as a whole. Mixtures of hazardous materials shall be classified in accordance with nationally recognized reference standards; by an approved qualified organization, individual, or Material Safety Data Sheet (MSDS); or by other approved methods.

5001.2.2 Hazard categories. Hazardous materials shall be classified according to hazard categories. The categories include materials regulated by this chapter and materials regulated elsewhere in this code.

5001.2.2.1 Physical hazards. The material categories listed in this section are classified as physical hazards. A material with a primary classification as a physical hazard can also pose a health hazard.

- 1. Explosives and blasting agents.*
- 2. Combustible liquids.*
- 3. Flammable solids, liquids and gases.*
- 4. Organic peroxide solids or liquids.*
- 5. Oxidizer, solids or liquids.*
- 6. Oxidizing gases.*
- 7. Pyrophoric solids, liquids or gases.*
- 8. Unstable (reactive) solids, liquids or gases.*
- 9. Water-reactive materials solids or liquids.*
- 10. Cryogenic fluids.*

5001.2.2.2 Health hazards. The material categories listed in this section are classified as health hazards. A material with a primary classification as a health hazard can also pose a physical hazard.

1. *Highly toxic and toxic materials.*
2. *Corrosive materials.*

Combustible fibers do not fit into those parameters. A review of the definition of hazardous materials found within the code also documents that the materials regulated by Chapter 52 are not hazardous materials.

[F] HAZARDOUS MATERIALS. *Those chemicals or substances that are physical hazards or health hazards as classified in Section 307 and the International Fire Code, whether the materials are in usable or waste condition.*

[F] HEALTH HAZARD. *A classification of a chemical for which there is statistically significant evidence that acute or chronic health effects are capable of occurring in exposed persons. The term "health hazard" includes chemicals that are toxic or highly toxic, and corrosive.*

[F] PHYSICAL HAZARD. *A chemical for which there is evidence that it is a combustible liquid, cryogenic fluid, explosive, flammable (solid, liquid or gas), organic peroxide (solid or liquid), oxidizer (solid or liquid), oxidizing gas, pyrophoric (solid, liquid or gas), unstable (reactive) material (solid, liquid or gas) or water- reactive material (solid or liquid).*

Since the scoping of Chapter 50, including the sections within Chapter 50, are for the regulation of hazardous materials, even basic requirements found within Chapter 50 such as control of ignition hazards would not apply to the activities regulated by Chapter 52.

CHAPTER 50 HAZARDOUS MATERIALS—GENERAL PROVISIONS

SECTION 5001 GENERAL

5001.1 Scope. *Prevention, control and mitigation of dangerous conditions related to storage, dispensing, use and handling of hazardous materials shall be in accordance with this chapter.*

This chapter shall apply to all hazardous materials, including those materials regulated elsewhere in this code, except that when specific requirements are provided in other chapters, those specific requirements shall apply in accordance with the applicable chapter. Where a material has multiple hazards, all hazards shall be addressed.

SECTION 5003 GENERAL REQUIREMENTS

5003.1 Scope. *The storage, use and handling of all hazardous materials shall be in accordance with this section.*

This proposal addresses this issue by adding a Section 5203.7 "Sources of ignition" by extracting requirements from current Section 5003.7 "Sources of ignition" that would be appropriate for combustible fibers. In reality, there isn't any other section of Chapter 50 that provides for the regulation of combustible fibers.

In addition, this proposal is building upon a separate proposal to recognize the ability to control the hazards of combustible fibers just as the code provides for recognition of the control of combustible dust by modifying the language found in Section 5204.1.

Section 5204.1 is proposed to be modified to point to Section 2808 "STORAGE AND PROCESSING OF WOOD CHIPS, HOGGED MATERIAL, FINES, COMPOST AND RAW PRODUCT ASSOCIATED WITH YARD WASTE AND RECYCLING FACILITIES" of the fire code as the appropriate standard for the exterior storage of combustible fibers. The materials and hazards presented are similar.

Section 5204.1 is further modified to indicate that the more restrictive indoor storage of combustible fibers regulated by Sections 5204.2 through 5204.6 is for those facilities that have amounts exceeding the maximum allowable quantity per control area as set forth in Section 5003.1. If the hazards are controlled eliminating the application of IFC Table 5003.1.1/IBC [F]307.1.1(1) and Sections 307.4 and 307.5 of the IBC, the increased protection levels are not necessary.

The Biomass Feedstock Industry Committee on Codes and Standards (BFICOCS), led by Oak Ridge National Laboratory (ORNL), is an initiative of the Department of Energy Biomass Technologies Office (BTO). As part of the BTO integrated biorefinery efforts, the BFICOCS was assembled to conduct analysis of existing fire and building codes and to prepare proposed code changes designed to facilitate the development of the commercial-scale biomass industry while maintaining a focus on safety. The committee is made up of managers, engineers and code officials from industry, government laboratories, consulting firms, and the American Society of Agricultural and Biological Engineers.

Fire codes related to storage, handling, and preprocessing of biomass are based on industries that operate in a significantly different manner than the growing biomass-based energy industry. Applying current research on biomass properties and knowledge of conventional and emerging storage, handling, and preprocessing technologies, the BFICOCS has identified changes in the IFC that benefit industry and the public.

Cost Impact: The code change proposal will not increase the cost of construction.

F300-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

5203.7 (NEW)-F-DAVIDSON

F301 – 13

Chapter 52; Chapter 37 (New)

Proponent: Robert J Davidson, Davidson Code Concepts, LLC, representing the Biomass Feedstock Industry Committee on Codes and Standards (BFICOCS) (rjd@davidsoncodeconcepts.com)

Revise as follows:

CHAPTER ~~52~~ 37 **COMBUSTIBLE FIBERS**

Reason: .Currently Chapter 52 regulating Combustible Fibers is located in a portion of the International Fire Code that applies to hazardous materials and the activities involving the handling, storage or use of hazardous materials.

Part V—Hazardous Materials

CHAPTER 50 **HAZARDOUS MATERIALS—GENERAL PROVISIONS**

SECTION 5001 **GENERAL**

5001.1 Scope. *Prevention, control and mitigation of dangerous conditions related to storage, dispensing, use and handling of hazardous materials shall be in accordance with this chapter.*

This chapter shall apply to all hazardous materials, including those materials regulated elsewhere in this code, except that when specific requirements are provided in other chapters, those specific requirements shall apply in accordance with the applicable chapter. Where a material has multiple hazards, all hazards shall be addressed.

5001.2 Material classification. *Hazardous materials are those chemicals or substances defined as such in this code. Definitions of hazardous materials shall apply to all hazardous materials, including those materials regulated elsewhere in this code.*

5001.2.1 Mixtures. *Mixtures shall be classified in accordance with hazards of the mixture as a whole. Mixtures of hazardous materials shall be classified in accordance with nationally recognized reference standards; by an approved qualified organization, individual, or Material Safety Data Sheet (MSDS); or by other approved methods.*

5001.2.2 Hazard categories. *Hazardous materials shall be classified according to hazard categories. The categories include materials regulated by this chapter and materials regulated elsewhere in this code.*

5001.2.2.1 Physical hazards. *The material categories listed in this section are classified as physical hazards. A material with a primary classification as a physical hazard can also pose a health hazard.*

1. Explosives and blasting agents.
2. Combustible liquids.
3. Flammable solids, liquids and gases.
4. Organic peroxide solids or liquids.
5. Oxidizer, solids or liquids.
6. Oxidizing gases.
7. Pyrophoric solids, liquids or gases.
8. Unstable (reactive) solids, liquids or gases.
9. Water-reactive materials solids or liquids.
10. Cryogenic fluids.

5001.2.2.2 Health hazards. *The material categories listed in this section are classified as health hazards. A material with a primary classification as a health hazard can also pose a physical hazard.*

1. Highly toxic and toxic materials.
2. Corrosive materials.

Combustible fibers do not fit into those parameters. A review of the definition of hazardous materials found within the code documents that the materials regulated by Chapter 52 are not by definition hazardous materials.

[F] HAZARDOUS MATERIALS. *Those chemicals or substances that are physical hazards or health hazards as classified in Section 307 and the International Fire Code, whether the materials are in usable or waste condition.*

[F] HEALTH HAZARD. A classification of a chemical for which there is statistically significant evidence that acute or chronic health effects are capable of occurring in exposed persons. The term "health hazard" includes chemicals that are toxic or highly toxic, and corrosive.

[F] PHYSICAL HAZARD. A chemical for which there is evidence that it is a combustible liquid, cryogenic fluid, explosive, flammable (solid, liquid or gas), organic peroxide (solid or liquid), oxidizer (solid or liquid), oxidizing gas, pyrophoric (solid, liquid or gas), unstable (reactive) material (solid, liquid or gas) or water- reactive material (solid or liquid).

Because the scoping of Chapter 50 is for the regulation of hazardous materials, the requirements of Chapter 50 would not apply to the materials or activities regulated by Chapter 52 Combustible Fibers.

SECTION 5003 GENERAL REQUIREMENTS

5003.1 Scope. The storage, use and handling of all hazardous materials shall be in accordance with this section.

SECTION 5004 STORAGE

5004.1 Scope. Storage of hazardous materials in amounts exceeding the maximum allowable quantity per control area as set forth in Section 5003.1 shall be in accordance with Sections 5001, 5003 and 5004. Storage of hazardous materials in amounts not exceeding the maximum allowable quantity per control area as set forth in Section 5003.1 shall be in accordance with Sections 5001 and 5003. Retail and wholesale storage and display of nonflammable solid and nonflammable and noncombustible liquid hazardous materials in Group M occupancies and Group S storage shall be in accordance with Section 5003.11.

SECTION 5005 USE, DISPENSING AND HANDLING

5005.1 General. Use, dispensing and handling of hazardous materials in amounts exceeding the maximum allowable quantity per control area set forth in Section 5003.1 shall be in accordance with Sections 5001, 5003 and 5005. Use, dispensing and handling of hazardous materials in amounts not exceeding the maximum allowable quantity per control area set forth in Section 5003.1 shall be in accordance with Sections 5001 and 5003.

IFC Code Commentary for Chapter 52 Combustible Fibers:

"The operations involving combustible fibers are typically associated with salvage, paper milling, recycling, cloth manufacturing, carpet and textile mills and agricultural operations, among others. The primary hazard associated with these operations is the abundance of materials and their ready ignitability. The greatest hazard presented would be a dust explosion hazard and in that case Section 5203.5 requires an approved dust-collecting and exhaust system be installed and compliance with Chapter 22 "Combustible Dust-Producing Operations".

It appears that the Chapter for Combustible Fibers ended up in the hazardous materials portion of the International Fire Code simply because the presence of more than a threshold amount of fibers could result in a Group H classification. In comparison, a combustible dust hazard, which could also result in a Group H classification, has the requirements for controlling the hazard located in Chapter 22 in the Special Occupancies and Operations portion of the code.

This proposal does not make any technical changes and simply suggests taking the existing Combustible Fiber requirements and move them to the Special Occupancies and Operations portion of the code book as a more appropriate location. This is additionally supported by the fact that the combustible fiber activities are linked to Chapter 22 Combustible Dusts by Section 5203.5. The Biomass Feedstock Industry Committee on Codes and Standards (BFICOCS), led by Oak Ridge National Laboratory (ORNL), is an initiative of the Department of Energy Biomass Technologies Office (BTO). As part of the BTO integrated biorefinery efforts, the BFICOCS was assembled to conduct analysis of existing fire and building codes and to prepare proposed code changes designed to facilitate the development of the commercial-scale biomass industry while maintaining a focus on safety. The committee is made up of managers, engineers and code officials from industry, government laboratories, consulting firms, and the American Society of Agricultural and Biological Engineers.

Fire codes related to storage, handling, and preprocessing of biomass are based on industries that operate in a significantly different manner than the growing biomass-based energy industry. Applying current research on biomass properties and knowledge of conventional and emerging storage, handling, and preprocessing technologies, the BFICOCS has identified changes in the IFC that benefit industry and the public.

Cost Impact: The code change proposal will not increase the cost of construction.

F301-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

CHAPTER 52-F-DAVIDSON

F302 – 13

5301.1, Chapter 80

Proponent: Robert Boyd, Boyd Hydrogen, LLC, representing self (Bob@BoydH2.com)

Revise as follows:

5301.1 Scope. Storage, use and handling of compressed gases in compressed gas containers, cylinders, tanks and systems shall comply with this chapter, including those gases regulated elsewhere in this code. Partially full compressed gas containers, cylinders or tanks containing residual gases shall be considered as full for the purposes of the controls required.

Exceptions:

1. Gases used as refrigerants in refrigeration systems (see Section 606).
2. Compressed natural gas (CNG) for use as a vehicular fuel shall comply with Chapter 23, NFPA 52 and the *International Fuel Gas Code*.
3. Compressed hydrogen (CH₂) for use as a vehicular fuel shall comply with Chapter 23, NFPA 2 and the *International Fuel Gas Code*.

Add new standard to Chapter 80 as follows:

NFPA

2-11 Hydrogen Technologies Code 5301.1

Reason: The fueling, use, and operation of hydrogen powered fuel cell vehicles is functionally equivalent to the fueling, use, and operation of CNG powered vehicles.

The California Fuel Cell Partnership's 2012 update on FCV deployment plans provides details on the expectation and goal of government agencies including the Department of Energy, California EPA, California Energy Commission and South Coast Air Quality Management District to have an established fleet of at least 50,000 hydrogen powered fuel cell hybrid electric vehicles deployed from 7 automakers* and operating in California sometime between 2015 and 2018.

A link to "A California Road Map: The Commercialization of Hydrogen Fuel Cell Vehicles"

Is shown below:

[http://cafcp.org/sites/files/A%20California%20Road%20Map%20June%202012%20\(CaFCP%20technical%20version\)_1.pdf](http://cafcp.org/sites/files/A%20California%20Road%20Map%20June%202012%20(CaFCP%20technical%20version)_1.pdf)

Without this proposed change and additional exception to 5301.1, local AHJ's might be confused and believe that hydrogen powered vehicles should comply with chapter 53

*7 automakers with stated plans to deploy hydrogen powered fuel cell electric vehicles: GM, Honda, Toyota, Nissan, Kai, Hyundai, VW/Audi/Porsche.

Cost Impact: None

Analysis: A review of the standard proposed for inclusion in the code, NFPA 2-11, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28), will be posted on the ICC website on or before April 1, 2013.

F302-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

5301.1-F-BOYD

F303 – 13

5301.1, 5305.7

Proponent: Robert J Davidson, Davidson Code Concepts, LLC, representing the National Renewable Energy Laboratory (NREL) (rjd@davidsoncodeconcepts.com)

Revise as follows:

5301.1 Scope. Storage, use and handling of compressed gases in compressed gas containers, cylinders, tanks and systems shall comply with this chapter, including those gases regulated elsewhere in this code. Partially full compressed gas containers, cylinders or tanks containing residual gases shall be considered as full for the purposes of the controls required.

Exceptions:

1. Gases used as refrigerants in refrigeration systems (see Section 606).
2. Compressed natural gas (CNG) for use as a vehicular fuel shall comply with Chapter 23, NFPA 52 and the International Fuel Gas Code.
3. Compressed hydrogen (CH₂) for use as a vehicular fuel shall comply with Chapters 23 and 58 of this code, the *International Fuel Gas Code* and NFPA 2.

5305.7 Transfer. Transfer of gases between containers, cylinders and tanks shall be performed by qualified personnel using equipment and operating procedures in accordance with CGA P-1.

Exception: The f Fueling of vehicles with compressed natural gas (CNG) or compressed hydrogen gas, that is being conducted in accordance with Chapter 23.

Add new referenced standard to Chapter 80 as follows:

NFPA

2-11 Hydrogen Technologies Code

Reason: These two items are a proposed as a correlation cleanup. In retrospect this cleanup should have been added back in 2003 editions when hydrogen motor fueling was added to Chapter 23.

The added Section 5301.1, Exception 3 mirrors the language for CNG found at Exception 2 with a point to Chapter 23, Chapter 58 and an additional pointer to NFPA 2 to coordinate this proposal with previous proposals in this grouping submitted on behalf of NREL.

With the modification of the exception at Section 5305.7, in addition to adding fueling of vehicles with compressed hydrogen gas, the proposal makes it clear that the exception is due to compliance with Chapter 23 provisions, it is not a unrestricted exception.

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: A review of the standard proposed for inclusion in the code, NFPA 2-11, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28), will be posted on the ICC website on or before April 1, 2013.

F303-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

5301.1-F-DAVIDSON

F304 – 13

5301.1, 5303.6.2

Proponent: Patrick A. McLaughlin McLaughlin & Associates, representing the Compressed Gas Association (pmclaugma@aol.com)

Revise as follows:

5301.1 Scope. Storage, use and handling of *compressed gases* in *compressed gas* containers, cylinders, tanks and systems shall comply with this chapter and NFPA 55, including those gases regulated elsewhere in this code. Partially full *compressed gas* containers, cylinders or tanks containing residual gases shall be considered as full for the purposes of the controls required.

Exceptions:

1. Gases used as refrigerants in refrigeration systems (see Section 606).
2. Compressed natural gas (CNG) for use as a vehicular fuel shall comply with Chapter 23, NFPA 52 and the International Fuel Gas Code.

Cutting and welding gases shall also comply with Chapter 35.

Cryogenic fluids shall comply with Chapter 55. Liquefied natural gas for use as a vehicular fuel shall also comply with NFPA 52 and NFPA 59A.

Compressed gases classified as hazardous materials shall also comply with Chapter 50 for general requirements and chapters addressing specific hazards, including Chapters 58 (Flammable Gases), 60 (Highly Toxic and Toxic Materials), 63 (Oxidizers, Oxidizing Gases and Oxidizing Cryogenic Fluids) and 64 (Pyrophoric Materials).

LP-gas shall also comply with Chapter 61 and the International Fuel Gas Code.

5303.6.2 Caps and plugs. *Compressed gas* containers, cylinders and tanks designed for valve protection caps or other protective devices shall have the caps or devices in place. ~~attached~~. When valve outlet caps or plugs are provided for valve outlet protection they shall be in place.

Exception: *Compressed gas* containers, cylinders or tanks in use, being serviced or being filled.

Reason:

- 5301.1: Flammable gases and flammable and oxidizing cryogenic fluids are currently also required to comply with NFPA 55. It seems reasonable that all compressed gases comply with NFPA 55, as it is the source of many of the IFC provisions. Because of the three year adoption cycle, and the adoption processes of the two entities being out of sync, the IFC may be up to five or more years out of date. This change will also help keep the IFC updated to current technology. For example, NFPA 55 is the source document for the fundamental requirements for compressed hydrogen gas (GH2), or liquefied hydrogen gas (LH2) system installations. It serves as a source for the fundamental controls used by NFPA 2, *Hydrogen Technologies Code*, 2011 Edition, which contains requirements for vehicular fueling.
- 5306.6.2: The code change clarifies that when provided, both the protective devices and valve caps must be in place. It also aligns with NFPA 55 requirements.

Cost Impact: The code change proposal will not increase the cost of construction.

F304-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

5301.1-F-MCLAUGHLIN

F305 – 13

5305.7

Proponent: Robert Boyd, Boyd Hydrogen, LLC, representing self (Bob@BoydH2.com)

Revise as follows:

5305.7 Transfer. Transfer of gases between containers, cylinders and tanks shall be performed by qualified personnel using equipment and operating procedures in accordance with CGA P-1

Exception: Fueling of vehicles with compressed natural gas (CNG) or compressed hydrogen.

Reason: fueling of hydrogen powered fuel cell vehicles is functionally equivalent to fueling CNG powered cars used by normal licensed private vehicle operators.

The training and expertise required for consumer training of operators of CNG and compressed hydrogen vehicles are quite similar and quite different from what is specified in CGA P-1.

All Compressed Hydrogen or CNG dispensers are required by NFPA-2 (H2) and NFPA-52 (CNG) to have a pressure sensor and automatic shut off valve and the dispenser must conduct an integrity check of the dispenser hose, the vehicle fueling system and the integrity of the nozzle / reprisal connection. The dispenser must perform the integrity check at the beginning of fueling and then at least once during the fueling process. If the dispenser senses any leaks it must terminate the fueling process.

The California Fuel Cell Partnership's 2012 update on FCV deployment plans \ the expectation of government agencies including the Department of Energy, California EPA, California Energy Commission and South Coast Air Quality Management District clearly defines the goals to have an established fleet of at least 50,000 hydrogen powered fuel cell hybrid electric vehicles deployed from 7 automakers* and operating in California sometime between 2015 and 2018.

Without this change local AHJ's might be confused and believe that qualified personnel using equipment and operating procedures in accordance with CGA P-1 are required to fill vehicles that are fueled with compressed hydrogen.

*7 automakers with stated plans to deploy hydrogen powered fuel cell electric vehicles: GM, Honda, Toyota, Nissan, Kai, Hyundai, VW/Audi/Porsche.

5306, 5306.1, 5306.4

Proponent: John Williams, CBO, Chair, ICC Ad Hoc Committee on Health Care (john.williams@doh.wa.gov) and Carl Baldassarra, P.E., FSFPE, Chair, ICC Code Technology Committee (cbaldassarra@RJAGroup.com)

Revise as follows:

SECTION 5306 MEDICAL GASES SYSTEMS

5306.1 General. ~~Compressed~~ Medical gases at healthcare related hospitals and similar facilities intended for patient care, inhalation or sedation including, but not limited to, analgesia systems for dentistry, podiatry, veterinary and similar uses shall comply with Sections 5306.2 through 5306.4 in addition to other requirements of this chapter.

5306.4 Transfilling. Transfilling areas and operations including, but not limited to, ventilation and separation, shall comply with NFPA 99.

(Renumber remaining section.)

Reason: This proposal addresses CMS KTag 143. This KTag is concerned with the transferring or what is often termed transfilling of oxygen in a gaseous or liquid form within hospitals and other medical facilities. The current provisions in the IFC are actually fairly consistent with NFPA 99 and the requirements of the KTags in this respect. The only major differences found were that the IFC requirements do not specifically address transfilling and the type of floor surface allowed. Transfilling is the transfer of oxygen to smaller portable containers from larger storage containers. This can occur in liquid or gaseous state. Currently the provisions only relate to storage. This has been revised by the proposal. The reference to NFPA will provide restrictions on the floor used to concrete or ceramic due to the noncombustible nature of the floors.

This proposal addresses two other issues as follows:

Title 5306. This was changed to delete the term “systems” since transfilling and storage of oxygen is not necessarily part of a system. This will be a more general title which is more applicable to all of Section 5306.

Section 5306.1. The terms hospitals and similar facilities were deleted in favor of a more all encompassing set of terms “Healthcare related facilities.” The current language seems to give priority to hospitals and can be somewhat unclear that it would also apply to ambulatory care facilities and nursing homes.

This proposal is submitted by the ICC Ad Hoc Committee for Healthcare (AHC). The AHC was established by the ICC Board of Directors to evaluate and assess contemporary code issues relating to hospitals and ambulatory healthcare facilities. The AHC is composed of building code officials, fire code officials, hospital facility engineers, and state healthcare enforcement representatives. The goals of the committee are to ensure that the ICC family of codes appropriately addresses the fire and life safety concerns of a highly specialized and rapidly evolving healthcare delivery system. This process is part of a joint effort between ICC and the American Society for Healthcare Engineering (ASHE), a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. Since its inception in April, 2011, the AHC has held 8 open meetings and over 150 workgroup calls which included members of the AHC as well as any interested party to discuss and debate the proposed changes. All meeting materials and reports are posted on the AHC website at: <http://www.iccsafe.org/cs/AHC/Pages/default.aspx>

This proposal is being co-sponsored by the ICC Code Technology Committee. The ICC Board established the ICC Code Technology Committee (CTC) as the venue to discuss contemporary code issues in a committee setting which provides the necessary time and flexibility to allow for full participation and input by any interested party. The code issues are assigned to the CTC by the ICC Board as “areas of study”. Information on the CTC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CTC effort can be downloaded from the following website: <http://www.iccsafe.org/cs/CTC/Pages/default.aspx>. Since its inception in April/2005, the CTC has held twenty five meetings - all open to the public.”

Cost impact: The code change proposal should not increase the cost of construction because compliance is already required by facility licensure requirements.

5306.1-F-BALDASSARRA-WILLIAMS-ADHOC

F307 – 13

5306.2

Proponent: Masoud Sabounchi, Advanced Consulting Engineers Inc., representing self
(masoud@acecode.com)

Revise as follows:

5306.2 Interior supply location. Medical gases shall be stored in areas dedicated to the storage of such gases without other storage or uses. Where containers of medical gases in quantities greater than the permit amount are located inside buildings, they shall be in a 1-hour exterior room, a 1-hour interior room or a gas cabinet in accordance with Section 5306.2.1, 5306.2.2 or 5306.2.3, respectively. Rooms or areas where medical gases are stored or used in quantities exceeding the *maximum allowable quantity per control area* as set forth in Section 5003.1 shall be in accordance with the *International Building Code* for high-hazard Group H occupancies.

Exceptions:

1. In Group I-2 and ambulatory health care occupancies, areas containing medical gas cabinets or medical gas rooms constructed in accordance with Sections 5306.2.1, 5306.2.2 or 5306.2.3, where quantity of the stored oxidizing gases exceeds the maximum allowable quantities shall not be considered Group H.
2. In Group I-2 and ambulatory health care occupancies, oxygen cylinders that are in use shall comply with applicable provisions of NFPA 99.

Reason: This proposal reverts the provisions of 2012 IFC Section 5306.2 to that of 2006 IFC Section 3006.2.1 regarding storage and use of the medical gases in health care occupancies without declaration of the storage/use rooms/areas as hazardous occupancy where quantity of oxidizing gases exceed the maximum allowable quantities (MAQs). This proposal does not change the existing requirements where flammable medical gases are used or stored.

IFC Section 5306 requires 1-hour fire resistance rated interior or exterior medical gas rooms where quantity of medical gases exceeds the permit amount. Per IFC Table 105.6.8 permit amounts of oxidizing gases is 504 cubic feet.

In a 10 story hospital, number of control areas and quantity of oxidizing gases per control area varies based on location of the control areas. Per IBC Table 414.2.2 floors (above grade plane) 4, 5 and 6 may have two control areas and limit quantity of hazardous materials to 12.5% of the MAQs. Quantity of oxidizing gases in each control area on floors 4, 5, and 6 would be limited to 1500×2 (due to sprinkler protection) $\times 12.5/100=375$ cubic feet unless these rooms are considered H-3 Occupancy. This quantity is less than the 504 cubic feet which is the permit quantity. It is not clear if the 504 cubic feet permit limit or the limit of 375 cubic feet would govern the occupancy designation of the medical gas rooms.

If the 375 cubic feet limit is the MAQ, the control area has to be declared an H-3 occupancy. As such, IBC would require 2-hour fire resistance rated separation to enclose the medical gas storage rooms in hospitals and IBC Section 415.5 would require these H-3 occupancy medical gas storage rooms to have 25% of the wall area as exterior walls. Most health care occupancies have oxygen cylinders for patient use-if quantity of in use oxidizing gases exceed 375 cubic feet on floors 4, 5 and 6, the occupancy group of these health care floors would have to be H-3 which clearly is not the intent of the code.

On floors 7 and up quantity of oxidizing gases would be limited to 5% of MAQs or 150 cubic feet without declaration of an H-3 occupancy for the floor or reduction of the in use oxygen to less than 150 cubic feet and introduction of H-3 occupancy rooms for storage of oxidizing gases. This quantity is extremely limiting considering a large hospital floor area. On floor levels above the 9th, only one control area with total quantity of 150 cubic feet oxidizing gases is permitted which mandates creation of H-3 occupancy rooms and would limit total quantity of "in use" oxygen cylinders to 150 cubic feet in the remainder of the floor. Reference to NFPA 99 regarding "in use" quantities noted in exception number two would coordinate IFC provisions with NFPA 99.

Cost Impact: This change will not affect the cost of construction.

F307-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

5306.2-F-SABOUNCHI

F308 – 13

5306.2.1

Proponent: John Williams, CBO, Chair, ICC Ad Hoc Committee on Health Care (john.williams@doh.wa.gov) and Carl Baldassarra, P.E., FSFPE, Chair, ICC Code Technology Committee (cbaldassarra@RJAGroup.com)

Revise as follows:

5306.2.1 One-hour exterior rooms. A 1- hour exterior room shall be a room or enclosure separated from the remainder of the building by fire barriers constructed in accordance with Section 707 of the *International Building Code* or horizontal assemblies constructed in accordance with Section 711 of the *International Building Code*, or both, with a fire- resistance rating of not less than 1- hour. Openings between the room or enclosure and interior spaces shall be self-closing smoke- and draft-control assemblies having a fire protection rating of not less than 1hour. Rooms shall have at least one exterior wall that is provided with at least two non-closable louvered vents. Each vent shall have a minimum free opening area of 24 square inches (155 cm²) for each 1,000 cubic feet (28 m³) at normal temperature and pressure (NTP) of gas stored in the room and shall not be less than ~~36 72~~ square inches (~~0.023 m²~~ 465 cm²) in aggregate free opening area. One vent shall be within 6 inches (152 mm) of the floor and one shall be within 6 inches (152 mm) of the ceiling. Rooms shall be provided with at least one automatic sprinkler to provide container cooling in case of fire.

Reason: The purpose of this proposal is to update Section 5306.2.1 on Medical Gas Systems to clarify and address the differences with the language in NFPA 99-2012, Section 9.3.7.5.2 with which hospitals are required to comply.

This proposed revision requires the vents to be of the non-closable type which is not currently required in the IFC, and to be of a larger size. It further defines the louver opening as “aggregate free opening” as required which is not currently specified in the IFC.

NFPA 99 is the more restrictive and sets the design of the louver to be specifically fixed where the IFC language may result is a “closable” louver which is not the intent of this code section. It also provides clarification on the sizing of the louver as it relates to the amount of gas being stored in the room where the IFC currently does not.

This proposal is submitted by the ICC Ad Hoc Committee for Healthcare (AHC). The AHC was established by the ICC Board of Directors to evaluate and assess contemporary code issues relating to hospitals and ambulatory healthcare facilities. The AHC is composed of building code officials, fire code officials, hospital facility engineers, and state healthcare enforcement representatives. The goals of the committee are to ensure that the ICC family of codes appropriately addresses the fire and life safety concerns of a highly specialized and rapidly evolving healthcare delivery system. This process is part of a joint effort between ICC and the American Society for Healthcare Engineering (ASHE), a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. Since its inception in April, 2011, the AHC has held 8 open meetings and over 150 workgroup calls which included members of the AHC as well as any interested party to discuss and debate the proposed changes. All meeting materials and reports are posted on the AHC website at: <http://www.iccsafe.org/cs/AHC/Pages/default.aspx>

This proposal is being co-sponsored by the ICC Code Technology Committee. The ICC Board established the ICC Code Technology Committee (CTC) as the venue to discuss contemporary code issues in a committee setting which provides the necessary time and flexibility to allow for full participation and input by any interested party. The code issues are assigned to the CTC by the ICC Board as “areas of study”. Information on the CTC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CTC effort can be downloaded from the following website: <http://www.iccsafe.org/cs/CTC/Pages/default.aspx>. Since its inception in April/2005, the CTC has held twenty five meetings - all open to the public. In 2012, three of the 25 face-to face meetings were held. In addition to the CTC meetings, the CTC established Study Groups (SG) of interested parties for each of the areas of study. These SG’s are responsible for reviewing the available information and making recommendations to the CTC. All totaled, the SG’s held over 70 conference calls in 2012.

Cost impact: The code change proposal should not increase the cost of construction because compliance is already required by facility licensure requirements.

F308-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

5306.2.1-F-BALDASSARRA-WILLIAMS-ADHOC-CTC

F309– 13

5306.4

Proponent: John Williams, CBO, Chair, ICC Ad Hoc Committee on Health Care
(john.williams@doh.wa.gov)

Revise as follows:

5306.4 Medical gas systems. Medical gas systems including, but not limited to, distribution piping, supply manifolds, connections, pressure regulators and relief devices and valves, shall be installed in accordance with NFPA 99 and the general provisions of this chapter. Existing medical gas systems shall be maintained in accordance with the maintenance, inspection and testing provisions of NFPA 99 for medical gas systems.

Reason: This proposal clarifies that once medical gas systems are installed in accordance with NFPA 99 that the new construction requirements of NFPA 99 are not intended to be retroactively enforced. Instead the intention is that the systems be maintained in accordance with the maintenance provisions of NFPA 99. This addresses CMS K-Tag K78.

This proposal is submitted by the ICC Ad Hoc Committee for Healthcare (AHC). The AHC was established by the ICC Board of Directors to evaluate and assess contemporary code issues relating to hospitals and ambulatory healthcare facilities. The AHC is composed of building code officials, fire code officials, hospital facility engineers, and state healthcare enforcement representatives. The goals of the committee are to ensure that the ICC family of codes appropriately addresses the fire and life safety concerns of a highly specialized and rapidly evolving healthcare delivery system. This process is part of a joint effort between ICC and the American Society for Healthcare Engineering (ASHE), a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. Since its inception in April, 2011, the AHC has held 8 open meetings and over 150 workgroup calls which included members of the AHC as well as any interested party to discuss and debate the proposed changes. All meeting materials and reports are posted on the AHC website at: <http://www.iccsafe.org/cs/AHC/Pages/default.aspx>

Cost impact: The code change proposal should not increase the cost of construction because compliance with the standard is already required by facility licensure requirements.

F310 – 13

5307 (New), 908.7 (New), 105.6.4 (New), Table 105.6.8

Proponent: Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azubiamia@yahoo.com)

Add new text as follows:

SECTION 5307 **CARBON DIOXIDE (CO₂) SYSTEMS USED IN BEVERAGE DISPENSING APPLICATIONS**

5307.1 General. Carbon dioxide systems with 100 or more pounds of carbon dioxide used in beverage dispensing applications shall comply with Sections 5307.2 through 5307.5.2.

5307.2 Permits. Permits shall be required as set forth in Section 105.6.

5307.3 Equipment. The storage, use, and handling of liquid carbon dioxide shall be in accordance with Chapter 53 and the applicable requirements of NFPA 55, Chapter 13.

5307.4 Protection from damage. Carbon dioxide systems shall be installed so the storage tanks, cylinders, piping and fittings are protected from damage by occupants or equipment during normal facility operations.

5307.5 Required protection. Where carbon dioxide storage tanks, cylinders, piping and equipment are located indoors, rooms or areas containing carbon dioxide storage tanks, cylinders, piping and fittings and other areas where a leak of carbon dioxide can collect shall be provided with either ventilation in accordance with Section 5307.5.1 or an emergency alarm system in accordance with Section 5307.5.2.

5307.5.1 Ventilation. Mechanical ventilation shall be in accordance with the *International Mechanical Code* and shall comply with all of the following:

1. Mechanical ventilation in the room or area shall be at a rate of not less than 1 cubic foot per minute per square foot [0.00508 m³/(s • m²)].
2. Exhaust shall be taken from a point within 12 inches (305 mm) of the floor.
3. The ventilation system shall be designed to operate at a negative pressure in relation to the surrounding area.

5307.5.2 Emergency alarm system. An emergency alarm system shall comply with all of the following:

1. Continuous gas detection shall be provided to monitor areas where carbon dioxide can accumulate.
2. The threshold for activation of an alarm shall not exceed 5,000 parts per million (9,000 mg/m³).
3. Activation of the emergency alarm system shall initiate a local alarm at an approved location.

908.7 Carbon dioxide (CO₂) systems. Emergency alarm systems in accordance with Section 5307.5.2 shall be provided where required for compliance with Section 5307.5.

105.6.4 Carbon dioxide systems used in beverage dispensing applications. An operational permit is required for carbon dioxide systems used in beverage dispensing applications with more than 100 pounds of carbon dioxide.

(Renumber subsequent sections.)

Revise as follows:

**TABLE 105.6.8
PERMIT AMOUNTS FOR COMPRESSED GASES**

TYPE OF GAS	AMOUNT (cubic feet at NTP)
Inert and simple asphyxiant ^a	6,000

(Portions of table not shown remain unchanged)

For SI: 1 cubic foot = 0.02832 m³.

a. For carbon dioxide used in beverage dispensing applications, see Section 105.6.4.

Reason: This proposal is submitted by the ICC Fire Code Action Committee (FCAC). This ICC committee was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portions thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the Fire-CAC has held 6 open meetings and numerous Regional Work Group and Task Group meetings and conference calls which included members of the committees as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the FAC website at:
<http://www.iccsafe.org/cs/CAC/Pages/default.aspx>.

This proposal is intended to address fatal CO₂ poisoning incidents in restaurants where CO₂ leaked from large storage tanks and displaced oxygen in these areas. Two such incidents can be found at:

http://articles.orlandosentinel.com/2005-02-12/news/0502120303_1_carbon-dioxide-central-florida-sanford

<http://savannahnow.com/news/2011-09-14/carbon-dioxide-blamed-pooler-mcdonalds-death>

Individual requirements are proposed based on the following:

105.6.4 and Table 105.6.8 – Operational permits are required for CO₂ systems used in the beverage dispensing applications covered by new Section 5307.

5307.1 – The intent of the proposal is to address locations where CO₂ is used in conjunction with carbonators to produce carbonated beverages. A minimum trigger of 100 lbs. was selected for these requirements because it was felt that systems with lesser amounts of CO₂ do not pose as great a risk of asphyxiation as is present with large quantities of the gas.

5307.2 – Provides a reference to permit requirements that is consistent with other such references in the code.

5307.3 - Components in a compressed gas system are already required to comply with Chapter 53 which will cover items such as pressure vessel and piping requirements, among others. An additional reference to NFPA 55, Chapter 13 brings in additional requirements that relate specifically to these installations.

5307.4 - This section includes basic requirements that are intended to protect CO₂ storage tanks, cylinders, piping and fittings are protected from damage by occupants or equipment during normal facility operations. This will decrease the chance of damage that may cause leaks, which is especially important in the facilities in which gas detection systems are not provided.

5307.5 – This section requires buildings in which the CO₂ systems are installed to be provided with either ventilation that complies with Section 5307.5.1 or an emergency alarm system that complies with Section 5307.5.2. It does not require that both ventilation and gas detection be required.

The hazard associated with these systems is that the heavier than air CO₂ may accumulate and displace oxygen, creating an asphyxiation hazard. Leaks are most likely from fittings and connections, but could also be from plastic or other runs of piping.

5307.5.2 – When the emergency alarm system option is selected, it shall include a continuous gas detection system with CO₂ detectors of adequate number and spacing to cover the protected area. The trigger level of 5000 ppm CO₂ is the OSHA Permissible Exposure Limit (PEL).

Cost Impact: This proposal will add to the cost of construction.

F310-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

5307 (NEW)-F-ZUBIA-FCAC

F311 – 13

5501.1, 5503.1.3.1, 5503.2.6, Table 5504.3.1.1

Proponent: Patrick A. McLaughlin McLaughlin & Associates, representing the Compressed Gas Association (pmclaugma@aol.com)

Revise as follows:

5501.1 Scope. Storage, use and handling of *cryogenic fluids* shall comply with this chapter and NFPA 55. *Cryogenic fluids* classified as hazardous materials shall also comply with the general requirements of Chapter 50 for general requirements. Partially full containers containing residual *cryogenic fluids* shall be considered as full for the purposes of the controls required.

Exceptions:

1. Fluids used as refrigerants in refrigeration systems (see Section 606).
2. Liquefied natural gas (LNG), which shall comply with NFPA 59A.

Oxidizing *cryogenic fluids*, including oxygen, shall comply with ~~NFPA 55~~ and Chapter 63, as applicable.

Flammable *cryogenic fluids*, including hydrogen, methane and carbon monoxide, shall comply with ~~NFPA 55~~ and Chapters 23 and 58, as applicable.

Inert *cryogenic fluids*, including argon, helium and nitrogen, shall comply with ANSI/CGA P-18.

5503.1.3.1 Temperature effects. When container foundations or supports are subject to exposure to temperatures below -130°F (-90°C) ~~-450°F (-404°C)~~, the foundations or supports shall be constructed of materials to withstand the low-temperature effects of *cryogenic fluid* spillage.

5503.2.6 Shutoffs between pressure relief devices and containers. Shutoff valves shall not be installed between pressure relief devices and containers.

Exceptions:

1. A shutoff valve is allowed on containers equipped with multiple pressure-relief device installations where the arrangement of the valves provides the full required flow through the minimum number of required relief devices at all times.
2. A locking type shutoff valve, is allowed to be used upstream of the pressure relief device for service-related work performed by the supplier when in accordance with the requirements of the ASME Boiler and Pressure Vessel Code.

**TABLE 5504.3.1.1
SEPARATION OF STATIONARY CONTAINERS FROM
EXPOSURE HAZARDS**

EXPOSURES	MINIMUM DISTANCE (feet)
Building exits	10

(Portions of table not shown remain unchanged)

Reason:

5501.1: The proposal requires compliance to NFPA 55 for all cryogenic fluids and provides the correct title for the already reference P-18. Without the expanded NFPA 55 reference, the scope is inconsistent. It currently requires compliance with NFPA 55 oxidizing and flammable cryogenic fluids. If it is appropriate for these materials it is appropriate for all cryogenic fluids.

- 5503.1.3.1:** A cryogenic fluid is defined as having a boiling point lower than -130 F by the IFC, DOT, OSHA, and internationally. The requirements should apply at that temperature otherwise the foundation or supports of those cryogenic fluids within the range not covered are at risk. . Also, the change brings the IFC into alignment with NFPA 55.
- 5503.2.6:** The proposal brings the IFC into alignment with NFPA 55. The ASME Boiler and Pressure Vessel code allows the use of a locking valve on the upstream side of a pressure relief device in instances where it is impractical to install multiple pressure relief devices and valves, or where having the multiple valves creates more potential safety hazards during maintenance work on the devices. The BPV code has detailed requirements for working on relief devices with the use of upstream valves, including the requirement to lock the valve open when not working on the valve and the requirement to lower pressure vessel pressure before maintenance. The BPV code also requires that personnel monitor vessel pressure during maintenance and have access to an alternate valve other than a pressure relief valve to relieve unexpected pressure rises during maintenance activities. Petrochemical plants and industrial gas plant personnel have used the procedures successfully for many years, as evidenced by the continued allowance of the procedure in the BPV code.

Table

- 5504.3.1.1:** The proposal correlates this Table with IFC Table 5504.3.1.2.1, Separation of Portable Containers from Exposure Hazards and NFPA 55.

Cost Impact: The code change proposal will not increase the cost of construction.

F311-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

5501.1-F-MCLAUGHLIN

F312 – 13

5601.3

Proponents: Glenn A. Dean, Virginia State Fire Marshal's Office (glenn.dean@vdfp.virginia.gov); Adolf Zubia, Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azubiamia@yahoo.com)

Revise as follows:

5601.3 Prohibited explosives. Permits shall not be issued or renewed for possession, manufacture, storage, handling, sale or use of the following materials and such materials currently in storage or use shall be disposed of in an *approved* manner.

1. Liquid nitroglycerin.
2. Dynamite containing more than 60-percent liquid *explosive* ingredient.
3. Dynamite having an unsatisfactory absorbent or one that permits leakage of a liquid *explosive* ingredient under any conditions liable to exist during storage.
4. Nitrocellulose in a dry and uncompressed condition in a quantity greater than 10 pounds (4.54 kg) of net weight in one package.
5. Fulminate of mercury in a dry condition and fulminate of all other metals in any condition except as a component of manufactured articles not hereinafter forbidden.
6. *Explosive* compositions that ignite spontaneously or undergo marked decomposition, rendering the products of their use more hazardous, when subjected for 48 consecutive hours or less to a temperature of 167°F (75°C).
7. New *explosive materials* until *approved* by DOTn, except that permits are allowed to be issued to educational, governmental or industrial laboratories for instructional or research purposes.
8. *Explosive materials* ~~condemned~~ forbidden for transport by DOTn.
9. *Explosive materials* containing an ammonium salt and a chlorate.
10. *Explosives* not packed or marked as required by DOTn 49 CFR Parts 100–185.

Exception: Gelatin dynamite.

Reason - DEAN: The U.S. Department of Transportation (DOTn) does not “condemn” materials. It never has. What DOTn does do, when appropriate, is list explosive products as “forbidden” by any mode of transport. This change is simply to reflect that reality by deleting the antiquated language that has for decades wrongly existed in the model codes, and replace it with specific, enforceable language.

A complete list of materials forbidden to transport by DOTn is available at <http://www.phmsa.dot.gov>.

Reason - ZUBIA: While it does prohibit transporting certain materials on the public highways, the Federal Department of Transportation (DOTn) does not condemn explosives.

Example: Triacetone Triperoxide (TATP)

These materials are already banned or prohibited from transportation by DOT. The DOT prohibition is not affected by the deletion of this outdated language.

Cost Impact: The code change proposal will not increase the cost of construction.

F312-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

5601.3-F-DEAN-ZUBIA-FCAC

F313 – 13

5601.1.3

Proponent: Carl Baldassarra, P.E., FSFPE, Chair, ICC Code Technology Committee
(cbaldassarra@RJAGroup.com)

Revise as follows:

5601.1.3 Fireworks. The possession, manufacture, storage, sale, handling and use of fireworks are prohibited.

Exceptions:

1. Storage and handling of fireworks as allowed in Section 5604.
2. Manufacture, assembly and testing of fireworks as allowed in Section 5605.
3. The use of fireworks for fireworks displays as allowed in Section 5608.
4. The possession, storage, sale, handling and use of specific types of Division 1.4G fireworks where allowed by applicable laws, ordinances and regulations, provided such fireworks comply with NFPA 1124, CPSC 16 CFR Parts 1500 and 1507, and DOTn 49 CFR Parts 100 – 185, for consumer fireworks.

Reason: Consumer fireworks present an unusually high risk to the public. This is reflected in the general provision of this paragraph – a prohibition of such facilities – although certain exceptions are allowed. Incidents have been documented in a report prepared for the NFPA Fire Protection Research Foundation by Schirmer Engineering Corporation, *Fire Safety in Consumer Fireworks Storage and Retail Facilities – Hazard Assessment, October, 2007*, available from The Research Foundation. The report further identified concerns about the lack of technical documentation for various design criteria, including the lack of a basis for appropriate automatic sprinkler protection design criteria for such facilities.

The current provision in Exception 4 is inadequate to assure that a reasonable level of safety will be provided. Reference to NFPA will provide additional important criteria related to construction, allowable area, egress and protection which is not identified in CPSC 16 CFR, Parts 1500 and 1507, or DOTn 49 CFR, Parts 100 – 185. NFPA has recently undertaken a major review of the consumer fireworks provisions in NFPA 1124 to assure that the provisions are technically sound and provide a reasonable level of safety for this hazard.

Cost Impact: This proposal may have a negative impact on the construction of large consumer fireworks facilities. The exact impact cannot be quantified. Nevertheless, the industry will have options to safely operate its businesses.

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

5704.2.5-F-KLAUSBRUCKNER

F315 – 13

5704.2.7.1, 5704.2.11, 5704.2.11.1

Proponent: Bob Eugene, representing UL LLC (Robert.Eugene@ul.com)

Revise as follows:

5704.2.7.1 Materials used in tank construction. The materials used in tank construction shall be in accordance with NFPA 30. The materials of construction for tanks and their appurtenances shall be compatible with the liquids to be stored.

5704.2.11 Underground tanks. Underground storage of flammable and *combustible liquids* in tanks shall comply with Section 5704.2 and Sections 5704.2.11.1 through 5704.2.11.4.2 ~~5704.2.11.5.2~~.

~~**5704.2.11.1 Contents.** Underground tanks shall not contain petroleum products containing mixtures of a nonpetroleum nature, such as ethanol or methanol blends, without evidence of compatibility.~~

(Renumber subsequent sections)

Reason: Combustible and flammable liquid tanks are being used to store an ever increasing number of liquids, including gasoline/ethanol blends and diesel/biodiesels blends. A sentence was added to the general tank storage section requiring the tank materials to be compatible with the stored liquids. This is consistent with NFPA 30, Section 21.4.1.1. With this requirement in place for all tanks, it is no longer necessary to include a similar compatibility requirement for underground tanks in Section 5704.2.11.1.

Cost Impact: None

F315-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

5704.2.7.1-F-EUGENE

F316 – 13

5704.2.7.3.6

Proponent: Lynne M. Kilpatrick, Sunnyvale Department of Public Safety, representing California Fire Chiefs Association (lkilpatrick@sunnyvale.ca.gov)

Delete without substitution:

~~5704.2.7.3.6 Tank venting for tanks and pressure vessels storing Class IB and Class IC liquids.~~

~~Tanks and pressure vessels storing Class IB or Class IC liquids shall be equipped with venting devices which shall be normally closed except when venting under pressure or vacuum conditions, or with listed flame arresters. The vents shall be installed and maintained in accordance with Section 21.4.3 of NFPA 30 or API 2000.~~

Reason: Revisions to Section 5704.2.7.3.2 that were approved during the last code cycle fully address the requirements for venting tanks containing Class IB and IC flammable liquids currently found in Section 5704.2.7.3.6, making this Section redundant.

Cost Impact: The code change proposal will not increase the cost of construction.

F316-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

5704.2.7.3.6-F-KILPATRICK

F317 – 13

5704.2.9.7.3

Proponent: Lynne M. Kilpatrick, Sunnyvale Department of Public Safety, representing California Fire Chiefs Association (lkilpatrick@sunnyvale.ca.gov)

Delete without substitution:

~~5704.2.9.7.3 Flame arresters.~~ ~~Approved flame arresters or pressure breather valves shall be installed in normal vents.~~

Reason: As written, this code section requires that a flame arrester or pressure-vacuum (PV) vent be installed in the normal vent of all protected aboveground tanks (UL 2085) containing flammable or combustible liquids. Because the primary function of a flame arrester is to prevent the unrestricted propagation of flame through flammable gas or vapor mixtures, there is no technical reason to require a flame arrester on tanks containing combustible liquids. Other national standards (i.e. NFPA 30: 21.4.3.9) require the venting devices or flame arresters only on tanks containing Class I flammable liquids. Even the provisions found in Section 5704.2.7.3.2 of this code addressing other tanks whose design and construction provide less protection and control than a protected aboveground tank, only require tanks to be equipped with such venting devices when the tank contains a Class I liquid. Consider the following example of this inconsistency: A diesel generator with an integral UL142 (steel aboveground) tank is not required to be equipped with a flame arrester on the normal vent, but the same diesel generator with an integral UL 2085 tank is required to have a flame arrester.

Approving this code change proposal deletes the special requirement for all protected aboveground tanks to be equipped with a venting device or flame arrester regardless of the tank contents and relies on Section 5704.2.7.3.2 to drive the conditions under which the device is needed. This is consistent with the current code requirement for tanks other than protected aboveground tanks and other national standards and maintains a requirement for all tanks to be equipped with a tank venting device or flame arrester when there is a sound technical reason to provide one.

Cost Impact: The code change proposal will not increase the cost of construction.

F317-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

5704.2.9.7.3-F-KILPATRICK

F318 – 13

5704.3.3.2

Proponent: Elley Klausbruckner representing Klausbruckner & Associates Inc (ek@klausbruckner.com)

Revise as follows:

5704.3.3.2 Incompatible materials. Materials that will react with water or other liquids to produce a hazard shall not be stored in the same room with flammable and *combustible liquids* except where stored in accordance with Section 5003.9.8.

Reason: The code section, as it is currently written, provides conflicting information. Materials that will react with water or other liquids to produce a hazard are allowed in the same room as flammable and combustible liquids when restricted by container size isolated from each other by methods listed in 5003.9.8 (1) through (4) . Therefore the language stating "shall not be stored in the same room" is in conflict with "in accordance with Section 5003.9.8."

We believe the intent is to isolate the two materials to avoid a reaction. The language as it is can be problematic in places such as lab facilities where a storage area using hazardous materials cabinets are used to store small vials of materials.

Cost Impact: The code change proposal will not increase the cost of construction.

F318-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

5704.3.3.2-F-KLAUSBRUCKNER

F319 – 13

Table 5704.3.6.3(7), Table 5704.3.7.5.1, 5704.3.8.5

Proponent: Elley Klausbruckner representing Klausbruckner & Associates Inc (ek@klausbruckner.com)

Revise as follows:

TABLE 5704.3.6.3(7)

AUTOMATIC AFFF WATER PROTECTION REQUIREMENTS FOR RACK STORAGE OF LIQUIDS IN METAL CONTAINERS GREATER THAN 5-GALLON CAPACITY^{a, b}

(No changes to table)

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 square foot = 0.0929 m², 1 pound per square inch = 6.895 kPa, 1 gallon = 3.785 L, 1 gallon per minute = 3.785 L/m, 1 gallon per minute per square foot = 40.75 L/min/m².

- a. System shall be a closed-head wet system with *approved* devices for proportioning aqueous film-forming foam.
- b. Except as modified herein, in-rack sprinklers shall be installed in accordance with NFPA 13.
- c. The height of storage shall not exceed 25 feet.
- d. Hose stream demand includes 1½-inch inside hose connections ~~hand hose~~, when required.

TABLE 5704.3.7.5.1

AUTOMATIC AFFF-WATER PROTECTION REQUIREMENTS FOR SOLID-PILE AND PALLETIZED STORAGE OF LIQUIDS IN METAL CONTAINERS OF 5-GALLON CAPACITY OR LESS^{a, b}

(No changes to table)

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 square foot = 0.0929 m², 1 gallon per minute = 3.785 L/m, 1 gallon per minute per square foot = 40.75 L/min/m², °C. = [(°F)-32]/1.8.

- a. System shall be a closed-head wet system with approved devices for proportioning aqueous film-forming foam.
- b. Maximum ceiling height of 30 feet.
- c. Hose stream demand includes 1½-inch inside hose connections ~~hand hose~~, when required.

5704.3.8.5 Warehouse hose lines. In liquid storage warehouses, either 1½-inch (38 mm) lined or 1-inch (25 mm) hard rubber ~~hand~~ hose lines shall be provided in sufficient number to reach all liquid storage areas and shall be in accordance with Section 903 or Section 905.

Reason: The term “hand hose” is only used in Chapter 57, while the remainder of the IFC uses the term “hose connections.”

Cost Impact: The code change proposal will not increase the cost of construction.

F319-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

5704.6.3T-F-KLAUSBRUCKNER

F320 – 13

5705.5, 5705.5.1

Proponent: John Williams, CBO, Chair, ICC Ad Hoc Committee on Health Care (john.williams@doh.wa.gov) and Carl Baldassarra, P.E., FSFPE, Chair, ICC Code Technology Committee (cbaldassarra@RJAGroup.com)

Revise as follows:

5705.5 Alcohol-based hand rubs classified as Class I or II liquids. The use of wall-mounted dispensers containing alcohol-based hand rubs classified as Class I or II liquids shall be in accordance with all of the following:

1. The maximum capacity of each dispenser shall be 68 ounces (2 L).
2. The minimum separation between dispensers shall be 48 inches (1219 mm).
3. The dispensers shall not be installed ~~directly adjacent to, directly above, or below, or closer than 1 inch to~~ an electrical receptacle, switch, appliance, device or other ignition source. The wall space between the dispenser and the floor or intervening counter top shall be free remain clear and unobstructed of electrical receptacles, switches, appliances, devices, or other ignition sources.
4. Dispensers shall be mounted so that the bottom of the dispenser is a minimum of 42 inches (1067 mm) and a maximum of 48 inches (1219 mm) above the finished floor.
5. Dispensers shall not release their contents except when the dispenser is manually activated. Facilities shall be permitted to install and use automatically activated “touch free” alcohol-based hand-rub dispensing devices with the following requirements:
 - 5.1. The facility or persons responsible for the dispensers shall test the dispensers each time a new refill is installed in accordance with the manufacturer’s care and use instructions.
 - 5.2. Dispensers shall be designed and must operate in a manner that ensures accidental or malicious activations of the dispensing device are minimized. At a minimum, all devices subject to or used in accordance with this section shall have the following safety features:
 - 5.2.1. Any activations of the dispenser shall only occur when an object is placed within 4 inches (98 mm) of the sensing device.
 - 5.2.2. The dispenser shall not dispense more than the amount required for hand hygiene consistent with label instructions as regulated by the United States Food and Drug Administration (USFDA).
 - 5.2.3. An object placed within the activation zone and left in place will cause only one activation.
6. Storage and use of alcohol-based hand rubs shall be in accordance with the applicable provisions of Sections 5704 and 5705.
7. Dispensers installed in occupancies with carpeted floors shall only be allowed in smoke compartments or fire areas equipped throughout with an approved automatic sprinkler system in accordance with Section 903.3.1.1 or 903.3.1.2.

5705.5.1 Corridor installations. In addition to the provisions of Section 5705.5, W where wall-mounted dispensers containing alcohol-based hand rubs are installed in corridors or rooms and areas open to the corridor, they shall be in accordance with all of the following:

1. Level 2 and 3 aerosol containers shall not be allowed in corridors.
2. The maximum capacity of each Class I or II liquid dispenser shall be 41 ounces (1.21 L) and the maximum capacity of each Level 1 aerosol dispenser shall be 18 ounces (0.51 kg).
3. The maximum quantity allowed in a corridor within a control area shall be 10 gallons (37.85 L) of Class I or II liquids or 1135 ounces (32.2 kg) of Level 1 aerosols, or a combination of Class I or II liquids and Level 1 aerosols not to exceed, in total, the equivalent of 10 gallons (37.85 L) or 1,135 ounces (32.2 kg) such that the sum of the ratios of the liquid and aerosol quantities divided by the allowable quantity of liquids and aerosols, respectively, shall not exceed one.

4. The minimum corridor width shall be 72 inches (1829 mm).
5. Projections into a corridor shall be in accordance with Section 1003.3.3.

Reason: Because ABHR dispensers are often installed above fixed casework countertops, Section 5705.5(3) is being revised to address the practical issue of clearances from the dispenser to ignition sources associated with the countertop installation. Establishing the minimum clearance requirements provides clarity to the fire code official and to designers and facility administrators.

As part of an institution's infection control protocol, many places where ABHR dispensers are installed in healthcare facilities are areas that are open to the corridor as permitted by Section 407 of the *International Building Code*. As such, Section 5705.5.1 is being revised to include such areas.

This proposal is submitted by the ICC Ad Hoc Committee for Healthcare (AHC). The AHC was established by the ICC Board of Directors to evaluate and assess contemporary code issues relating to hospitals and ambulatory healthcare facilities. The AHC is composed of building code officials, fire code officials, hospital facility engineers, and state healthcare enforcement representatives. The goals of the committee are to ensure that the ICC family of codes appropriately addresses the fire and life safety concerns of a highly specialized and rapidly evolving healthcare delivery system. This process is part of a joint effort between ICC and the American Society for Healthcare Engineering (ASHE), a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. Since its inception in April, 2011, the AHC has held 8 open meetings and over 150 workgroup calls which included members of the AHC as well as any interested party to discuss and debate the proposed changes. All meeting materials and reports are posted on the AHC website at: <http://www.iccsafe.org/cs/AHC/Pages/default.aspx>

This proposal is being co-sponsored by the ICC Code Technology Committee. The ICC Board established the ICC Code Technology Committee (CTC) as the venue to discuss contemporary code issues in a committee setting which provides the necessary time and flexibility to allow for full participation and input by any interested party. The code issues are assigned to the CTC by the ICC Board as "areas of study". Information on the CTC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CTC effort can be downloaded from the following website: <http://www.iccsafe.org/cs/cc/ctc/index.html>. Since its inception in April, 2005, the CTC has held 25 meetings – all open to the public. In 2012, three of the 25 face-to face meetings were held. In addition to the CTC meetings, the CTC established Study Groups (SG) of interested parties for each of the areas of study. These SG's are responsible for reviewing the available information and making recommendations to the CTC. All totaled, the SG's held over 70 conference calls in 2012.

Cost impact: This proposal will not increase the cost of construction.

F320-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

5705.5-F-BALDASSARRA-WILLIAMS-ADHOC-CTC

F321 – 13

5706.5.1.5

Proponent: Elley Klausbruckner representing Klausbruckner & Associates Inc (ek@klausbruckner.com)

Revise as follows:

5706.5.1.5 Spill control and secondary containment. Areas where transfer operations are located shall be provided with spill control and secondary containment in accordance with Section 5703.4. The spill control and secondary containment system in bulk plants, bulk terminals, and refineries shall have a design capacity capable of containing the capacity of the largest tank compartment located in the area where transfer operations are conducted. Containment of the rainfall volume specified in Section 5004.2.2.6 is not required.

Reason: The requirements of spill control above is under 5706, "Special Operation." These requirements are mostly intended for large flammable/combustible liquids bulk tanks, plants and terminals. However since Bulk Transfer is defined as:

***BULK TRANSFER.** The loading or unloading of flammable or combustible liquids from or between tank vehicles, tank cars or storage tanks.*

Since most flammable/combustible liquids storage tanks will need refilling, the requirements of 5706.5.1.5 [as it is written] apply to ALL flammable/combustible liquids storage tanks, not just in bulk terminals and plants. In other words, the design of secondary containment having a design capacity capable of containing the capacity of the largest tank **compartment** would be applied to the largest tank vehicle or tank car compartment filling or fuelling regular tanks on site. This section was clearly intended bulk plants, terminals and refineries.

For example if a single double walled tank for a generator is proposed, Section 5706.5.1.5, as it exists, would still require that a spill control and secondary containment be designed and installed. The containment would have to be designed to contain the largest tank compartment [which can be a tank car, tank vehicle, etc.]. There is no method of verifying what tank vehicle or tank car [i.e. largest compartment on that tank] will be refilling the on-site diesel generator tank. This was clearly intended for bulk plants, bulk terminals and refineries, not for single tanks used on site.

Please also note that overfill protection is required for tanks that do not fall under "Special Operations" in sections 5704.2.7.5.8, 5704.2.8.18, 5704.2.9.5.1, 5704.2.9.7.6, 5704.2.11.4. These overfill protection requirements address the hazards associated with possibly overfilling tanks.

Cost Impact: The code change proposal will not increase the cost of construction.

F321-13

	Assembly:	ASF	AMF	DF

5706.5.1.5-F-KLAUSBRUCKNER

F322 – 13

5706.8 (New), 5706.1

Proponent: Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azubiamia@yahoo.com)

Revise as follows:

5706.8 Liquid Biofuels. Production, processing and storing of liquid biofuels shall comply with all applicable requirements in this chapter. Biofuel dispensing operations shall be in accordance with Chapter 23.

(Renumber subsequent sections)

5706.1 General. This section shall cover the provisions for special operations which include, but are not limited to, storage, use, dispensing, mixing or handling of flammable and *combustible liquids*. The following special operations shall be in accordance with Sections 5701, 5703, 5704 and 5705, except as provided in Section 5706.

1. Storage and dispensing of flammable and *combustible liquids* on farms and sites.
2. Well drilling and operating.
3. Bulk plants or terminals.
4. Bulk transfer and process transfer operations utilizing tank vehicles and tank cars.
5. Tank vehicles and tank vehicle operation.
6. Refineries.
7. Liquid biofuels.
- ~~7~~8. Vapor recovery and vapor-processing systems.

Reason: A growing number of citizens are obtaining used cooking grease and other combustible liquids, to then distill into biodiesel and other liquid biofuels. This proposal provides clear cut requirements for code officials to use to prevent this processing operation from being conducted unless in conformance with the code.

Cost Impact: The code change will not increase the cost of construction.

F322-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

5706.8 (NEW)-F-ZUBIA-FCAC

F323 – 13

5801.1, Chapter 80

Proponent: Robert J Davidson, Davidson Code Concepts, LLC, representing the National Renewable Energy Laboratory (NREL) (rjd@davidsoncodeconcepts.com)

Revise as follows:

5801.1 Scope. The storage and use of flammable gases and flammable cryogenic fluids shall be in accordance with this chapter and NFPA 55. Compressed gases shall also comply with Chapter 53 and cryogenic fluids shall also comply with Chapter 55. Flammable cryogenic fluids shall comply with Section 5806. Hydrogen motor fuel-dispensing stations and repair garages and their associated above-ground hydrogen storage systems shall also be designed , ~~and~~ constructed and maintained in accordance with Chapter 23 and NFPA 2.

Exceptions:

1. Gases used as refrigerants in refrigeration systems (see Section 606).
2. Liquefied petroleum gases and natural gases regulated by Chapter 61.
3. Fuel-gas systems and appliances regulated under the International Fuel Gas Code other than gaseous hydrogen systems and appliances.
4. Pyrophoric gases in accordance with Chapter 64.

Add new standard to Chapter 80 as follows:

NFPA

2-11 Hydrogen Technologies Code 5801.1

Reason: This minor modification to Section 5801.1 clarifies that hydrogen motor fuel dispensing stations and repair garages must be maintained in accordance with Chapter 23 in addition to being design and constructed in accordance with that chapter. Additionally, a reference is added to NFPA 2 to coordinate with previous proposals in this series of changes submitted on behalf of NREL.

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: A review of the standard proposed for inclusion in the code, NFPA 2-11, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28), will be posted on the ICC website on or before April 1, 2013.

F323-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

5801.1-F-DAVIDSON

F324 – 13

5803.1.1

Proponent: Robert J Davidson, Davidson Code Concepts, LLC, representing the National Renewable Energy Laboratory (NREL) (rjd@davidsoncodeconcepts.com)

Revise as follows:

5803.1.1 Special limitations for indoor storage and use. Flammable gases shall not be stored or used in Group A, E, I or R occupancies or in offices in Group B occupancies.

Exceptions:

1. Cylinders of nonliquefied compressed gases not exceeding a capacity of 250 cubic feet (7.08 m³) or liquefied gases not exceeding a capacity of 40 pounds (18 kg) each at normal temperature and pressure (NTP) used for maintenance purposes, patient care or operation of equipment.
2. Food service operations in accordance with Section 6103.2.1.7.
3. Hydrogen gas systems located in a hydrogen cutoff room constructed in accordance with Section 421 of the *International Building Code*.

Reason: Starting with the 2003 edition of the I-Codes there were provisions for the use of a "hydrogen cutoff room" as an incidental use for the storage and use of hydrogen. The purpose was to provide rules for the indoor application of new hydrogen fuel technology.

Though language was added to Chapter 23 pointing to the hydrogen cutoff room provisions for indoor fueling operations, no pointer was provided for other uses of the new technology such as the use of hydrogen fuel cells with hydrogen gas cylinders as a fuel supply for clean energy backup power systems.

The use of the hydrogen fuel cell backup power supplies is not Group specific and though Exception 1 currently permits the hydrogen for operation of equipment, the amount permitted, 250 cubic feet, is insufficient for the backup power application.

The new pointer to the use of the hydrogen cutoff room will provide for the safe use of this technology in the Groups currently restricted by Section 5803.1.1 by allowing the application of the hydrogen cutoff rooms which have increased protective measures. The limiting factor would be the MAQ for flammable gas currently specified by the code.

Cost Impact: The code change proposal will not increase the cost of construction.

F324-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

5803.1.1-F-DAVIDSON

F325 – 13

6003.1.4.1

Proponent: Elley Klausbruckner representing Klausbruckner & Associates Inc (ek@klausbruckner.com)

Revise as follows:

6003.1.4.1 Floors. In addition to the requirements set forth in Section 5004.12, floors of storage areas where highly toxic and toxic liquids are stored shall be of liquid-tight construction.

Reason: Liquid tight flooring for storage of highly toxic and toxic solids is illogical. We believe the code section was intended for storage of liquids only.

Cost Impact: The proposal will not increase the cost of construction.

F325-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

6003.1.4.1-F-KLAUSBRUCKNER

F326 – 13

6003.1.5.2, 6003.1.5.3

Proponent: Elley Klausbruckner representing Klausbruckner & Associates Inc (ek@klausbruckner.com)

Revise as follows:

6003.1.5.2 Exhaust ventilation for open systems. Mechanical exhaust ventilation shall be provided for highly toxic and toxic liquids used in *open systems* in accordance with Section 5005.2.1.1.

Exception: Liquids ~~or solids~~ that do not generate highly toxic or toxic fumes, mists or vapors.

6003.1.5.3 Exhaust ventilation for closed systems. Mechanical exhaust ventilation shall be provided for highly toxic and toxic liquids used in *closed systems* in accordance with Section 5005.2.2.1.

Exception: Liquids ~~or solids~~ that do not generate highly toxic or toxic fumes, mists or vapors.

Reason: Editorial Change. The charging statement is specific to highly toxic and toxic liquids. However the exception mentions solids.

Cost Impact: The proposal will not increase the cost of construction.

F326-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

6003.1.5.2-F-KLAUSBRUCKNER

F327 – 13

Table 6104.3

Proponent: Bruce Swiecicki representing National Propane Gas Association (bswiecicki@npga.org)

Revise as follows:

**TABLE 6104.3
LOCATION OF LP-GAS CONTAINERS**

LP-GAS CONTAINER CAPACITY (water gallons)	MINIMUM SEPARATION BETWEEN LP-GAS CONTAINERS AND BUILDINGS, PUBLIC WAYS OR LOT LINES OF ADJOINING PROPERTY THAT CAN BE BUILT UPON		MINIMUM SEPARATION BETWEEN LP-GAS CONTAINERS ^{b, c} (feet)
	Mounded or underground LP-gas containers ^a (feet)	Above-ground LP-gas containers ^b (feet)	

(Portions of table not shown remain unchanged)

Reason: The definition in the International Fire Code of “public way” is:

“A street, alley or other parcel of land open to the outside air leading to a street, that has been deeded, dedicated or otherwise permanently appropriated to the public for public use and which has a clear width and height of not less than 10 feet.”

The Commentary to the IFC elaborates by saying:

“The Public way marks the termination of the exit discharge portion of the means of egress system. It is the final destination for occupants, and is presumed to be safe from the emergency occurring in the structure or that it will directly connect to other routes so that occupants can move a distance away from the danger.”

Based on the history of the term “public way,” the chief concern is being able to egress the occupants of a building in a manner that allows them to have access to a safe space outside the building. The presumption is that an emergency has occurred inside the building and the occupants must egress the building safely.

The restriction on the placement of a propane container with respect to a public way is not consistent with the purpose for establishing a public way because the threat to the occupants does not come from the propane container. The container is required to be located a specific distance from the building based on its size and therefore, the container will not be threatened by a fire event that occurs within the building. It has been shown that the distances required by Table 6104.3 are sufficient to maintain the safety of the container even if the building is on fire. Therefore, there is no threat to the occupants from the propane container as they egress the building. In addition, the potential concern of vehicular impact to the propane container is already addressed in Section 312 of the IFC.

Chapter 61 refers to NFPA 58 as a standard that “fills in the gaps” that may not be addressed in Chapter 61. In this case, NFPA 58 has a restriction (Table 6.5.3) on the location of product transfers with respect to public ways and places of public assembly. Transfers of propane into or out of the container are prohibited within 10 feet of a public way and within 50 feet of outdoor places of public assembly. Therefore, the threat to the general public during product transfer operations is addressed by NFPA 58.

The limitation in the IFC on the placement of containers with respect to public ways creates a conflict between Section 6104.3 with Table 6104.3 in the IFC and Section 6.3.1 with Table 6.3.1 in NFPA 58. This conflict has led to differing interpretations by various authorities having jurisdiction and we propose to delete the term “public ways” to resolve the conflict.

In summary, elimination of the term “public way” will not compromise the safety of the occupants of the building and will resolve a conflict between the IFC and NFPA 58.

Cost Impact: This proposal will not increase the cost of construction.

F327-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

6104.3-F-SWIECICKI

F328 – 13

Table 6104.3

Proponent: Bruce Swiecicki representing National Propane Gas Association (bswiecicki@npga.org)

Revise as follows:

**TABLE 6104.3
LOCATION OF LP-GAS CONTAINERS**

LP-GAS CONTAINER CAPACITY (water gallons)	MINIMUM SEPARATION BETWEEN LP-GAS CONTAINERS AND BUILDINGS, PUBLIC WAYS OR LOT LINES OF ADJOINING PROPERTY THAT CAN BE BUILT UPON		MINIMUM SEPARATION BETWEEN LP-GAS CONTAINERS ^{b, c} (feet)
	Mounded or underground LP-gas containers ^a (feet)	Above-ground LP-gas containers ^b (feet)	
Less than 125 ^{c, d}	10	5 e	None
501 to 2,000	10	25 e, f	3

(Portions of table not shown remain unchanged)

a through d (No changes to current text)

e. The following shall apply to above-ground containers installed alongside buildings:

1. LP-gas containers of less than a 125-gallon water capacity are allowed next to the building they serve and with no separation from a property line when in compliance with Items 2, 3 and 4.
2. Department of Transportation (DOTn) specification LP-gas containers shall be located and installed so that the discharge from the container pressure relief device is at least 3 feet horizontally from building openings below the level of such discharge and shall not be beneath buildings unless the space is well ventilated to the outside and is not enclosed for more than 50 percent of its perimeter. The discharge from LP-gas container pressure relief devices shall be located not less than 5 feet from exterior sources of ignition, openings into direct-vent (sealed combustion system) appliances or mechanical ventilation air intakes.
3. ASME LP-gas containers of less than a 125-gallon water capacity shall be located and installed such that the discharge from pressure relief devices shall not terminate in or beneath buildings and shall be located at least 5 feet horizontally from building openings below the level of such discharge and not less than 5 feet from exterior sources of ignition, openings into direct vent (sealed combustion system) appliances, or mechanical ventilation air intakes.
4. The filling connection and the vent from liquid-level gauges on either DOTn or ASME LP-gas containers filled at the point of installation shall not be less than 10 feet from exterior sources of ignition, openings into direct vent (sealed combustion system) appliances or mechanical ventilation air intakes.

f. *(No changes to current text)*

Reason: This proposal will bring the IFC into closer correlation with NFPA 58 regarding the installation of small containers next to buildings. There is no technical basis for permitting the installation of a small container next to a building and still mandating a separation distance from a lot line, as Note e to Table 6104.3 may currently be interpreted to require. ICC staff previously responded to a request for interpretation and agrees that an installation in which a small container is located next to a building does not constitute a violation if the property line is within 5 feet of the container.

The other change would strike the reference to Note e in the cell for 501-2000 gallon above-ground containers. Since Note e is only applicable to containers less than 125 gallons, there is no need to reference it in that cell.

Cost Impact: This proposal will not increase the cost of construction.

Public Hearing: Committee: AS AM D
Assembly: ASF AMF DF

6104.3T #1-F-SWIECICKI

F329 – 13

6105.2

Proponent: Bruce Swiecicki representing National Propane Gas Association. (bswiecicki@npga.org)

Revise as follows:

6105.2 Release to the atmosphere. LP-gas shall not be released to the atmosphere, except in accordance with Section 7.3 of NFPA 58. ~~through an approved liquid level gauge or other approved device.~~

Reason: Currently, the IFC permits LP-gas to be released to the atmosphere only while the container is being filled, through the fixed maximum liquid level gauge. However, there are many other situations that require the release of LP-gas under controlled conditions. Referencing Section 7.3 of NFPA 58 will accomplish the intent of this proposal by recognizing all the different circumstances that necessitate the release of gas to the atmosphere, including the following:

- The release of gas when the filling hose is disconnected from the filler valve on the container.
- The release of gas necessary to make cylinders and other containers safe prior to being serviced.
- The release of gas that may be necessary in order to properly purge a container of air to make it safe for filling.

These are a few of the common occurrences in the propane industry that necessitate the release of LP-gas to the atmosphere.

Cost Impact: This proposal will not increase the cost of construction.

6105.2-F-SWIECICKI

F330 – 13

6106.2

Proponent: Bruce Swiecicki representing National Propane Gas Association (bswiecicki@npga.org)

Revise as follows:

6106.2 Overfilling. LP-gas containers shall not be filled or maintained with LP-gas in excess of either the volume determined using the fixed maximum liquid-level gauge ~~installed by the manufacturer~~ installed in accordance with the manufacturer's specifications and in accordance with Section 5.7.5 of NFPA 58, or the weight determined by the required percentage of the water capacity marked on the container. Portable LP-gas containers shall not be refilled unless equipped with an overfilling prevention device (OPD) where required by Section 5.7.3 of NFPA 58.

Reason: This paragraph requires usage of manufacturer installed liquid level gauge to fill a container. It is common practice in the industry to field repair and replace valves and gauges on both ASME tanks and DOT cylinders as needed.

The liquid level gauge is generally an integral part of the service valve which is used to turn the tank on and off. Service valves have rubber or plastic o-rings that can start to leak over time. When a service valve becomes faulty, a new valve is installed with a liquid level gauge tube of exactly the same length. In addition, OPD systems on DOT cylinders may also require periodic replacement. The propane industry has procedures and training to successfully perform these replacements and repair.

The current code text eliminates the ability to service and repair propane containers in the field. The proposed rewrite would correct this and acknowledge that the service and repair of propane containers in the field does take place. NFPA 5.7.5 "Liquid Level Gauging Device" covers the requirements for proper installation and the use of liquid level gauges.

Cost Impact: This proposal will not increase the cost of construction.

F330-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

6106.2-F-SWIECICKI

F331 – 13

6107.4, 6109.13

Proponent: Jeffrey M. Shapiro, International Institute of Ammonia Refrigeration
(jeff.shapiro@intlcodeconsultants.com)

Revise as follows:

6107.4 Protecting containers from vehicles. Where exposed to vehicular damage due to proximity to alleys, driveways or parking areas, LP-gas containers, regulators and piping shall be protected in accordance with NFPA 58, Section 342.

6109.13 Protection of containers. LP-gas containers shall be stored within a suitable enclosure or otherwise protected against tampering. Vehicular protection shall be provided as required by Section 6107.4, the fire code official.

Reason: Sections 6107.4 and 6109.13 both require vehicle impact protection for LP-gas containers, but the requirements are not consistent between the two sections. Furthermore, Section 6109.13 provides no guidance on when protection is necessary or what type of protection should be provided. The proposed revisions correlate the two sections and provide a reference to NFPA 58 for design requirements that are specific to LP-gas equipment. Because NFPA 58 is specific to LP-gas and it contains requirements for vehicle impact protection, as well as annex guidance on how to accomplish such protection, it makes sense for Chapter 61 to reference NFPA 58 for this topic, as it does for various other LP gas topics, to avoid conflicts between the code and the reference standard.

Cost Impact: The code change proposal will not increase the cost of construction.

F331-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

6107.4-F-SHAPIO

F332 – 13

6110.1, 6110.2

Proponent: Bruce Swiecicki representing National Propane Gas Association (bswiecicki@npga.org)

Revise as follows:

6110.1 ~~Temporarily out of service~~ Containers disconnected from service at consumer sites. LP-gas containers ~~disconnected from service whose use has been temporarily discontinued at consumer sites~~ shall comply with all of the following:

- ~~1. Be disconnected from appliance piping.~~
- ~~21. Have The~~ LP-gas container outlets, except pressure relief valves, shall be closed or and plugged or capped.
- ~~32. Be The container shall be~~ positioned with the pressure relief valve in direct communication with the LP-gas container vapor space.

6110.2 ~~Permanently out of service~~ Retrieval of disconnected containers. ~~LP-gas containers to be placed permanently out of service shall be removed from the site.~~ LP-gas containers that have been disconnected from service shall be retrieved by the owner.

Reason: As currently worded, the text in Section 6110 is confusing and difficult to implement. A reading of the 2012 Commentary indicates that the concern is over LP-gas containers that have been disconnected from service due to a customer's request, usually because the customer wants to switch suppliers. The text proposed above will clarify in concise terms what needs to be done in order to avoid the release of gas from a container that has been disconnected from service. The proposal accomplishes the following:

- The changed titles clarify the intent of these sections.
- The deletion of current #1 occurs because the first sentence of the paragraph establishes that the container has already been disconnected from the piping system.
- Changing "outlets" to "appurtenances" is more accurate since not every valve on a container is an "outlet." Container appurtenances are defined in NFPA 58 as "devices installed in container openings for safety, control or operating purposes."
- It is necessary not only to close the valve, but also to plug or cap it.

Current 6110.2 was reworded slightly to establish the responsibility lies with the container owner by recognizing that although the majority of propane tanks are owned by the propane marketer, some are owned by the property owner and therefore the marketer has no control over them.

Cost Impact: This proposal will not increase the cost of construction.

F332-13

6110.1-F-SWIECICKI

F333 – 13

6111.2, 6111.2.1, 6111.2.2

Proponent: Bruce Swiecicki representing National Propane Gas Association (bswiecicki@npga.org)

Revise as follows:

6111.2 Unattended parking. The unattended parking of LP-Gas cargo tank vehicles not in service shall be in accordance with ~~Sections 6111.2.1 and 6111.2.2~~ one of the following:

1. Vehicles shall be parked within a LP-Gas Bulk Plant.
2. Vehicles shall be parked off of public streets, highways, public avenues or public alleys.
3. Vehicles shall be parked at other *approved* locations not less than 50 feet (15. 240 m) from buildings, other than those *approved* for the storage or servicing of such vehicles.

~~**6111.2.1 Near residential, educational and institutional occupancies and other high-risk areas.** LP-gas tank vehicles shall not be left unattended at any time on residential streets or within 500 foot (152 m) of a residential area, apartment or hotel complex, educational facility, hospital or care facility. Tank vehicles shall not be left unattended at any other place that would, in the opinion of the *fire code official*, pose an extreme life hazard.~~

~~**6111.2.2 Durations exceeding 1 hour.** LP-gas tank vehicles parked at any one point for longer than 1 hour shall be located as follows:~~

- ~~1. Off public streets, highways, public avenues or public alleys.~~
- ~~2. Inside of a bulk plant.~~
- ~~3. At other *approved* locations not less than 50 feet (15-240 mm) from buildings other than those *approved* for the storage or servicing of such vehicles.~~

Reason: LP-gas tank vehicles are more commonly referred to as “cargo tank vehicles” and they are under the jurisdiction of the U.S. Department of Transportation, Title 49 of the Code of Federal Regulations. The transportation of hazardous materials (propane is classified as a flammable gas, Division 2.1) is regulated by the Hazardous Materials Regulations (Parts 171-185) and the Federal Motor Carrier Safety Regulations (Parts 350-399).

The current text in 6111.2 addresses “unattended” parking, in which the operator of the vehicle is not present and able to react to an emergency situation by either driving the vehicle or controlling the flow of product into or out of the cargo tank. A vehicle that is parked for the purpose of transferring product into or out of the cargo tank would not be considered to be “unattended” because paragraph 177.834 (i) requires the operator to be in attendance during the product transfer operation. Therefore, the requirements in 6111.2 would not be applicable whenever the cargo tank vehicle was being loaded or unloaded.

The requirements in 6111.2.1 address unattended parking with respect to certain occupancies and other locations that are termed “high-risk” areas. This paragraph is not needed in the code because it imposes requirements that are unwarranted and contradictory as compliance with 6111.2.1 and 6111.2.2 is muddled, i.e., it is not uncommon for LP-gas bulk plants to be located within 500 feet of the occupancies and locations that are mentioned in 6111.2.1. Therefore, the parking of cargo tank vehicles *even within the confines of the bulk plant could constitute a violation*.

Furthermore, the requirements from 49 CFR Part 397.7(b) makes no mention of the occupancies or locations described in 6111.2.1:

§ 397.7 Parking

(b) A motor vehicle which contains hazardous materials other than Division 1.1, 1.2, or 1.3 materials must not be parked on or within five feet of the traveled portion of public street or highway except for brief periods when the necessities of operation require the vehicle to be parked and make it impracticable to park the vehicle in any other place.

The requirements in current paragraph 6111.2.2 are reasonable and do not impose an undue burden on operators of LP-gas cargo tank vehicles. Those requirements are more consistent (but not identical) with those in paragraph 9.7.2 of NFPA 58. Therefore, this wording is retained in 6111.2.

The 50-foot separation distance has been shown to be a valid separation distance to protect the cargo tank from exposure to nearby fires. The 50-foot separation is required for stationary containers greater than 2,000 gallons water capacity and has been justified by numerical modeling of steel containers exposed to fire. The research paper, (*Journal of Hazardous Materials*, April 2006) analyzed steel propane containers of the sizes referred to in Table 6104.3 that were exposed to a severe petroleum pool fire 100 feet in diameter. The modeling indicated that the temperatures of the container walls were well below the temperature at which steel begins to yield. Since all LPG cargo tank motor vehicles are less than 30,000 gallons water capacity, the fifty foot separation distance is justified.

Cost Impact: This proposal will not increase the cost of construction.

	Assembly:	ASF	AMF	DF

6111.2-F-SWIECICKI

F334 – 13

6303.1.1.2, 6303.2, 6304.1, 6304.2.1

Proponent: Patrick A. McLaughlin McLaughlin & Associates, representing the Lonza Group and PPG Industries, Inc.(pmclaugma@aol.com)

Revise as follows:

6303.1.1.2 Class 3 liquid and solid oxidizers. A maximum of 200 pounds (91 kg) of solid or 20 gallons (76 L) of liquid Class 3 oxidizer is allowed in ~~Group I occupancies storage and use~~ when such materials are necessary for maintenance purposes or operation of equipment. The oxidizers shall be stored in *approved* containers and in an *approved* manner.

~~**6303.2 Quantities exceeding the maximum allowable quantity per control area.** The storage and use of oxidizing materials in amounts exceeding the *maximum allowable quantity per control area* indicated in Section 5003.1 shall be in accordance with Chapter 50 and this chapter.~~

6303.2 Class 1 oxidizer storage configuration. The storage configuration of Class I liquid and solid oxidizers shall be as set forth in Table 6303.2

~~**6304.2.1 Distance from storage to exposures for liquid and solid oxidizers.** Outdoor storage areas for liquid and solid oxidizers shall be located in accordance with Table 6304.1.2.~~

6304.1 Indoor storage. Indoor storage of oxidizing materials in amounts exceeding the *maximum allowable quantity per control area* indicated in Table 5003.1.1(1) shall be in accordance with Sections 5001, 5003 and 5004 and this chapter.

~~**6304.1.1 Detached storage.** Storage of liquid and solid oxidizers shall be in detached buildings when required by Section 5003.8.2.~~

~~**6304.1.2 Distance from detached storage buildings to exposures.** In addition to the requirements of the *International Building Code*, detached storage buildings shall be located in accordance with Table 6304.1.2.~~

~~TABLE 6304.1.2 OXIDIZER LIQUIDS AND SOLIDS-DISTANCE FORM DETACHED BUILDINGS AND OUTDOOR STORAGE AREAS TO EXPOSURES~~

~~**6304.1.3 6304.1.1 Explosion control.** Indoor storage rooms, areas and buildings containing Class 4 liquid or solid oxidizers shall be provided with explosion control in accordance with Section 911.~~

~~**6304.1.4 6304.1.2 Automatic sprinkler system.** The *automatic sprinkler system* for oxidizer storage shall be designed in accordance with NFPA 430 400.~~

~~**6304.1.5 6304.1.3 Liquid-tight floor.** In addition to Section 5004.12, floors of storage areas for liquid and solid oxidizers shall be of liquid-tight construction.~~

~~**6304.1.6 6304.1.4 Smoke detection.** An *approved* supervised smoke detection system in accordance with Section 907 shall be installed in liquid and solid oxidizer storage areas. Activation of the smoke detection system shall sound a local alarm.~~

Exception: Detached storage buildings protected by an *approved* automatic fire-extinguishing system.

~~6304.1.7~~ 6304.1.5 Storage conditions. The maximum quantity of oxidizers per building in ~~detached~~ storage buildings shall not exceed those quantities set forth in Tables 6304.1.7 ~~5(1)~~ through 6304.1.7 ~~5(4 3)~~. The storage configuration for liquid and solid oxidizers shall be as set forth in Tables 6304.1.7 ~~5(1)~~ through 6304.1.7 ~~5(4 3)~~. Class 2 oxidizers shall not be stored in *basements* except when such storage is in stationary tanks. Class 3 and 4 oxidizers in amounts exceeding the *maximum allowable quantity per control area* set forth in Section 5003.1 shall be stored on the ground floor only.

~~6304.1.8~~ 6304.1.6 Separation of Class 4 oxidizers from other materials. In addition to the requirements in Section 5003.9.8, Class 4 oxidizer liquids and solids shall be separated from other hazardous materials by not less than a 1- hour *fire barrier* or stored in hazardous materials storage cabinets. ~~Detached storage buildings for Class 4 oxidizer liquids and solids shall be located a minimum of 50 feet (15 240 mm) from other hazardous materials storage.~~

~~6304.1.9~~ 6304.1.7 Contamination. Liquid and solid oxidizers shall not be stored on or against combustible surfaces. Liquid and solid oxidizers shall be stored in a manner to prevent contamination.

~~6304.1.4~~ 6304.1.8 Detached storage. Storage of liquid and solid oxidizers shall be in detached buildings when required by Section 5003.8.2. *(moved from Section 6304.1.1)*

6304.1.8.1 Separation Distance. Detached storage buildings for Class 4 oxidizer liquids and solids shall be located a minimum of 50 feet (15 240 mm) from other hazardous materials storage.

Table ~~6304.1.7(1)~~ 6303.2
STORAGE OF CLASS 1 OXIDIZER LIQUIDS AND SOLIDS IN COMBUSTIBLE CONTAINERS^a

STORAGE CONFIGURATION	LIMITS (feet)
Piles	
Maximum length	No Limit
Maximum width	50 <u>24 (7.3 m)</u>
Maximum height	20 (6.1 m)
Maximum distance to aisle	<u>12 (3.7 m)</u>
Minimum distance to next pile ^b	3 <u>4 (1.2 m)</u>
Minimum distance to walls ^c	2 (0.6 m)
Maximum quantity per pile	No Limit <u>200 tons (181 met ton)</u>
Maximum quantity per building	No Limit

a. Storage in noncombustible containers or in bulk in detached storage buildings is not limited as to quantity or arrangement.

b. The minimum aisle width shall be equal to the pile height, but not less than 4 (1.2m) ft. and not greater than 8 (2.4m) ft.

c. There shall be no minimum distance from the pile to a wall for amounts less than 9000 lb. (4082 kg).

Table 6304.1.7 (2) 6304.1.5(1)
STORAGE OF CLASS 2 OXIDIZER LIQUIDS AND SOLIDS ^{d a, b}

STORAGE CONFIGURATION	<u>Segregated storage</u> <u>Control Area Storage</u>	LIMITS <u>Cutoff storage rooms^e</u> <u>Group H Occupancy Storage</u>	<u>Detached building</u> <u>Storage</u>
Piles Maximum width Maximum height <u>Maximum distance to aisle</u> Minimum distance to next pile Minimum distance to walls	16 feet (4.9 m) 40 feet <u>Note a</u> <u>8 feet (2.4 m)</u> Note d <u>b</u> 2 feet (0.6 m)	25 feet (7.6 m) 42 feet <u>Note a</u> <u>12 feet (3.7)</u> Note d <u>b</u> 2 feet ^c (0.6 m)	25 feet (7.6 m) 42 feet <u>Note a</u> <u>12 feet (3.7)</u> Note d <u>b</u> 2 feet ^c (0.6 m)

- d b. The minimum aisle width shall be equal to the pile height, but not less than 4 (1.2m) ft. and not greater than 8 (2.4m) ft. Aisle width shall not be less than the pile height.
- c. For Protection Level and Detached Storage under 2300 lb (1043 kg), there shall be no minimum separation distance between the pile and any wall.

Table ~~6304.1.7(4)~~ 6304.1.5(3)
STORAGE OF CLASS 4 OXIDIZER LIQUIDS AND SOLIDS

(Portions of table not shown remain unchanged)

Add new standard to Chapter 80 as follows:

NFPA

400-10 Hazardous Materials Code

Reason: The Chapter 63 provisions on liquid and solid oxidizers were originally extracted from NFPA 430. As a result, Chapter 63 contains terminology that does not exist in the IFC, and creates conflicts and confusion. Furthermore, NFPA developed a new standard on hazardous materials, NFPA 400, using the UFC as the base and NFPA 430 requirements were moved into it, and updated to incorporate the terminology of the IFC relating to hazardous material, and, subsequently, NFPA 430 was withdrawn. However, the IFC was not updated to reflect the new NFPA requirements, nor the current IFC hazardous material requirements. This code change updates Chapter 63 so that it now parallels the terminology of the hazardous materials provisions in the IFC.

6303.1.1.2 - This section, as written, could lead the user to believe that 200 pounds are not allowed in other occupancies because they are not mentioned. However IFC Table 5003.1.1(1) footnote k allows 200 pounds for these purposes in all occupancies. The result of the change would be to provide clarity. Group I occupancies would not be impacted as the section would continue to apply to them.

6303.2 - Class 1 oxidizer storage configuration limits are currently referenced in Section 6304.1.7 which only applies to oxidizers in excess of the maximum allowable quantity. Since there is no maximum allowable quantity for sprinklered Class 1 oxidizers, the reference is added here and the tables renumbered. The current Section is deleted because it is redundant.

6304.1.2 - This section which applies to detached oxidizer storage distances, conflicts with IBC Sections 415.5.1.2 and 415.5.1.3 so it is deleted. Also, the Class 4 oxidizer distances were extracted from NFPA 430 where they apply only to distances of tanks from buildings and not liquid and solid oxidizer from exposures as the current table indicates.

6304.1.4 - The reference to NFPA 430 is changed to NFPA 400 because NFPA 430 no longer exists. The automatic fire sprinkler requirements for oxidizer storage have been moved to Chapter 15 of NFPA 400. The Standard is available to read at: <http://www.nfpa.org/aboutthecodes/AboutTheCodes.asp?DocNum=400>.

6304.1 - The material is reorganized by moving the detached building requirement to the end for clarity. Also, 6304.1.2 which applies to detached oxidizer storage conflicts with IBC Sections 415.5.1.2 and 415.5.1.3. The Class 4 oxidizer distances, which are deleted, were from NFPA 430 where they applied only to distances of tanks from buildings and not liquid and solid oxidizer from exposures as the current table indicates. Lastly, the newly renumbered Section 6304.1.5 is amended to clarify that it applies to all storage of liquid and solid oxidizers, not just detached building storage.

Tables 6304.1.7(1), 6304.1.7(2) and 6304.1.7(3) These tables were amended in NFPA 400 to make them consistent with the International Fire Code terminology, to replace "segregated storage" with "control area storage" and "cutoff storage rooms" with "protection level storage". The quantity allowances were also modified to reflect those found in the IFC for those storage areas. Finally, the Tables were renumbered to reflect the relocation of the Class 1 Table to the general requirements section and the relocation of the charging paragraph.

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: A review of the standard proposed for inclusion in the code, NFPA 400-10, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28), will be posted on the ICC website on or before April 1, 2013.

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

6303.1.1.2-F-MCLAUGHLIN

F335 – 13

6303.1.1.2

Proponent: Kirk Mitchell, Kirk Mitchell & Associates, LLL, representing Isocyanurates Industry Ad Hoc Committee (IIAHC) (pkmitchell@bellsouth.net)

Revise as follows:

6303.1.1.2 Class 3 liquid and solid oxidizers. A maximum of 200 pounds (91 kg) of solid or 20 gallons (76 L) of liquid Class 3 oxidizers is allowed in Group A,B, E, I and R occupancies when such materials are necessary for maintenance purposes or operation of equipment. The oxidizers shall be stored in *approved* containers and in an *approved* manner.

Reason: The current language contained in 2012 IFC infers that the storage allowance is extended to Group I (Institutional) group settings. What about the other settings (e.g., Group A – Assembly, Group B – Business, etc.? These other assemblies have the same potential “*maintenance*” and/or “*operational*” needs as the Group I occupancies.

Cost Impact: No anticipated or projected cost impact with this proposal.

F335-13

6304.1.4 #1-F-MITCHELL

F337 – 13

Appendix C101, C102, C103, C104, C105

Proponent: Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azubiamia@yahoo.com)

Revise as follows:

APPENDIX C FIRE HYDRANT LOCATIONS AND DISTRIBUTION

The provisions contained in this appendix are not mandatory unless specifically referenced in the adopting ordinance.

SECTION C101 GENERAL

C101.1 Scope. In addition to the requirements of Section 507.5.1 of the *International Fire Code*, fire hydrants shall be provided in accordance with this appendix for the protection of buildings, or portions of buildings, hereafter constructed or moved into the jurisdiction.

~~C102~~ ~~LOCATION~~

~~**C102.1 Location.** Fire hydrants shall be provided along required fire apparatus access roads and adjacent public streets.~~

~~C102 C103~~ ~~NUMBER OF FIRE HYDRANTS~~

~~**C102.1 C103.1 Minimum number of fire hydrants for a building available.** The minimum number of fire hydrants available to a building shall not be less than the minimum specified that listed in Table C102.1 C105.1.~~

~~The number of fire hydrants available to a complex or subdivision shall not be less than that determined by spacing requirements listed in Table C105.1 when applied to fire apparatus access roads and perimeter public streets from which fire operations could be conducted~~

SECTION C104 CONSIDERATION OF EXISTING FIRE HYDRANTS

~~**C104.1 Existing fire hydrants.** Existing fire hydrants on public streets are allowed to be considered as available. Existing fire hydrants on adjacent properties shall not be considered available unless fire apparatus access roads extend between properties and easements are established to prevent obstruction of such roads.~~

SECTION ~~C103~~ C105 FIRE HYDRANT SPACING DISTRIBUTION OF FIRE HYDRANTS

C103.1 C105.1 Hydrant spacing. Fire apparatus access roads and public streets providing required access to buildings in accordance with Section 503 of the *International Fire Code* shall be provided with one or more fire hydrants, as determined by Section C102.1. Where more than one fire hydrant is required, the distance between required fire hydrants shall be in accordance with Sections C103.2 and C103.3

C103.2 Average spacing. The average spacing between fire hydrants shall ~~be in accordance with not~~ exceed that listed in Table C102.1 C105.1.

Exception: ~~The fire chief is authorized to accept a deficiency of up to 10 percent~~ The average spacing shall be permitted to be increased by 10 percent where existing fire hydrants provide all or a portion of the required number of fire hydrants service.

C103.3 Maximum spacing. ~~Regardless of the average spacing, fire hydrants shall be located such that all points on streets and access roads adjacent to a building are within the distances listed in Table C105.1 and the minimum number of hydrants are provided. The maximum spacing between fire hydrants shall be in accordance with Table C102.1.~~

**TABLE C102.1 C105.1
REQUIRED NUMBER AND SPACING DISTRIBUTION OF FIRE HYDRANTS**

FIRE-FLOW REQUIREMENT (gpm)	MINIMUM NUMBER OF HYDRANTS	AVERAGE SPACING BETWEEN HYDRANTS ^{a,b,c,f,g}	MAXIMUM DISTANCE FROM ANY POINT ON STREET OR ROAD FRONTAGE TO A HYDRANT ^{d,f,g}
1,750 or less	1	500	250
2,000-2,250	2	450	225
2,500	3	450	225
3,000	3	400	225
3,500-4,000	4	350	210
4,500-5,000	5	300	180
5,500	6	300	180
6,000	6	250	150
6,500-7,000	7	250	150
7,500 or more	8 or more ^e	200	120

For SI: 1 foot = 304.8 mm, 1 gallon per minute = 3.785 L/m.

- a. Reduce by 100 feet for dead-end streets or roads.
- b. Where streets are provided with median dividers which cannot be crossed by fire fighters pulling hose lines, or where arterial streets are provided with four or more traffic lanes and have a traffic count of more than 30,000 vehicles per day, hydrant spacing shall average 500 feet on each side of the street and be arranged on an alternating basis ~~up to a fire-flow requirement of 7,000 gallons per minute and 400 feet for higher fire-flow requirements.~~
- c. Where new water mains are extended along streets where hydrants are not needed for protection of structures or similar fire problems, fire hydrants shall be provided at spacing not to exceed 1,000 feet to provide for transportation hazards.
- d. Reduce by 50 feet for dead-end streets or roads.
- e. One hydrant for each 1,000 gallons per minute or fraction thereof.
- f. A 50 percent spacing increase shall be permitted where the building is equipped throughout with an approved automatic sprinkler system in accordance with Section 903.3.1.1 of the *International Fire Code*.
- g. A 25 percent spacing increase shall be permitted where the building is equipped throughout with an approved automatic sprinkler system in accordance with Sections 903.3.1.2 or 903.3.1.3 of the *International Fire Code* or Section P2904 of the *International Residential Code*.

SECTION C104 CONSIDERATION OF EXISTING FIRE HYDRANTS

C104.1 Existing fire hydrants. Existing fire hydrants on public streets are allowed to be considered as available ~~to meet the requirements of Sections C102 and C103. Existing fire hydrants on adjacent properties shall not be considered available unless are allowed to be considered as available to meet the requirements of Sections C102 and C103 provided that a fire apparatus access roads extends between properties and that an and easements are is established to prevent obstruction of such roads.~~

Reason: This code change proposal:

1. Clarifies how the requirements of 507.5.1 are to be utilized with Appendix C when Appendix C is adopted by the jurisdiction. Previously, it was not clear how these two sections were to be integrated when Appendix C was adopted.
2. States the buildings moved into the jurisdiction are also under the scope of this appendix. These buildings should be treated like new buildings when they are relocated.

3. The location language, in the current C102.1, is now addressed in the revised C102.1 by addressing the minimum number of hydrants for a building. The location spacing language has been provide in the new C103.1. The proposed C102.1 and title has been revised for better clarity as to the intent and the minimum number of hydrant that are available to a building.
4. The "complex" and "subdivision" paragraph has been deleted as basing the spacing on individual building fire flow covers every building in a complex or subdivision. There is no need for additional "complex or subdivision" text which can't be applied without an identifiable fire flow.
5. C103.1 has been revised for better clarity and application by the user. Poor code language, such as "regardless of the average spacing" has been replaced with clearer code text.
6. Table C102.1 has three modifications to the footnotes. First, the 7,000 GPM threshold for arranging hydrants on an alternating basis does not appear to have any basis in application and creates confusion as to its true intent so it has been deleted. Second, a modifier for a 50% increase in hydrant spacing is proposed for building protected by a fire sprinkler system installed in accordance with NFPA 13. Lastly, a modifier for a 25% increase in hydrant spacing is proposed for those buildings protected by a fire sprinkler system installed in accordance with NFPA 13D, 13R or P2904. This spacing increase is justified due to the documented success of fire sprinklers systems in extinguishing and controlling fires.
7. The existing hydrant section was relocated for better flow of the appendix and additional text was provided to clarify how it should be applied.

Cost Impact: The code change proposal will not increase the cost of construction.

F337-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

C101.1-F-ZUBIA-FCAC

F338 – 13

Appendix C Table C105.1

Proponent: Anthony C. Apfelbeck, City of Altamonte Springs Building/Fire Safety Division, representing self (ACApfelbeck@Altamonte.org)

Revise as follows:

**TABLE C105.1
NUMBER AND DISTRIBUTION OF FIRE HYDRANTS**

FIRE-FLOW REQUIREMENT (gpm)	MINIMUM NUMBER OF HYDRANTS	AVERAGE SPACING BETWEEN HYDRANTS^{a,b,c}	MAXIMUM DISTANCE FROM ANY POINT ON STREET OR ROAD FRONTAGE TO A HYDRANT^d
1,750 1,250 or less	1	500	250
2,000 1,500-2,250	2	450	225
2,500	3	450	225
3,000	3	400	225
3,500-4,000	4	350	210
4,500-5,000	5	300	180
5,500	6	300	180
6,000	6	250	150
6,500-7,000	7	250	150
7,500 or more	8 or more ^e	200	120

For SI: 1 foot = 304.8 mm, 1 gallon per minute = 3.785 L/m.

- Reduce by 100 feet for dead-end streets or roads.
- Where streets are provided with median dividers which cannot be crossed by fire fighters pulling hose lines, or where arterial streets are provided with four or more traffic lanes and have a traffic count of more than 30,000 vehicles per day, hydrant spacing shall average 500 feet on each side of the street and be arranged on an alternating basis.
- Where new water mains are extended along streets where hydrants are not needed for protection of structures or similar fire problems, fire hydrants shall be provided at spacing not to exceed 1,000 feet to provide for transportation hazards.
- Reduce by 50 feet for dead-end streets or roads.
- One hydrant for each 1,000 gallons per minute or fraction thereof.

Reason: This proposal changes the fire-flow threshold within the table which, in turn, changes the minimum number of hydrants and spacing for the modified threshold numbers. As an example a building with a required fire flow of 1,750 GPM would only require a single fire hydrant under the current provisions of Table C105.1. Under this proposal, that same building would require two fire hydrants.

The reasons for this change are:

- ISO only recognizes a maximum of 1,000 GPM of flow per fire hydrant in the Fire Suppression Rating Schedule as specified in Section 614. The current table could result in a grading deficiency of 750 gallons per minute if the full 1,750 is provided from a single hydrant for a protected property.
- There are practical fire flow delivery problems when the entire 1,750 GPM is provide from a single hydrant. Typically, a single fire apparatus is supplied from a single hydrant. Fire departments are not normally set up to operate in a dual pumping operation from a single fire hydrant. Two hydrants providing the 1,750 GPM would provide improved spacing, access and flexibility for responding units.
- A single hydrant providing 1,750 GPM does not provide a backup in case the hydrant is out of service due to maintenance, obstructions or cold weather conditions.

Cost Impact: This code change proposal will increase the cost of construction.

F338-13

Public Hearing: Committee: AS AM D
Assembly: ASF AMF DF

C105.1T-F-APFELBECK

F339 – 13

Appendix D103.5

Proponent: Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azubiamia@yahoo.com)

Revise as follows:

D103.5 Fire apparatus access road gates. Gates securing the fire apparatus access roads shall comply with all of the following criteria:

- ~~1. The minimum gate width shall be 20 feet (6096 mm). Where a single gate is provided, the gate width shall be not less than 20 feet (6096 mm). Where a fire apparatus road consists of a divided roadway the gate width shall be not less than 12 feet (3658 mm).~~
2. Gates shall be of the swinging or sliding type.
3. Construction of gates shall be of materials that allow manual operation by one person.
4. Gate components shall be maintained in an operative condition at all times and replaced or repaired when defective.
5. Electric gates shall be equipped with a means of opening the gate by fire department personnel for emergency access. Emergency opening devices shall be approved by the fire code official.
- ~~6. Manual opening gates shall not be locked with a padlock or chain and padlock unless they are capable of being opened by means of forcible entry tools or when a key box containing the key(s) to the lock is installed at the gate location.~~
- ~~76. Methods of locking device specifications~~ shall be submitted for approval by the fire code official.
- ~~87.~~ Electric gate operators, where provided, shall be listed in accordance with UL 325.
- ~~98.~~ Gates intended for automatic operation shall be designed, constructed and installed to comply with the requirements of ASTM F 2200.

Reason: This proposal is designed to clarify and simplify the list of criteria for security gates.

Item 1 is revised to address the reality that many locations are now splitting the roadway with a guard station or island which holds the gate operating mechanism. When the roadway is split, a gate that is 20' wide is not necessary on each side. Item 1 is reworded to specify that when there is a single gate, the gate width must be 20', but in the situation of a split roadway, a 12' wide gate in each direction is adequate.

The requirements in Item 6 are easily covered in the revision to Item 7. Item 6 currently lists specific methods of locking access gates. Item 6 then becomes unnecessary so it is proposed to be deleted.

The reality is that there are many other methods available which can be utilized to lock a gate. Whatever the method of locking, the need is to have the method approved. This will now be covered in the new Item 6.

Cost Impact: The code change proposal will not increase the cost of construction.

Appendix B105.1, Table B105(1) (New), B105.2, Table B105(2) (New), Table B105.1

Proponent: Adolf Zubia, Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azubiamia@yahoo.com)

Revise as follows:

B105.1 One- and two-family dwellings, congregate living facilities of Groups R-3 and R-4 and townhouses. The minimum fire-flow and flow duration requirements for one- and two-family dwellings, congregate living facilities of Group R-3 and R-4 and townhouses having a fire-flow calculation area that does not exceed 3,600 square feet (344.5 m²) shall be 1,000 gallons per minute (3785.4 L/min) for 1 hour. Fire-flow and flow duration for dwellings having a fire-flow calculation area in excess of 3,600 square feet (344.5 m²) shall not be less than that specified in Table B105.1. shall be as specified in Tables B105(1) and B105(3).

Exception: A reduction in required fire-flow of 50 percent, as approved, is allowed when the building is equipped with an approved automatic sprinkler system.

TABLE B105(1)
REQUIRED FIRE-FLOW FOR ONE- AND TWO-FAMILY DWELLINGS, CONGREGATE LIVING FACILITIES OF GROUP R-3 AND R-4 AND TOWNHOUSES,

<u>FIRE-FLOW CALCUATION AREA (square feet)</u>	<u>AUTOMATIC SPRINKLER SYSTEM (Design Standard)</u>	<u>MINIMUM FIRE-FLOW (gallons per minute)</u>	<u>FLOW DURATION (hours)</u>
0-3,600	No automatic sprinkler system	1,000	1
3,601-greater	No automatic sprinkler system	Value in Table B105(3)	Duration in Table B105(3) at the required fire-flow rate
0-3,600	Section 903.3.1.3 of the <i>International Fire Code</i> . or Section P2904 of the <i>International Residential Code</i>	500	0.5
3,601-greater	Section 903.3.1.3 of the <i>International Fire Code</i> . or Section P2904 of the <i>International Residential Code</i>	½ value in Table B105(3)	1

B105.2 Buildings other than one- and two-family dwellings, congregate living facilities of Group R-3 and R-4 and Townhouses. The minimum fire-flow and flow duration for buildings other than one- and two-family dwellings, congregate living facilities of Group R-3 and R-4 and Townhouses shall be as specified in Tables B105.1 B105(2) and B105(3).

Exception: A reduction in required fire-flow of up to 75 percent, as approved, is allowed when the building is provided with an approved automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.3.1.2. The resulting fire-flow shall not be less than 1,500 gallons per minute (5678 L/min) for the prescribed duration as specified in Table B105.1.

TABLE B105(2)
REQUIRED FIRE-FLOW FOR BUILDINGS OTHER THAN ONE- AND TWO-FAMILY DWELLINGS,
CONGREGATE LIVING FACILITIES OF GROUP R-3 AND R-4 AND TOWNHOUSES,

<u>AUTOMATIC SPRINKLER SYSTEM(Design Standard)</u>	<u>MINIMUM FIRE-FLOW (gallons per minute)</u>	<u>FLOW DURATION (hours)</u>
No automatic sprinkler system	Value in Table B105.3	Duration in Table B105(3)
Section 903.3.1.1 of the <i>International Fire Code</i> .	25% of the value in Table B105(3) ^a	Duration in Table B105(3) at the reduced flow rate
Section 903.3.1.2 of the <i>International Fire Code</i> .	25% of the value in Table B105(3) ^b	Duration in Table B105(3) at the reduced flow rate

a. The reduced fire-flow shall not be less than 1,000 gallons per minute (5678 L/min)

b. The reduced fire-flow shall not be less than 1,500 gallons per minute (3785 L/min)

B105.3 Water supply for buildings equipped with an automatic sprinkler system. For buildings equipped with an approved *automatic sprinkler system*, the water supply shall be capable of providing the greater of:

1. The automatic sprinkler system demand, including hose stream allowance.
2. The required fire-flow.

TABLE B105.1 B105(3)
MINIMUM REQUIRED FIRE FLOW AND FLOW DURATION FOR BUILDINGS
REFERENCE TABLE FOR TABLES B105(1) AND B102(2)

(Portions of table not shown remain unchanged)

Reason: This proposal is submitted by the ICC Fire Code Action Committee (FCAC). This ICC committee was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portions thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the Fire-CAC has held 6 open meetings and numerous Regional Work Group and Task Group meetings and conference calls which included members of the committees as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the FCAC website at: <http://www.iccsafe.org/cs/CAC/Pages/default.aspx>.

1. Clarifies that "Townhouses" R-3 and R-4 congregate living facilities are to be treated as one-and-two family dwellings with respect to developing needed fire flow in accordance with appendix B.
2. Relocates the fire flow modifiers from the paragraph to a table format in B105(1) and B105(2) for easier readability and application by the user.
3. Recognizes the provisions of P2904 in the IRC as equivalent to NFPA 13D when determining needed fire flow.
4. Provides a reduction in the required duration of fire flow for fully sprinklered one-and two-family dwellings less than 3,600 square feet as a reasonable incentive for the installation of a fire sprinkler system. Experience with fire sprinklers shows that a vast majority of fires in one and two family dwellings will be controlled or extinguished by the fire sprinkler system. This duration modifier also provides an achievable fire flow in rural applications where the development of a 1 hour duration is unrealistic.
5. Provides reduction to 1,000 GPM, rather than 1,500 GPM, for buildings other than one-and two-family dwellings and townhomes protected in accordance with NFPA 13 sprinkler systems. Currently, the appendix treats both NFPA 13R and NFPA 13 systems similarly permitting a reduction in fire flow to 1,500 GPM. An NFPA 13 system provides a significantly greater level of protection via the system design area, water supply and protection of concealed combustible spaces. Due to this level of protection, there should be a reduced minimum fire flow for buildings protected in accordance with NFPA 13 systems as opposed to NFPA 13R systems.
6. The current language provides no guidance to the Fire Chief as to criteria upon which to base approval of the required fire flow reduction for sprinkler protected buildings. The change simply allows the reduction by the elimination of the exceptions and codifying the credits in the tables.
7. This code change proposal clarifies in B105.3 that a fire sprinkler demand should not be added to the manual fire flow demand in developing the needed fire flow. The greater of the sprinkler demand or the demand developed in accordance with Appendix B will be the required fire flow.
8. IFC Section 903.3.1.3 was revised last cycle to include Group R-3 and R-4 congregate residences as well as townhouses. Fair Housing by law requires group homes to be considered the same as single family.

Cost Impact: This code change will not increase the cost of construction

B105.1-F-ZUBIA-FCAC

F341 – 13

Appendix D106.3 (New)

Proponent: Anthony C. Apfelbeck, City of Altamonte Springs Building/Fire Safety Division, representing self (ACApfelbeck@Altamonte.org)

Add new text as follows:

D106.3 Remoteness. Where two fire apparatus access roads are required, they shall be placed a distance apart equal to not less than one half of the length of the maximum overall diagonal dimension of the property or area to be served, measured in a straight line between accesses.

Reason: Currently, Section D106, Multiple-Family Residential Developments, does not require fire apparatus access roads to be remote when more than one access road is required. D104, Commercial and Industrial Developments, and D107, One- or Two-Family Residential Developments already contain a “remoteness” provision.

This code change proposal duplicates the language from D104.3 into a new 106.3 placing new “Remoteness” language within the Section D106 that is directly relevant to Multiple-Family Residential Developments.

Cost Impact: This code change will increase the cost of construction.

F341-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

D106.3-F-APFELBECK

F342 – 13

Appendix D107.1, D107.2 (New)

Proponent: Anthony C. Apfelbeck, City of Altamonte Springs Building/Fire Safety Division, representing self (ACApfelbeck@Altamonte.org)

Revise as follows:

D107.1 One- or two-family dwelling residential developments. Developments of one- or two-family dwellings where the number of dwelling units exceeds 30 shall be provided with separate and approved fire apparatus access roads, ~~and shall meet the requirements of Section D104.3.~~

Exceptions:

1. Where there are more than 30 dwelling units on a single public or private fire apparatus access road and all dwelling units are equipped throughout with an approved automatic sprinkler system in accordance with Section 903.3.1.1., 903.3.1.2 or 903.3.1.3.3, access from two directions shall not be required.
2. The number of dwelling units on a single fire apparatus access road shall not be increased unless fire apparatus access roads will connect with future development, as determined by the fire code official.

D107.2 Remoteness. Where two fire apparatus access roads are required, they shall be placed a distance apart equal to not less than one half of the length of the maximum overall diagonal dimension of the property or area to be served, measured in a straight line between accesses.

Reason: This proposal is an editorial change that is intended to clarify the remoteness reference in D107.1. This proposal does not modify the technical aspect of the code.

The current Section D107.1 refers the user to Section D104.3 which is titled "Commercial and Industrial Developments." Referring to Section D104.3 places the user in a section that is not germane to one-and two family dwelling and has to potential to create confusion to the fire code official and the code user.

This code change proposal duplicates the language from D104.3 into a new 107.2 placing new "Remoteness" language within the Section D107 that is directly relevant to one-and two-family dwellings. This code change does not modify any technical aspect of the current code remoteness requirement for one-and two-family dwellings.

Cost Impact: This code change will not increase the cost of construction.

F342-13

Public Hearing:	Committee:	AS	AM	D

F343 – 13

Appendix E102.1.7.1

Proponent: Kirk Mitchell, Kirk Mitchell & Associates, LLL, representing Isocyanurates Industry Ad Hoc Committee (IIAHC) (pkmitchell@bellsouth.net)

Revise as follows:

E102.1.7.1 Examples of liquid and solid oxidizers according to hazard.

Class 4: ammonium perchlorate (particle size greater than 15 microns), ammonium permanganate, guanidine nitrate, hydrogen peroxide solutions more than 91 percent by weight, perchloric acid solutions more than 72.5 percent by weight, potassium superoxide, tetranitromethane.

Class 3: ammonium dichromate, calcium hypochlorite (over 50 percent by weight), chloric acid (10 percent maximum concentration), hydrogen peroxide solutions (greater than 52 percent up to 91 percent), mono-(trichloro)-tetra-(monopotassium di-chloro)-penta-s-triazinetriene, nitric acid, (fuming - more than 86 percent concentration), perchloric acid solutions (60 percent to 72 percent by weight), potassium bromate, potassium chlorate, potassium dichloro-s-triazinetriene (potassium dichloro-isocyanurate), potassium perchlorate (99 percent), potassium permanganate (greater than 97.5 percent), sodium bromate, sodium chlorate, sodium chlorite (over 40 percent by weight) and sodium dichloro-s-triazinetriene anhydrous (sodium dichloro-isocyanurate anhydrous).

Class 2: barium bromate, barium chlorate, barium hypochlorite, barium perchlorate, barium permanganate, 1-bromo-3-chloro-5, 5-dimethylhydantoin, calcium chlorate, calcium chlorite, calcium hypochlorite (50 percent or less by weight), calcium perchlorate, calcium permanganate, calcium peroxide (75 percent), chromium trioxide (chromic acid), copper chlorate, halane (1, 3-di-chloro-5, 5-dimethylhydantoin), hydrogen peroxide (greater than 27.5 percent up to 52 percent), lead perchlorate, lithium chlorate, lithium hypochlorite (more than 39 percent available chlorine), lithium perchlorate, magnesium bromate, magnesium chlorate, magnesium perchlorate, mercurous chlorate, nitric acid (more than 40 percent but less than 86 percent), perchloric acid solutions (more than 50 percent but less than 60 percent), ~~potassium perchlorate, potassium permanganate~~, potassium peroxide, potassium superoxide, silver peroxide, sodium chlorite (40 percent or less by weight), sodium perchlorate, sodium perchlorate monohydrate, sodium permanganate, sodium peroxide, sodium persulfate (99 percent), strontium chlorate, strontium perchlorate, thallium chlorate, ~~trichloro-s-triazinetriene (trichloroisocyanuric acid)~~, urea hydrogen peroxide, zinc bromate, zinc chlorate and zinc permanganate.

Class 1: all inorganic nitrates (unless otherwise classified), all inorganic nitrites (unless otherwise classified), ammonium persulfate, barium peroxide, ~~calcium peroxide~~, hydrogen peroxide solutions (greater than 8 percent up to 27.5 percent), lead dioxide, lithium hypochlorite (39 percent or less available chlorine), lithium peroxide, magnesium peroxide, manganese dioxide, nitric acid (40 percent concentration or less), perchloric acid solutions (less than 50 percent by weight), potassium dichromate, potassium monopersulfate (45 percent KHSO₅ or 90 percent triple salt), potassium percarbonate, potassium persulfate, sodium carbonate peroxide, sodium dichloro-s-triazinetriene dihydrate, sodium dichromate, sodium perborate (anhydrous), sodium perborate monohydrate, sodium perborate tetra-hydrate, sodium percarbonate, ~~sodium persulfate~~, strontium peroxide, trichloro-s-triazinetriene (trichloroisocyanuric acid) and zinc peroxide.

Reason: This proposal suggests moving Trichloro-s-triazinetriene (trichloroisocyanuric acid) from a Class 2 oxidizer to a Class 1 oxidizer. Trichloro-s-triazinetriene (trichloroisocyanuric acid) is a Class 1 oxidizer (See NFPA 400 – Hazardous Materials Code 2013 Edition – Section G.3.2 Class 1 Oxidizers.)

NFPA reclassified trichloro-s-triazinetriene (trichloroisocyanuric acid) as a Class 1 Oxidizer in the 1995 edition of NFPA 430 based on extensive test data supplied by a consortium of chlorinated isocyanurate manufacturers and reported out in large scale burn tests conducted at Safety Engineering Laboratories, Inc. Since then, trichloro-s-triazinetriene (trichloroisocyanuric acid) has been one of very few oxidizers which are listed in different classes by the IFC compared to NFPA 430/400.

Additionally, recent work by Elizabeth Buc provided supplementary experimental burn rate data on trichloro-s-triazinetriene (trichloroisocyanuric acid). This work confirmed that trichloro-s-triazinetriene (trichloroisocyanuric acid) is appropriately classified as a Class 1 Oxidizer. Reference: E. Buc, Oxidizer Classification Research Project: Tests and Criteria, Fire and Materials Research Laboratory, LLC, November 2, 2009.

(See attached electronic PDF titled *FMRL_Oxidizer_Classification_Research_Project_Report*)

This proposal also suggests making changes to typical oxidizers based on test results and criteria from Table G.1.2(a) – NFPA Oxidizer Class Tests and Criteria of NFPA 400 Hazardous Materials Code (2013 Edition) and Section G.2.2 Class 1 Oxidizer through G.2.4 Class 3 Oxidizer and Table 5.2.1.13.3(a) Maximum Allowable Quantity (MAQ) per Indoor and Outdoor Control Area for Selected Hazard Categories in Merchantile, Storage and Industrial Occupancies.

Cost Impact: The portion of this proposal reclassifying trichloro-s-triazinetriene (trichloroisocyanuric acid) may result in reduced cost of construction and protection of referenced material due to its proper oxidization classification in appendix.

With the exception of the inclusion of 'anhydrous' following sodium dichloro-s-triazinetriene, the other proposed changes to Appendix E Section E102.1.7.1 Examples of Liquid and Solid Oxidizers According to Hazard may result in an increase in the cost of construction and/or protection as the other identified changes represents a categorical increase in the oxidizer classification ranking based on the newly adopted oxidizer testing and classification scheme.

Appendix K (New)

Proponent: John Williams, CBO, Chair, ICC Ad Hoc Committee on Health Care
(john.williams@doh.wa.gov)

Revise as follows:

APPENDIX K

CONSTRUCTION REQUIREMENTS FOR EXISTING AMBULATORY CARE FACILITIES

The provisions contained in this appendix are not mandatory unless specifically referenced in the adopting ordinance.

K101.1 Scope. The provisions of this chapter shall apply to existing buildings containing ambulatory care facilities in addition to the requirements of Chapter 11. Where the provisions of this chapter conflict with either the construction requirements within Chapter 11 or the construction requirements that applied at the time of construction, the most restrictive provision shall apply.

K101.2 Intent. The intent of this appendix is to provide a minimum degree of fire and life safety to persons occupying and existing buildings containing ambulatory care facilities where such building do not comply with the minimum requirements of the *International Building Code*.

SECTION K102

FIRE SAFETY REQUIREMENTS FOR EXISTING AMBULATORY CARE FACILITIES

K102.1 Separation. Ambulatory care facilities where the potential for four or more care recipients are to be incapable of self-preservation at any time, whether rendered incapable by staff or staff accepted responsibility for a care recipient already incapable, shall be separated from adjacent spaces, corridors or tenants with a fire partition installed in accordance with Section 708 of the *International Building Code*.

K102.2 Smoke compartments. Where the aggregate area of one or more ambulatory care facilities is greater than 10,000 square feet (929 m²) on one story, the story shall be provided with a smoke barrier to subdivide the story into no fewer than two smoke compartments. The area of any one such smoke compartment shall be not greater than 22,500 square feet (2092 m²). The travel distance from any point in a smoke compartment to a smoke barrier door shall be not greater than 200 feet (60 960 mm). The smoke barrier shall be installed in accordance with Section 709 of the *International Building Code* with the exception that smoke barriers shall be continuous from outside wall to an outside wall, a floor to a floor, or from a smoke barrier to a smoke barrier or a combination thereof.

K102.2.1 Refuge area. Not less than 30 net square feet (2.8 m²) for each nonambulatory care recipient shall be provided within the aggregate area of corridors, care recipient rooms, treatment rooms, lounge or dining areas and other low-hazard areas within each smoke compartment. Each occupant of an ambulatory care facility shall be provided with access to a refuge area without passing through or utilizing adjacent tenant spaces.

K102.2.2 Independent egress. A means of egress shall be provided from each smoke compartment created by smoke barriers without having to return through the smoke compartment from which means of egress originated.

K102.3 Ambulatory care automatic sprinkler system. An automatic sprinkler system shall be provided throughout the entire floor containing an ambulatory care facility in Type II-B, III-B and V-B construction where either of the following conditions exist at any time:

1. Four or more care recipients are incapable of self preservation, whether rendered incapable by staff of staff has accepted responsibility for care recipients already incapable.
2. One or more care recipients that are incapable of self preservation are located at other than the level of exit discharge serving such a facility.

In buildings where ambulatory care is provided on levels other than the level of exit discharge, an automatic sprinkler system shall be installed throughout the entire floor where such care is provided and all floors below, and all floors between the level of ambulatory care and the nearest level of exit discharge, including the level of exit discharge.

K102.4 Ambulatory care automatic fire alarm system. Fire areas containing ambulatory care facilities shall be provided with an electronically supervised automatic smoke detection system installed within the ambulatory care facility and in public use areas outside of tenant spaces, including public corridors and elevator lobbies.

Exception: Buildings equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 of the *International Fire Code*, provided the occupant notification appliances will activate throughout the notification zones upon sprinkler waterflow.

SECTION K103 **INCIDENTAL USES IN EXISTING AMBULATORY CARE FACILITIES**

K103.1 General. Incidental uses associated with and located within existing ambulatory care facilities required to be separated by Section 422 in the *International Building Code*, and that generally pose a greater level of risk to such occupancies shall comply with the provisions of Sections K103.2 through K103.4.2.1. Incidental uses in ambulatory care facilities required to be separated by Section 422 in the *International Building Code* are limited to those listed in Table K103.1.

K103.2 Occupancy classification. Incidental uses shall not be individually classified in accordance with Section 302.1 of the *International Building Code*. Incidental uses shall be included in the building occupancies within which they are located.

K103.3 Area limitations. Incidental uses shall not occupy more than 10 percent of the building area of the story in which they are located.

K103.4 Separation and protection. The incidental uses listed in Table K103.1 shall be separated from the remainder of the building or equipped with an automatic sprinkler system, or both, in accordance with the provisions of that table.

K103.4.1 Separation. Where Table K103.1 specifies a fire-resistance-rated separation, the incidental uses shall be separated from the remainder of the building in accordance with Section 509.4.1 of the *International Building Code*.

K103.4.2 Protection. Where Table K103.1 permits an automatic sprinkler system without a fire-resistance-rated separation, the incidental uses shall be separated from the remainder of the building by construction capable of resisting the passage of smoke in accordance with Section 509.4.2 of the *International Building Code*.

K103.4.2.1 Protection limitation. Except as otherwise specified in Table K103.1 for certain incidental uses, where an automatic sprinkler system is provided in accordance with Table K103.1, only the space occupied by the incidental use need be equipped with such a system.

TABLE K103.1
INCIDENTAL USES IN EXISTING AMBULATORY CARE FACILITIES

<u>ROOM OR AREA</u>	<u>SEPARATION AND/OR PROTECTION</u>
<u>Furnace room where any piece of equipment is over 400,000 Btu per hour input.</u>	<u>1 hour or provide automatic sprinkler system</u>
<u>Rooms with boilers where the largest piece of equipment is over 15 psi and 10 horsepower</u>	<u>1 hour or provide automatic sprinkler system</u>
<u>Refrigerant machinery room</u>	<u>1 hour or provide automatic sprinkler system</u>
<u>Hydrogen cutoff rooms, not classified as Group H</u>	<u>1 hour in ambulatory care facilities</u>
<u>Incinerator rooms</u>	<u>2 hours and provide automatic sprinkler system</u>
<u>Laboratories not classified as Group H</u>	<u>1 hour or provide automatic sprinkler system</u>
<u>Laundry rooms over 100 square feet</u>	<u>1 hour or provide automatic sprinkler system</u>
<u>Waste and linen collection rooms with containers with total volume of 10 cubic feet or greater.</u>	<u>1 hour or provide automatic sprinkler system</u>
<u>Storage rooms greater than 100 square feet</u>	<u>1 hour or provide automatic sprinkler system</u>
<u>Stationary storage battery systems having a liquid electrolyte capacity of more than 50 gallons for flooded lead-acid, nickel cadmium or VRLA, or more than 1,000 pounds for lithium-ion and lithium metal polymer used for facility standby power, emergency power or uninterruptable power supplies</u>	<u>1 hour in ambulatory care facilities</u>

For SI: 1 square foot = 0.0929 m², 1 pound per square inch (psi) = 6.9 kPa, 1 British thermal unit (Btu) per hour = 0.293 watts, 1 horsepower = 746 watts, 1 gallon = 3.785 L.

SECTION K104 **MEANS OF EGRESS REQUIREMENTS FOR EXISTING AMBULATORY CARE FACILITIES**

K104.1 Size of doors. The minimum width of each door opening shall be sufficient for the *occupant load* thereof and shall provide a clear width of not less than 28 inches (711 mm). Where this section requires a minimum clear width of 28 inches (711 mm) and a door opening includes two door leaves without a mullion, one leaf shall provide a clear opening width of 28 inches (711 mm). In ambulatory care facilities, doors serving as means of egress from patient treatment rooms shall provide a clear width of not less than 32 inches (813 mm). The maximum width of a swinging door leaf shall be 48 inches (1219 mm) nominal. The height of doors openings shall not be less than 80 inches (2032 mm).

Exceptions:

1. Door openings to storage closets less than 10 square feet (0.93 m²) in area shall not be limited by the minimum width.
2. Width of door leaves in revolving doors that comply with Section 1008.1.4.1 shall not be limited.
3. Exit access doors serving a room not larger than 70 square feet (6.5 m²) shall be not less than 24 inches (610 mm) in door width.
4. Door closers and door stops shall be permitted to be 78 inches (1980 mm) minimum above the door.

K104.2 Corridor and Aisle width. Corridor width shall be as determined in Section 1005.1 of the *International Fire Code* and this section. The minimum width of corridors and aisles that serve gurney traffic in areas where patients receive care that causes them to be incapable of self preservation shall be not less than 72 inches (1829mm).

K104.3 Existing elevators. Existing elevators, escalators, dumbwaiters and moving walks shall comply with the requirements of Sections K104. 3.1 and K104.3.2.

K104.3.1 Elevators, escalators, dumbwaiters and moving walks. Existing elevators, escalators, dumbwaiters and moving walks in ambulatory care facilities required to be separated by Section 422 shall comply with ASME A17.3.

K104.3.2 Elevator emergency operation. Existing elevators with a travel distance of 25 feet (7620 mm) or more above or below the main floor or other level of a building and intended to serve the needs of emergency personnel for fire-fighting or rescue purposes shall be provided with emergency operation in accordance with ASME A17.3.

SECTION J 105 REFERENCED STANDARDS

ICC IBC-15 International Building CodeK101.2, K102.1, K102.2, K103.1, K103.2, K103.3.1, K104.1, K104.2

ICC IFC-15 International Fire Code.....K102.4, K104.2

ASME A17.3-08.....K104.3.1, K104.3.2

Reason: This proposal is submitted by the ICC Ad Hoc Committee for Healthcare (AHC). The AHC was established by the ICC Board of Directors to evaluate and assess contemporary code issues relating to hospitals and ambulatory healthcare facilities. The AHC is composed of building code officials, fire code officials, hospital facility engineers, and state healthcare enforcement representatives. The goals of the committee are to ensure that the ICC family of codes appropriately addresses the fire and life safety concerns of a highly specialized and rapidly evolving healthcare delivery system. This process is part of a joint effort between ICC and the American Society for Healthcare Engineering (ASHE), a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. Since its inception in April, 2011, the AHC has held 8 open meetings and over 150 workgroup calls which included members of the AHC as well as any interested party to discuss and debate the proposed changes. All meeting materials and reports are posted on the AHC website at: <http://www.iccsafe.org/cs/AHC/Pages/default.aspx>

The intent of this section is to provide jurisdictions an option for assessing a minimum fire and life safety requirements for buildings containing ambulatory care facilities. While this appendix is written with the intent to apply retroactive minimum standards, we recognize that the ambulatory care requirements are relatively recent additions to the code. For that reason, these requirements are presented as an appendix, so that the adopting authority can exercise judgment in the adoption and application of this section.

This is an especially important option for federal authorities having jurisdiction, who have long standing minimum fire and life safety standards for ambulatory care facilities. Those federal standards were applied to new and existing construction long before the creation of the ambulatory care use that currently in the International Building Code. Therefore, we have a situation where some (but not all) ambulatory care facilities were built very specific defend-in-place features. This subset of facilities was those that were certified by the federal government as "ambulatory surgical facilities." Many other medical facilities that would be classified today as ambulatory care were not required to have defend in place features, such a smoke compartmentation. The federal AHJs highly value these defend-in-place concepts and need retroactive standard. This appendix would be that standard.

This appendix would also be useful for those local and state jurisdictions that are specifically focused in ensuring the safety for existing ambulatory care. If a surgery center was constructed as recently as 2009, there would have been no defend in place features required by the ICC family of codes. Post adoption of the 2009 IBC, there would have been. This appendix could be used to assess post 2009 surgery centers and free standing emergency departments. It could also be used to bring those earlier facilities into compliance with the current standards at the discretion of the adopting jurisdiction.

The technical requirements are based on the current IBC language, as well as several concepts approved in the 2012 Group A changes. The significant difference is a relaxation of the sprinkler requirement for existing facilities. This appendix would only require retroactive sprinklering of unprotected construction, which is consistent with the overall concept of the current federal requirements.

Cost impact: The code change proposal should not increase the cost of construction because compliance is already required by facility licensure requirements.

APPENDIX X (NEW)-F-WILLIAMS-ADHOC

F345 – 13

Appendix K (new)

Proponent: Carl Baldassarra, P.E., FSFPE, Chair, ICC Code Technology Committee
(cbaldassarra@rjagroup.com)

Add new text as follows:

Appendix K **Employee Qualifications**

The provisions contained in this appendix are not mandatory unless specifically referenced in the adopting ordinance.

SECTION K101 **FIRE INSPECTOR** **AND FIRE PLAN EXAMINER QUALIFICATIONS**

K101.1. Fire inspector and fire plan examiner. The fire code official shall appoint or hire such number of officers, fire inspectors, fire plan examiners, assistants and other employees as shall be authorized by the jurisdiction. A person shall not be appointed or hired as a fire inspector or fire plans examiner who has less than five years' experience as a contractor, engineer, architect, a member of the fire service, or a member of a fire prevention organization. Any combination of education and experience that would confer equivalent knowledge and ability shall be deemed to satisfy this requirement. Fire inspectors and fire plan examiners shall be certified through a recognized certification program for such position.

Reason: This proposed change is a result of the CTC's investigation of the area of study entitled "NIST Charleston Sofa Store Fire Recommendations". The scope of the activity is noted as:

Review the NIST and other investigative reports on the fire that occurred on the evening of June 18, 2007 in the Sofa Super Store in Charleston, South Carolina to identify issues that can be addressed by the International Codes.

In connection with their investigation, NIST analyzed the fire ground, consulted with other experts, and performed computer simulations of fire growth alternatives. Based on these analyses, NIST concluded that the following sequence of events is likely to have occurred. A fire began in packing material and discarded furniture outside an enclosed loading dock area. The fire spread to the loading dock, then into both the retail showroom and warehouse spaces. During the early stages of the fire in the two latter locations, the fire spread was slowed by the limited supply of fresh air. This under-ventilation led to generation of a large mass of pyrolyzed and only partially oxidized effluent. The smoke and combustible gases flowed into the interstitial space below the roof and above the suspended ceiling of the main retail showroom. As this space filled with unburned fuel, the hot smoke also seeped through the suspended ceiling into the main showroom and formed a hot smoke layer below the suspended ceiling. Up to this time, the extent of fire spread into the interstitial space was not visible to fire fighters in the store. If the fire spread had been visible to the fire fighters in the store, it would have provided a direct indication of a fire hazard in the showroom. Meanwhile, the fire at the back of the main showroom and the gas mixture below the suspended ceiling were both still fuel rich. When the front windows were broken out or vented, the inflow of additional air allowed the heat release rate of the fire to intensify rapidly and added air to the layer of unburned fuel below the suspended ceiling enabling the ignition of the unburned fuel/air mixture. The fire swept from the rear to the front of the main showroom extremely quickly, and then into the west and east showrooms. Nine fire fighters were killed in the Sofa Super Store fire. NIST developed eleven recommendations to help mitigate such future losses.

Recommendation 3 of the NIST report reads as follows:

"Qualified Fire Inspectors and Building Plan Examiners: NIST recommends that all state and local jurisdictions ensure that fire inspectors and building plan examiners are professionally qualified to a national standard such as NFPA 1031 Standard for Professional Qualifications for Fire Inspector and Plan Examiner. Professional qualification may be demonstrated through a nationally accepted certification examination, such as the Fire Plan Examiner; Fire Inspector I and II, and Certified Fire Marshal."

Following a review of recommendation 3 of the NIST report a new Appendix K is proposed. This proposal is similar in scope and intent to Section A101.3 of Appendix A of the International Building Code where suggested qualifications for building official, chief inspector, inspector and plan examiner are established.

The purpose of this proposal is to provide optional criteria for qualifications of employees who enforce the Fire Code through inspections and plan examinations. A jurisdiction that wants to make this appendix a mandatory part of the code would need to

specifically list this appendix in its adoption ordinance. In recognition of the fact that some jurisdictions are mandated by applicable state law to employ only persons licensed by the state to perform certain duties, the proposal was drafted as an Appendix.

This proposal would not require fire inspectors or fire plan examiners to have had previous experience in Fire Code enforcement, but would merely require that they possess experience in a related job category. It is not our intent to prohibit a plan review and inspection staff from hiring and training entry level employees. The training of entry level shall be supervised by trained and certified personnel.

This proposal is submitted by the ICC Code Technology Committee. The ICC Board established the ICC Code Technology Committee (CTC) as the venue to discuss contemporary code issues in a committee setting which provides the necessary time and flexibility to allow for full participation and input by any interested party. The code issues are assigned to the CTC by the ICC Board as "areas of study". Information on the CTC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CTC effort can be downloaded from the following website: <http://www.iccsafe.org/cs/CTC/Pages/default.aspx>. Since its inception in April/2005, the CTC has held twenty-five meetings - all open to the public. In 2012, three of the 25 face-to face meetings were held. In addition to the CTC meetings, the CTC established Study Groups (SG) of interested parties for each of the areas of study. These SG's are responsible for reviewing the available information and making recommendations to the CTC. All totaled, the SG's held over 70 conference calls in 2012.

Cost Impact: This code change proposal will not increase the cost of construction.

APPENDIX K (NEW)-F-BALDASSARRA-CTC

F346 – 13

Appendix K (New), 508.1.5

Proponent: Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azubiamia@yahoo.com)

Add new text as follows:

APPENDIX K **REQUIREMENTS FOR FIREFIGHTER AIR REPLENISHMENT SYSTEMS**

The provisions contained in this appendix are not mandatory unless specifically referenced in the adopting ordinance.

SECTION K101 **GENERAL**

K101.1 Scope. Firefighter air replenishment systems (FARS) shall be provided in accordance with this appendix. The adopting ordinance shall specify building characteristics or special hazards that establish thresholds triggering a requirement for the installation of a FARS. The requirement shall be based upon the fire department's capability of replenishing firefighter breathing air during sustained emergency operations. Considerations shall include:

1. Building characteristics, such as number of stories above or below grade plane, floor area, type of construction, and fire-resistance of the *primary structural frame* to allow sustained firefighting operations based on a rating of not less than 2-hours.
2. Special hazards, other than buildings, that require unique accommodations to allow the fire department to replenish firefighter breathing air.
3. Fire department staffing level.
4. Availability of a fire department breathing air replenishment vehicle.

SECTION K102 **DEFINITIONS**

K102.1 Definitions. For the purpose of this appendix, certain terms are defined as follows:

FIREFIGHTER AIR REPLENISHMENT SYSTEM (FARS). A permanently installed arrangement of piping, valves, fittings and equipment to facilitate the replenishment of breathing air in self contained breathing apparatus (SCBA) for firefighters engaged in emergency operations.

SECTION K103 **PERMITS**

K103.1 Permits. Permits shall be required to install and maintain a FARS. Permits shall be in accordance with Sections 103.2 and 103.3.

K103.2 Construction permit. A construction permit is required for installation of or modification to a FARS. The construction permit application shall include documentation of an acceptance and testing plan as specified in Section K105.

K103.3 Operational permit. An operational permit is required to maintain a FARS

SECTION K104
DESIGN AND INSTALLATION

K104.1 Design and installation. A FARS shall be designed and installed in accordance with Sections K104.2 through K104.15.

K104.2 Standards. Firefighter air replenishment systems shall be in accordance with Sections K104.2.1 and K104.2.2.

K104.2.1 Pressurized system components. Pressurized system components shall be designed and installed in accordance with ASME B31.3.

K104.2.2 Air quality. The system shall be designed to convey breathing air complying with NFPA 1989.

K104.3 Design and operating pressure. The minimum design pressure shall be 110 percent of the fire department's normal SCBA fill pressure. The system design pressure shall be marked in an approved manner at the supply connections, and adjacent to pressure gauges on any fixed air supply components. Pressure shall be maintained in the system within five percent of the design pressure.

K104.4 Cylinder refill rate. The FARS shall be capable of refilling breathing air cylinders of a size and pressure used by the fire department at a rate of not less than two empty cylinders in two minutes.

K104.5 Breathing air supply. Where a fire department mobile air unit is available, the FARS shall be supplied by an external mobile air connection in accordance with Section K104.13. Where a fire department mobile air unit is not available, a stored pressure air supply shall be provided in accordance with Section K104.4.1. A stored pressure air supply shall be permitted to be added to a system supplied by an external mobile air connection provided that a means to bypass the stored pressure air supply is located at the external mobile air connection.

K104.5.1. Stored pressure air supply. A stored pressure air supply shall be designed based on NFPA 1901, Chapter 24, except that provisions applicable only to mobile apparatus or not applicable to system design shall not apply. A stored pressure air supply shall be capable of refilling a minimum of fifty empty breathing air cylinders of a size and pressure used by the fire department

K104.5.2. Retrofit of external mobile air connection. A FARS not initially provided with an external mobile air connection due to the lack of a mobile air unit shall be retrofitted with an external mobile air connection if a mobile air unit becomes available. Where an external mobile air connection is provided, a means to bypass the stored pressure air supply shall be located at the external mobile air connection. The retrofit shall be completed not more than 12 months after notification by the fire code official.

K104.6 Isolation valves. System isolation valves that are accessible to the fire department shall be installed on the system riser to allow piping beyond any air cylinder refill panel to be blocked.

K104.7 Pressure relief valve. Pressure relief valves shall be installed at each point of supply and at the top or end of every riser. The relief valve shall meet the requirements of the CGA S-1.3 and shall not be field adjustable. Pressure relief valves shall discharge in a manner that does not endanger personnel who may be in the area. Valves, plugs or caps shall not be installed in the discharge of a pressure relief valve. Where discharge piping is used the end shall not be threaded.

K104.8 Materials and equipment. Pressurized system components shall be listed or approved for their intended use and rated for the maximum allowable design pressure in the system. Piping and fittings shall be stainless steel.

K104.9 Welded connections. Piping connections that are concealed shall be welded.

K104.10 Protection of piping. System piping shall be protected from physical damage in an approved manner.

K104.11 Compatibility. Fittings and connections intended to be used by the fire department shall be compatible with the fire department's equipment.

K104.12 Security. Connections to a FARS shall be safeguarded from unauthorized access in an approved manner.

K104.13 Fill stations. Firefighter air replenishment fill stations shall comply with Section K104.12.1 through K104.12.3.

K104.13.1 Location. Fill stations for refilling breathing air cylinders shall be located as follows:

1. Fill stations shall be provided at the fifth floor above and below the ground level floor and every third floor level thereafter.
2. On floor levels requiring fill stations, one fill station shall be provided adjacent to a required exit stair at a location designated by the Fire Code Official. In buildings required to have three or more exit stairs, additional fill stations shall be provided at a ratio of one fill station for every three stairways.

K104.13.2 Design Fill stations for breathing air cylinders shall be designed to meet the following requirements:

1. Pressure control, A pressure gauge and pressure-regulating devices and controls shall be provided to allow the operator to control the fill pressure and fill rate on each cylinder fill hose.
2. Valves controlling cylinder fill hoses shall be slow operating valves
3. A separate flow restriction device shall be provided on each fill hose.
4. A method shall be provided to bleed each cylinder fill hose.
5. The fill station shall be designed to provide a containment area that 1) fully encloses any cylinder being filled and flexible cylinder fill hoses, and 2) directs the energy from a failure away from personnel. Fill stations shall be designed to prohibit filling of cylinders that are not enclosed within the containment area.

Exception: Where required or approved by the Fire Chief, fill stations providing for the direct refilling of the firefighters' breathing air cylinders using Rapid Intervention Crew/Company Universal Air Connection (RIC/UAC) fittings shall be used in lieu of cylinder fill stations that utilize containment areas.

K104.13.3 Cylinder refill rate. Fill stations shall be capable of simultaneously filling two or more empty breathing air cylinders equivalent to those used by the fire department to their design pressure within two (2) minutes.

K104.14 External mobile air connection. An external mobile air connection shall be provided for fire department mobile air apparatus where required by Section K104.4 to supply the system with breathing air.

K104.14.1 Location. The location of the external mobile air connection shall be accessible to mobile air apparatus and approved by the fire chief.

K104.14.2 Protection from vehicles. A means of vehicle impact protection in accordance with Section 312 shall be provided to protect mobile air connections that are subject to vehicular impact.

K104.14.3 Clear space around connections. A working space of not less than 36 inches (762 mm) in width, 36 inches (914 mm) in depth and 78 inches (1981 mm) in height shall be provided and maintained in front of and to the sides of external mobile air connections.

K104.15 Air monitoring system. An approved air monitoring system shall be provided. The system shall automatically monitor air quality, moisture and pressure on a continual basis. The air monitoring system shall be equipped with a minimum of two content analyzers capable of detecting carbon monoxide, carbon dioxide, nitrogen, oxygen, moisture and hydrocarbons.

K104.15.1 Alarm conditions. The air monitoring system shall transmit a supervisory signal when any of the following levels are detected:

1. Carbon monoxide exceeds 5 ppm
2. Carbon dioxide exceeds 1,000 ppm
3. An oxygen level below 19.5 percent or above 23.5 percent
4. A nitrogen level below 75 percent or above 81 percent
5. Hydrocarbon (condensed) content exceeds 5 milligrams per cubic meter of air
6. The moisture concentration exceeds 24 ppm by volume
7. The pressure falls below 90% of the maintenance pressure specified in Section K104.2

K104.15.2 Alarm supervision, monitoring and notification. The air monitoring system shall be electrically supervised and monitored by an approved supervising station, or when approved, shall initiate audible and visual supervisory signals at a constantly attended location.

K104.15.3 Air quality status display. Air quality status shall be visually displayed at the external mobile air connection required by K104.13.

SECTION K105 **ACCEPTANCE TESTS**

K105.1 Acceptance tests. Upon completion of the installation, a FARS shall be acceptance tested to verify compliance with equipment manufacturers' instructions and design documents. Oversight of the acceptance tests shall be provided by a registered design professional. Acceptance testing shall include the following:

1. A pneumatic test in accordance with ASME B31.3 of the complete system at a minimum test pressure of 110 percent of the system design pressure using oil free dry air, nitrogen or argon shall be conducted.. Test pressure shall be maintained for a minimum of 24 hours. During this test, all fittings, joints and system components shall be inspected for leaks. Any defects in the system or leaks detected shall be documented and repaired.
2. A cylinder filling performance test shall be conducted to verify compliance with the required breathing air cylinder refill rate from the exterior mobile air connection and, where provided, a stored air pressure supply system.
3. The air quality monitoring system shall be tested to verify that: 1) Visual indicators required by Section K104.14.1 function properly, and 2) Supervisory signals are transmitted as required by Section K104.14.2 for each sensor based on a sensor function test.
4. Connections intended for fire department use shall be confirmed as compatible with the fire department's mobile air unit, SCBA cylinders and, where provided, RIC/UAC connections.
5. Air samples shall be taken from not less than two fill stations and submitted to an approved gas analysis laboratory to verify compliance with NFPA 1989. The FARS shall not be placed into service until a written report verifying compliance with NFPA 1989 has been provided to the code official.

SECTION K106 **INSPECTION, TESTING AND MAINTENANCE**

K106.1 Periodic inspection, testing, and maintenance. A FARS shall be continuously maintained in an operative condition and shall be inspected at least annually. At least quarterly, an air sample shall be taken from the system and tested to verify compliance with NFPA 1989. The laboratory test results shall be maintained onsite and readily available for review by the fire code official.

NFPA 1901-09	Standard for Automotive Fire Apparatus K104.5.1,
NFPA 1989-13	Breathing Air Quality for Fire Emergency Services Respiratory Protection K104.2.2, K105.1, K106.1

Revise as follows:

508.1.5 Required features. The *fire command center* shall comply with NFPA 72 and shall contain the following features:

- 1 through 11. *(No change to current text)*
12. Schematic building plans indicating the typical floor plan and detailing the building core, *means of egress, fire protection systems, firefighter air replenishment system, fire-fighting equipment and fire department access, and the location of fire walls, fire barriers, fire partitions, smoke barriers and smoke partitions.*
13. through 18. *(No change to current text)*

Reason: This proposal is submitted by the ICC Fire Code Action Committee (FCAC). This ICC committee was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portions thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the Fire-CAC has held 6 open meetings and numerous Regional Work Group and Task Group meetings and conference calls which included members of the committees as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the FAC website at: <http://www.iccsafe.org/cs/CAC/Pages/default.aspx>.

Breathing air is critical for firefighting operations. Historically, fire departments have supplied air bottles by means of a "bottle brigade", whereby firefighters manually transport air bottles up stairways. This is usually accomplished by stationing a firefighter on alternating floors, and each firefighter carries two to four bottles at a time up two floors, passes them to the next firefighter, then goes down two flights of stairs and receives more air bottles from the firefighter stationed below. This process is extraordinarily firefighter intensive, and takes firefighters away from their primary mission of rescue and firefighting. Even when fires are insignificant or controlled by sprinklers, copious amounts of smoke and other combustion byproducts require the use of self contained breathing apparatus (SCBA) for extended periods of time to conduct search, rescue, suppression, and overhaul. These extended missions require a large number of air bottles to be transported to support the operation. Transporting bottles is not the highest and best use of highly trained firefighters – it is a costly solution to a serious problem that can be addressed by installing firefighter breathing air replenishment systems.

Technology exists at this point in time to address the issue using in-building air supply systems. Firefighter Breathing Air Systems were introduced in the late 1980's. These systems are now required in a number of communities throughout the United States, and several hundred systems have been installed and are now operational. The system has been called a "standpipe for air", which is an accurate description. The system consists of stainless steel, high pressure piping that is supplied by on site air storage, fire department air supply units, or both; a few systems have breathing air compressors installed. Air filling stations are then strategically located throughout the building, using either quick fill connections or rupture containment fill stations complying with NFPA 1901. These systems allow firefighters to refill breathing air cylinders inside the fire building, negating the required "bottle brigade", and making more firefighters available for search, rescue, and fire suppression operations.

While not every jurisdiction will necessarily embrace this technology, there is a need to standardize the installation criteria in jurisdictions that determine the systems are needed. It is now being recognized as a basic principle of fire protection that once a community has identified an unacceptable risk that risk mitigation must occur to reduce that risk to a level that allows the fire department to be both efficient and effective in coping with it. Thus, an adoptable appendix to provide guidance to these jurisdictions is appropriate and needed in the International Fire Code. More and more jurisdictions are considering requiring these systems, and guidance from the International Fire Code is needed.

Cost Impact: This code change will add to the cost of construction

Analysis: A review of the standards proposed for inclusion in the code, NFPA 1901-09 and NFPA 1989-08, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28), will be posted on the ICC website on or before April 1, 2013. ASME B31.3-

04 and CGA S1.3 (2005) are currently referenced in the IFC. Updates in year editions will be accomplished by an administrative standards update code change to be heard by the ADM Code Development Committee.

APPENDIX K (NEW) #1-F-ZUBIA-FCAC

F347 – 13

Appendix K (New)

Proponent: Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azubiamia@yahoo.com)

Add new text as follows:

APPENDIX K

HIGH-RISE BUILDINGS - RETROACTIVE AUTOMATIC SPRINKLER REQUIREMENT

SECTION K101

SCOPE

K101.1 Scope. An automatic sprinkler system shall be installed in all existing high-rise buildings in accordance with the installation requirements and compliance schedule of this appendix.

SECTION K102

WHERE REQUIRED

K102.1 High-Rise Buildings. An automatic sprinkler system installed in accordance with Section 903.3.1.1 of the International Fire Code shall be provided throughout existing high-rise buildings.

Exceptions:

1. Airport traffic control towers.
2. Open parking structures.
3. Group U Occupancies.
4. Occupancies in Group F-2.

SECTION K103

COMPLIANCE

K103.1 Compliance Schedule. Building owners shall file a compliance schedule with the fire code official no later than 365 days after the first effective date of this code. The compliance schedule shall not exceed 12 years for an automatic sprinkler system retrofit.

SECTION K104

REFERENCED STANDARDS

ICC IFC-15 International Fire CodeK102.1

Reason: This proposal provides model code text for adoption by jurisdictions that choose to require existing high-rise buildings to be retrofitted with fire sprinklers. It is recognized that not all jurisdictions may choose to or have legal authority to enact a retroactive construction requirement of this nature, so the proposal has been suggested for inclusion in the IFC as an adoptable appendix.

Modern fire and building codes require complete automatic fire sprinkler protection and a variety of other safety features in new high-rise construction. Many older high-rise buildings lack automatic fire sprinkler protection and other basic fire protection features necessary to protect the occupants, emergency responders, and the structure itself. Without complete automatic fire sprinkler protection, fire departments cannot provide the level of protection that high-rise buildings demand.

Existing high-rise buildings that are not protected with fire sprinklers represent a significant hazard to the occupants and firefighters. Additionally, High-Rise fires can significantly impact a communities' infrastructure and the economic viability.

Between 2003 and 2006, there was an average of 13,400 reported structure fires in high-rise buildings annually. These incidents resulted in 62 civilian deaths, 490 civilian injuries, and \$179 million in direct property damage per year. Furthermore, from 1977 to 2009, 25 firefighters died from non-stress related cardiac death during fire suppression operations in high-rise buildings. By their very nature, high-rise fires present unique firefighting challenges that are extremely difficult for firefighters to mitigate without the presence of fire sprinkler systems. Some of these challenges include:

High-rise structure fires require significantly more resources, such as personnel and equipment, to extinguish than do fires in other types of occupancies. This further strains the responding fire department and firefighters.

Due to their height, smoke movement in high-rise structures is very different from that of other structures. Temperature gradients result in varying pressures throughout the structure, which can allow for the rapid, uncontrolled movement of smoke and flame (known as the "stack effect"). By design, exits from high-rise structures are limited. In an emergency, the movement of people out of a building is particularly difficult. A prime example of this hazard is the One Meridian Plaza fire. This fire occurred on the 22nd floor of the 38-story Meridian Bank Building and was reported to the Philadelphia Fire Department on February 23, 1991 at approximately 2040 hours and burned for more than 19 hours. The fire caused three firefighter fatalities and injuries to 24 firefighters. The 12-alarms brought 51 engine companies, 15 ladder companies, 11 specialized units, and over 300 firefighters to the scene. It was the largest high-rise office building fire in modern American history, completely consuming eight floors of the building, and was only controlled only when it reached a floor that was protected by automatic sprinklers. In 1999 the building was torn down amidst a storm of litigation. The HVAC and other utilities in some high-rises service multiple levels and can facilitate the spread of smoke and flame through a building.

Due to the height of the building, response times for the fire department to reach the actual fire itself are extended, contributing to larger fire growth thereby attributing to extensive smoke spread throughout the building.

This proposal is submitted by the ICC Fire Code Action Committee (FCAC). This ICC committee was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portions thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the Fire-CAC has held 6 open meetings and numerous Regional Work Group and Task Group meetings and conference calls which included members of the committees as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the FAC website at: <http://www.iccsafe.org/cs/CAC/Pages/default.aspx>.

Cost Impact: This change will increase the cost of operating an existing High-Rise building.

APPENDIX K (NEW) #2-F-ZUBIA-FCAC

F348 – 13

907.2.6.2 (IBC [F] 907.2.6.2); IBC [F] 407.8

Proponent: John Williams, CBO, Chair, ICC Ad Hoc Committee on Health Care (john.williams@doh.wa.gov) and Carl Baldassarra, P.E., FSFPE, Chair, ICC Code Technology Committee (cbaldassarra@RJAGroup.com)

Revise as follows:

907.2.6.2 (IBC [F] 907.2.6.2) Group I-2. An automatic smoke detection system shall be installed in corridors in Group I-2 Condition 1 ~~nursing homes, long term care facilities, detoxification facilities~~ and spaces permitted to be open to the corridors by Section 407.2. The system shall be activated in accordance with Section 907.4. Group I-2 Condition 2 Hospitals shall be equipped with an automatic smoke detection system as required in Section 407.

Exceptions:

1. Corridor smoke detection is not required in smoke compartments that contain sleeping units where such units are provided with smoke detectors that comply with UL 268. Such detectors shall provide a visual display on the corridor side of each sleeping unit and shall provide an audible and visual alarm at the care provider's station attending each unit.
2. Corridor smoke detection is not required in smoke compartments that contain sleeping units where sleeping unit doors are equipped with automatic door-closing devices with integral smoke detectors on the unit sides installed in accordance with their listing, provided that the integral detectors perform the required alerting function.

IBC [F] 407.8 Automatic fire smoke detection. An automatic smoke detection system shall be installed in corridors in Group I-2 Condition 1 ~~nursing homes, long term care facilities, detoxification facilities~~ and spaces permitted to be open to the corridors by Section 407.2 ~~shall be equipped with an automatic fire detection system.~~ The system shall be activated in accordance with Section 907.4. Group I-2 Condition 2 Hospitals shall be equipped with an automatic smoke detection system as required in Section 407.2 and 407.4.3.

Exceptions:

1. ~~Corridor smoke detection is not required where sleeping rooms in smoke compartments that contain sleeping units where such units are provided with smoke detectors that comply with UL 268. Such detectors shall provide a visual display on the corridor side of each sleeping room and unit and shall provide an audible and visual alarm at the care provider's station attending each unit.~~
2. ~~Corridor smoke detection is not required where sleeping room in smoke compartments that contain sleeping units where sleeping unit doors are equipped with automatic door-closing devices with integral smoke detectors on the unit sides installed in accordance with their listing, provided that the integral detectors perform the required alerting function.~~

Reason: The proposed language in IBC 407.8 and IBC/IFC 907.2.6.2 coordinates with the proposed language automatic smoke detection system requirements in IBC 407.4.3 submitted by the Adhoc Health Care committee during Group A hearings. The intent is also to make the language consistent between the two sections.

This proposal is submitted by the ICC Ad Hoc Committee for Healthcare (AHC). The AHC was established by the ICC Board of Directors to evaluate and assess contemporary code issues relating to hospitals and ambulatory healthcare facilities. The AHC is composed of building code officials, fire code officials, hospital facility engineers, and state healthcare enforcement representatives. The goals of the committee are to ensure that the ICC family of codes appropriately addresses the fire and life safety concerns of a highly specialized and rapidly evolving healthcare delivery system. This process is part of a joint effort between ICC and the American Society for Healthcare Engineering, a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. Since its inception in April 2011, the AHC has held 8 open meetings and over 150 workgroup calls which included members of the AHC as well as any interested party to discuss and debate the proposed changes. All meeting materials and reports are posted on the AHC website at: <http://www.iccsafe.org/cs/AHC/Pages/default.aspx>.

This proposal is being co-sponsored by the ICC Code Technology Committee. The ICC Board established the ICC Code Technology Committee (CTC) as the venue to discuss contemporary code issues in a committee setting which provides the necessary time and flexibility to allow for full participation and input by any interested party. The code issues are assigned to the CTC by the ICC Board as "areas of study". Information on the CTC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CTC effort can be downloaded from the following website: <http://www.iccsafe.org/cs/CTC/Pages/default.aspx>. Since its inception in April/2005, the CTC has held twenty five meetings - all open to the public.

Cost Impact: None

407.8-F-BALDASSARRA-WILLIAMS-ADHOC

F349 – 13

3203.4

Proponent: Darren Meyers, P.E., International Energy Conservation Consultants, LLC, representing the Biomass Feedstock Industry Committee on Codes and Standards (dmeyers@ieccode.com)

Revise as follows:

3203.4 Class III commodities. Class III commodities are commodities of wood, paper, natural fiber cloth, or Group C plastics or products thereof, with or without pallets. Products are allowed to contain limited amounts of Group A or B plastics, such as metal bicycles with plastic handles, pedals, seats and tires. Group A plastics shall be limited in accordance with Section 3203.7.4. Examples of Class III commodities include, but are not limited to, the following:

- Aerosol, Level 1 (see Chapter 28)
- Biomass briquettes, bagged, totes and static piles
- Biomass pellets, bagged, totes and static piles
- Charcoal
- Combustible fiberboard
- Cork, baled
- Corn cobs, static piles
- Corn stover, baled and chopped
- Feed, bagged
- Fertilizers, bagged
- Firewood
- Food in plastic containers
- Forest residue, round wood or chipped (branches, bark, cross-cut ends, edgings and treetops)
- Furniture: wood, natural fiber, upholstered, non-plastic, wood or metal with plastic-padded and covered armrests
- Glycol in combustible containers not exceeding 25 percent
- Lubricating or hydraulic fluid in metal cans
- Lumber
- Mattresses, excluding foam rubber and foam plastics
- Noncombustible liquids in plastic containers having a capacity of more than 5 gallons (19 L)
- Paints, oil base, in metal cans
- Paper, waste, baled
- Paper and pulp, horizontal storage, or vertical storage that is banded or protected with *approved* wrap
- Paper in cardboard boxes
- Peanut hulls, bagged, totes and static piles
- Pillows, excluding foam rubber and foam plastics
- Plastic-coated paper food containers
- Plywood
- Rags, baled
- Recovered construction wood
- Rice hulls, bagged, totes and static piles
- Rugs, without foam backing
- Seasonal grasses, baled and chopped
- Straw, baled
- Sugar, bagged
- Wood, baled
- Wood chips, bagged, totes and static piles
- Woody biomass, round wood or chipped (vase-shaped stubby bushes, bamboo, willows; branches, bark and stem wood)
- Wood doors, frames and cabinets
- Wood pellets, bagged, totes and static piles

Yarns of natural fiber and viscose

Reason: The additions clarify that certain “crop-residue” as solid, biomass feedstock as biofuel are appropriately identified as Class III commodities.

The Biomass Feedstock Industry Committee on Codes and Standards (BFICOCs), led by Oak Ridge National Laboratory (ORNL), is an initiative of the Department of Energy Biomass Technologies Office (BTO). As part of the BTO integrated biorefinery efforts, the BFICOCs was assembled to conduct analysis of existing fire and building codes and to prepare proposed code changes designed to facilitate the development of the commercial-scale biomass industry while maintaining a focus on safety. The committee is made up of managers, engineers and code officials from industry, government laboratories, consulting firms, and the American Society of Agricultural and Biological Engineers (ASABE).

Fire codes related to storage, handling, and pre-processing of biomass are based on industries that operate in a significantly different manner than the growing biomass-based energy industry. Applying current research on biomass properties and knowledge of conventional and emerging storage, handling, and pre-processing technologies, the BFICOCs has identified changes in the IFC that benefit both industry and the public.

Cost Impact: The code change proposal will not increase the cost of construction.

2801.1, 2802.1, 2804.1, 2808.1, 2808.2, 2809.1, 2809.2, 202

Proponent: Darren Meyers, P.E., International Energy Conservation Consultants, LLC, representing the Biomass Feedstock Industry Committee on Codes and Standards (dmeyers@ieccode.com)

Revise as follows:

CHAPTER 28 LUMBER YARDS, AGRO-INDUSTRIAL, SOLID BIOMASS AND WOODWORKING FACILITIES

SECTION 2801 GENERAL

2801.1 Scope. The storage, manufacturing and processing of solid biomass feedstock, timber, lumber, plywood, veneers and agro-industrial byproducts shall be in accordance with this chapter.

SECTION 2802 DEFINITIONS

2802.1 Definitions. The following terms are defined in Chapter 2:

AGRO-INDUSTRIAL.
BIOMASS.
STATIC PILES.
SOLID BIOFUEL.
SOLID BIOMASS FEEDSTOCK.

SECTION 2804 FIRE PROTECTION

2804.1 General. Fire protection in timber and lumber production mills, ~~and~~ plywood and veneer mills, and agro-industrial facilities shall comply with Sections 2804.2 through 2804.4.

SECTION 2808 STORAGE AND PROCESSING OF WOOD CHIPS, HOGGED MATERIAL, FINES, COMPOST, SOLID BIOMASS FEEDSTOCK, AND RAW PRODUCT ASSOCIATED WITH YARD WASTE, AGRO-INDUSTRIAL AND RECYCLING FACILITIES

2808.1 General. The storage and processing of wood chips, hogged materials, fines, compost, solid biomass feedstock and raw product produced from yard waste, debris, agro-industrial and recycling facilities shall comply with Sections 2808.2 through 2808.10.

2808.2 Storage site. Storage sites shall be level and on solid ground, elevated soil lifts or other all-weather surface. Sites shall be thoroughly cleaned before transferring wood products to the site.

SECTION 2809 EXTERIOR STORAGE OF FINISHED LUMBER AND SOLID BIOFUEL PRODUCTS

2809.1 General. Exterior storage of finished lumber and solid biofuel products shall comply with Sections 2809.1 through 2809.5.

2809.2 Size of piles. Exterior ~~lumber~~ storage shall be arranged to form stable piles with a maximum height of 20 feet (6096 mm). Piles shall not exceed 150,000 cubic feet (4248 m³) in volume.

2809.3 Fire apparatus access roads. Fire apparatus access roads in accordance with Section 503 shall be located so that a maximum grid system unit of 50 feet by 150 feet (15 240 mm by 45 720 mm) is established.

2809.4 Security. Permanent ~~lumber~~ storage areas shall be surrounded with an *approved* fence. Fences shall be a minimum of 6 feet (1829 mm) in height.

Exceptions:

1. Lumber piles inside of buildings and production mills for lumber, plywood and veneer.
2. Solid biofuel piles inside of buildings and agro-industrial processing facilities for solid biomass feedstock.

2809.5 Fire protection. An *approved* hydrant and hose system or portable fire-extinguishing equipment suitable for the fire hazard involved shall be provided for open storage yards. Hydrant and hose systems shall be installed in accordance with NFPA 24. Portable fire extinguishers complying with Section 906 shall be located so that the travel distance to the nearest unit does not exceed 75 feet (22 860 mm).

SECTION 202 GENERAL DEFINITIONS

AGRO-INDUSTRIAL. Technologies, methods and associated machinery used in transforming raw agricultural products into intermediate or consumable products.

BIOMASS. Plant or animal-based material of biological origin, including but not limited to materials originating from arboriculture, agriculture, aquaculture, horticulture and forestry, excluding material embedded in geological formations or transformed into fossil.

STATIC PILES. Piles in which processed wood product or solid, biomass feedstock is mounded and is not being turned or moved.

SOLID BIOFUEL. Densified biomass made with or without additives in the form of cubiform, polyhedral, polyhydric or cylindrical units, produced by compressing milled biomass.

SOLID BIOMASS FEEDSTOCK. The basic materials, including agricultural residues, including but not limited to corn cobs, corn stover, rice hulls, and peanut hulls; herbaceous crops, including but not limited to warm- and cool-seasonal grasses; forest residue, including but not limited to branches, bark, cross-cut ends, edgings and treetops; short-rotation woody crops, including but not limited to vase-shaped stubby bushes, bamboo, willows with five to ten-year rotations and their branches, bark and stem wood; agricultural waste, including but not limited to garden or park waste, grass or flower cuttings and hedge trimmings; and dried manure; from which biofuel is comprised, manufactured or made.

Reason: The proposed language facilitates fire control and reduces exposures to and from facilities storing and processing “crop-residue” as solid biomass feedstock for biofuel production.

The Biomass Feedstock Industry Committee on Codes and Standards (BFICOCS), led by Oak Ridge National Laboratory (ORNL), is an initiative of the Department of Energy Biomass Technologies Office (BTO). As part of the BTO integrated biorefinery efforts, the BFICOCS was assembled to conduct analysis of existing fire and building codes and to prepare proposed code changes designed to facilitate the development of the commercial-scale biomass industry while maintaining a focus on safety. The committee is made up of managers, engineers and code officials from industry, government laboratories, consulting firms, and the American Society of Agricultural and Biological Engineers (ASABE).

Fire codes related to storage, handling, and pre-processing of biomass are based on industries that operate in a significantly different manner than the growing biomass-based energy industry. Applying current research on biomass properties and knowledge of conventional and emerging storage, handling, and pre-processing technologies, the BFICOCS has identified changes in the IFC that benefit both industry and the public.

Cost Impact: The code change proposal will not increase the cost of construction.

FG1– 13

IFGC [F] 413.2.3, IFGC [F] 413.3, IFGC [F] 413.4

Proponent: James Ranfone, American Gas Association (jranfone@aga.org)

Revise as follows:

IFGC [F] 413.2.3 General. Residential fueling *appliances* shall be *listed*. ~~The capacity of a residential fueling appliance shall not exceed 5 standard cubic feet per minute (0.14 standard cubic meter/min) of natural gas.~~

IFGC [F] 413.3 Location of dispensing operations and equipment. Compression, storage and dispensing *equipment* shall be located above ground ~~outside outdoors~~.

Exceptions:

1. Compression, storage or dispensing *equipment* is allowed in buildings of noncombustible construction, as set forth in the *International Building Code*, that are unenclosed for three-quarters or more of the perimeter.
2. Compression, storage and dispensing *equipment* is allowed to be located indoors or in vaults in accordance with the *International Fire Code*.
3. Residential fueling *appliances* and *equipment* in accordance with Section 413.4, ~~shall be allowed to be installed indoors in accordance and the equipment manufacturer's instructions and Section 413.4.3.~~

IFGC [F] 413.4 Residential fueling appliance installation. Residential fueling *appliances* shall be installed in accordance with Sections 413.4.1 through 413.4.3.

IFGC [F] 413.4.2 Outdoor installation. Residential fueling *appliances* located outdoors shall be listed for outdoor installation and installed in accordance with the *appliance* manufacturer's instructions. Residential fueling *appliances* located outdoors shall be installed on a firm, noncombustible base.

IFGC [F] 413.4.3 Indoor installation. Residential fueling *appliances* located indoors shall be listed for indoor installation and installed in accordance with the *appliance* manufacturer's instructions. ~~Where located indoors,~~ Residential fueling *appliances* shall be vented to the outdoors. A gas detector set to operate at one-fifth of the lower limit of flammability of natural gas shall be installed in the room or space containing the *appliance*. The detector shall be located within 6 inches (152 mm) of the highest point in the room or space. The detector shall stop the operation of the *appliance* and activate an audible or visual alarm.

Reason: Residential fueling of natural gas vehicles represents a nationally-important opportunity to increase adoption of natural gas passenger cars and other light duty vehicles. Natural gas promises to be a major contributor toward reducing U. S. dependence upon foreign oil and petroleum products and making use of abundant, low cost U. S. natural gas supplies, the development of which is adding significantly to the recovery of U. S. economy.

However, the current text in IFGC Section 413.2.3 is inconsistent with modern approaches and gas flow rates being proposed for vehicle residential fueling by arbitrarily restricting residential fueling appliances to a gas flow rate of 5 standard cubic feet (of natural gas) per minute (scfm). Current research and technology development programs are targeting delivering natural gas at higher flow rates, especially at the initiation of the fueling cycle, to achieve practical vehicle refueling rates. A wide variety of technologies and commercial interests are focused on approaches for which the 5 scfm flow rate limitation would represent a technology barrier.

The current 5 scfm flow rate limitation in Section 413.2.3 raises a number of issues, including whether it is a reasonable, meaningful, or enforceable limit:

- The 5 scfm flow rate limit, if inferred as a potential leakage limit to an indoor garage or other space, is provided without a release time duration or profile, which would be required to determine how such a leak would present flammability hazards. As such, a 5 scfm limitation appears arbitrary and incomplete.
- Detailed fault tree analysis, failure modes and effects analysis, and computational fluid dynamics analysis of residential fueling appliance releases conducted by TIAx in 2004 showed that leak rates from various release scenarios and median residential garage air tightnesses and ventilation rates should be below 1 scfm to maintain steady state gas-in-air concentrations below

combustible levels. The TIAX analysis suggests that a 5 scfm flow rate, when inferred as a potential leak rate, may be unsafe with respect combustion hazards in residential garages from releases from the vehicle fueling appliance and dispenser hose, as well as from the onboard vehicle fuel system.

- The 5 scfm flow limit may not be enforceable by code authorities, particularly if the listing standard (which is undefined by the current code language) does not readily provide a code official with gas flow information.
- Review of ICC records suggests that according to the 2006 ICC Code Commentary the 5 scfm limit as well as other technical provisions of Section 413 were adopted for consistency with National Fire Protection Association (NFPA) Standard 52 and based on flow rates for residential fueling appliances available at that time. NFPA Standard 52 records show that the flow rate was adopted in the 1988 standard cycle, but no specific technical justification for the flow rate limitation was provided.

Since requirements in Section 413.2.3 apply to the residential refueling appliance and specifically require it to be listed, leakage prevention and mitigation is most properly addressed in the listing standard. The proponent of this code change and a vast array of other organizations have convened a Technical Advisory Group (TAG) to draft a national consensus standard under the American National Standards Institute (ANSI) processes of CGA Group, an ANSI- recognized standards development organization (SDO) for natural gas vehicle standards. Completion of the standard is expected between 18 and 24 months from the submission date of this proposal.

The ANSI standard development activity is directly addressing the requirement in Section 413.2.3 for the residential fueling appliance to be listed and is addressing prevention and mitigation of leak hazards consistent with the 2004 TIAX analysis for critical leaks relevant to indoor refueling operations. In doing so, the ANSI standard is addressing the intent of the 5 scfm gas flow limitation but is based on preventing and mitigation releases must more conservatively than the current flow limitation approach. Leak mitigation is being included in the standard through a variety of performance-based automatic and redundant means and verified in standards-based methods of test in the design certification process. Since the ANSI process is open and invites public review, the adequacy and appropriateness of the listing requirements and methods of test a open to public input from all stakeholders and expertise. Therefore, the basis for leak prevention and mitigation will be likewise open to public review and comment.

Changes proposed to Section 413.4 address the lack of differentiation of residential fueling appliances designed for outdoor and indoor installation. The new language directs the authority having jurisdiction to the specific listing for outdoor or indoor installation and associated listing requirements for those environments, including leak prevention and hazard mitigation, environmental conditions, and other requirements for germane to the installation location. The proposed language is consistent with current direction in development of the ANSI standard, which makes this differentiation and applies relevant requirements to the appliance design certification.

Cost Impact: None.

G1 – 13

IBC [F] 307.1

Proponent: Maureen Traxler, City of Seattle, WA representing Washington Association of Building Officials (Maureen.Traxler@seattle.gov)

Revise as follows:

IBC [F] 307.1 High-hazard Group H. High-hazard Group H occupancy includes, among others, the use of a building or structure, or a portion thereof, that involves the manufacturing, processing, generation or storage of materials that constitute a physical or health hazard in quantities in excess of those allowed in *control areas* complying with Section 414, based on the maximum allowable quantity limits for *control areas* set forth in Tables 307.1(1) and 307.1(2). Hazardous occupancies are classified in Groups H-1, H-2, H-3, H-4 and H-5 and shall be in accordance with this section, the requirements of Section 415 and the *International Fire Code*. Hazardous materials stored, or used on top of roofs or canopies shall be classified as outdoor storage or use and shall comply with the *International Fire Code*.

Exceptions: The following shall not be classified as Group H, but shall be classified as the occupancy that they most nearly resemble.

1. Buildings and structures occupied for the application of flammable finishes, provided that such buildings or areas conform to the requirements of Section 416 and the *International Fire Code*.
2. Wholesale and retail sales and storage of flammable and combustible liquids in mercantile occupancies conforming to the *International Fire Code*.
3. Closed piping system containing flammable or combustible liquids or gases utilized for the operation of machinery or equipment.
4. Cleaning establishments that utilize combustible liquid solvents having a flash point of 140°F (60°C) or higher in closed systems employing equipment *listed* by an *approved* testing agency, provided that this occupancy is separated from all other areas of the building by 1-hour *fire barriers* constructed in accordance with Section 707 or 1-hour *horizontal assemblies* constructed in accordance with Section 711, or both.
5. Cleaning establishments that utilize a liquid solvent having a flash point at or above 200°F (93°C).
6. Liquor stores and distributors without bulk storage.
7. The storage of distilled spirits and wines in wooden barrels and casks
- ~~78.~~ Refrigeration systems.
- ~~89.~~ The storage or utilization of materials for agricultural purposes on the premises.
- ~~910.~~ Stationary batteries utilized for facility emergency power, uninterruptable power supply or telecommunication facilities, provided that the batteries are provided with safety venting caps and *ventilation* is provided in accordance with the *International Mechanical Code*.
- ~~4011~~ Corrosives shall not include personal or household products in their original packaging used in retail display or commonly used building materials.
- ~~4412.~~ Buildings and structures occupied for aerosol storage shall be classified as Group S-1, provided that such buildings conform to the requirements of the *International Fire Code*.
- ~~4213.~~ Display and storage of nonflammable solid and nonflammable or noncombustible liquid hazardous materials in quantities not exceeding the maximum allowable quantity per *control area* in Group M or S occupancies complying with Section 414.2.5.
- ~~4314.~~ The storage of black powder, smokeless propellant and small arms primers in Groups M and R-3 and special industrial explosive devices in Groups B, F, M and S, provided such storage conforms to the quantity limits and requirements prescribed in the *International Fire Code*.

Reason: IFC Section 5001.1 has an exception providing that "The storage of distilled spirits and wines in wooden barrels and casks" is not required to comply with the chapter's general requirements for hazardous materials. IFC Section 5701.2 states that

Chapter 57's provisions for flammable and combustible liquids do not apply to "The storage of distilled spirits and wines in wooden barrels and casks". Similarly, Chapter 9 of NFPA 30-2012 Flammable and Combustible Liquids Code, exempts the storage of distilled spirits and wines in wooden barrels or casks from the general requirements for storage of liquids in containers. However, the Building Code classifies that same storage as an H-3 occupancy. It is inconsistent for the Building Code to classify an occupancy as a hazardous occupancy due to the presence of this type of storage if none of the mitigation measures are required by the Fire Code. The IFC exempts storage of spirits in wooden containers from all the IBC provisions that would otherwise apply. For example, IBC Section 415.4 requires sprinklers for all Group H occupancies—IFC Section 5004.5 requires sprinklers in indoor storage, but storage of spirits in wooden containers is not required to comply because it is exempt from Chapter 50. Adding this exception to the list of exceptions in IBC section 307.1 will eliminate this inconsistency between the codes and will eliminate unnecessary confusion about how to classify such uses and apply the IBC provisions.

Cost Impact: The code change will not increase the cost of construction.

G1-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

[F] 307.1 #1-G-TRAXLER

G2 – 13

IBC [F] 307.1

Proponent: William E. Koffel, P.E., Koffel Associates, Inc., representing American Pyrotechnics Association (APA) (wkoffel@koffel.com)

Revise as follows:

IBC [F] 307.1 High-hazard Group H. High-hazard Group H occupancy includes, among others, the use of a building or structure, or a portion thereof, that involves the manufacturing, processing, generation or storage of materials that constitute a physical or health hazard in quantities in excess of those allowed in *control areas* complying with Section 414, based on the maximum allowable quantity limits for *control areas* set forth in Tables 307.1(1) and 307.1(2). Hazardous occupancies are classified in Groups H-1, H-2, H-3, H-4 and H-5 and shall be in accordance with this section, the requirements of Section 415 and the *International Fire Code*. Hazardous materials stored, or used on top of roofs or canopies shall be classified as outdoor storage or use and shall comply with the *International Fire Code*.

Exceptions: The following shall not be classified as Group H, but shall be classified as the occupancy that they most nearly resemble.

1 through 13 (*No change to current text*)

14. Retail sales of consumer fireworks in Group M occupancies in accordance with the requirements of Section 5601.1.3 of the *International Fire Code* and NFPA 1124.

Reason: Chapter 7 of NFPA 1124 provides requirements for both new and existing facilities in which consumer fireworks are sold. The intent is to reduce the risk to that comparable to occupants within other mercantile occupancies. Some of the requirements include:

- Limitations on the use of aerial devices
- Automatic sprinkler protection when in excess of 3000 sq ft for new, 7500 sq ft for existing
- Fire alarm system
- Separation distances
- 75 ft travel distance with no dead ends and in most instances a requirement for three exits
- Increased egress capacity factor
- Minimum four foot aisles
- Flame breaks
- Fuse covers
- Maximum shelf height
- Limitations on the proximity the consumer fireworks may be to an exit

Full scale fire tests have demonstrated the effectiveness of the fuse cover requirement to greatly decrease the likelihood of ignition and the growth of a fire, should one occur.

Cost Impact: None since it provides another compliance alternative

IBC [F] 307.1; IBC [F] 307.1.1 (New)

Proponent: Charles S. Bajnai, Chesterfield County, VA, ICC Building Code Action Committee
(bajnaic@chesterfield.gov)

Revise as follows:

IBC [F] 307.1 High-hazard Group H. High-hazard Group H occupancy includes, among others, the use of a building or structure, or a portion thereof, that involves the manufacturing, processing, generation or storage of materials that constitute a physical or health hazard in quantities in excess of those allowed in control areas complying with Section 414, based on the maximum allowable quantity limits for control areas set forth in Tables 307.1(1) and 307.1(2). Hazardous occupancies are classified in Groups H-1, H-2, H-3, H-4 and H-5 and shall be in accordance with this section, the requirements of Section 415 and the International Fire Code. Hazardous materials stored, or used on top of roofs or canopies shall be classified as outdoor storage or use and shall comply with the International Fire Code.

Exceptions: The following **IBC [F] 307.1.1 Uses other than Group H.** The storage, use or handling of hazardous materials as described in one or more of the following items shall not cause the occupancy to be classified as Group H, but shall be classified as the occupancy that they most nearly resemble:

1. Buildings and structures occupied for the application of flammable finishes, provided that such buildings or areas conform to the requirements of Section 416 and the International Fire Code.
2. Wholesale and retail sales and storage of flammable and combustible liquids in mercantile occupancies conforming to the International Fire Code.
3. Closed piping system containing flammable or combustible liquids or gases utilized for the operation of machinery or equipment.
4. Cleaning establishments that utilize combustible liquid solvents having a flash point of 140°F (60°C) or higher in closed systems employing equipment listed by an approved testing agency, provided that this occupancy is separated from all other areas of the building by 1-hour fire barriers constructed in accordance with Section 707 or 1-hour horizontal assemblies constructed in accordance with Section 711, or both.
5. Cleaning establishments that utilize a liquid solvent having a flash point at or above 200°F (93°C).
6. Liquor stores and distributors without bulk storage.
7. Refrigeration systems.
8. The storage or utilization of materials for agricultural purposes on the premises.
9. Stationary batteries utilized for facility emergency power, uninterruptable power supply or telecommunication facilities, provided that the batteries are provided with safety venting caps and ventilation is provided in accordance with the *International Mechanical Code*.
10. Corrosive ~~s shall not include~~ personal or household products in their original packaging used in retail display, ~~or~~
11. Commonly used corrosive building materials.
- ~~11.~~ 12. Buildings and structures occupied for aerosol storage shall be classified as Group S-1, provided that such buildings conform to the requirements of the *International Fire Code*.
- ~~12-13.~~ 13. Display and storage of nonflammable solid and nonflammable or noncombustible liquid hazardous materials in quantities not exceeding the maximum allowable quantity per control area in Group M or S occupancies complying with Section 414.2.5.
- ~~13-14.~~ 14. The storage of black powder, smokeless propellant and small arms primers in Groups M and R-3 and special industrial explosive devices in Groups B, F, M and S, provided such storage conforms to the quantity limits and requirements prescribed in the *International Fire Code*.

[F] 307.1.1 307.1.2 Hazardous materials. Hazardous materials in any quantity shall conform to the requirements of this code, including Section 414, and the *International Fire Code*.

Reason: This proposal is submitted by the ICC Building Code Action Committee (BCAC). The BCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance an assigned International Code or portion thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the BCAC has held 6 open meetings and numerous workgroup calls which included members of the BCAC as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: <http://www.iccsafe.org/cs/BCAC/Pages/default.aspx>.

This proposal takes a long "exception list" and turns the language into a positive statement list of hazardous material activities that would not be classified as a High Hazard Group occupancy.

Cost Impact: This proposal will not increase the cost of construction.

G3-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

[F] 307.1-G-BAJNAI-BCAC

G4 – 13

IBC [F] 403.3.2 (IFC 914.3.1.2)

Proponent: Jeffrey M. Shapiro, International Institute of Ammonia Refrigeration
(jeff.shapiro@intlcodeconsultants.com)

Revise as follows:

IBC [F] 403.3.2 (IFC 914.3.1.2) Water supply to required fire pumps. In buildings that are more than 420 feet (128 m) in building height, required fire pumps shall be supplied by connections to no fewer than two water mains located in different streets. Separate supply piping shall be provided between each connection to the water main and the pumps. Each connection and the supply piping between the connection and the pumps shall be sized to supply the flow and pressure required for the pumps to operate.

Exception: Two connections to the same main shall be permitted provided the main is valved such that an interruption can be isolated so that the water supply will continue without interruption through no fewer than one of the connections.

Reason: The text in this section originated with Proposal G46-07/08. That proposal was accepted based on a public comment that had a reason statement that began with "*The purpose of this public comment is to increase the reliability of fire sprinkler systems in very tall buildings, those that exceed 420 feet in height, by requiring a minimum of two risers for each sprinkler zone and pumps to be supplied by a minimum of two connections to the municipal distribution system.*" Although Section 403.3.1, which was also created by the same public comment included the 420 foot threshold, the threshold was clearly overlooked in the text of 403.3.2. The text as written technically applies to any high-rise building, which comes at very significant cost, yet there is no documented justification as a basis for applying the code in that manner. The proposed revision resolves the apparent oversight in the current code text.

Cost Impact: The code change proposal will not increase the cost of construction.

G4-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

[F] 403.3.2-G-SHAPIRO

G5 – 13

IBC [F] 414.3

Proponent: Charles S. Bajnai, Chesterfield County, VA, ICC Building Code Action Committee
(bajnaic@chesterfield.gov)

Revise as follows:

IBC [F] 414.3 Ventilation. Rooms, areas or spaces of Group H in which explosive, corrosive, combustible, flammable or highly toxic dusts, mists, fumes, vapors or gases are or may be emitted due to the processing, use, handling or storage of materials shall be mechanically ventilated as where required by this code, the *International Fire Code* or and the *International Mechanical Code*.

~~Ducts conveying explosives or flammable vapors, fumes or dusts shall extend directly to the exterior of the building without entering other spaces. Exhaust ducts shall not extend into or through ducts and plenums.~~

Exception: ~~Ducts conveying vapor or fumes having flammable constituents less than 25 percent of their lower flammable limit (LFL) are permitted to pass through other spaces.~~

Emissions generated at workstations shall be confined to the area in which they are generated as specified in the International Fire Code and the International Mechanical Code.

~~The location of supply and exhaust openings shall be in accordance with the *International Mechanical Code*. Exhaust air contaminated by *highly toxic* material shall be treated in accordance with the *International Fire Code*.~~

~~A manual shutoff control for ventilation equipment required by this section shall be provided outside the room adjacent to the principal access door to the room. The switch shall be of the break-glass type and shall be labeled: VENTILATION SYSTEM EMERGENCY SHUTOFF.~~

Reason: This proposal is submitted by the ICC Building Code Action Committee (BCAC). The BCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance an assigned International Code or portion thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the BCAC has held 6 open meetings and numerous workgroup calls which included members of the BCAC as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: <http://www.iccsafe.org/cs/BCAC/Pages/default.aspx>.

This proposal clarifies that ventilation may be required when hazardous materials are handled regardless of whether the activity is located in a H Group. The proposal also eliminates language that is covered by the IMC for the design and installation of the exhaust systems.

Note that this section does not trigger the installation of the exhaust systems, it refers to the IBC, IFC and IMC for those triggers such as: IBC [F] 415.8.2.7, IBC [F] 415.10.1.6, IBC [F] 415.10.5.8, IMC 502.1, IMC 502.2 – IMC 502.17, IFC 2105.2.3, IFC 2106.3.3, IFC 5003.8.4.2, IFC 5003.8.5.2, and IFC 5004.3 as a few examples.

Cost Impact: This proposal will not increase the cost of construction.

G5-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

[F] 414.3-G-BAJNAI-BCAC

G6 – 13

IBC [F] 414.5, IBC [F] 414.6, IBC [F] 414.7

Proponent: Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azubiamia@yahoo.com)

Revise as follows:

IBC [F] ~~414.5~~ 415.6 Inside storage, dispensing and use. The inside storage, dispensing and use of hazardous materials shall be in accordance with Sections ~~414.5.1~~ 415.6.1 through ~~414.5.4~~ 415.6.3 of this code and the *International Fire Code*.

IBC [F] ~~414.5.1~~ 415.6.1 Explosion control. (No change to current text)

IBC [F] Table ~~414.5.1~~ 415.6.1 Explosion Control Requirements (No change to current text)

IBC [F] 414.5.2 Monitor control equipment. (No change to current text)

IBC [F] ~~414.5.3~~ 415.6.2 Emergency or standby power. (No change to current text)

IBC [F] ~~414.5.4~~ 415.6.3 Spill control, drainage and containment. Rooms, buildings or areas occupied for the storage or use of solid and liquid hazardous materials shall be provided with a means to control spillage and to contain or drain off spillage and fire protection water discharged in the storage area where required in the *International Fire Code*. The methods of spill control shall be in accordance with the *International Fire Code*.

IBC [F] 414.6 Outdoor storage, dispensing and use. (No change to current text)

IBC [F] 414.6.1 Weather protection. (No change to current text)

IBC [F] 414.6.1.1 Walls. (No change to current text)

IBC [F] 414.6.1.2 Separation distance. (No change to current text)

IBC [F] 414.6.1.3 Noncombustible construction. (No change to current text)

IBC [F] ~~414.7~~ 415.7 Emergency alarms. (No change to current text)

IBC [F] ~~414.7.1~~ 415.7.1 Storage. (No change to current text)

IBC [F] ~~414.7.2~~ 415.7.2 Dispensing, use and handling. (No change to current text)

IBC [F] ~~414.7.3~~ 415.7.3 Supervision. (No change to current text)

(Renumber subsequent sections)

Reason: The above sections apply only to Group H occupancies. Section 414 contains requirements which apply to all hazardous materials. Section 415 contains the requirements which apply to Group H occupancies, where the MAQ has been exceeded.

Even the text in these sections state that they only apply to Group H occupancies. For example, Section 414.5.1 starts off by saying;

"Explosion control shall be provided in accordance with the International Fire Code as required by Table 414.5.1 **where quantities of hazardous materials specified in that table exceed the maximum allowable quantities in Table 307.1(1)**..."

Therefore, all of these sections are relocated into Section 415. The only two changes in text occur in Section 415.6 and 415.6.3. Section 415.6 contains an editorial revision so that it references the correct relocated sections. Section 415.6.3 is revised to include the term 'use' in addition to 'storage'. This section addresses spill control and secondary containment. Spill control is required in

areas of 'use'. Secondary containment is required in areas of 'storage' and 'use'. Therefore, including the term 'use' just correlates this section with the rest of the code.

This proposal is submitted by the ICC Fire Code Action Committee (FCAC). This ICC committee was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portions thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the Fire-CAC has held 6 open meetings and numerous Regional Work Group and Task Group meetings and conference calls which included members of the committees as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the FAC website at: <http://www.iccsafe.org/cs/CAC/Pages/default.aspx>.

Cost Impact: This code change will not increase the cost of construction

	Assembly:	ASF	AMF	DF

[F] 414.5-G-ZUBIA-FCAC

G7 – 13

IBC [F] 414.5.2

Proponent: Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azubiamia@yahoo.com)

Delete without substitution:

~~IBC [F] 414.5.2 Monitor control equipment.~~ ~~Monitor control equipment shall be provided where required by the International Fire Code.~~

(Renumber subsequent sections)

Reason: Section 414.5.2 refers to regulations in the IFC for application to “monitor control equipment”. The term “monitor control equipment” is not used in the IFC as suggested by this reference to the IFC.

This IBC section is referring to a term that is not utilized, therefore, this section is proposed to be deleted. The term is not used and do not relate to building construction requirements.

Process control equipment is already addressed in the IFC and the provisions in the IFC cover these items. The proposal eliminates the confusion which occurs when the user refers to the IFC and finds nothing specified for ‘monitor control equipment’. Deleting this section does not eliminate any of the requirements.

This proposal is submitted by the ICC Fire Code Action Committee (FCAC). This ICC committee was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portions thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the Fire-CAC has held 6 open meetings and numerous Regional Work Group and Task Group meetings and conference calls which included members of the committees as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the FAC website at: <http://www.iccsafe.org/cs/CAC/Pages/default.aspx>.

Cost Impact: This code change will not increase the cost of construction

IBC [F] 414.7, [F] 414.7.1, [F] 414.7.2, [F] 414.7.3

Proponent: Charles S. Bajnai, Chesterfield County, VA, ICC Building Code Action Committee
(bajnaic@chesterfield.gov)

Revise as follows:

IBC [F] 414.7 ~~415.5~~ Emergency alarms. Emergency alarms for the detection and notification of an emergency condition in Group H occupancies shall be provided as set forth herein.

IBC [F] ~~414.7.1~~ 415.5.1 Storage. An approved manual emergency alarm system shall be provided in buildings, rooms or areas used for storage of hazardous materials. Emergency alarm-initiating devices shall be installed outside of each interior exit or exit access door of storage buildings, rooms or areas. Activation of an emergency alarm-initiating device shall sound a local alarm to alert occupants of an emergency situation involving hazardous materials.

IBC [F] ~~414.7.2~~ 415.5.2 Dispensing, use and handling. Where hazardous materials having a hazard ranking of 3 or 4 in accordance with NFPA 704 are transported through corridors, interior exit stairways or ramps, or exit passageways there shall be an emergency telephone system, a local manual alarm station or an approved alarm-initiating device at not more than 150-foot (45 720 mm) intervals and at each exit and exit access doorway throughout the transport route. The signal shall be relayed to an approved central, proprietary or remote station service or constantly attended on-site location and shall initiate a local audible alarm.

IBC [F] ~~414.7.3~~ 415.5.3 Supervision. Emergency alarm systems shall be supervised by an approved central, proprietary or remote station service or shall initiate an audible and visual signal at a constantly attended on-site location.

(Renumber subsequent sections)

Reason: This proposal is submitted by the ICC Building Code Action Committee (BCAC). The BCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance an assigned International Code or portion thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the BCAC has held 6 open meetings and numerous workgroup calls which included members of the BCAC as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: <http://www.iccsafe.org/cs/BCAC/Pages/default.aspx>.

The scope of Section 414 applies to all buildings and structures where hazardous materials are present.

[F] 414.1 General. *The provisions of Sections 414.1 through 414.7 shall apply to buildings and structures occupied for the manufacturing, processing, dispensing, use or storage of hazardous materials.*

However, current Section 414.5 only applies to Group H occupancies. For clarification the section is proposed to be relocated to Section 415 which is the portion of the IBC that applies to H Group occupancies.

Cost Impact: This proposal will not increase the cost of construction.

G8-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

[F] 414.7-G-BAJNAI-BCAC

G9 –13

IBC [F] 415.6

Proponent: Homer Maiel, PE, CBO, Town of Atherton (CA), representing ICC Tri-Chapter (Peninsula, East Bay, Monterey Bay)

Revise as follows:

IBC [F] 415.6 Special provisions for Group H-1 occupancies. Group H-1 occupancies shall be in ~~buildings used for no other purpose, shall not exceed one story in height and be without basements, crawl spaces or other under floor spaces.~~ detached buildings. Roofs shall be of lightweight construction with suitable thermal insulation to prevent sensitive material from reaching its decomposition temperature. Group H-1 occupancies containing materials that are in themselves both physical and health hazards in quantities exceeding the maximum allowable quantities per *control area* in Table 307.1(2) shall comply with requirements for both Group H-1 and H-4 occupancies.

Reason: This is only an editorial change. The entire stricken out portion is the definition for “detached buildings”. Hence replacing it with “detached buildings”

Cost Impact: This code change will not increase the cost of construction.

G9-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

[F] 415.6-G-MAIEL.doc

G10 – 11

IBC [F] 415.7.1

Proponent: Homer Maiel, PE, CBO, Town of Atherton (CA), representing ICC Tri-Chapter (Peninsula, East Bay, Monterey Bay)

Delete without substitution as follows:

~~**IBC [F] 415.7.1 Detached buildings.** Detached buildings shall not exceed one story in height and shall be without basements, crawl spaces or other under-floor spaces.~~

Reason: Since this section is already covered in Chapter 2 as a definition, there is no need to be repeated here.

Cost Impact: This code change will not increase the cost of construction.

G10-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

[F] 415.7-G-MAIEL.doc

G11 – 13

IBC [F] 415.7.5

Proponent: Tony Crimi, A.C. Consulting Solutions Inc, representing North American Insulation Manufacturers Association (NAIMA) (tcrimi@sympatico.ca)

Add new text as follows:

IBC [F] 415.7.5. Noncombustible Roof Insulation. Roof insulation for Group H-2, H-3 or H-4 occupancies shall comply with the requirements for Class NC (noncombustible core) in accordance with the requirements of FM 4470.

(Renumber subsequent sections.)

Reason: This proposal introduces a new type class of non-combustible roof insulation products which are specifically evaluated for a higher level of resistance to ignition based upon testing and conformance with the current edition of FM 4470 Approval Standard for Single-Ply, Polymer-Modified Bitumen Sheet, Built-Up Roof (BUR) and Liquid Applied Roof Assemblies. It does not preclude the use of other roof insulation materials. This proposal does not preclude the use of other roof insulation materials. It merely recognizes that in order for a roof insulation to be considered non-combustible, it needs to comply with the new FM 4470 standard.

There is a long history of losses connected with fires in roofing materials and roof coverings. According to NFPA statistics, an average of 4,200 fires starting with exterior roof coverings, surfaces or finishes made of sawn wood occurred per year during the five year period from 1994 through 1998. These fires caused an average of five civilian deaths, 23 civilian injuries and an estimated \$7.0 million in direct property damage per year. During this time period, these fires accounted for 0.7% of the 567,100 total reported structure fires, 0.1% of the 3,744 civilian structure fire deaths, 0.1% of the 21,293 civilian structure fire injuries, and 1.1% of the \$7.2 billion in direct property damage. These totals exclude from the analysis fires where the roof covering was recorded as composed of hardboard, plywood, fiberboard or wood pulp, as these products are considered more likely to refer to decking or framing, rather than to shingles and covering. Also excluded are fires where the roof covering was recorded as growing wood, felled but unsawn wood, wood shavings, or unclassified or unknown-type wood. More importantly, this analysis excludes fires that begin with some other fuel but grow and spread primarily through secondary involvement of wooden roof coverings. Such fires cannot be identified in existing national databases.¹

The roof insulation is one of the most vulnerable parts of a building. Group H buildings are designed to address hazards beyond the other occupancies to provide minimum regulations intended to mitigate the risk to life and structures.

¹ Marty Ahrens, NFPA Report, Wood Shingle or Wood Shake Roof Fires, Statistical Analysis, July 2001

Cost Impact: This proposal will not increase the cost of construction.

Analysis: FM 4470 (1992) is currently referenced in the IBC. Updates in the year edition will be accomplished by an administrative standards update code change to be heard by the ADM Code Development Committee.

G11-13

Public Hearing:	Committee:	AS	AM	D

[F] 415.7.5-(NEW)-G-CRIMI

G12 – 13

IBC [F] 415.10.3.2, IBC [F] 415.10.5.8

Proponent: Patrick A. McLaughlin McLaughlin & Associates, representing the Semiconductor Industry Association (pmclaugma@aol.com)

Revise as follows:

IBC [F] 415.10.3.2 Mechanical ventilation. *Service corridors* shall be mechanically ventilated as required by Section 415.10.1.6 or at not less than six air changes per hour, ~~whichever is greater.~~

IBC [F] 415.10.5.8 Ventilation. Mechanical exhaust *ventilation* shall be provided in liquid storage rooms, HPM rooms and gas rooms at the rate of not less than 1 cubic foot per minute per square foot (0.044 L/s/m²) of floor area or six air changes per hour, ~~whichever is greater, for categories of material.~~

Exhaust *ventilation* for gas rooms shall be designed to operate at a negative pressure in relation to the surrounding areas and direct the exhaust *ventilation* to an exhaust system.

Reason: The six air changes per hour was developed assuming a maximum ceiling height of 10 feet. Currently some of the rooms have ceiling height in excess of 25 feet. There is no justification for the air movement that is required to reach the 6 air changes per hour. The NPFA handbook ventilation discussion states "NFPA 30 allows the use of the traditional approach of 1 cfm of ventilation per square foot (0.3 m3/min/m2) of floor area. This is based on an old, but very effective, rule of thumb: areas where liquids are used should be ventilated at a rate of six air changes per hour. However, most industrial facilities are high-ceilinged; six air changes per hour involve exhausting a great volume of air, with a correspondingly large energy loss in winter. Because most vapors are generated and tend to remain at or near floor level, it is reasonable to assume an arbitrary ceiling height of 10 ft (3 m). With each square foot of floor area translating to 10 ft³, six air changes per hour equals 60 ft³ per hour, or 1 cfm for that one square foot of floor area". As the semiconductor industry moves to future technologies, the ceiling heights of HPM rooms are in some cases over 25', which would require massive amounts of make-up air and result in a large energy loss due to cooling and heating of the space. This proposed change would then align the IFC and IBC provisions with NFPA 30, while still maintaining requirements for adequate makeup air into HPM rooms.

Cost Impact: The code change proposal will not increase the cost of construction.

G13 – 13

IBC [F] 415.10.6.4

Proponent: Robert J Davidson, Davidson Code Concepts, LLC, representing self (BFICOCS)
(rjd@davidsoncodeconcepts.com)

Revise as follows:

IBC [F] 415.10.6.4 Installations in corridors and above other occupancies. The installation of HPM piping and tubing within the space defined by the walls of corridors and the floor or roof above, or in concealed spaces above other occupancies, shall be in accordance with Sections 415.10.6.1 through 415.10.6.3 and the following conditions:

1. through 3. *(No change to current text.)*
4. HPM supply piping and tubing and nonmetallic waste lines shall be separated from the corridor and from occupancies other than Group H-5 by fire barriers or by an approved piping protective system that have a fire-resistance rating of not less than 1 hour Where gypsum wallboard is used, joints on the piping side of the enclosure are not required to be taped, ~~provided the joints occur over framing members.~~ Access openings into the enclosure shall be protected by approved fire protection-rated assemblies.
5. *(No change to current text.)*

Exception: Transverse crossings of the corridors by supply piping that is enclosed within a ferrous pipe or tube for the width of the corridor need not comply with Items 1 through 5.

Reason: The purpose of this proposal is to allow for additional methods of fire-resistance protection for supply piping and tubing. Depending on the configuration and installation details, a fire-resistance wrap material can provide the required fire-resistance rating.

An additional change is to eliminate the wording ", provided the joints occur over framing members" which addresses the elimination of taping joints on the supply piping side of the fire-resistance protection. The IBC Commentary states:
The elimination of the taping of the wallboard joints on the piping side of a rated assembly is in recognition of actual installation difficulties and the reduced likelihood of a fire on the interior of the wall cavity. To eliminate the taping of joints, however, the joints must occur over framing members.

If the elimination is related to the practical difficulty of taping on the inside of the barrier and the reduces likelihood of a fire on the interior of the cavity, in other words the protection is for an exposure fire, then elimination of the interior taping is not reliant on the joints being over framing members.

Cost Impact: The code change proposal will reduce the cost of construction.

IBC [F] 421, Table 509.1, 202; IFC 5808 (New); 5802.1, 202

Proponent: Robert J Davidson, Davidson Code Concepts, LLC, representing National Renewable Energy Laboratory (NREL) (rjd@davidsoncodeconcepts.com)

Revise as follows:

IBC SECTION 421 HYDROGEN CUTOFF GAS ROOMS

[F] 421.1 **General.** Where required by the International Fire Code, hydrogen ~~cutoff~~ gas rooms shall be designed and constructed in accordance with Sections 421.1 through 421.8.

[F] 421.2 **Definitions.** The following terms are defined in Chapter 2:

GASEOUS HYDROGEN SYSTEM.

HYDROGEN CUTOFF GAS ROOM.

[F] 421.3 **Location.** Hydrogen ~~cutoff~~ gas rooms shall not be located below grade.

[F] 421.4 **Design and construction.** Hydrogen ~~cutoff~~ gas rooms ~~not classified as Group H shall be classified with respect to occupancy in accordance with Section 302.1 and separated from other areas of the building in accordance with Section 509.1 by not less than 1-hour fire barriers constructed in accordance with Section 707 or horizontal assemblies constructed in accordance with Section 711, or both; or as required by Section 508.2, 508.3 or 508.4, as applicable~~.

[F] 421.4.1 ~~**Opening protectives Pressure control.** Doors within the fire barriers, including doors to corridors, shall be self-closing in accordance with Section 716. Interior door openings shall be electronically interlocked to prevent operation of the hydrogen system when doors are opened or ajar or the room shall be provided with a mechanical exhaust ventilation system designed in accordance with Section 421.4.1.1.~~ Hydrogen gas rooms shall be provided with a ventilation system designed to maintain the room at a negative pressure in relation to surrounding rooms and spaces.

[F] 421.4.1.1 ~~**Ventilation alternative.** Where an exhaust system is used in lieu of the interlock system required by Section 421.4.1, exhaust ventilation systems shall operate continuously and shall be designed to operate at a negative pressure in relation to the surrounding area. The average velocity of ventilation at the face of the door opening with the door in the fully open position shall not be less than 60 feet per minute (0.3048 m/s) and not less than 45 feet per minute (0.2287 m/s) at any point in the door opening.~~

[F] 421.4.2 **Windows.** Operable windows in interior walls shall not be permitted. Fixed windows shall be permitted where in accordance with Section 716.

[F] 421.5 **Exhaust Ventilation.** ~~Cutoff~~ Gas rooms shall be provided with mechanical exhaust ventilation in accordance with the applicable provisions for repair garages in Chapter 5 of Section 502.16.1 of the *International Mechanical Code*.

[F] 421.6 **Gas detection system.** Hydrogen ~~cutoff~~ gas rooms shall be provided with an approved flammable gas detection system in accordance with Sections 421.6.1 through ~~421.6.3~~ 421.6.4.

[F] 421.6.1 **System design.** The flammable gas detection system shall be listed for use with hydrogen and any other flammable gases used in the room. The gas detection system shall be designed to activate when the level of flammable gas exceeds 25 percent of the lower flammability limit (LFL) for the gas or mixtures present at their anticipated temperature and pressure.

[F] 421.6.2 Gas detection system components. Gas detection system control units shall be listed and labeled in accordance with UL 864 or UL 2017. Gas detectors shall be listed and labeled in accordance with UL 2075 for use with the gases and vapors being detected.

[F] 421.6.3 421.6.2 Operation. Activation of the gas detection system shall result in all of the following:

1. Initiation of distinct audible and visual alarm signals both inside and outside of the ~~cutoff~~ gas room.
2. Activation of the mechanical exhaust ventilation system.

[F] 421.6.4 421.6.3 Failure of the gas detection system. Failure of the gas detection system shall result in activation of the mechanical exhaust ventilation system, cessation of hydrogen generation and the sounding of a trouble signal in an approved location.

[F] 421.7 Explosion control. Explosion control shall be provided in accordance with Chapter 9 of the ~~International Fire Code~~ where required by Section [F] 414.5.1. Mechanical ventilation and gas detection systems shall be connected to a standby power system in accordance with Chapter 27.

**IBC TABLE 509.1
INCIDENTAL USES**

ROOM OR AREA	SEPARATION AND/OR PROTECTION
Hydrogen cutoff <u>gas</u> rooms, not classified as Group H	1 hour in Group B, F, M, S and U occupancies; 2 hours in Group A, E, I and R occupancies.

(Portions of table not shown remain unchanged)

**IBC SECTION 202
DEFINITIONS**

[F] HYDROGEN CUTOFF GAS ROOM. A room or space that is intended exclusively to house a gaseous hydrogen system.

Add new IFC text as follows:

**SECTION 5808
HYDROGEN GAS ROOMS**

5808.1 General. Where required by the International Fire Code, hydrogen gas rooms shall be designed and constructed in accordance with Sections 5808.1 through 5808.7 and the *International Building Code*.

5808.2 Location. Hydrogen gas rooms shall not be located below grade.

5808.3 Design and construction. Hydrogen gas rooms not exceeding the maximum allowable quantities in Table 5003.1.1(1) shall be separated from other areas of the building in accordance with Section 509.1 of the *International Building Code*.

5808.3.1 Pressure control. Hydrogen gas rooms shall be provided with a ventilation system designed to maintain the room at a negative pressure in relation to surrounding rooms and spaces.

5808.3.2 Windows. Operable windows in interior walls shall not be permitted. Fixed windows shall be permitted where in accordance with Section 716 of the *International Building Code*.

5808.4 Exhaust Ventilation. Gas rooms shall be provided with mechanical exhaust ventilation in accordance with the applicable provisions of Section 502.16.1 of the *International Mechanical Code*.

5808.5 Gas detection system. Hydrogen gas rooms shall be provided with an approved flammable gas detection system in accordance with Sections 5808.5.1 through 5808.5.4.

5808.5.1 System design. The flammable gas detection system shall be listed for use with hydrogen and any other flammable gases used in the room. The gas detection system shall be designed to activate when the level of flammable gas exceeds 25 percent of the lower flammability limit (LFL) for the gas or mixtures present at their anticipated temperature and pressure.

5808.5.2 Gas detection system components. Gas detection system control units shall be listed and labeled in accordance with UL 864 or UL 2017. Gas detectors shall be listed and labeled in accordance with UL 2075 for use with the gases and vapors being detected.

5808.5.3 Operation. Activation of the gas detection system shall result in all of the following:

1. Initiation of distinct audible and visual alarm signals both inside and outside of the gas room.
2. Activation of the mechanical exhaust ventilation system.

5808.5.4 Failure of the gas detection system. Failure of the gas detection system shall result in activation of the mechanical exhaust ventilation system, cessation of hydrogen generation and the sounding of a trouble signal in an approved location.

5808.6 Explosion control. Explosion control shall be provided where required by Section 911.

5808.7 Standby power. Mechanical ventilation and gas detection systems shall be connected to a standby power system in accordance with Chapter 6.

Add new IFC definition as follows:

IFC SECTION 202 DEFINITIONS

GASEOUS HYDROGEN SYSTEM. An assembly of piping, devices and apparatus designed to generate, store, contain, distribute or transport a nontoxic, gaseous hydrogen containing mixture having at least 95-percent hydrogen gas by volume and not more than 1-percent oxygen by volume. Gaseous hydrogen systems consist of items such as *compressed gas* containers, reactors and appurtenances, including pressure regulators, pressure relief devices, manifolds, pumps, compressors and interconnecting piping and tubing and controls.

HYDROGEN GAS ROOM. A room or space that is intended exclusively to house a *gaseous hydrogen system*.

Revise as follows:

5802.1 Definitions. The following terms are defined in Chapter 2:

FLAMMABLE GAS.

FLAMMABLE LIQUEFIED GAS.

GASEOUS HYDROGEN SYSTEM.

HYDROGEN GAS ROOM.

METAL HYDRIDE.

METAL HYDRIDE STORAGE SYSTEM.

Reason:

IBC Changes: The purpose of this submittal is cleanup of language, correlation with NFPA 2 "Hydrogen Technologies Code", and correlation with other portions of the IBC. NFPA 2 has been formed to provide a source document for the storage, use and handling

of hydrogen and much work has gone into refining terms and requirements. For consistency the concepts and terms within the IFC, the IBC and NFPA should correlate for effective and efficient application of hydrogen technologies.

From the 2011 edition of NFPA 2:

Origin and Development of NFPA 2

"With the increased interest in hydrogen being used as a fuel source, the National Fire Protection Association was petitioned to develop an all-encompassing document that establishes the necessary requirements for hydrogen technologies. In 2006, the Technical Committee on Hydrogen Technology was formed and tasked to develop a document that addresses all aspects of hydrogen storage, use, and handling, that draws from existing NFPA codes and standards, and that identifies and fills technical gaps for a complete functional set of requirements for code users and enforcers. This document is also structured so that it works seamlessly with building and fire codes."

The term "Hydrogen Cutoff Room" is proposed to be changed to "Hydrogen Gas Room" which is the phrase used by NFPA 2 for consistency. The change would be reflected in the definition, titles and technical language found within the code.

Section [F]421.4 is modified to improved correlation of this section with Section 509 Incidental Uses. Hydrogen cutoff rooms not classified as a Group H are in Table 509 as an Incidental use. The specifications for separation are covered by 509.4.1. The "hydrogen cutoff room" was not intended to be an H Group, so the language referring to Group separated or non-separated uses is not necessary. That language will apply if a Group H classification is determined to apply. The change provides a cleaner, easier to understand application of these requirements

Section [F] 421.4.1 is modified to be consistent with the newer requirements found within NFPA 2 for hydrogen gas rooms.

Section [F]421.5 is modified to clarify that it is an "exhaust" ventilation system that is required and a pointer to the specific section in the IMC has been added instead of the generic Chapter 5 reference for clarity.

A new Section [F] 421.6.2 has been added to provide standards for the required gas detection system. This language and the referenced standards already exists in the IFC,IBC and IMC for when gas detection systems are required to be installed.

Section [F]421.6.2, Item 2 and Section [F]421.6.3 are proposed to be modified by adding the word "exhaust" to add clarity that it is a "mechanical exhaust system" that is be required.

Section [F]421.7 has been modified to point to the explosion control requirements located within Chapter 4 of the IBC, they are a match for the requirements of the IFC.

IFC Changes: This is duplication of language that is currently in the building code. Because most of the requirements for hydrogen are in the Fire Code, there is a tendency to only use the IFC along with the IFGC and IMC for detailed requirements. The existence of the allowance for use of a hydrogen gas room is not always recognized. By copying the existing language to this new section in the fire code officials will not only provide for increase awareness on the application of hydrogen gas rooms, but will also highlight the systems that must be maintained.

The only modifications made were to fit the language to application out of this code as compared to the IBC as has been done with similar language duplication on other topics.

Cost Impact: The code change proposal will not increase the cost of construction.

IBC [F] 425 (New), [F] 415.8.1

Proponent: Robert J Davidson, Davidson Code Concepts, LLC, representing the Biomass Feedstock Industry Committee on Codes and Standards (BFICOCS) (rjd@davidsoncodeconcepts.com)

Revise as follows:

IBC SECTION [F] 425 **COMBUSTIBLE DUSTS, GRAIN PROCESSING AND STORAGE**

[F] ~~415.8.1~~ 425.1 Combustible dusts, grain processing and storage. The provisions of Sections ~~415.8.1.1~~ ~~425.1.1~~ through ~~415.8.1.6~~ ~~425.1.6~~ shall apply to buildings in which materials that produce combustible dusts are stored or handled. Buildings that store or handle combustible dusts shall comply with the applicable provisions of NFPA 61, NFPA 85, NFPA 120, NFPA 484, NFPA 654, NFPA 655 and NFPA 664, and the International Fire Code.

[F] ~~415.8.1.1~~ 425.1.1 Type of construction and height exceptions. Buildings shall be constructed in compliance with the height and area limitations of Table 503 ~~for Group H-2~~; except that where erected of Type I or II construction, the heights and areas of grain elevators and similar structures shall be unlimited, and where of Type IV construction, the maximum building height shall be 65 feet (19 812 mm) and except further that, in isolated areas, the maximum building height of Type IV structures shall be increased to 85 feet (25 908 mm).

[F] ~~415.8.1.2~~ 425.1.2 Grinding rooms. Every room or space occupied for grinding or other operations that produce combustible dusts ~~in such a manner that the room or space is classified as a Group H-2 occupancy~~ shall be enclosed with fire barriers constructed in accordance with Section 707 or horizontal assemblies constructed in accordance with Section 711, or both. The fire-resistance rating of the enclosure shall be not less than 2 hours where the area is not more than 3,000 square feet (279 m²), and not less than 4 hours where the area is greater than 3,000 square feet (279 m²).

[F] ~~415.8.1.3~~ 425.1.3 Conveyors. *(No change to current text)*

[F] ~~415.8.1.4~~ 425.1.4 Explosion control. *(No change to current text)*

[F] ~~415.8.1.5~~ 425.1.5 Grain elevators. *(No change to current text)*

[F] ~~415.8.1.6~~ 425.1.6 Coal pockets. *(No change to current text)*

Reason: The IBC requirements for *Combustible dusts, grain processing and storage* are located in a section of the IBC that only applies to activities that have been designated as High Hazard Groups involving hazardous materials, yet, starting with the 2012 edition IFC Table 5003.1.1(1) / IBC Table 307.1(1) provides for an exception to the High Hazard Group designation if the combustible dust hazard is controlled, in that event the requirements would not apply when some of them should apply, including the height and area exceptions, regardless of the Group classification.

[F] 415.1 Scope.

*The provisions of Sections 415.1 through 415.10 shall apply to the **storage and use of hazardous materials** in excess of the maximum allowable quantities per control area listed in Section 307.1. Buildings and structures with an occupancy in Group H shall also comply with the applicable provisions of Section 414 and the International Fire Code.*

Further, combustible dusts and fibers are not "hazardous materials" as defined by the IFC/IBC and should not be merged in with hazardous material requirements regardless of Group classification.

[F] HAZARDOUS MATERIALS. *Those chemicals or substances that are physical hazards or health hazards as classified in Section 307 and the International Fire Code, whether the materials are in usable or waste condition.*

[F] HEALTH HAZARD. *A classification of a chemical for which there is statistically significant evidence that acute or chronic health effects are capable of occurring in exposed persons. The term "health hazard" includes chemicals that are toxic or highly toxic, and corrosive.*

[F] PHYSICAL HAZARD. *A chemical for which there is evidence that it is a combustible liquid, cryogenic fluid, explosive, flammable (solid, liquid or gas), organic peroxide (solid or liquid), oxidizer*

Based upon the scoping of Section [F]415.1 and the definitions for hazardous materials, the current location for [F]415.8.1 is a mismatch. Though the presence of combustible dusts can cause a high hazard group classification, the material involved is not necessarily a "hazardous material" by definition.

From a practical standpoint, this proposal is a follow up coordination with the code change F187-09/10 which added "combustible dusts" to IFC Table 5003.1.1(1) / IBC Table 307.1(1) along with Note q that provides for elimination of the Group H-2 classification where the hazards are controlled. Prior to that code change the existence of a combustible dust caused an H-2 classification and section [F] 415.8.1 would have applied, (though a designer/facility operator could still question the hazardous materials scoping of Section 415.1 mentioned above).

Some of the provisions found in existing IBC Sections [F]415.8.1 through [F]415.8.1.6 need to be applied regardless of the H Group classification and in most cases it will be compliance with these sections that assists the occupancy to avoid the H Group classification.

This proposal moves the requirements for Combustible dusts, grain processing and storage to a new Section [F]425 to eliminate the H Group scoping limitation and makes minor modifications necessitated by the relocation.

Sections [F]415.8.1.1, proposed as [F]425.1.1, has been modified to eliminate the reference to the H-2 Group, the section provides for a height exception for these occupancies which should apply regardless of the Group classification. Another way to express this is to point out that if the height increase was warranted for an H-2 Group classification, it is clearly warranted for an S, F or U Group classification.

[F]415.8.1.2, proposed as [F]425.1.2, is modified to clarify that those construction requirements are for occupancies that are classified as Group H, which is the hazard classification they are based upon in the current code language. If the hazard is controlled providing for elimination of the Group H designation, then the increased construction requirements are not necessary. The remaining sections are not modified as they should apply in all cases as appropriate.

The Biomass Feedstock Industry Committee on Codes and Standards (BFICOCs), led by Oak Ridge National Laboratory (ORNL), is an initiative of the Department of Energy Biomass Technologies Office (BTO). As part of the BTO integrated biorefinery efforts, the BFICOCs was assembled to conduct analysis of existing fire and building codes and to prepare proposed code changes designed to facilitate the development of the commercial-scale biomass industry while maintaining a focus on safety. The committee is made up of managers, engineers and code officials from industry, government laboratories, consulting firms, and the American Society of Agricultural and Biological Engineers.

Fire codes related to storage, handling, and preprocessing of biomass are based on industries that operate in a significantly different manner than the growing biomass-based energy industry. Applying current research on biomass properties and knowledge of conventional and emerging storage, handling, and preprocessing technologies, the BFICOCs has identified changes in the IFC that benefit industry and the public.

Cost Impact: The code change proposal will not increase the cost of construction.

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

[F] 425 (NEW)-G-DAVIDSON

G16 – 13

IBC [F] 501.2

Proponent: Tim Swanson, City of Greeley, representing Colorado Chapter of the International Code Council

Revise as follows:

IBC [F] 501.2 Address identification. New and existing buildings shall be provided with *approved* address numbers or letters. Each character shall be ~~not less than 4 inches (102 mm) in height and not less than 0.5 inch (12.7 mm) in width. a minimum of 4 inches (101.6 mm) high with a minimum stroke width of 0.5 inch (12.7 mm).~~ They shall be installed on a contrasting background and be plainly visible from the street or road fronting the property. When required by the fire code official, address numbers shall be provided in additional *approved* locations to facilitate emergency response. Where access is by means of a private road and the building address cannot be viewed from the *public way*, a monument, pole or other *approved* sign or means shall be used to identify the structure. Address numbers shall be maintained.

Reason: The language in the current IBC would literally allow the entire character to be as narrow as ½" wide. I know that is not the intent, but that is what the current language it would allow. The intent of requiring a visible, recognizable character is better stated with the language that was in the 2006 IBC and is currently in the 2012 IFC, and the 2012 IRC.

Cost Impact: None

Analysis: Current IFC Section 505.1, IPMC Section 304.3 and IRC R319.1 contain the proposed phraseology.

G16-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

[F]501.2-G-SWANSON

G17 – 13

IBC [F] 2702.2.10, [F] 2702.2.11, [F] 2702.2.12

Proponent: Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azumiamia@yahoo.com)

Revise as follows:

IBC [F] 2702.2.10 Hazardous materials. Emergency or standby power shall be provided in occupancies with hazardous materials ~~in accordance with Section 414.5.3 where required by the *International Fire Code*.~~

IBC [F] 2702.2.11 Highly toxic and toxic materials. Emergency power shall be provided for occupancies with highly toxic or toxic materials ~~in accordance with the *International Fire Code*.~~

IBC [F] 2702.2.12 Organic peroxides. Standby power shall be provided for occupancies with organic peroxides ~~in accordance with the *International Fire Code*.~~

(Renumber subsequent sections)

Reason: This proposal is intended to simplify the IBC requirements and correlate the IBC with the requirements in the IFC. This proposal does not change any requirements, it only reformats them.

Section 2702.2.10 currently references back to 414.5.3. Section 414.5.3 states that "...systems shall be provided with an emergency or standby power system in accordance with Chapter 27." So the reality is that both sections reference each other. To solve this confusion, IBC 414.5.3 is retained to reference Chapter 27, and 2702.2.10 is revised to reference the IFC.

Sections 2702.11 and 2702.12 are deleted since they are covered under the definition of 'hazardous materials' addressed in Section 2702.10 and the revision to 2702.10 covers their reference to the IFC.

This proposal is submitted by the ICC Fire Code Action Committee (FCAC). This ICC committee was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portions thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the Fire-CAC has held 6 open meetings and numerous Regional Work Group and Task Group meetings and conference calls which included members of the committees as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the FAC website at: <http://www.iccsafe.org/cs/CAC/Pages/default.aspx>.

Cost Impact: This code change will not increase the cost of construction

	Assembly:	ASF	AMF	DF

[F] 2702.2.10-G-ZUBIA-FCAC

M1-13

IMC [F] Table 1103.1

Proponent: Debra Kennoy, Arkema Inc., representing self (debra.kennoy@arkema.com)

Revise as follows:

**IMC [F] TABLE 1103.1
REFRIGERANT CLASSIFICATION, AMOUNT AND OEL**

REFRIGERANT	FORMULA	CHEMICAL NAME OF BLEND	REFRIGERANT CLASSIFICATION	DEGREES OF HAZARD ^a	[M] AMOUNT OF REFRIGERANT PER OCCUPIED SPACE			
					Pounds per 1,000 cubic feet	ppm	g/m ³	OEL ^e
R-32	CH ₂ F ₂	difluoromethane (methylene fluoride)	A2	<u>1-4-0</u>	4.8	36,000	77	1,000
R-141b	CH ₃ CCl ₂ F	1,1-dichloro-1-fluoroethane	—	<u>2-1-0</u>	0.78	2,600	12	500
R-142b	CH ₃ CClF ₂	1-chloro-1,1-difluoroethane	A2	<u>2-4-0</u>	5.1	20,000	83	1,000
R-427A	zeotrope	R-32/125/143a/134a (15.0/25.0/10.0/50.0)	A1	<u>2-1-0</u>	18	76,000	280	1,000

(Portions of table not shown remain unchanged)

Reason: Several refrigerants including R-32, R-141b, R-142b, and R-427A are missing the Degrees of Hazard information in ANSI/ASHRAE Standard 34, Designation and Safety Classification of Refrigerants. The information for these refrigerants is provided in the modification to Table 1103.1 as shown above.

Cost Impact: The code change proposal will not increase the cost of construction.

[F] 1103.1T-M-KENNOY

P1– 13

IPC [F] 1202.1; IPC Chapter 14

Proponent: Jonathan Humble (Chairman), representing ICC Reference Standards Committee and Sharon Myers, RA, MPE, CBO. State of Ohio, representing Division of Industrial Compliance, Bureau of Building Code Compliance (SHARON.MYERS@COM.STATE.OH.US)

Revise as follows:

IPC [F] 1202.1 Nonflammable medical gases. Nonflammable medical gas systems, inhalation anesthetic systems and vacuum piping systems shall be designed and installed in accordance with NFPA 99C.

Exceptions:

1. This section shall not apply to portable systems or cylinder storage.
2. Vacuum system exhaust terminations shall comply with the *International Mechanical Code*.

Revise IPC Chapter 14 as follows:

NFPA	National Fire Protection Association 1 Batterymarch Park Quincy, MA 02169-7471	
Standard reference number	Title	Referenced in code section number
NFPA 99C-05	Gas and Vacuum Systems	1202.1
<u>NFPA 99-2012</u>	<u>Health Care Facilities Code</u>	

Reason (Humble): NFPA has also announced that starting 2012 NFPA 99C will no longer be a stand-alone document, which makes this proposal necessary in order to be consistent with the updating of the NFPA referenced standards. NFPA 99C represented an "extract reprint" of NFPA 99, specifically from Chapter 5 of NFPA 99.

As a result, the proposal before you is recommending that the above changes be accepted to reflect the current state of the reference standards.

Further information about this change can be found on the www.nfpa.org web page or at <http://www.nfpa.org/aboutthecodes/AboutTheCodes.asp?DocNum=99&cookie%5Ftest=1> to view a copy of the read-only NFPA 99.

Reason (Myers): NFPA 99C has been incorporated into NFPA 99 and the reference is no longer valid. This proposal simply revises the reference to NFPA 99 and the edition to 2012 to be consistent with other references to NFPA 99 throughout the I-Codes.

Cost Impact: The code change proposal will not increase the cost of construction.

TENTATIVE ORDER OF DISCUSSION 2013 PROPOSED CHANGES TO THE INTERNATIONAL PROPERTY MAINTENANCE CODE

The following is the tentative order in which the proposed changes to the code will be discussed at the public hearings. Proposed changes which impact the same subject have been grouped to permit consideration in consecutive changes.

Proposed change numbers that are indented are those which are being heard out of numerical order. Indentation **does not** necessarily indicate that one change is related to another. Proposed changes may be grouped for purposes of discussion at the hearing at the discretion of the chair. Note that some IPMC code change proposals may not be included on this list, as they are being heard by other committees. Please consult the Cross Index of Proposed Changes.

PM1 – 13

202 (New)

Proponent: Wayne R. Jewell, CBO, Green Oak Charter Township, representing self
(wayne.jewell@twp.green-oak.mi.us)

Add new definition as follows:

SECTION 202 DEFINITIONS

COST OF SUCH DEMOLITION OR EMERGENCY REPAIRS. The costs shall include the actual costs of the demolition or repair of the structure less all revenues obtained if salvage was conducted prior to demolition or repair. Costs shall also include, but not be limited to, all expenses incurred or necessitated related to demolition or emergency repairs, such as asbestos survey and abatement if necessary; costs of inspectors, testing agencies or experts retained relative to the demolition or emergency repairs; costs of testing; surveys for other materials that are controlled or regulated from being dumped in a land-fill; title searches; mailing(s); postings; recording; and all attorney fees expended for recovering of the cost of emergency repairs or to obtain or enforce an order of demolition made by a *code official*, the governing body or board of appeals.

Reason: This provides a definition that summarizes the existing language of the code text in Sections 106.3, 105.5 and 110.3. All of these sections make reference to the jurisdiction's ability to recover costs. This provides a descriptive definition as to what those "costs" are to include. Without a definition that brings the scope of these three sections together there is a lack of uniform enforcement as to what are the actual costs of actions taken by a jurisdiction. This provides a basis of what is to be considered when preparing an invoice of expenses paid by the jurisdiction to protect the public due to the lack of action by an owner of property after receiving a proper notice(s) or order(s) from a code official, governing body or board of appeals.

Cost Impact: The code change proposal will properly place the cost of actions taken by a jurisdiction to provide for the safety and welfare of the public upon the property owner.

PM1-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

202-COST OF SUCH DEMOLITION OR EMERGENCY REPAIRS-PM-JEWELL.DOC

PM2 – 13

202 (New)

Proponent: Jim Edelson, New Buildings Institute (jedelson@comcast.net); Ric Cochrane, National Trust for Historic Preservation; David Collins, The Preview Group representing The American Institute of Architects

Add new definition as follows:

SECTION 202 DEFINITIONS

HISTORIC BUILDING. Any building or structure that is one or more of the following:

1. Listed, or certified as eligible for listing by the State Historic Preservation Officer or the Keeper of the National Register of Historic Places, in the National Register of Historic Places
2. Designated as historic under an applicable state or local law; or
3. Certified as a contributing resource within a National Register listed or locally designated historic district.

Reason: There is no definition for Historic Buildings in the IPMC, even though the term is used in many places. The current language for Historic Buildings in the IECC-Commercial, the IECC-Residential and the IEBC is confusing and does not clearly describe how buildings and districts are listed or determined to be eligible to be listed as historic.

This proposal adds a consistent definition to the IPMC, while solving two problems with the Historic Buildings definitions in the IECC and the IEBC. First, it remedies the confusion caused by the sheer complexity of the defining language by converting the running list of qualifications into a clearly delineated numbered list. Second, the proposal gives the language clarity and specificity as to how a building is officially determined to be eligible for the various lists of historic buildings. In accordance with the Code of Federal Regulations, Title 36, Chapter I, Part 63, determinations of eligibility for listing in the National Register of Historic Places are made by State Historic Preservation Offices in coordination with the Keeper of the National Register of Historic Places. This is an official process conducted in accordance with federal standards. This proposal aligns the code language with the language of this official process and removes any ambiguity as to who can make determinations of eligibility.

This proposal is one of four proposals in Cycle B to create this consistency for Historic Buildings across the I-codes. The other three proposals are being made to the IECC-Residential, the IECC-Commercial and the IEBC.

Cost Impact: There is no cost impact to this proposal.

Analysis: EB1-13 and CE7, CE8 and CE9-13 also propose a similar definition for Historic Building for the IEBC and IECC, respectively.

PM2-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

202-HISTORIC BUILDING-PM-COCHRANE-COLLINS-EDELSON

PM3 – 13

202

Proponent: Rebecca Morley, representing National Center for Healthy Housing

Revise as follows:

SECTION 202 DEFINITIONS

INFESTATION. The presence, within or contiguous to, a structure or premises of: insects including cockroaches, fleas, and bedbugs; pest rodents including rats and mice; vermin; or other pests. Visible pest residue or debris constitutes an infestation unless there is clear evidence that the pest is no longer present.

Reason: The current definition of infestation would appear to exclude rodents other than rats. However, rodents carry disease and, in the case of mice, may trigger an asthma attack. The proposal applies the term to all rodents.

Cockroaches, fleas and bedbugs are public health problems; the proposal specifies these insects to make clear that they are included.

The proposal clarifies that visible evidence of pest residues is a sufficient basis for action by a code official. The code official does not have to see a live pest. Many of the pests of most concern are nocturnal and their residue is the only evidence available during daylight.

Cost Impact: The proposal will not increase the cost of maintenance since this is a definition not a requirement.

PM3-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

202-INFESTATION-PM-MORLEY

PM4 – 13

202 (New)

Proponent: Rebecca Morley, representing National Center for Healthy Housing

Add new definition as follows:

SECTION 202 DEFINITIONS

SANITARY. A condition that is clean and free of *infestation*; rodent residues such as droppings, urine, gnaw marks, grease marks, or nest debris; insect residues such as droppings, debris, or body parts; human or animal waste; mold; wastewater; sewage; rotting material; and accumulation of rubbish or garbage.

Reason: Although used extensively in the code, “sanitary” currently lacks a definition. Therefore the varying contexts in which it appears give the word different connotations. As a result, the term is ambiguous allowing for differing interpretations. The ambiguity means that the code official's interpretation is open to challenge. As a result, code officials may be reluctant to cite for unsanitary conditions absent other violations such as active infestation.

Pest residues that remain after pest elimination may carry infectious diseases and allergens that cause allergies, cause asthma or trigger an asthma attack. Accumulations of rubbish or garbage can provide harborage and a food source for rodents or insects and become the source of disease.

The definition of sanitary addresses those situations commonly understood to spread or support disease. It includes the term infestation to make clear that an infestation is never sanitary.

Cost Impact: This code change proposal will not increase the cost of construction.

PM4-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

202-SANITARY (NEW)-PM-MORLEY

PM5 – 13

304.1.1

Proponent: Andy Williams, Metal Construction Association (afwilliams@metalconstruction.org)

Revise as follows:

304.1.1 Unsafe conditions. The following conditions shall be determined as unsafe and shall be repaired or replaced to comply with the *International Building Code* or the *International Existing Building Code* as required for existing buildings:

1 through 7 (*No change to current text*)

8. Roofing or roofing components that have defects that reduce the roof covering fire classification, or admit rain, roof surfaces with inadequate drainage, or any portion of the roof framing that is not in good repair with signs of *deterioration*, fatigue or without proper anchorage and incapable of supporting all nominal loads and resisting all load effects;

9 through 13 (*No change to current text*)

Exceptions:

1. When substantiated otherwise by an *approved* method.
2. Demolition of unsafe conditions shall be permitted when *approved* by the *code official*.

Reason: An unsafe condition can occur when the roof covering does not maintain the fire classification mandated by the IBC or the IEBC. Failure to maintain this level of performance may allow the spread fire from roof to roof. This unsafe condition is not presently listed in the IPMC. By listing this as an unsafe condition, the Code Official will have language in the IPMC to insure that a roof covering fire classification is maintained.

Cost Impact: The code change proposal will not increase the cost of construction.

PM5-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

304.1.1.1-PM-WILLIAMS.DOC

PM6 – 13

304.2.1 (New), 305.3.1 (New), Chapter 8

Proponent: Rebecca Morley, representing National Center for Healthy Housing

Add new text as follows:

304.2.1 Disturbance of existing painted surfaces. In any Group E, I-4, R-2, R-3, R-4 occupancies completed prior to 1978, where repairs disturb painted surfaces, the work shall comply with the information distribution, certification and work practice requirements of 40 CFR 745 for renovations.

Exception: Where documentation is provided from an approved test in accordance with 40 CFR 745.82(a)(1) or (2) that proves that the disturbed paint contains lead levels below specified levels, the work is not required to comply with this section.

305.3.1 Disturbance of existing painted surfaces. In any Group E, I-4, R-2, R-3, R-4 occupancies completed prior to 1978, where repairs disturb painted surfaces, the work shall comply with the information distribution, certification and work practice requirements of 40 CFR 745 for renovations.

Exception: Where documentation is provided from an approved test in accordance with 40 CFR 745.82(a)(1) or (2) that proves that the disturbed paint contains lead levels below specified levels, the work is not required to comply with this section.

Add new standard to Chapter 8 as follows:

EPA U.S. Environmental Protection Agency

40 CFR 745– July 1, 2012 Lead-Based Paint Poisoning Prevention in Certain Residential Structures

Reason: The purpose of this proposed code language for the surfaces of the structure is to incorporate measures that reflect current knowledge about working with paint that may contain lead-based paint and thereby prevent lead poisoning. The code already requires repair of paint in poor condition. This new subsection would further require compliance with federal regulations to promote the safe repair of deteriorated paint that is likely to contain lead. These regulations have been in effect since April 2010. This change would only affect structures likely to contain lead-based paint.

Multiple studies have demonstrated that lead dust, which is caused by deteriorated lead-based paint and some methods of paint repair, is the major source of lead exposure for young children. The dangers associated with exposure to lead based paint hazards are well-known: lead is associated with a range of serious health effects on children, including detrimental effects on cognitive and behavioral development with serious personal and social consequences that may persist throughout their lifetime. More than 36 million pre-1978 US housing units contain lead-based paint.

Sections 304.2 and 305.3 fail to specifically require, on older structures that are likely to contain lead-based paint, the use of precautionary practices in order to prevent the dispersal of lead before, during, and after the repair work, in the course of complying with the code requirement to repair peeling, flaking and chipping paint. The proposal improves the current Code by adding to each section a health-protective requirement to perform the repair safely around lead-based paint, a subject currently acknowledged in the Commentary but not in the Code. The addition of the proposed new language will protect children from lead poisoning by specifying the use of federally – or state - approved lead safe work practices in making the required repairs. The lead-safe work practices are required by EPA effective April 22, 2010, for most renovation, repair and painting work in all pre-1978 homes. The federal renovation rule and this proposal are based on a rebuttable presumption of lead's presence, which allows the property owner to demonstrate that lead is not present to be exempt from the requirements. The proposed new language includes these exceptions: structures built after lead was banned from paint used in residential structures (1977 US; earlier in some US cities; 1909 France, Belgium, Austria), and structures where the deteriorated paint has been documented to not contain lead (such as by a lead-based paint inspection or risk assessment, by the use of a test kit by a certified renovator, or through completion of another government-approved test method or ANSI standard).

The EPA 40 CFR 745 standard is available at <http://www.gpo.gov/fdsys/pkg/CFR-2012-title40-vol32/xml/CFR-2012-title40-vol32-part745.xml>.

Cost Impact: This change will not increase the cost of maintenance since these federal and state requirements are already in place.

Staff analysis: A review of the standard proposed for inclusion in the code, EPA 40 CFR 745 with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 1, 2013.

PM_-13

Public Hearing: Committee: AS AM D

Assembly:

ASF

AMF

DF

304.2.1 (NEW)-PM-MORLEY

PM7 – 13

304.7.1, 304.7.1 (New), 304.7.2 (New)

Proponent: Andy Williams, Metal Construction Association (afwilliams@metalconstruction.org)

Revise as follows:

304.7 Roofs and drainage. Roof drainage and fire classification shall comply with Sections 304.7.1 and 304.7.1 respectively.

304.7.1 Roof drainage. The roof and flashing shall be sound, tight and not have defects that admit rain. Roof drainage shall be adequate to prevent dampness or *deterioration* in the walls or interior portion of the structure. Roof drains, gutters and downspouts shall be maintained in good repair and free from obstructions. Roof water shall not be discharged in a manner that creates a public nuisance.

304.7.2 Fire classification. The roof covering fire classification shall not be reduced due to repairs from the fire classification required when installed. The roof covering fire classification for a recovering shall comply with the fire classification in the *International Building Code*.

Reason: The proposal to 304.7 to identify that an unsafe condition exists when the roof covering has defects that reduce its fire classification is not adequate unless there is direction on how to address the unsafe condition. Section 304.7.2 is to clarify that the roof covering is required to comply with the fire classification mandated by the IBC. For repairs to a roof covering, the repair must maintain the roof covering fire classification required by the IBC when the roof covering was initially installed. For a recovering, the roof covering must have the fire classification required by the IBC adopted at the time of the recovering.

Cost Impact: The code change proposal will not increase the cost of construction.

PM7-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

304.7-PM-WILLIAMS.DOC

PM8 – 13

304.20 (New)

Proponent: Charles S. Bajnai, Chesterfield County, VA, ICC Building Code Action Committee
(BajnaiC@chesterfield.gov)

Add new text as follows:

304.20 Prohibitions in open parking garages. Partial or complete closing of required openings in exterior walls by tarpaulins or any other means shall be prohibited in open parking structures.

Reason: This proposal is submitted by the ICC Building Code Action Committee (BCAC). The BCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance an assigned International Code or portion thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the BCAC has held 6 open meetings and numerous workgroup calls which included members of the BCAC as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: <http://www.iccsafe.org/cs/BCAC/Pages/default.aspx>.

This language is currently required by section 406.5.11 of the International Building Code and should also be appropriately placed in the Property Maintenance Code.

Cost Impact: This proposal does not increase the cost of construction.

PM8-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

304.20 (NEW)-PM-BAJNAI-BCAC.DOC

PM9 – 13

305.3

Proponent: Rebecca Morley, representing National Center for Healthy Housing

Revise as follows:

305.3 Interior surfaces. All interior surfaces, including windows and doors, shall be maintained in good, clean and sanitary condition. Peeling, chipping, flaking or abraded paint shall be repaired, removed or covered. Cracked or loose plaster, decayed wood and other defective surface conditions shall be corrected. Surfaces such as but not limited to wood, textiles, paint, cellulose insulation, and paper, including paper-faced gypsum board, shall have no signs of chronic or persistent excessive moisture. Material discolored or deteriorated by mold or mildew shall be cleaned, dried and repaired and the underlying cause shall be corrected. If the material has decayed or failed beyond repair, it shall be removed and replaced and the and the underlying cause shall be corrected.

Exception: Porous materials that do not contain organic material, such as clean unpainted bricks and concrete.

Reason: Mold typically grows in buildings affected by water damage. According to the Institute of Medicine of the National Academies' *Damp Indoor Spaces and Health* (2004), mold and damp indoor environments are associated with asthma symptoms in sensitized persons, coughing, wheezing, and upper respiratory tract symptoms. See www.nap.edu/books/0309091934/html/

In December 2007, the National Center for Healthy Housing (NCHH) and the U.S. Centers for Disease Control and Prevention (CDC) convened an Expert Panel consistent with National Institute of Health guidelines to assess the effectiveness of various interventions to make homes healthier and safer. NCHH and CDC published the report of the experts in January 2009. See www.nchh.org/LinkClick.aspx?fileticket=2lvaEDNBldU%3d&tabid=229 for the full report.

The Expert Panel reviewed five peer-reviewed research studies on the issue of mold and allergens and concluded that "when implemented together, eliminating moisture intrusion and leaks and removal of moldy items were found to be effective in reducing asthma triggers and reducing exposures." Other provisions of the IPMC address eliminating moisture intrusion. But no provisions require action on building materials with chronic moisture issues including those materials that have failed beyond repair.

This proposal implements the Expert Panel's recommendation while providing flexibility in response to actual conditions – repair for reparable material, replacement for failed material. To ensure the health of the building's occupants, mitigation of moisture problems must be a part of the code.

Cost Impact: This code change proposal will increase the cost of maintenance.

PM9-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

305.3-PM-MORLEY

PM10 – 13

202, 306.1, 306.1.2 New

Proponent: Meg Waltner, representing National Resource Defense Council, Andrew Burr, representing Institute for Market Transformation and Eric Makela, representing Britt Makela Group, Inc.

Add new definition as follows:

SECTION 202 DEFINITIONS

RETRO-COMMISSIONING. A systematic process for optimizing the energy efficiency of existing base building systems through the identification and correction of deficiencies in such systems, including but not limited to repairs of defects, cleaning, adjustments of valves, sensors, controls or programmed settings, and/or changes in operational practices.

Revise as follows:

SECTION 306 COMPONENT SERVICEABILITY

306.1 General. The components of a structure and equipment therein shall be maintained in good repair and operation, structurally sound and in a sanitary condition.

306.1.1 Unsafe conditions. (no change to current text)

306.1.2 Retro-commissioning. Retro-commissioning shall be performed on the base building systems for buildings 25,000 ft² or greater starting 5 years after issuance of the certificate of occupancy and continuing every 5 years for the life of the building. The building owner shall provide evidence that *retro-commissioning* has been performed and the evidence shall document that sufficient analysis, corrections and testing have been done so indicating that the base building systems meet items 1 through 4 below.

Exception: Retro-commissioning is not required for *let for occupancy* spaces of buildings.

1. Operating protocols, calibration, and sequencing for HVAC and service water heating systems:
 - 1.1. HVAC temperature and humidity set points and setbacks are appropriate and operating schedules reflect major space occupancy patterns and the current facility requirements;
 - 1.2. HVAC sensors are properly calibrated;
 - 1.3. HVAC controls are functioning and control sequences are appropriate for the current facility requirements;
 - 1.4. Loads are distributed equally across equipment when appropriate, such as for fans, boilers and pumps that operate in parallel;
 - 1.5. Ventilation rates are appropriate for the current facility requirements;
 - 1.6. System automatic reset functions are functioning appropriately, if applicable;
 - 1.7. Adjustments have been made to compensate for oversized or undersized equipment so that it is functioning as efficiently as possible;
 - 1.8. Simultaneous heating and cooling does not occur unless intended;
 - 1.9. HVAC system economizer controls are properly functioning, if applicable;
 - 1.10. The HVAC distribution systems, both air and water side, are balanced;
 - 1.11. Domestic hot water systems have been checked to ensure proper temperature settings.
 - 1.12. Water pumps are functioning as designed;

- 1.13. System water leaks have been identified and repaired;
- 1.14. HVAC equipment, such as vents, ducts, coils, valves and soot bins, is clean;
- 1.15. Filters are clean and protocols are in place to replace, as appropriate.
- 2. Operating protocols, calibration, and sequencing for lighting systems:
 - 2.1. Light levels are appropriate to the task;
 - 2.2. Lighting sensors and controls are functioning properly according to occupancy, schedule, and/or available daylight, where applicable;
- 3. Cleaning and repair:
 - 3.1. Motors, fans, and pumps, including components such as belts, pulleys, and bearings, are in good operating condition;
 - 3.2. Steam traps have been replaced as required to maintain efficient operation, if applicable;
 - 3.3. Manual overrides on existing equipment have been remediated;
 - 3.4. Boilers have been tuned for optimal efficiency, if applicable;
 - 3.5. Exposed hot and chilled water and steam pipes three (3) inches or greater in diameter with associated control valves are insulated in accordance with the International Energy Conservation Code;
 - 3.6. In all easily accessible locations, sealants and weather stripping are installed where appropriate and are in good condition.
- 4. Documentation:
 - 4.1. Permits for all HVAC, electrical and plumbing equipment are in order;
 - 4.2. Operational and maintenance record keeping procedures, such as log books and computer maintenance records, have been implemented;
 - 4.3. The operations and maintenance manuals, if such manuals are still available from the manufacturer, the maintenance contracts, and the most recent retro-commissioning report is on site and accessible.

Reason: A critical aspect of building maintenance is ensuring that the energy systems of a building are maintained in a state of good repair and are functioning efficiently. It has been found that, over time, due to system breakdowns and uncoordinated repairs and renovations, building energy systems drift out of proper performance -- sometimes quite dramatically. Sensors and controls can be reset so that building systems are running 24/7 rather than only when necessary, repairs can be made that solve an immediate problem but result in heating and cooling systems running simultaneously, etc. The result of these problems is a poorly performing building that can waste considerable energy while often being uncomfortable or even unhealthy.

For other equipment, such as automobiles, a regular tune-up to ensure safe and efficient operation is considered standard practice. This is becoming standard in buildings, also, through retro-commissioning. Retro-commissioning (RCx) is a process that has been developed in recent decades to ensure that building energy systems are essentially tuned up -- that they are running efficiently and that they are in a state of good repair. Retro-commissioning takes a careful look at the systems that are in place, analyzes how they could be repaired to run more efficiently, and then performs those repairs.

Several U.S. cities recently adopted RCx requirements for large buildings. In 2009, New York City passed an ordinance, Local Law 87, that requires nonresidential and multifamily housing properties over 50,000 square feet to perform RCx once every 10 years. In 2011, San Francisco passed an ordinance requiring energy audits or RCx once every 5 years.

Cost Impact: In 2009, Lawrence Berkeley National Laboratory published a study of building commissioning costs and benefits, looking at 643 buildings with a cumulative square footage of 100 million square feet. RCx was found to cost an average of \$0.30 per square foot. The RCx resulted in a 16% whole-building median energy savings with an average payback of 1.1 years.

PM10-13

Public Hearing: Committee:	AS	AM	D
Assembly:	ASF	AMF	DF

306.1-PM-BURR-MAKELA-WALTNER.DOC

PM11 – 13

307.1

Proponent: Roy Fyffe, Building Official, representing City of Burnet, TX (rfyffe@cityofburnet.com)

Revise as follows:

307.1 General. Every exterior and interior flight of stairs having more than four risers shall have a handrail on one side of the stair and every open portion of a stair, landing, balcony, porch, deck, ramp or other walking surface which is more than 30 inches (762mm) above the floor or grade below shall have *guards*. Handrails shall not be less than ~~30-34~~ inches (~~762mm-864 mm~~) in height or more than ~~42~~ 38 inches (~~1067~~ 965mm) in height measured vertically above the nosing of the tread or above the finished floor of the landing or walking surfaces. *Guards* shall not be less than ~~30~~ 36 inches (~~762~~ 914 mm) in height above the floor of the landing, balcony, porch, deck, or ramp or other walking surface.

Exception: *Guards* shall not be required where exempted by the adopted building code.

Reason: The revised text will provide for continuity and clarity between both IPMC and IRC codes, thus lessening any confusion for building and property maintenance inspectors.

Cost Impact: The code change proposal will not increase the cost of construction.

PM11-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

307.1-PM-FYFFE

PM12 – 13

310 (New)

Proponent: Jim Edelson, New Buildings Institute (jedelson@comcast.net)

Add new text as follows:

SECTION 310 **ENERGY REQUIREMENTS**

310.1 General. Nonresidential *buildings* shall be maintained and operated to achieve a source energy use intensity, sEUI, less than or equal to the value from Table 310.1 based on the *building* type and climate zone of the *building* and calculated in accordance with Section 310.2. Where a *building* has multiple use types from Table 310.1, the maximum allowable energy use shall be based on the total gross floor area of each use type in relation to the total gross floor area of all use types within the *building*.

TABLE 310.1^a
SOURCE ENERGY USE INTENSITY (sEUI) TARGETS

Climate Zone^a	1A	2A	2B	3A	3B	3B	3C	4A	4B	4C	5A	5B	6A	6B	7	8

a. Climate zones as determined in accordance with Section C301 of the International Energy Conservation Code.

310.2 Calculation of energy use. The sEUI shall be based on 12 continuous months of energy use data for the whole *building*. The annual sEUI for electric energy shall be calculated by converting energy use at the *building* to kBtu's and multiplying by the conversion factor in Table 310.2.1 based on the geographical location of the *building*. The annual sEUI for fossil fuels shall be calculated by converting energy use at the *building* to kBtu's and multiplying by the conversion factors in Table 310.2.2. The annual sEUI for district cooling shall be calculated by converting energy use at the *building* to kBtu's, multiplying by 0.33, and then multiplying by the conversion factor in Table 310.2.1 based on the geographical location of the *building*. The annual sEUI for district heating shall be calculated by converting energy use at the *building* to kBtu's and multiplying by 1.35 for hot water and 1.45 for steam. The annual sEUI for all other energy sources shall be calculated by converting energy use at the *building* to kBtu's and multiplying by 1.1.

TABLE 310.2.2
U.S. AVERAGE BUILDING FUELS ENERGY CONVERSION FACTORS BY FUEL TYPE

Fuel Type	Energy Conversion Factor
Natural Gas	1.09
Fuel Oil	1.13
LPG	1.12

Reason: According to the Urban Land Institute, New Construction and Major Renovations account for only 1-2% of the building stock in a typical year. For the larger population of existing buildings, building codes' primary means of improving energy efficiency are through alterations. However, as current codes are formulated, the scope of that impact is generally limited to the scope of the alteration. Code requirements generally apply only to the alterations and not to the energy efficiency of the whole building. This highlights the inability of a jurisdiction's energy code to improve the energy efficiency of its whole building stock.

Bearing in mind the dangers of unintended consequences, it is wise to carefully target any new code requirements for existing buildings, and so this proposal is built on two principles:

- Many existing buildings perform quite well, so requirements should focus only on very poorly performing buildings rather than indiscriminately covering all buildings.
- As this represents new territory in building codes, requirements should be built upon existing code mechanisms, code language and code requirements as much as possible.

The International Property Maintenance Code provides a natural and logical home for this kind of code requirement. The IPMC is already scoped around the fundamental concept of establishing a minimum standard for the condition of a building. Energy performance falls directly within this scope. The IPMC already has the administrative mechanisms needed to set this minimum standard for energy performance. Section 104 gives the code official authority to inspect and require reports. Section 106 provides means for dealing with violations. This proposal, therefore, only sets a minimum threshold for energy performance. This leverages the existing procedures and remedies already built into the IPMC, and avoids the need to create new code enforcement mechanisms.

The performance threshold values in the table are based on the 2003 Commercial Building Energy Consumption Survey (the same dataset that serves as the basis for commercial building Energy Star Scores and the targets for existing buildings in ASHRAE Standard 100). Based on either the table of values or an Energy Star Score threshold of 26, the requirements will only kick in for a building that would have fallen in the worst performing quartile of the building stock in that building survey. This represents the worst 25% of the buildings around a decade ago, effectively making these requirements only apply to buildings that can be reasonably considered "energy hogs." CBECS is a nationwide survey conducted by the Energy Information Administration, so climate zone diversity for the table was created using the same, nationally vetted process used to create the performance targets for existing buildings proposed for ASHRAE Standard 100.

The target EUIs in the proposal are presented in source kBtu units because the only EUI metric in an I-Code, the 2012 IgCC, uses the same source kBtu metric. The calculation language and conversion factors for source energy are also taken directly from the IgCC, but the language has been slightly altered for greater clarity.

Current energy codes have a limited means of impacting the energy performance of the vast majority of buildings in the entire building stock. This proposed addition to the IPMC will address the significant energy efficiency opportunities in existing buildings, and do it in a way that simply expands upon current code mechanisms.

Cost Impact: There is no cost impact to this proposal.

Analysis: EB51-13 also proposes similar requirements for the IEBC.

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

310.2 (NEW)-PM-EDELSON

PM13 – 13

[F] 702.4 (IFC 1030.7)

THIS CHANGE WILL BE HEARD BY THE IFC COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

Proponent: Charles S. Bajnai, Chesterfield County, VA, ICC Building Code Action Committee
(BajnaiC@chesterfield.gov)

Revise as follows:

[F] 702.4 (IFC 1030.7) Emergency escape and rescue openings. Required emergency escape and rescue openings shall be maintained in accordance with the code in effect at the time of construction, and the following. Required emergency escape and rescue openings shall be operational from the inside of the room without the use of keys or tools. Bars, grilles, grates or similar devices are permitted to be placed over emergency escape and rescue openings provided the minimum net clear opening size complies with the code that was in effect at the time of construction and such devices shall be releasable or removable from the inside without the use of a key, tool or force greater than that which is required for normal operation of the escape and rescue opening. Where new bars, grilles, grates or similar devices, are installed in existing buildings where none presently exist, smoke alarms shall be installed in accordance with Section 907.2.11 of the *International Building Code*.

Reason: This proposal is submitted by the ICC Building Code Action Committee (BCAC). The BCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance an assigned International Code or portion thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the BCAC has held 6 open meetings and numerous workgroup calls which included members of the BCAC as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: <http://www.iccsafe.org/cs/BCAC/Pages/default.aspx>.

This code proposal is attempting to clarify the requirements for existing openings that have previously approved bars, grilles, grates and similar devices on them, vs. existing or new openings that will be installing such devices on them.

The existing IBC Code Section 1029.4 states:

1029.4 Operational constraints. Emergency escape and rescue openings shall be operational from the inside of the room without the use of keys or tools. Bars, grilles, grates or similar devices are permitted to be placed over emergency escape and rescue openings provided the minimum net clear opening size complies with Section 1029.2 and such devices shall be releasable or removable from the inside without the use of a key, tool or force greater than that which is required for normal operation of the escape and rescue opening. Where such bars, grilles, grates or similar devices are installed in existing buildings, smoke alarms shall be installed in accordance with Section 907.2.11 regardless of the valuation of the alteration.

Existing IPMC Section 702.4's last sentence was revised to clearly state that it is only applicable to existing openings that have previously approved bars, grilles, grates and similar devices on them.

The new proposed last sentence in this code proposal is attempting to correlate the requirement of IBC Section 1029.4 with the IPMC Section 702.4. If a new opening is provided, or an existing opening is going to be provided, with bars, grilles, grates and similar devices, then the smoke alarm requirements of IBC Section 907.2.11 are applicable to the affected residential unit. If previously approved bars, grilles, grates and similar devices are only being repaired or replaced on an existing opening then the smoke alarm requirement of IBC Section 907.2.11 would still not be applicable.

The title and first sentence were revised to indicate "rescue" openings to be consistent with other I-code language.

Cost Impact: This proposal will not increase the cost of construction.

[F] 704.1.2 (New)

THIS CHANGE WILL BE HEARD BY THE IFC COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

Proponent: Charles S. Bajnai, Chesterfield County, VA, ICC Building Code Action Committee
(BajnaiC@chesterfield.gov)

Add text as follows:

[F] 704.1 General. All systems, devices and equipment to detect a fire, actuate an alarm, or suppress or control a fire or any combination thereof shall be maintained in an operable condition at all times in accordance with the *International Fire Code*.

[F] 704.1.1 Automatic sprinkler systems. (No change to current text)

[F] 704.1.2 Fire Department Connection. Where the fire department connection is not visible to approaching fire apparatus, the fire department connection shall be indicated by an approved sign mounted on the street front or on the side of the building. Such sign shall have the letters "FDC" at least 6 inches (152 mm) high and words in letters at least 2 inches (51 mm) high or an arrow to indicate the location. Such signs shall be subject to the approval of the fire code official.

Reason: This proposal is submitted by the ICC Building Code Action Committee (BCAC). The BCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance an assigned International Code or portion thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the BCAC has held 6 open meetings and numerous workgroup calls which included members of the BCAC as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: <http://www.iccsafe.org/cs/BCAC/Pages/default.aspx>.

This language is currently found in section 912.2.2 of the International Building Code and should be in the IPMC. FDCs on existing buildings may not always be readily visible. A sign is critical to approaching fire-fighting operations.

Cost Impact: This proposal will not increase the cost of construction.

PM15 – 13

[F] 704.2.1 (New), [F] 704.2.2 (New)

THIS CHANGE WILL BE HEARD BY THE IFC COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

Proponent: Charles S. Bajnai, Chesterfield County, VA, ICC Building Code Action Committee, and Adolf Zubia, Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (BajnaiC@chesterfield.gov)

Add text as follows:

[F] 704.2 Smoke alarms. Single- or multiple-station smoke alarms shall be installed and maintained in Groups R-2, R-3, R-4 and in dwellings not regulated in Group R occupancies, regardless of *occupant* load at all of the following locations:

1. On the ceiling or wall outside of each separate sleeping area in the immediate vicinity of *bedrooms*.
2. In each room used for sleeping purposes.
3. In each story within a *dwelling unit*, including *basements* and cellars but not including crawl spaces and uninhabitable attics. In dwellings or *dwelling units* with split levels and without an intervening door between the adjacent levels, a smoke alarm installed on the upper level shall suffice for the adjacent lower level provided that the lower level is less than one full story below the upper level.

Single- or multiple-station smoke alarms shall be installed in other groups in accordance with the *International Fire Code*.

[F] 704.2.1 Installation near cooking appliances. Smoke alarms shall not be installed in the following locations unless this would prevent placement of a smoke alarm in a location required by Section R314.3.

1. Ionization smoke alarms shall not be installed less than 20 feet (6.1 m) horizontally from a permanently installed cooking appliance.
2. Ionization smoke alarms with an alarm-silencing switch shall not be installed less than 10 feet (3 m) horizontally from a permanently installed cooking appliance.
3. Photoelectric smoke alarms shall not be installed less than 6 feet (1.8 m) horizontally from a permanently installed cooking appliance.

[F] 704.2.2 Installation near bathrooms. Smoke alarms shall be installed not less than 3 feet (0.91 m) horizontally from the door or opening of a bathroom that contains a bathtub or shower unless this would prevent placement of a smoke alarm required by Section R314.3.

Reason: This proposal is submitted by the ICC Building Code Action Committee (BCAC) and the ICC Fire Code Action Committee (FCAC). These ICC committees were established by the ICC Board of Directors to pursue opportunities to improve and enhance an assigned International Codes or portion thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the these committees have held 6 open meetings and numerous workgroup meetings which included members of the committees as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the CAC website at: <http://www.iccsafe.org/cs/CAC/Pages/default.aspx>. It is the intent of the ICC committees to have these sections scoped to the Fire Code Committee if approved.

This proposal is intended to reduce nuisance alarms attributed to locating smoke alarms in close proximity to cooking appliances and bathrooms in which steam is produced. The proposed provisions are based on the findings in the Task Group Report - Minimum Performance Requirements for Smoke Alarm Detection Technology - February 22, 2008, and are consistent with similar requirements included in Section 29.8.3.4 of the 2010 and 2013 editions of NFPA 72.

Cost Impact: None

705 (New)

Proponent: Rebecca Morley, representing National Center for Healthy Housing

Add new text as follows:

SECTION 705 **CARBON MONOXIDE ALARMS**

705.1 General. Carbon monoxide alarms shall be installed in accordance with Section 1103.9 of the *International Fire Code* in Group R occupancies and in dwellings not regulated as Group R occupancies.

Reason: Carbon monoxide (CO) is an odorless, tasteless, invisible gas that kills more than 300 people in homes each year. Thousands more are admitted to the hospital with carbon monoxide poisoning. This is a serious issue that affects people nationwide in all regions of the country.

The International Residential Code requires CO alarms for residences with fuel-fired appliances or attached garages. This change would make the IPMC consistent with the IRC.

This proposal expands on the requirement to specifically include portable fuel burning space heaters since these devices may not be considered an appliance, since these devices may be introduced by the property owner after construction.

The following states have required CO alarms in existing residences: Alaska, California, Colorado, Illinois, Massachusetts, Michigan, Minnesota, Montana, New Jersey, New York, North Carolina, Oklahoma, Oregon, Rhode Island, Vermont and Wisconsin. Deaths from CO are spread throughout the country as residents unwittingly use dangerous methods to stay warm in unusually cold weather.

Cost Impact: Yes, this code change proposal will increase the cost of property maintenance. A carbon monoxide alarm typically costs approximately \$25.

Appendix B (New)

Proponent: Lynn Underwood, Norfolk, VA, representing the ICC Abatement of Dangerous Buildings Ad Hoc Committee.

Add new text as follows:

APPENDIX B **Provisions for Abatement of Dangerous Buildings**

The provisions contained in this appendix are not mandatory unless specifically referenced in the adopting ordinance

CHAPTER B1 **SCOPE AND ADMINISTRATION**

SECTION B101 **GENERAL**

B101.1 Title. These provisions shall be known as the *Provisions for the Abatement of Dangerous Buildings* hereafter will be referred to as “The Abatement Provisions”.

B101.2 Scope. The Abatement Provisions apply to all buildings, or structures or portions of buildings or structures that have been deemed dangerous by the *building official*, which are now in existence or which hereafter become dangerous in this jurisdiction.

B101.3 Intent. The purpose of The Abatement Provisions is to provide for the repair, vacation or demolition of buildings or structures, which from any cause, endanger the life, limb, health, property, safety or welfare of the general public.

The purpose of The Abatement Provisions is not to create or otherwise establish or designate any particular class or group of persons who will or should be especially protected by or who would benefit from the terms of The Abatement Provisions.

B101.4 Application of other codes. Where determined appropriate by the building official, The Abatement Provisions are applicable in combination with the other codes of the jurisdiction, including, but not limited to, building, fire and property maintenance codes.

SECTION B102 **APPLICABILITY**

B102.1 General. Where, in any specific case, different sections of The Abatement Provisions specify different requirements, the most restrictive shall govern. Where there is a conflict between a general requirement and a specific requirement, the specific requirement shall be applicable.

B102.2 Other laws. The Abatement Provisions shall not be deemed to nullify any provisions of local, state or federal law and regulation.

B102.3 Application of references. References to chapter or section numbers, or to provisions not specifically identified by number, shall be construed to refer to such chapter, section or provision of The Abatement Provisions.

B102.4 Referenced codes and standards. The codes and standards referenced in The Abatement Provisions are considered part of the requirements of The Abatement Provisions to the prescribed extent

of each such reference. Where differences occur between The Abatement Provisions and referenced codes and standards, the requirements of The Abatement Provisions shall govern.

B102.5 Partial invalidity. In the event that any part or provision of The Abatement Provisions is held to be illegal or void, this shall not have the effect of making void or illegal any of the other parts or provisions.

B102.6 Existing remedies. The provisions to The Abatement Provisions shall not be construed to abolish or impair existing remedies of the jurisdiction or its officers or agencies relating to the removal or demolition of any structure which is dangerous, unsafe and insanitary.

SECTION B103

CONSTRUCTION IN COMPLIANCE WITH LOCALLY ADOPTED CODES

B103.1 General. Repairs, additions and alterations to buildings and structures shall be done in accordance with the procedures and provisions of the adopted codes of the jurisdiction.

SECTION B104

OWNER RESPONSIBILITY AND TRANSFER OF OWNERSHIP

B104.1 General. The owner of record shall be responsible for correcting all deficiencies in the notice and order, or appealing the notice and order.

B104.2 Transfer of ownership. It shall be unlawful for the owner of any building or structure who has received a compliance order or upon whom a notice of violation has been served to sell, transfer, mortgage, lease or otherwise dispose of such building or structure to another until the provisions of the compliance order or notice of violation have been complied with, or until such owner shall first furnish the grantee, transferee, mortgagee or lessee a true copy of any compliance order or notice of violation issued by the building official and shall furnish to the building official a signed and notarized statement from the grantee, transferee, mortgagee or lessee, acknowledging the receipt of such compliance order or notice of violation and fully accepting the responsibility without condition for abating the violation as required by such compliance order or notice of violation.

SECTION B105

DUTIES AND POWERS OF BUILDING OFFICIAL

B105.1 General. The building official is authorized to enforce The Abatement Provisions. The building official shall have the authority to interpret The Abatement Provisions and to adopt policies and procedures to clarify the application of its provisions. Such interpretations, rules and regulations shall be in conformity with the intent and purpose of The Abatement Provisions.

B105.2 Authority to disconnect service utilities. The building official shall have the authority to order disconnection of any electricity, fuel gas, water, or all other utility service to a building, structure or system where necessary to eliminate an immediate hazard to life or property. The building official shall notify the serving utility and, whenever practical, the owner and occupant of the building, structure or service system prior to taking such action. If not notified prior to disconnection, the owner and occupant of the building, structure or service system shall be notified as soon as practical thereafter.

B105.3 Liability. The building official, member of the board of appeals or employee charged with the enforcement of The Abatement Provisions, while acting for the jurisdiction, in good faith and without malice in the discharge of the duties required by The Abatement Provisions or other pertinent law or ordinance, shall not thereby be rendered liable personally, and is hereby relieved from all personal liability for any damage accruing to persons or property as a result of an act or by reason of an act or omission in the discharge of official duties. Any suit instituted against any officer or employee because of an act performed by that officer or employee in the lawful discharge of duties and under the provisions of The Abatement Provisions shall be defended by the legal representative of the

jurisdiction until the final termination of the proceedings. The building official or any subordinate shall not be liable for costs in an action, suit or proceeding that is instituted in pursuance of the provisions of The Abatement Provisions.

SECTION B106 **INSPECTION OF WORK**

B106.1 General. Buildings, structures or equipment within the scope of The Abatement Provisions shall be subject to inspection by the building official in accordance with The Abatement Provisions and the inspection provisions of the jurisdiction.

B106.2 Right of entry. Where it is necessary to make an inspection to enforce the provisions of The Abatement Provisions, or whenever the building official has reasonable cause to believe that there exists in a building or upon any premises a condition in violation of The Abatement Provisions which make the building or premises dangerous, the building official is authorized to enter the building or premises at reasonable times to inspect or to perform the duties imposed upon the building official by The Abatement Provisions. Where such building or premises is occupied, the building official shall present credentials to the occupant and request entry. Where such building or premises is unoccupied, the building official shall first make a reasonable effort to locate the owner or other person having charge or control of the building or premises and request entry. If entry is refused, the building official shall have recourse to the remedies provided by law to secure entry.

B106.2.1 Warrant. When the building official has first obtained a proper inspection warrant or other remedy provided by law to secure entry, an owner or occupant or person having charge, care or control of the building or premises shall not fail or neglect to permit entry by the building official for the purpose of inspection and examination pursuant to The Abatement Provisions.

SECTION B107 **ABATEMENT**

B107.1 General. Buildings or portions thereof which are determined after inspection by the building official to be dangerous are declared to be public nuisances and shall be abated by repair, rehabilitation, demolition or removal in accordance with the procedure specified in Section B109.

SECTION B108 **IMMINENT DANGER**

B108.1 General. When the building official finds that there is imminent danger of failure or collapse of a building or structure which endangers life, or when any structure or part of a structure has fallen and life is endangered by the occupation of the structure, or when there is actual or potential danger to building occupants or those in the proximity of any structure because of explosives, explosive fumes or vapors or the presence of toxic fumes, gases or materials, or operation of *dangerous equipment*, the building official is authorized and empowered to order and require the occupants to vacate the building or structure.

SECTION B109 **NOTICES AND ORDERS OF BUILDING OFFICIAL**

B109.1. General. Notices and orders of the building official, and the service of such notices and orders shall comply with the provisions of Sections B109.1.1 through B109.1.5.

B109.1.1 Commencement of proceedings. Whenever the building official has inspected or caused to be inspected any building or structure and determined that such building or structure is dangerous, the building official shall commence proceedings to cause the repair, vacation or demolition of the building or structure.

B109.1.2 Notice and order. The building official shall issue a notice and order to the owner of the building. The notice and order shall be in writing and shall contain the following:

1. The street address and a legal description sufficient for identification of the premises on which the building or structure is located.
2. A statement that the building or structure has been found to be dangerous, with a description of the conditions found to render the building dangerous under the provisions of Section B202.
3. A statement of the action required to be taken as determined by the building official.
 - 3.1. Where the building official has determined that the building or structure is required to be repaired, the order shall require that all required permits be secured therefore and the work physically commenced within such time and completed within such time as the building official shall determine is reasonable under all of the circumstances. Nothing in this section shall be deemed to prohibit vacating and demolishing a building ordered to be repaired. Work shall physically commence within 60 days of the order, or within the number of days set by the order, whichever occurs first.
 - 3.2. Where the building official has determined that the building or structure is required to be vacated, the order shall require that the building or structure shall be vacated within a time certain from the date of the order as determined by the building official to be reasonable. Nothing in this section shall be deemed to prohibit demolishing a building ordered to be vacated.
 - 3.3. Where the building official has determined that the building or structure is required to be demolished, the order shall require that the building be vacated within such time as the building official shall determine is reasonable; that all required permits be secured therefore within 60 days from the date of the order; and that the demolition be completed within such time as the building official shall determine is reasonable.
4. Statements advising that when required repair or demolition work is not commenced within the time specified, the building official is authorized to:
 - 4.1. Order the building vacated and posted to prevent further occupancy until the work is completed, and
 - 4.2. Proceed to cause the work to be done. Where the building official has caused work to be done, the costs of the work shall be charged against the property or its owner.
5. A statement of the right of the jurisdiction to file a lien.
6. Statements advising that:
 - 6.1. Any person having any title or legal interest in the building has the right to appeal from the notice and order or any action of the building official to the board of appeals; and
 - 6.2. Failure to appeal shall constitute a waiver of all rights to an administrative hearing and determination of the matter.
 - 6.3. Appeals shall be in writing as provided in Section B110 and filed with the building official within 20 days from the date of service of such notice and order.
7. In the case of buildings and structures to be vacated or demolished, the building official shall include, in the notice and order, notification specifying the emergency and conditions which necessitate placarding in accordance with Section B109.4.

B109.1.3 Service of notice and order. The notice and order, and any amended or supplemental notice and order, shall be:

1. Served on the owner;
2. Posted on the property;

Where known to the building official or disclosed from official public records, a copy of the notice and order also shall be served on:

1. The holder of any mortgage or deed of trust or other lien or encumbrance of record;
2. The owner or holder of any lease of record; and
3. The holder of any other estate or legal interest of record in or to the building or the land on which it is located.

The failure of the building official to serve any person required herein to be served shall not invalidate any proceedings hereunder as to any other person duly served or relieve any such person from any duty or obligation imposed by the provisions of this section.

B109.1.4 Method of service. The notice and order shall be deemed to be properly serviced where a copy thereof is:

1. Delivered personally; or
2. Sent by certified or first-class mail addressed to the last known address; or
3. Delivered by private delivery service with proof of delivery; or
4. When the notice is returned showing that the letter was not delivered, a copy thereof shall be posted in a conspicuous place in or about the structure affected by such notice.

B109.1.5 Proof of service. Proof of service of the notice and order shall be certified to at the time of service by a written declaration under penalty of perjury executed by the persons effecting service, declaring the time, date and manner in which service was made. The declaration, together with any receipt card returned in acknowledgment of receipt by certified mail shall be affixed to the copy of the notice and order retained by the building official. Proof of service by private delivery service shall be in the form usually used by said service in the normal course of business.

B109.2 Recordation of notice and order. Notices and orders shall be recorded according to this section.

B109.2.1 Non-compliance. If compliance is not had with the order within the time specified therein, and no appeal has been properly and timely filed, the building official shall file in the office of the county recorder a certificate describing the property and certifying the following:

1. The building is a *dangerous building*, and
2. The owner has been so notified.

B109.2.2 Compliance. When the corrections ordered have been completed or the building demolished so that it no longer exists as a *dangerous building* on the property described in the certificate, the building official shall file a new certificate with the county recorder certifying that the building has been demolished or all required corrections have been made so that the building is no longer dangerous, whichever is appropriate.

B109.3 Repair, vacation and demolition. Where a *dangerous building* or structure is subject to an order to be repaired, vacated or demolished, the building official shall comply with the following criteria. Where the order follows the conclusion of an appeal, the board of appeals shall follow the same criteria.

1. Where the building is declared a *dangerous building* under The Abatement Provisions, it shall be made to comply with one of the following:
 - 1.1. The building shall be repaired in accordance with the adopted building codes of the jurisdiction;
 - 1.2. The building shall be demolished either in compliance with an order to demolish, or where the owner chooses to demolish rather than repair the building; or
 - 1.3. Where the building does not constitute an immediate danger to the life, limb, property or safety of the public, the building is vacated, secured and maintained against entry.
2. Where the building or structure is in such condition as to make it immediately dangerous to the life, limb, property or safety of the public or its occupants, it shall be ordered to be vacated.

B109.4. Placard Posting. Properties subject to notice and order shall be posted and placarded in accordance with Sections B109.4.1 through B109.4.4.

B109.4.1 Posting. In addition to the required serving of the notice in B109.1.3, whenever the building official has ordered the vacation or demolition of a building or structure, notice, in the form of placarding,

shall be posted at or near the entrances of the building and in one or more conspicuous places in or about the structure affected by such notice.

B109.4.2 Placarding. The posted placard shall be in substantially the following form:

DO NOT ENTER
UNSAFE TO OCCUPY

It shall be unlawful to enter or occupy this building, or to remove or deface this notice.

[Name]

Building Official

[Jurisdiction]

For more information please contact...

B109.4.3 Prohibited occupancy and entry. No person shall enter, occupy, or remain in any building placarded by the building official in accordance with Section B109.4. Any person who enters or occupies a placarded premises or any owner or any person responsible for the premises who allows anyone enter or occupy a placarded premises shall be subject to the penalties provided for in The Abatement Provisions.

Exception: The building official is permitted to allow entry into the structure or premises.

B109.4.4 Placard removal. The building official shall remove the placard whenever the *dangerous conditions* for which the placard was required have been eliminated. Any person who defaces or removes a placard without the approval of the building official shall be subject to the penalties provided for in The Abatement Provisions.

SECTION B110
APPEAL

B110.1 General. Appeals to a notice or order of the building official shall comply with Sections B110.2 through B110.5.

B110.2 Right to appeal. Any person served a notice or order under the provisions of Section B109 has the right to appeal the order or notice to the Board of Appeals.

B110.2.1 Failure to appeal. Failure of any person to file an appeal in accordance with the provisions of Section B110.5 shall constitute a waiver of the right to an administrative hearing and adjudication of the notice and order or any portion thereof.

B110.3 Imminent danger. Where the building is an imminent danger to public safety, the building official shall have the authority to direct abatement of the hazard in accordance with Section B108 of The Abatement Provisions prior to the filing of an appeal, or resolution of any filed appeal.

B110.4 Board of appeals established. In order to hear and decide appeals of orders, decisions or determinations made by the building official relative to the application and interpretations of The Abatement Provisions, there shall be and is hereby created a board of appeals

B110.4.1 Appointment. The board of appeals shall be appointed by the governing body and shall hold office at its pleasure. The board of appeals shall consist of members who are qualified by experience and training to pass on matters pertaining to building construction and maintenance. The members shall not be employees of the jurisdiction. The building official shall be an ex officio member and shall act as secretary to said board but shall have no vote on any matter before the board.

B110.4.2 Rules. The board shall adopt rules of procedure for conducting its business. The decisions and findings of the board shall be in writing and provided to the appellant. A copy of each decision and finding shall be provided to the building official. Appeals to the board shall be processed in accordance with the

provisions contained in Sections B110.5 through B110.6.2 of The Abatement Provisions. Copies of all rules or regulations adopted by the board shall be delivered to the building official, who shall make them freely accessible to the public.

B110.4.3 Limitations of Authority. An application for appeal shall be based on the following:

1. A claim that the true intent of The Abatement Provisions or the rules legally adopted thereunder have been incorrectly interpreted;
2. The provisions of The Abatement Provisions do not fully apply; or
3. An equally good or better form of compliance is proposed.

The board shall have no authority to waive requirements of The Abatement Provisions.

B110.5 Form of appeal. Any person entitled to service under Section B109.1.3 has the right to appeal any notice and order or any action of the building official under The Abatement Provisions by filing at the office of the building official a written appeal on a form provided by the board of appeal.

The appeal shall be filed within 20 days from the date of the service of such order or notice of the building official; provided, however, that if the building or structure is in such condition as to make it immediately dangerous to the life, limb, property or safety of the public or adjacent property, is ordered vacated and is posted in accordance with Section B109.4, such appeal shall be filed within 10 days from the date of the service of the notice and order of the building official.

B110.6 Processing of appeal. Upon receipt of any appeal filed pursuant to this section, the building official shall present it at the next regular or special meeting of the board of appeals.

B110.6.1 Scheduling of appeal hearing. As soon as practicable after receiving the written appeal, the building official shall review the petition and determine whether the appeal is complete. When determined to be incomplete, the appellant shall be notified as to additional information required, to make the petition complete. When the appeal is determined to be complete, the appeal request shall be processed in accordance with Sections B110.6 and B110.6.2. The hearing date shall not be less than 10 days nor more than 60 days from the date the complete appeal was filed with the building official.

B110.6.2. Notice of appeal hearing. Written notice of the time and place of the hearing shall be given at least 10 days prior to the date of the hearing to each appellant by the secretary of the board either, by causing a copy of such notice to be delivered to the appellant personally, or by mailing a copy thereof, postage prepaid, addressed to the appellant at the address shown on the appeal.

B110.6.3 Scope of hearing. A hearing on appeal shall only consider matters within the scope of The Abatement Provisions. Only those matters or issues specifically raised by the appellant shall be considered in the hearing of the appeal.

B110.6.4 Staying an order under appeal. Except for vacation orders made pursuant to Section B109.4 and imminent danger pursuant to Section B108.1, enforcement of any notice and order of the building official issued under The Abatement Provisions shall be stayed during the pendency of an appeal therefrom which is properly and timely filed.

B110.7 Procedure for conduct of appeal hearings. The procedures for conduct of hearing appeals shall be as determined by the jurisdiction. All rules shall be available to appellant in advance of the hearing date. In jurisdictions where rules have not been established, procedures for conduct of hearing appeals provided in Chapter B3 of The Abatement Provisions shall be used.

SECTION B111
ENFORCEMENT OF THE ORDER OF THE BUILDING OFFICIAL
OR THE BOARD OF APPEALS

B111.1 Compliance. After any order of the building official or the board of appeals made pursuant to The Abatement Provisions has become final, no person to whom any such order is directed shall fail, neglect or refuse to obey any such order.

B111.2 Failure to obey order. Where a person fails to comply with a final order or notice issued by the building official, or issued by the board of appeals subsequent to the resolution of an appeal, the building official is authorized to take appropriate action to abate such building or premises as a public nuisance.

B111.3 Failure to commence work. Whenever the required repair or demolition is not commenced within 30 days after any final notice and order issued under The Abatement Provisions becomes effective:

1. The building official is authorized to cause the building described in such notice and order to be vacated by posting at each entrance thereto a notice as described in Section B109.4.
2. No person shall occupy any building which has been posted as specified in this section. No person shall remove or deface any such notice so posted until the repairs, demolition or removal ordered by the building official have been completed and a certificate of occupancy, as applicable, has been issued.
3. In addition to any other remedy herein provided, the building official is authorized to cause the building or structure to be repaired to the extent necessary to correct the conditions which render the building or structure dangerous as set forth in the notice and order; or, if the notice and order requires demolition, to cause the building or structure to be demolished and the materials, rubble and debris therefrom removed and the lot cleaned. Any such repair or demolition work shall be accomplished and the cost thereof paid and recovered in the manner hereinafter provided in The Abatement Provisions.

B111.4 Extension of time to perform work. The building official is authorized to grant an extension of time, not to exceed an additional 120 days, within which to complete said repair, rehabilitation or demolition, provided the building official determines that such an extension of time will not create or perpetuate a situation imminently dangerous to life or property. The building official's authority to extend time is limited to the physical repair, rehabilitation or demolition of the premises and will not in any way affect the time to appeal the notice and order.

B111.5 Interference with repair or demolition work prohibited. It shall be unlawful for any person to obstruct, impede or interfere with any officer, employee, contractor or authorized representative of this jurisdiction or with any person who owns or holds any estate or interest in any building which has been ordered repaired, vacated or demolished under The Abatement Provisions; or with any person to whom such building has been lawfully sold pursuant to The Abatement Provisions, whenever such officer, employee, contractor or authorized representative of this jurisdiction, person having an interest or estate in such building or structure, or purchaser is engaged in the work of repairing, vacating and repairing, or demolishing any such building, pursuant to The Abatement Provisions, or in performing any necessary act preliminary to or incidental to such work or authorized or directed pursuant to The Abatement Provisions.

SECTION B112
REPAIR OR DEMOLITION WORK PERFORMED BY THE JURISDICTION

B112.1 Procedure. When any work of repair or demolition is performed by the jurisdiction or at its direction pursuant to The Abatement Provisions, the required work is to be accomplished by the appropriate personnel of this jurisdiction or by private contract under the direction of the office designated by the jurisdiction

Plans and specifications necessary to perform such work shall be prepared according to the following:

1. By the office designated by the jurisdiction, or
2. Where deemed reasonably necessary the jurisdiction employ architectural and engineering assistance on a contract basis.

B112.2 Costs. The jurisdiction shall keep an itemized account of the expense incurred by this jurisdiction in the repair or demolition of any building done pursuant to the provisions of Section B111.3, of The Abatement Provisions. Upon the completion of the work of repair or demolition, an abatement expense report shall be prepared and filed, specifying the work done, the itemized and total cost of the work, a description of the real property on which the building or structure is or was located, and the names and addresses of the persons entitled to notice pursuant to Section B109.1.3.

All costs associated with such work shall be paid by the jurisdiction and shall be recovered by one of the following processes:

1. Apply a special assessment against the property involved,
2. Be made a personal obligation of the property owner, or
3. Be added to the tax roll of the premises, in conformance with applicable laws.

B112.3 Repair and demotion fund. The legislative body of this jurisdiction is authorized to establish a special revolving fund to be designated as the repair and demolition fund. Payment is authorized to be made out of said fund on the demand to defray the costs and expenses which are incurred by this jurisdiction in doing or causing to be done the necessary work of repair or demolition of *dangerous buildings*.

B112.3.1 Maintenance of Fund. The legislative body is authorized at any time to transfer to the repair and demolition fund, out of any money in the general fund of this jurisdiction, such sums as it deems necessary in order to expedite the performance of the work of repair or demolition, and any sum so transferred shall be deemed a loan to the repair and demolition fund and shall be repaid out of the proceeds of the collections hereinafter provided for. All funds collected under the proceedings hereinafter provided for shall be paid to the treasurer of this jurisdiction who shall credit the same to the repair and demolition fund.

B112.2.3 Salvage materials. Where any structure has been ordered demolished and removed, the governing body or other designated officer under said contract or arrangement aforesaid shall have the right to sell the salvage and valuable materials at the highest price obtainable. The net proceeds of such sale, after deducting the expenses of such demolition and removal, shall be promptly remitted with a report of such sale or transaction, including the items of expense and the amounts deducted, for the person who is entitled thereto, subject to any order of a court. If such a surplus does not remain to be turned over, the report shall so state.

SECTION B113 **VIOLATIONS**

B113.1 Violation penalties. Any person who violates a provision of The Abatement Provisions or fails to comply with any of the requirements thereof shall be subject to penalties as described by law. It is unlawful and a public nuisance for any person to maintain an unsafe or *dangerous building* or structure. Each and every day that a building or structure is maintained in an unsafe or *dangerous condition* is a new violation of The Abatement Provisions. It is a violation of The Abatement Provisions and unlawful to occupy a building or structure that has been ordered to be vacated.

CHAPTER B2 **DEFINITIONS**

SECTION B201 **GENERAL**

B201.1 Scope. Unless otherwise expressly stated, the following terms shall, for the purposes of The Abatement Provisions, have the meanings shown in this chapter.

B201.2 Interchangeability. Words stated in the present tense include the future; words stated in the masculine gender include the feminine and neuter; the singular number includes the plural and the plural, the singular.

B201.3 Terms defined in other codes. Where terms are not defined in this chapter and are defined in the *International Building Code*, *International Residential Code*, *International Fire Code*, *International Zoning Code*, *International Plumbing Code*, *International Mechanical Code*, *International Fuel Gas Code*, *NFPA 70*, or the adopted building codes of the jurisdiction, such terms shall have the meanings ascribed to them as in those codes.

B201.4 Terms not defined. Where terms are not defined through the methods authorized by this section, such terms shall have ordinarily accepted meanings such as the context implies.

SECTION B202 **DEFINITIONS**

Dangerous building. A *dangerous building* is a building or portion thereof which is found to be dangerous to the life, health, property or safety of the public or the occupants of the structure when described below as *dangerous structures*, having *dangerous equipment*, structures unfit for human occupancy, or having *dangerous conditions*.

Dangerous conditions. Any building, structure or part thereof that has one or more of the conditions or defects described below shall be deemed dangerous. *Dangerous conditions* include but are not limited to the following:

1. Any door, aisle, passageway, stairway, exit or other means of egress component that does not provide adequate access to an exit or sufficient capacity to provide a safe means of egress.
2. The walking surface of any aisle, passageway, stairway, exit or other means of egress is so warped, loose, torn or otherwise unsafe as to not provide safe and adequate means of egress.
3. Any portion of a building, structure or appurtenance that has been damaged by fire, earthquake, wind, flood, deterioration, neglect, abandonment, vandalism or by any other cause to such an extent that it is likely to partially or completely collapse, or to become detached or dislodged.
4. Any portion of a building, or any member, appurtenance or ornamentation on the exterior thereof that is not of sufficient strength or stability, or is not so anchored, attached or fastened in place so as to be capable of resisting loads of one half of that specified by the building code for new buildings or structures or similar construction, purpose and location without exceeding the working stresses permitted in the building code.
5. The building or structure, or part of the building or structure, because of dilapidation, deterioration, decay, faulty construction, the removal or movement of some portion of the ground necessary for the support, or for any other reason, is likely to partially or completely collapse, or some portion of the foundation or underpinning of the building or structure is likely to fail or give way.
6. The building or structure, or any portion thereof, is hazardous for its use and occupancy.
7. The building or structure is neglected, damaged, dilapidated, unsecured or abandoned so as to become an attractive nuisance to children who might play in the building or structure to their danger, becomes a harbor for vagrants, criminals, or enables persons to resort to the building or structure for committing an unlawful act.

8. Any building or structure that has been constructed, exists or is maintained in violation of any specific requirement or prohibition applicable to such building or structure provided by the building or fire code of the jurisdiction, or of any law or ordinance to such an extent as to present either a substantial risk of fire, building collapse or any other threat to life and safety.
9. A building or structure, used or intended to be used for dwelling purposes, because of inadequate maintenance, dilapidation, decay, damage, faulty construction or arrangement, inadequate light, ventilation, mechanical or plumbing system, or otherwise, is determined by the building official to be insanitary, unfit for human habitation or in such a condition that is likely to cause sickness or disease.
10. Any building or structure, because of a lack of maintenance of fire-resistance-rated construction, fire protection systems, electrical system, fuel connections, mechanical system, plumbing system or other cause, is determined by the building official to be a threat to life or health.
11. Any portion of a building remains on a site after the demolition or destruction of the building or structure or whenever any building or structure is abandoned so as to constitute such building or portion thereof as an attractive nuisance or hazard to the public.

Dangerous equipment. *Dangerous equipment* includes any boiler, heating equipment, elevator, moving stairway, electrical wiring or device, flammable liquid containers, or other equipment which is in such disrepair or condition that such equipment is a hazard to life, health, property or safety of the public or occupants.

Dangerous structure. The building or structure, or part of the building or structure, because of dilapidation, deterioration, decay, damage, unstable foundation or faulty construction is in a condition that partial or complete collapse is possible and is judged to be hazardous.

Structure unfit for human occupancy. A structure is unfit for human occupancy whenever the structure contains a *dangerous condition* or the building official finds that such structure is dangerous due to the degree to which the structure is in disrepair, lacks maintenance, is insanitary, vermin or rat infested, contains filth and contamination, lacks ventilation, illumination, heating, sanitary facilities or other essential equipment, or the location of the structure constitutes a hazard to the occupants of the structure or to the public.

CHAPTER B3 **PROCEDURES FOR CONDUCT OF APPEAL HEARING**

SECTION B301 **GENERAL**

B301.1 Hearing. The hearing for any appeal case brought to the board of appeals, shall be conducted in one of the following manners:

1. By the board of appeals;
2. By one or more members of the board designated by the board to serve as hearing examiners;
or
3. By one or more hearing examiners appointed by the board who are not members of the board.

B301.1.1 Authority. The examiner hearing the case shall exercise all powers relating to the conduct of hearings until it is submitted to the board of appeals for decision.

B301.2 Record. A record of the entire proceedings related to an appeal hearing shall be made. The record shall be retained in the records of the board of appeals in a manner and length of time established by the board.

B301.3 Transcripts. At the request of any party a transcript shall be made of the proceedings. The requesting party shall be responsible for any and all costs of recording the proceeding and producing the

transcripts. If a transcript is produced, the transcript shall be made available to all parties upon request and upon payment of any required fee. Where required by written policy of the board, requests for transcripts shall be submitted to the jurisdiction. The jurisdiction is authorized to establish necessary fees, but in no event shall the fees be greater than the costs involved.

B301.4 Continuances. The board of appeals is authorized to grant continuances in the proceedings related to an appeal hearing for good cause shown. Where a hearing has been assigned to a hearing examiner, the examiner is authorized to grant such continuances provided the matter remains before the examiner.

B301.5 Oaths—certification. In any proceedings under this chapter, the board of appeals, or the hearing examiner has the authority to administer oaths and affirmations and to certify to official acts.

B301.6 Reasonable dispatch. The board of appeals and its representatives shall proceed with reasonable dispatch to conclude any matter before it. Due regard shall be shown for the convenience and necessity of any parties or their representatives.

B301.7 Timeliness of process. When an appeal has been filed in accordance with Section B110.5, a hearing shall be scheduled within the time period required by Section B110.6.1. The board of appeals shall issue its final decision within 180 calendar days of the date when the appeal was filed. Where agreed to by all parties to the appeal, extensions in deadline for final action by the board are authorized if good cause is shown.

SECTION B302 **FORM OF NOTICE OF HEARING**

B302.1 General. The notice to appellant shall be substantially in the following form. The notice shall include the information specified below as well as additional information determined necessary to provide complete notice.

"You are hereby notified that a hearing will be held before [the board of appeals or name of hearing examiner] at [] on [] day of [], 20[], at the hour [], on the notice and order served on you. You may be present at the hearing. You may be, but need not be, represented by counsel. You may present any relevant evidence and will be given full opportunity to cross-examine all witnesses testifying against you. You may request the issuance of subpoenas to compel the attendance of witnesses and the production of books, documents or other things by filing an affidavit therefor with [board of appeals or name of hearing examiner]."

SECTION B303 **SUBPOENAS**

B303.1 Filing of Affidavit. The board of appeals or hearing examiner is authorized to obtain the issuance and service of a subpoena for the attendance of witnesses or the production of other evidence at a hearing on the request of a member of the board or on the written demand of any party to the appeal. The issuance and service of such subpoena shall be obtained on the filing of an affidavit therefor which states the name and address of the proposed witness; specifies the exact things sought to be produced and the materiality thereof in detail to the issues involved; and states the witness has the desired things in possession or under control. A subpoena need not be issued when the affidavit is defective in any particular.

B303.2 Cases referred to hearing examiner. In cases where a hearing is referred to a hearing examiner, all subpoenas shall be obtained through the examiner.

B303.3 Penalties. Any person who refuses, without lawful excuse, to attend any hearing or to produce material evidence which the person possesses or controls as required by any subpoena served on such person as provided for herein shall be guilty of a misdemeanor.

SECTION B304

CONDUCT OF HEARING

B304.1 Rules. The board of appeals shall regulate the course of the hearings, and require the presentation of evidence in such manner and order that is most beneficial to the board. To the extent not inconsistent with The Abatement Provision and to the extent it advances the purposes of The Abatement Provision, practice before the board of appeal shall be guided by prevailing laws and regulations.

B304.2 Oral evidence. Oral evidence shall be taken only on oath or affirmation.

B304.3 Hearsay evidence. Hearsay evidence is permissible for the purpose of supplementing or explaining any direct evidence, but shall not be sufficient in itself to support a finding unless it would be admissible over objection in civil actions in courts of competent jurisdiction in this state.

B304.4 Admissibility of evidence. Any relevant evidence shall be admitted if it is the type of evidence on which responsible persons are accustomed to rely in the conduct of serious affairs, regardless of the existence of any common law or statutory rule which might make improper the admission of such evidence over objection in civil actions in courts of competent jurisdiction in this state.

B304.5 Exclusion of evidence. Irrelevant and unduly repetitious evidence shall be excluded.

B304.6 Rights of parties. Each party shall have these rights, among others:

1. To call and examine witnesses on any matter relevant to the issues of the hearing;
2. To introduce documentary and physical evidence;
3. To cross-examine opposing witnesses on any matter relevant to the issues of the hearing;
4. To impeach any witness regardless of which party first called the witness to testify;
5. To rebut the evidence; and
6. To be represented by anyone who is lawfully permitted to do so.

B304.7 Official notice. The official notice procedure shall be in accordance with Sections B304.7.1 through B304.7.4.

B304.7.1 What may be noticed. In reaching a decision, official notice may be taken, either before or after submission of the case for decision, of any fact which may be judicially noticed by the courts of this state or of official records of the board or departments and ordinances of the city or rules and regulations of the board.

B304.7.2 Parties to be notified. Parties present at the hearing shall be informed of the matters to be noticed, and these matters shall be noted in the record, referred to therein, or appended thereto.

B304.7.3 Opportunity to refute. Parties present at the hearing shall be given a reasonable opportunity, on request, to refute the officially noticed matters by evidence or by written or oral presentation of authority, the manner of such refutation to be determined by the board or hearing examiner.

B304.7.4 Inspection of the premises. The board of appeals or the hearing examiner is authorized to inspect any building or premises involved in the appeal during the course of the hearing, provided that:

1. Notice of such inspection shall be given to the parties before the inspection is made,
2. The parties are given an opportunity to be present during the inspection, and
3. The board of appeals or the hearing examiner shall state for the record upon completion of the inspection the material facts observed and the conclusions drawn therefrom.

Each party then shall have a right to rebut or explain the matters so stated by the board or hearing examiner.

SECTION B305

METHOD AND FORM OF DECISION

B305.1 Hearing before board of appeals. When a contested case is heard before the board of appeals, any member who did not hear the evidence or has not read the entire record of the proceedings shall not vote on or take part in the decision.

B305.2 Hearing before hearing examiner. If a contested case is heard by a hearing examiner alone, the examiner shall, within 30 days from the date the hearing is closed, submit a written report to the board of appeals. The report shall contain a brief summary of the evidence considered and state the examiner's findings, conclusions and recommendations. The report also shall contain a proposed decision in a form that it can be adopted by the board as its decision in the case. All examiner's reports filed with the board shall be matters of public record. A copy of each such report and proposed decision shall be mailed to each party on the date they are filed with the board.

B305.3 Consideration of report by board of appeals —notice. The board of appeals shall fix the time, date and place to consider the hearing examiner's report and proposed decision. Notice thereof shall be mailed to each interested party not less than five days prior to the date fixed, unless it is otherwise stipulated by all parties.

B305.4 Exceptions to report. Not later than two days before the date set to consider the report, any party has the right to file written exceptions to any part or all of the hearing examiner's report and offer an alternative to the proposed decision together with written argument in support of such decision. With permission of the board of appeals, any party has the right to present oral argument to the board.

B305.5 Disposition by the board of appeals. The board of appeals shall take one of the following actions regarding the proposed decision presented by the hearings examiner:

1. Adopt the decision in its entirety;
2. Reject the decision in its entirety; or
3. Modify the proposed decision.

B305.6 Proposed decision not adopted. When the proposed decision is not adopted by the board of appeals as provided in Section B305.5, the board shall either:

1. Decide the case on the entire record before it, with or without taking additional evidence, or
2. Refer the case to the same or another hearing examiner to take additional evidence. Where the case is reassigned to a hearing examiner, the examiner shall prepare a report and proposed decision as provided in Section B305.2 after any additional evidence is submitted. Consideration of such proposed decision by the board shall comply with the provisions of this section.

B305.7 Form of decision. The decision shall be in writing and shall contain findings of fact, a determination of the issues presented, the effective date of the decision, and those items that require compliance. A copy of the decision shall be delivered to the appellant personally or sent by certified mail, postage prepaid, and with a return receipt requested.

Appeal Application Form

Appellant Information:

Name: _____
Address: _____
Telephone Number: _____ Email Address: _____

Property Owner Information:

Name: _____
Address: _____
Telephone Number: _____ Email Address: _____

Order Under Appeal:

List date and details of order under appeal.

_____ Date of Order: _____

Description of Order:

Received from Municipality/Jurisdiction: _____

Name of Official issuing the order: _____

Property Description under APPEAL:

Name of Municipality/Jurisdiction: _____
Roll Number: _____
Legal Description: _____

Address: _____

Type of APPEAL:

Order for Demolition: _____
Order to Vacate Building: _____
Order to Repair Building: _____
Other: _____

Building Occupancy Type:

Examples: Residential - Single Family; Residential - Multi Family; Commercial; Duplex/ Fourplex; Row Housing; Condominium; Walkup Apartment; High-rise Apartment; Townhouse; Other

Reason for Appeal: *(must check one of the following)*. An application for appeal shall be based on _____1) a claim that the true intent of The Abatement Provisions or the rules legally adopted thereunder have been incorrectly interpreted, _____2) the provisions of The Abatement Provisions do not fully apply, or _____3) an equally good or better form of compliance is proposed.

Explain relief sought, why it is claimed that the protested order or action should be reversed, modified or otherwise set aside.

Signature of Appellant/Owner/Authorized representative

Date Appeal Filed/Accepted

Reason: The proposed code change would add a new Appendix B to the International Property Maintenance Code (IPMC) to provide an important tool for jurisdictions that need it, but not mandate the provisions for jurisdictions that might not need it. The new proposed Appendix B is titled Provisions for Abatement of Dangerous Buildings.

In 2010, the ICC Board of Directors established an Ad Hoc committee to draft provisions for the abatement of dangerous buildings. The initiative for the committee's work arose due to numerous requests from ICC members whose jurisdictions had formerly adopted the Uniform Code for Abatement of Dangerous Buildings (UCADB), published by the ICC Legacy organization ICBO. The concern was that as jurisdictions adopted ICC codes, this valuable tool for code enforcement officials, that had previously been available, was lost.

There are many jurisdictions where adoption of a full property maintenance code is simply politically untenable. For the code officials in those jurisdictions there remains a pressing need for the proposed document to provide legal authority and guidance to abate distinctly dangerous buildings and conditions. Many such jurisdictions are still using older versions of some abatement documents without good coordination with the adopted I-Codes.

The Ad Hoc committee reviewed and discussed several documents related to the abatement of dangerous buildings, including an internal draft document that had previously been developed by the ICC Hazard Abatement Ad Hoc Committee and the UCADB. The committee then decided to base its work on the UCADB's provisions but revise as needed and include provisions from other documents such as the Hazard Abatement committee work. The provisions were updated, streamlined and revised as needed to be consistent with current ICC practices and format.

This proposal would add a new Appendix B to the IPMC that would be suitable for adoption by jurisdictions that do not have other provisions for abatement of dangerous conditions in buildings and premises providing an important tool. The proposed appendix provides a means for enforcement, as well as procedures that can be used to conduct appeals. The proposal will not affect those jurisdictions that have no need for it.

The ICC Ad Hoc Committee for Abatement of Dangerous Buildings consisted of the following members:

Chair Lynn Underwood, CBO, MCP, City of Norfolk, VA;

Vice Chair Steven Rocklin, R.A. Assistant Director, Regional Services, Albany, NY

Members:

James Doody, Consulting Engineer, Calgary, Alberta, Canada

Joe Ehrlich, Senior Building Inspector, St. Paul, MN

Steve Ikkanda, JAS Pacific, VP Research and Code Development, Alhambra, CA (partial attendance)

Wayne R. Jewell, CBO, Building Official, Southfield, MI (partial attendance)

Paul R Klein, CBO, CASp, Chief Building Official, Yuba City, CA (partial attendance)

Paul R. Lopes, Littleton, NH

John H. Mertens, Fire Protection Engineer, Phoenix, AZ

Jim Olk, Building Official, Farmers Branch, TX

Linda Pieczynski, Attorney at Law, Hinsdale, IL

Anne R. vonWeller, Public Services Deputy Director, Murray, UT
Hector Buitrago, Chief of Code Enforcement Bureau, Los Angeles, CA (partial attendance)

Cost Impact: The Proposed code change will not increase the cost of construction.

APPENDIX B (NEW)-G-UNDERWOOD

PM18 – 13

Appendix B (New)

Proponent: Rebecca Morley, representing National Center for Healthy Housing

Add new text as follows:

APPENDIX B **ENVIRONMENTAL SAFETY**

B101 **GENERAL**

B101.1 Scope. The provisions of this chapter shall govern the minimum conditions and standards for the environmental safety a premises.

B101.2 Responsibility. The owner of a premise shall maintain the premises in compliance with these requirements. A person shall not occupy as owner-occupant, permit another person to occupy, or allow the public to use any premises which does not comply with the requirements of this appendix. Occupants of a dwelling unit, rooming unit or housekeeping unit shall not cause an area or space that they occupy and control to violate the provisions of this appendix.

B101.3 Approved Testing Methods. The code official is authorized to require testing or inspection consistent with approved methods as evidence of compliance with this appendix. The code official shall accept results from a recognized agency regularly engaged in conducting tests or furnishing inspection services or from an individual licensed in accordance with the statutory requirements of federal, state, or jurisdiction laws to conduct the testing or inspection. The testing or inspection results shall be deemed sufficient to establish whether a premise is in compliance with the requirements of this appendix. The building owner shall pay the cost of testing or inspection.

B101.4 Vacating. When an area is required to be vacated by this chapter due to a hazardous condition, entry shall be prohibited except by persons performing or overseeing the removal of the hazard. The code official shall order the area to be vacated in accordance with Section 108 of this code.

B102 **ANIMAL WASTES**

B102.1 Exterior accumulations. Animal wastes shall be contained and disposed of in a safe and sanitary manner so as to control insects, vermin, odor and the spread of disease.

B102.2 Interior accumulation. Animal waste shall not be allowed to accumulate in any dwelling unit except in an approved device which is properly maintained to contain excrement and control odor.

B103 **HAZARDOUS BUILDING MATERIALS**

B103.1 Maintenance. Building materials containing hazardous substances shall be maintained intact and in such a manner as to prevent the hazardous substances from becoming airborne or ingestible. Substances when present above the following amounts are deemed hazardous:

Asbestos (including vermiculite) – materials containing 1% asbestos by weight or area.

Formaldehyde - materials containing 0.00016% formaldehyde by weight or area.

Lead based paint– 0.5% lead by weight; 1.0 milligrams of lead per square centimeter.

Lead-based paint hazards - dust on floors containing 40 micrograms of lead per square foot; dust on interior window sills containing 250 micrograms of lead per square foot; bare soil in children's play

areas containing 400 parts per million (ppm) of lead; bare soil in areas of the yard that are not children's play areas containing 1200 ppm average.

When another adopted standard conflicts with these allowable levels, the more restrictive shall apply.

B103.2 Remediation. When building materials containing hazardous substances are deteriorated or have released hazardous substances, the condition causing the building material to deteriorate or to release hazardous substances shall be corrected and the exposed area shall be cleared of the hazardous substances. The code official is authorized to prohibit occupancy of the affected space as provided by section 108 of this code until the contaminated area and the cause of the building material becoming deteriorated has been remediated or removed.

B104 **HAZARDOUS GASES**

B104.1 Allowable levels. Within a dwelling unit, the following gases shall not exceed these specified allowable levels:

Carbon monoxide-- 9 PPM averaged over 8 hours; 35 PPM averaged over 1 hour; and 200 PPM maximum concentration as measured in general indoor air not directly above a combustion source.
Formaldehyde-- 0.05 PPM based on a 60 minute sampling period.
Radon-- 4 picocuries of radon per liter of air in the lowest occupied level.

When another adopted standard conflicts with these allowable levels, the more restrictive shall apply.

B104.2 Mitigation. Gaseous hazardous substances determined by an approved testing method to exceed the levels provided in section B104.1 shall be mitigated. The code official is authorized to order the affected area to be vacated until testing by an approved testing method finds the area to be in compliance with section B104.1.

B105 **PESTICIDES**

B105.1 General. Pesticides shall be stored in the manner prescribed by the manufacturer and shall be applied only in areas and at concentrations which comply with the labeling of the manufacturer.

B105.2 Mitigation. When it is determined by an approved method that a pesticide has been applied in -a location or at a concentration contrary to manufacturer labeling, the code official is authorized to order the area affected by or containing such pesticide to be vacated until the hazard has been mitigated.

B105.3 Removal. If a pesticide is stored in a location that does not comply with manufacturer labeling, the code official is authorized to order the area containing such pesticide to be vacated until the pesticide has been properly stored or removed.

B106 **CHEMICAL CONTAMINANTS**

B106.1 Vacating. When determined by an approved testing method that a dwelling unit is contaminated by a chemical at a concentration and in such a condition as to be hazardous to human health after short term exposure, the code official is authorized to order the dwelling unit to be vacated and remain vacated until the hazard has been abated.

B106.2 Illegal Methamphetamine manufacturing sites. A dwelling unit declared by a law enforcement agency or health official to be a site of illegal Methamphetamine manufacture shall be vacated and shall not be occupied until certified by an approved testing method as safe from hazardous materials related to the Methamphetamine manufacturing process.

B107
BIOLOGICAL HAZARDS

B107.1 Waterborne organisms. When determined by an approved testing method that the domestic water supply of a dwelling unit is contaminated with toxin producing bacteria, human parasite, or other organism deemed by an approved testing method as dangerous to human health, the water supply shall be made safe. The code official is authorized to order the dwelling unit to be vacated until such time as the water supply is safe as determined by an approved testing method. The code official is authorized to permit use of a water purification system capable of removing organisms or use of an alternative water supply on a temporary basis provided the water so supplied is safe for drinking and bathing.

B107.2 Airborne organisms. Heating, air conditioning and ventilation systems shall be kept clean and maintained so as to prevent the growth of harmful organisms within the system.

B108
AIR-BORNE CONTAMINATES

B108.1 Air-borne contaminants. Spaces in which air borne contaminants are generated shall comply with the International Mechanical Code requirements for hazardous exhaust systems. Air-borne contaminants shall not be circulated between tenant spaces or dwelling units except where contaminants have been removed by properly installed and maintained equipment.

B109
SANITARY CLEANUP

B109.1 Sanitary cleanup. After an event such as sewage spill or flooding makes occupancy of a space unsafe or unhealthful due to sanitation hazards, the space shall not be occupied until the unsafe or unhealthful conditions are removed in accordance with this section.

B109. 2 Prescriptive methods. When the prescriptive methods contained in sections B109. 2.1 through B109. 2.2 are used, the hazard shall be deemed to have been abated.

B109. 2.1 Sewage spills. All water containing sewage and all sewage solids shall be removed and disposed of in a safe and sanitary manner. Every absorbent material in contact with sewage or water which contains sewage shall be removed. Every non-absorbent material in contact with sewage or water which contains sewage shall be cleaned with detergent and disinfected household bleach in water.

B109.2.2 Flood damage. Any material that has been damaged or weakened by water shall be removed. Material saturated by water, such as insulation or gypsum board, shall be removed. All surfaces that support mold growth which have come in contact with water shall be removed or thoroughly dried and treated with a fungicide. All materials and systems required by this code, the International Building Code or the International Residential Code shall be replaced or restored to a dry condition and capable of performing the intended purpose. When flood water is known to be contaminated with harmful chemical compounds, the contamination shall be removed and the area shall be tested and found safe by an approved testing method in addition to the other requirements of this section.

B110
FOOD STORAGE AND PREPARATION AREAS

B110.1 Responsibility. The occupant of each space with a food storage or preparation area shall be responsible to maintain that area in accordance with this section.

B110.2 Food preparation areas. Food preparation areas shall be maintained free of spoiled or rotting foodstuffs. There shall be no accumulated grease on surfaces in food preparation areas, including counters, walls, floors, ceilings, appliances and storage areas.

B110.3 Food storage. Food shall be stored in a clean and sanitary condition and be protected from insect or animal pests.

Reason: Numerous hazards to health are present in the home environment. The proposed appendix provides parameters for the code official to recognize and address hazards such as those described below.

1. Asbestos products were extensively used in building materials. They continue to be legal to sell and to use. Intact asbestos is not a hazard. It becomes a hazard when damaged or deteriorated and releases friable asbestos. See www.epa.gov/asbestos/pubs/ashome.html for details. The U.S. Environmental Protection Agency (EPA) and most states license asbestos inspectors.
2. Radon is the leading cause of lung cancer in people who have never smoked. U.S. Environmental Protection Agency (EPA) has established a recommended maximum exposure level of four picocuries of radon per liter of air in occupied areas. This level can be achieved through established technology in a cost effective manner. The radon controls also reduce moisture and soil gas intrusion. See www.epa.gov/radon/pubs/newconst.html. Two national organizations and some states certify radon professionals to measure radon levels in residences.
3. Lead can cause permanent damage to a child's brain that is manifested as lower IQ levels, learning disorders and violent behavior. In adults, it can cause hypertension. The levels for lead in dust on floor and window sills are expected result in less than 5% of the children younger than six years of age playing on the floor to be lead poisoned. The current EPA standards of 40 micrograms of lead per square foot on the floor and 100 micrograms of lead per square foot on an interior window sill at 40 CFR Part 745 Subpart D. These levels can result in 15 to 20% of the children playing on the floor to be lead poisoned. See Dixon SL, Gaitens JM, Jacobs DE et al. (2009) Exposure of U.S. children to residential dust lead, 1999-2004: II: The contribution of lead-contaminated dust to children's blood lead levels. *Environmental Health Perspectives* 117(3) at www.nchh.org/LinkClick.aspx?fileticket=4Q/PvfvDTIs=&tabid=165. EPA and many states certify lead risk assessors, lead inspectors and dust sampling technicians to take the dust samples and make the determination.
4. Drinking water contamination at levels that exceed the contaminant standards established by EPA are unhealthy and can be dangerous. See U.S EPA standard at 40 Code of Federal Regulations Part 141 or www.epa.gov/safewater/contaminants. EPA and many states certify drinking water testing laboratories.
5. Arsenic is a known carcinogen and can be toxic. When properly sealed, the health risk is relatively low. However, arsenic from splinters that penetrate the skin can be a serious health problem that can be avoided by repairing wood that shows evidence of splintering.

This is the latest in efforts over several years to add health-related requirements to the code. Because the proposal addresses basic hazards that injure health and threaten life that can be present anywhere in the dwelling, these standards involve more building components and systems covered by more than one section of the IPC. The proposal clearly enumerates various health issues and describes minimum standards to enable the code official to have a more solid legal standing to address those issues. Although we have proposed it as an appendix, the material could also fit the code as a new Chapter 8.

Past comments concerned testing activities and concern about on what agency testing responsibility may fall. Here we propose that approved methods must be used when testing or inspections are required, and that the code official can order the property owner to pay for testing as needed. The code official is authorized to accept this documentation to establish compliance with other hazards where technical knowledge is required, much in the fashion an engineer's report would be accepted for a structural concern in a building. A clear basis for a decision strengthens the code official's position when challenged on appeal or in court.

Cost Impact: This proposal will not increase the cost of construction.

TENTATIVE ORDER OF DISCUSSION 2013 PROPOSED CHANGES TO THE INTERNATIONAL RESIDENTIAL CODE – BUILDING

The following is the tentative order in which the proposed changes to the code will be discussed at the public hearings. Proposed changes which impact the same subject have been grouped to permit consideration in consecutive changes.

Proposed change numbers that are indented are those which are being heard out of numerical order. Indentation **does not** necessarily indicate that one change is related to another. Proposed changes may be grouped for purposes of discussion at the hearing at the discretion of the chair. Note that some IRC code change proposals may not be included on this list, as they are being heard by other committees. Please consult the Cross Index of Proposed Changes.

RB1 – 13

R101.2

Proponent: Steve Thomas, Colorado Code Consulting, LLC representing Colorado Chapter ICC
(stthomas@coloradocode.net)

Revise as follows:

R101.2 Scope. The provisions of the International Residential Code for One- and Two-family Dwellings shall apply to the construction, alteration, movement, enlargement, replacement, repair, equipment, use and occupancy, location, removal and demolition of detached one- and two-family dwellings and townhouses not more than three stories above grade plane in height with a separate means of egress and their accessory structures.

Exceptions:

1. Live/work units located in townhouses and complying with the requirements of Section 419 of the International Building Code shall be permitted to be built as one- and two-family dwellings or townhouses constructed in accordance with the International Residential Code for One- and Two-Family Dwellings. Fire suppression required by Section 419.5 of the International Building Code when constructed under the International Residential Code for One- and Two-family Dwellings shall conform to Section P2904.
2. Owner-occupied lodging houses with five or fewer guestrooms shall be permitted to be constructed in accordance with the International Residential Code for One- and Two-family Dwellings when equipped with a fire sprinkler system in accordance with Section P2904.

Reason: Live/work units are regulated by Section 419 of the IBC. This exception has created enforcement problems for local jurisdictions as it applies to one- and two-family dwellings. The way the language is written, it creates serious enforcement problems for building departments. If a homeowner wants to open a home business in an existing home, this section would require them to sprinkler the home. The IRC only requires new homes to be provided with fire sprinklers. A contractor that uses their garage to store their tools or build cabinets would be classified as live-work units under this exception as well. Is that really what we want the code to say? This provision is over-restrictive and unenforceable for the building official. This proposal limits the use of the live-work provisions would only apply to townhouses.

Cost Impact: This will reduce the cost of construction.

RB1-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R101.2-RB-THOMAS

RB2 – 13

R102.7.1

Proponent: David Bonowitz, Chair, Existing Buildings Subcommittee, Code Advisory Committee, representing National Council of Structural Engineers Associations (dbonowitz@att.net)

Revise as follows:

R102.7.1 Additions, alterations or repairs. Additions, alterations or repairs to any structure shall conform to the requirements for a new structure ~~without requiring the existing structure to comply with all of the requirements of this code, unless otherwise stated. Additions, alterations or repairs shall not cause an existing structure to become unsafe or adversely affect the performance of the building.~~ Additions and repairs shall be such that the existing structure is no less complying with the provisions of this code than the existing structure was prior to the alteration or repair. For additions, alterations to the existing structure shall be made so that the existing structure with the addition is no less complying with the provisions of this code than the existing structure was prior to the addition.

Reason: This proposal updates the IRC language with respect to existing buildings, in coordination with the IBC and IEBC. It clarifies, but does not change, the current intent.

In general, the IRC (with or without Appendix J) is obsolete in its terminology and language regarding existing buildings. Especially regarding structural issues, its provisions continue to use terms and formulations that have long since been revised in IBC Chapter 34 and the IEBC Work Area method. (For examples, the term “unsafe” and the labels and definitions of project types in Appendix J.) This proposal does not seek complete uniformity with the other codes, but it does attempt to correct some obsolete language that is now prone to incorrect interpretation.

In the first sentence, the proposal clarifies the main purpose, which is to require the intended addition, alteration, or repair work itself to be as for new construction. The second half of the sentence is deleted, as it has been in IBC sections 3403.1 and 3404.1 and IEBC sections 402.1 and 403.1. The portion proposed for deletion is redundant, since the next sentence (either as is or as proposed) tells you when and how to consider the existing structure. It is also potentially confusing, since it incorrectly gives the impression that the only possibilities are either no upgrade or total upgrade of the entire building for “all of the requirements of this code.”

The proposal replaces the second sentence in order to correct four problems with the current text:

- The proposal removes the word “unsafe.” First, this term is redundant in R102.7.1, since any work that would make the building unsafe would certainly also “adversely affect the performance.” Second, the IRC does not define “unsafe” and so relies on the IBC, but the IBC’s definition is unorthodox, as it comes through the text of section 116.1, not through a formal definition. In any case, from a structural perspective, a building is unsafe when the structure is “dangerous” as defined in the IBC or IEBC, but that definition has in mind an extreme condition verging on collapse. We do not believe it is the intent of the IRC committee to allow structural modifications to dwellings that take them to a condition just shy of dangerous. (IRC Appendix J does have its own definition of dangerous, but section R102.7.1 must be able to stand on its own, since Appendix J will not necessarily be adopted. Besides, the Appendix J definition is obsolete as well and applies only to structural conditions.)
- It replaces the phrase “adversely affect the performance” with “no less complying” language consistent with IBC sections 3403.1 and 3404.1 and IEBC sections 402.1 and 403.1. The IRC is compliance-based, not performance-based, so vague reference to “performance” is not enforceable. More important, the “adversely affect” phrase suggests that the existing building cannot be made worse by any measure, a restriction more severe than is probably intended. That is, as long as the building still complies, some reduction in capacity should be allowed.
- It restates the provision as an enforceable instruction, not as a blanket prohibition. That is, provisions for existing buildings are more useful and effective when they say what must be done, not what is prohibited. The IBC and IEBC provisions have been revised and written with this approach since 2009.
- It separates the project types, where necessary. Here, the provisions for additions, alterations, and repairs do not vary much, but the proposal reorganizes the provision to set a precedent and make future revisions by project type easier. This is consistent with the 2009 revisions to IBC Chapter 34, the IEBC Work Area method and IRC Appendix J.

Cost Impact: None

RB2-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R102.7.1 #1-RB-BONOWITZ

RB3 – 13

R102.7.1

Proponent: David Bonowitz, Chair, Existing Buildings Subcommittee, Code Advisory Committee, representing National Council of Structural Engineers Associations (dbonowitz@att.net)

Revise as follows:

R102.7.1 Additions, alterations ~~or~~, repairs, or relocations. Additions, alterations or repairs to any structure shall conform to the requirements for a new structure without requiring the existing structure to comply with all of the requirements of this code, unless otherwise stated. Additions, alterations ~~or~~, repairs, or relocations shall not cause an existing structure to become unsafe or adversely affect the performance of the building.

Reason: This proposal adds relocations to the list of possible project types applicable to existing dwellings. The IBC and IEBC recognize five project types: Additions, alterations, repairs, relocations, and changes of occupancy. Change of occupancy need not be included here since it is already covered in IRC section R110.2, but relocations are common, and the IRC should consider them.

The proposal modifies the section title and the last sentence. The first sentence is not modified because that sentence refers to projects that affect only part of an existing structure, whereas relocations affect the entire structure.

The intent of this proposal is not to negate, reverse, or otherwise interfere with any other proposal for this section. Any other approved proposal should be made. Then, this proposal, if approved, would merely add relocations to the list of project types.

Per R201.4, it should not be necessary to add a definition of relocation to the IRC. That term is also used in the IBC and IEBC without definition.

Cost Impact: None

RB3-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R102.7.1 #2-RB-BONOWITZ

RB4 – 13

R104.10.1, R105.3.1.1, R112.2.1, R112.2.2, R301.2.4, R322.1

Proponent: Gregory Wilson, representing Department of Homeland Security, Federal Emergency Management Agency (Gregory.wilson2@fema.dhs.gov); Rebecca Quinn, RCQuinn Consulting, Inc., representing Federal Emergency Management Agency (rcquinn@earthlink.net)

Revise as follows:

R104.10.1 Flood hazard areas. The building official shall not grant modifications to any provisions related to flood hazard areas as established by Table R301.2(1) ~~without the granting of a variance to such provisions by the board of appeals unless a determination has been made that:~~

1. A showing of good and sufficient cause that the unique characteristics of the size, configuration or topography of the site render the elevation standards of Section R322 inappropriate.
2. A determination that failure to grant the modification would result in exceptional hardship by rendering the lot undevelopable.
3. A determination that the granting of a modification will not result in increased flood heights, additional threats to public safety, extraordinary public expense, cause fraud on or victimization of the public, or conflict with existing laws or ordinances.
4. A determination that the modification is the minimum necessary to afford relief, considering the flood hazard.
5. Submission to the applicant of written notice specifying the difference between the design flood elevation and the elevation to which the building is to be built, stating that the cost of flood insurance will be commensurate with the increased risk resulting from the reduced floor elevation, and stating that construction below the design flood elevation increases risks to life and property.

R105.3.1.1 Determination of substantially improved or substantially damaged existing buildings in flood hazard areas. For applications for reconstruction, rehabilitation, alteration, repair, addition or other improvement of existing buildings or structures located in a flood hazard area as established by Table R301.2(1), the building official shall examine or cause to be examined the construction documents and shall make a determination prepare a finding with regard to the value of the proposed work. For buildings that have sustained damage of any origin, the value of the proposed work shall include the cost to repair the building or structure to its predamage condition. If the building official finds that the value of proposed work equals or exceeds 50 percent of the market value of the building or structure before the damage has occurred or the improvement is started, ~~the finding shall be provided to the board of appeals for a determination of substantial improvement or substantial damage. Applications determined by the board of appeals to constitute substantial improvement or substantial damage the proposed work is a substantial improvement or restoration of substantial damage and the building official shall require all existing portions of the entire building or structure to meet the requirements of R322.~~

For the purpose of this determination, a substantial improvement means any repair, reconstruction, rehabilitation, addition or improvement of a building or structure, the cost of which equals or exceeds 50 percent of the market value of the building or structure before the improvement or repair is started. If the building or structure has sustained substantial damage, all repairs necessary to restore the building or structure to its pre-damaged condition are considered substantial improvement regardless of the actual repair work performed. The term does not include:

1. Improvements of a building or structure required to correct existing health, sanitary or safety code violations identified by the building official and which are the minimum necessary to assure safe living conditions; or
2. Any alteration of a historic building or structure, provided that the alteration will not preclude the continued designation as a historic building or structure. For the purposes of this exclusion, a historic building is:
 - 2.1. Listed or preliminarily determined to be eligible for listing in the National Register of

- Historic Places; or
- 2.2. Determined by the Secretary of the U.S. Department of Interior as contributing to the historical significance of a registered historic district or a district preliminarily determined to qualify as an historic district; or
- 2.3. Designated as historic under a state or local historic preservation program that is approved by the Department of Interior.

~~R112.2.1 Determination of substantial improvement in flood hazard areas.~~ When the building official provides a finding required in Section R105.3.1.1, the board of appeals shall determine whether the value of the proposed work constitutes a substantial improvement. A substantial improvement means any repair, reconstruction, rehabilitation, addition or improvement of a building or structure, the cost of which equals or exceeds 50 percent of the market value of the building or structure before the improvement or repair is started. If the building or structure has sustained substantial damage, all repairs are considered substantial improvement regardless of the actual repair work performed. The term does not include:

- ~~1. Improvements of a building or structure required to correct existing health, sanitary or safety code violations identified by the building official and which are the minimum necessary to assure safe living conditions; or~~
- ~~2. Any alteration of a historic building or structure, provided that the alteration will not preclude the continued designation as a historic building or structure. For the purposes of this exclusion, a historic building is:~~
 - ~~2.1. Listed or preliminarily determined to be eligible for listing in the National Register of Historic Places; or~~
 - ~~2.2. Determined by the Secretary of the U.S. Department of Interior as contributing to the historical significance of a registered historic district or a district preliminarily determined to qualify as an historic district; or~~
 - ~~2.3. Designated as historic under a state or local historic preservation program that is approved by the Department of Interior.~~

~~R112.2.2 Criteria for issuance of a variance for flood hazard areas.~~ A variance shall only be issued upon:

- ~~1. A showing of good and sufficient cause that the unique characteristics of the size, configuration or topography of the site render the elevation standards of Section 322 inappropriate.~~
- ~~2. A determination that failure to grant the variance would result in exceptional hardship by rendering the lot undevelopable.~~
- ~~3. A determination that the granting of a variance will not result in increased flood heights, additional threats to public safety, extraordinary public expense, cause fraud on or victimization of the public, or conflict with existing laws or ordinances.~~
- ~~4. A determination that the variance is the minimum necessary to afford relief, considering the flood hazard.~~
- ~~5. Submission to the applicant of written notice specifying the difference between the design flood elevation and the elevation to which the building is to be built, stating that the cost of flood insurance will be commensurate with the increased risk resulting from the reduced floor elevation, and stating that construction below the design flood elevation increases risks to life and property.~~

R301.2.4 Floodplain construction. Buildings and structures constructed in whole or in part in flood hazard areas (including A or V Zones) as established in Table R301.2(1), and substantial improvement and restoration of substantial damage of buildings and structures in flood hazard areas, shall be designed and constructed in accordance with the provisions of Section R322. Buildings and structures located in whole or in part in identified floodways shall be designed and constructed in accordance with ASCE 24.

R322.1 General. Buildings and structures constructed in whole or in part in flood hazard areas (including A or V Zones) as established in Table R301.2(1), and substantial improvement and restoration of substantial damage of buildings and structures in flood hazard areas, shall be designed and constructed

in accordance with the provisions contained in this section. Buildings and structures located in whole or in part in identified floodways shall be designed and constructed in accordance with ASCE 24.

Reason: This proposal does three things related to existing dwellings in flood hazard areas:

1. Moves language from R112.2.2 to R104.10. The effect is to parallel both the IBC and IEBC which charge the building official with making certain determinations before granting modifications, rather than have the Board of Appeals make such determinations.
2. Moves language from R112.2.1 to R105.3.1.1. The effect is to more closely align the IRC with the IBC and IEBC, which rely on the building official to determine whether work on existing buildings in flood hazard areas meets the definitions "substantial improvement" and "substantial damage," rather than have the building official make a finding and have the Board of Appeals make such determinations
3. Clearly identify in R301.2.4 and R322.1, that the flood provisions apply to substantial improvement and substantial damage; R102.7.1 already makes clear that the IRC applies to additions, alterations, or repairs.

The IRC currently requires the Board of Appeals to do two things that are done by the building official under both the IBC and the IEBC – (1) determine whether requests for modifications to the flood provisions meet certain criteria and (2) determine whether work on existing dwellings constitutes substantial improvement or substantial damage (SI/SD). As stated in R112.1, the purpose of a Board of Appeals is to hear appeals of decisions, orders, and determinations of the building official. If the Board is charged with making decisions, such as the granting of a modification (variance) and the determination of SI/SD, then permit applicants and permittees have no recourse to appeal those decisions, except perhaps the courts. If building officials are capable of making these determinations under IBC and IEBC, then they should be permitted to do the same under the IRC.

The proposed changes to R301.2.4 and R322.1, which have the same phrasing, is to make clear that, as stated in R102.7.1, because the IRC applies to work on existing dwellings, the flood provisions apply to substantial improvement and substantial damage of existing dwellings. The added phrase is the same as used in IBC 1612.1.

Cost Impact: Costs will be reduced for permit applicants and permittees who challenge SI/SD determinations and decisions on requests for modifications (variances) because they can appeal the building official's decisions to the Board of Appeals instead of the courts. There is no change in the cost of compliance because the IRC already applies to existing dwellings and communities that participate in the NFIP have long required existing buildings that are SI/SD to be brought into compliance with the requirements for new construction.

RB4-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R104.10.1-RB-QUINN-WILSON

RB5 – 13

R105.1

Proponent: Joseph D. Belcher, JDB Code Services, Inc, representing the International Hurricane Protection Association (joe@jdbcodeservices.com)

Revise as follows:

R105.1 Required. Any owner or authorized agent who intends to construct, enlarge, alter, repair, move, demolish or change the occupancy of a building or structure, or to erect, install, enlarge, alter, repair, remove, convert or replace any impact protective system, electrical, gas, mechanical or plumbing system, the installation of which is regulated by this code, or to cause any such work to be done, shall first make application to the *building official* and obtain the required *permit*.

Reason: Opening protection by impact protective systems is an important aspect in maintaining structural integrity during a hurricane event. In addition to increasing the structural performance of buildings, they play a role in the life safety of the people weathering the storm out in their residence. Observations in the field reveal many installations do not meet the standards adopted for these devices as became apparent during storms in recent years. Unfortunately, many jurisdictions do not require permits or inspections for these important structural safeguards and life safety devices because they are not addressed in the section of the code addressing required permits. With the emphasis of emergency management shifting to defending in place due to the inability of the infrastructure to handle mass evacuations, these impact protective systems, be they impact rated glass or devices, and their proper installation becomes even more important.

The hurricane protection industry estimates annual sales in unapproved and mostly bogus “hurricane protection devices” at \$30M to \$40M at the minimum. These products have not been tested or investigated by anyone and meet no standards. The sellers of these products target citizens and give residents a false sense of security. Requiring permits and inspections for all impact protective systems would dramatically increase the protection provided to the residents of single family dwellings.

Cost Impact: The proposal may result in a slight increase for the cost of a permit solely for projects involving installation, alteration, repair or replacement projects. For new construction there should be no cost as the permit for the building would include the installation of the impact protective system. The benefit of the requirement, however, will far outweigh any added cost in permitting by increasing the assurance that these important structural and life safety protection devices are properly designed and installed. The industry has noted cases of substandard materials, inappropriate testing or claims of testing, and improper installation of products. We believe closer scrutiny of the design and installation of these important property protection and life safety systems will result in greater protection to the public and a better value to the consumer.

Staff Analysis: Mr. Belcher has a companion change for a new Section 614 that has criteria for impact protective systems. Requirements for these types of systems are in the IRC in Section 301.2.1.2 and 612.6.

R105.1-RB-BELCHER

RB6 – 13

R105.2

Proponent: Rick Davidson, City of Maple Grove, representing Association of Minnesota Building Officials (rdavidson@maplegrovern.gov)

Revise as follows:

R105.2 Work exempt from permit. *Permits* shall not be required for the following. Exemption from *permit* requirements of this code shall not be deemed to grant authorization for any work to be done in any manner in violation of the provisions of this code or any other laws or ordinances of this *jurisdiction*.

Building:

1. One-story detached *accessory structures* used as tool and storage sheds, playhouses and similar uses, provided the floor area does not exceed 200 square feet (18.58 m²).
2. Fences not over 7 feet (2134 mm) high.
3. Retaining walls that are not over 4 feet (1219 mm) in height measured from the bottom of the footing to the top of the wall, unless supporting a surcharge.
4. Water tanks supported directly upon *grade* if the capacity does not exceed 5,000 gallons (18 927 L) and the ratio of height to diameter or width does not exceed 2 to 1.
5. Sidewalks and driveways.
6. Painting, papering, tiling, carpeting, cabinets, counter tops and similar finish work.
7. Prefabricated swimming pools that are less than 24 inches (610 mm) deep.
8. Swings and other playground equipment.
9. Window awnings supported by an exterior wall which do not project more than 54 inches (1372 mm) from the exterior wall and do not require additional support.
10. Decks ~~not exceeding 200 square feet (18.58 m²) in area~~, that are not more than 30 inches (762 mm) above *grade* at any point, ~~are not attached to a dwelling~~ and do not serve the exit door required by Section R311.4.

Reason: This proposal deletes certain provisions of the exemption for decks. 200 square feet is an arbitrary limit and without basis. If a jurisdiction wishes to limit the size of a deck, they may do so through their local zoning regulations. There is nothing unique about these structures that make a deck that is 210 square feet in area more dangerous than one that is 190 square feet.

Furthermore, whether or not it is attached to the dwelling should make no difference. It is common practice to set these low decks adjacent to the dwelling and often homeowners wish to attach them to the dwelling for added stability. Why would we want to discourage them from making their deck more secure by requiring a permit? All too often the regulations start to get pretty restrictive regarding the connections for these low decks. The owner may wish to add a few lag bolts to stabilize the deck or they may wish to support one entire length of the deck from the house.

The risks posed do not warrant the close regulations that permitting requires. Building department resources are stretched thin. Permit fees on these decks rarely cover the cost of enforcement. Public dollars can be better spent on more significant projects.

A common argument for requiring permits for these structures is for zoning compliance. That is a lousy reason for requiring a building permit. Local zoning ordinances often regulate other structures when a building permit is not required. Certain fences, arbors, trellises, and small accessory structures come to mind. Let the zoning folks carry their own water.

Cost Impact: None

RB6-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R105.2 #1-RB-DAVIDSON

RB7 – 13

R106.1.1, R106.1.3 (New)

Proponent: Michael D. Fischer, Kellen Company, representing the American Institute of Building Design (mfischer@kellencompany.com)

Revise as follows:

R106.1.1 Information on construction documents. *Construction documents* shall be drawn upon suitable material. Electronic media documents are permitted to be submitted when *approved* by the *building official*. *Construction documents* shall be of sufficient clarity to indicate the location, nature and extent of the work proposed and show in detail that it will conform to the provisions of this code and relevant laws, ordinances, rules and regulations, as determined by the *building official*. ~~Where required by the *building official*, all braced wall lines, shall be identified on the *construction documents* and all pertinent information including, but not limited to, bracing methods, location and length of braced wall panels, foundation requirements of braced wall panels at top and bottom shall be provided.~~

R106.1.2 Manufacturer's installation instructions. Manufacturer's installation instructions, as required by this code, shall be available on the job site at the time of inspection.

R106.1.3 Information on braced wall design. For buildings and structures utilizing braced wall design, and where required by the *building official*, all braced wall lines shall be identified on the *construction documents*. All pertinent information including, but not limited to, bracing methods, location and length of braced wall panels, foundation requirements of braced wall panels at top and bottom shall be provided.

Reason: The code contains confusing language regarding braced wall design, and suggests the building official is the one who "requires" braced wall design. It seems to us the intent of the code provision is to specify the necessary detail for those projects where the building official requires they be included in the construction documents. This proposal seeks to satisfy that intent and clear up the confusion. Additionally, R106.1.1 contains general information regarding the media used; this technical detail rightfully belongs in its own section.

Cost Impact: None.

R106.1.4 (New), R702.8 (New), R703.13 (New); Chapter 44, AJ301.1.1.1 (New), AJ701 (New)

Proponent: Rebecca Morley, representing National Center for Healthy Housing

Add new text as follows:

IRC SECTION R106 CONSTRUCTION DOCUMENTS

R106.1.4 Certifications and plans where painted surfaces are disturbed. Where a dwelling was completed prior to 1978 and repair, alteration or addition being performed will result in the disturbance of painted surfaces, the contractor shall provide to the code official one of the following:

1. Copies of EPA or state renovation firm certification, renovator certification and a plan for compliance in accordance with 40 CFR 745 requirements for renovations.
2. Documentation from an approved test in accordance with 40 CFR 745.82(a)(1) or (2) that shows that the disturbed paint contains lead that is below specified levels.

IRC SECTION R702 INTERIOR COVERINGS

R702.8 Disturbance of existing painted surfaces. In any dwelling completed prior to 1978, repairs, alteration and additions where painted surfaces are disturbed shall comply with the information distribution, certification and work practice requirements of 40 CFR 745 for renovations.

Exception: Where documentation is provided from an approved test in accordance with 40 CFR 745.82(a)(1) or (2) that proves that the disturbed paint contains lead levels below specified levels, the work is not required to comply with this section.

IRC SECTION R703 EXTERIOR COVERING

R703.13 Disturbance of existing painted surfaces. In any dwelling completed prior to 1978, repairs, alteration and additions where painted surfaces are disturbed shall comply with the information distribution, certification and work practice requirements of 40 CFR 745 for renovations.

Exception: Where documentation is provided from an approved test in accordance with 40 CFR 745.82(a)(1) or (2) that proves that the disturbed paint contains lead levels below specified levels, the work is not required to comply with this section.

CHAPTER 44 REFERENCED STANDARDS

EPA

U.S. Environmental Protection Agency

40 CFR 745-July 1, 2012 Lead-Based Paint Poisoning Prevention in Certain Residential Structures

SECTION AJ301 REPAIRS

AJ301.1.1.1 Disturbance of existing painted surfaces. In any dwelling completed prior to 1978, repairs, alteration and additions where painted surfaces are disturbed shall comply with the information distribution, certification and work practice requirements of 40 CFR 745 for renovations.

Exception: Where documentation is provided from an approved test in accordance with 40 CFR 745.82(a)(1) or (2) that proves that the disturbed paint contains lead levels below specified levels, the work is not required to comply with this section.

SECTION AJ701 REFERENCED STANDARDS

EPA

U.S. Environmental Protection Agency

40 CFR 745 Lead-Based Paint Poisoning Prevention in Certain Residential Structures

Reason: This code change proposal is to incorporate protection from lead-based paint by specifying (1) that additions, alterations, and repairs to pre-1978 homes comply with federal health-protective requirements to protect children from lead poisoning and (2) that permit applicants include, with the other construction documents, evidence of compliance.

The purpose of this proposed code language is to incorporate protection from lead-based paint into the Code through the requirement for construction documents. Once the Code requires permit applicants to demonstrate up front their knowledge of, and plans to follow, the federal and state renovation rule requirements, the code official will be positioned to provide important oversight and leadership in preventing lead poisoning without even leaving the office. This oversight will help level the playing field between contractors who are complying with the rule and noncompliant entities who are under-pricing and undercutting their competitors. By merely asking an applicant for the missing documents, the code official can influence entities not following the law into compliance before the work even starts. In a few cases, these entities may be unaware of the regulations. Although these regulations have been in effect since April 2010, and have been adopted by 12 states, reported non-compliance is affecting the compliant contractor and continuing the problem of lead poisoning in the US.

The proposed “plan for compliance in accordance with 40 CFR 745 requirements for renovations” with the federal disclosure and work practice requirements” can take different forms depending on what documents the builder is already using. Some builders who work on pre-1978 homes are already using a form to track their upfront assessments and another form for recordkeeping. Anyone working in pre-1978 homes should have an EPA or state certification for their firm, along with at least one individual renovator certification that the renovator received at the end of the required one-day training course. These requirements are already in effect in federal and state regulation.

The plan and certifications would only be needed for a structure likely to contain lead-based paint: a pre-1978 home. As noted under the exception, the requirement is waived if paint testing proves that the paint is not lead-based paint. A rebuttable presumption of lead’s presence allows the builder to demonstrate that lead is not present and obtain exemption from the requirements. EPA-approved tests include lead-based paint inspection or risk assessment, test kit used by a certified renovator, and collection of a lead-based paint chips for laboratory analysis.

Renovation of painted surfaces is a significant source of lead dust that poisons children. The dangers associated with lead poisoning are well-known: serious health effects, detrimental effects on cognitive and behavioral development, with serious personal and social consequences that may persist throughout their lifetime.

Multiple studies have demonstrated that lead dust is the major source of lead poisoning for young children. There is no safe level of lead exposure for children; lead affects intelligence even at very low levels.^{1,2,5,8,9} Indeed, the rate of IQ loss per 1 microgram of lead per deciliter of blood (µg/dL) is greatest at lead levels below 10 µg/dL. As a child’s BLL increases from 1 to 10 µg/dL, experts estimate a child may lose anywhere from 3.9 to 7.4 IQ points, but from 10 to 30 µg/dL the decrement is 2.5 to 3.0 IQ points. Low-level chronic exposure may have an even greater effect on IQ than a single instance of very high BLL.¹⁰

Research indicates that a five-point negative shift in IQ at the population level would increase the number of children with an “extremely low” IQ by 57%, substantially increasing the cost of special education programs.³ Considering the costs to the special education system alone, one study conservatively estimated that it costs \$38,000 over three years to educate a child with lead poisoning.¹¹ Low-level exposure to lead has also been linked to factors other than IQ that can further impact educational outcomes. EBLs are associated with Attention Deficit Hyperactivity Disorder (ADHD) and antisocial behavior, which in turn increase the likelihood of conduct disorder, criminal activity, and drug abuse.^{1,4} Each 1 µg/dL reduction in the average preschool blood lead level saves \$13.4 billion from the direct and indirect costs of crime.¹

Several recent studies have explored the specific effects of lead on educational outcomes. These studies show a strong relationship between slightly elevated blood lead levels in young children and decreased scores on end-of-grade tests in elementary school. While similar educational effects were documented for higher blood levels decades ago,¹² the recent studies confirm that the connection between blood lead and poor educational outcomes remains true for blood levels as low as 3-4 µg/dL. A more recent study of 57,000 North Carolina children found that children with a BLL as low as 4 µg/dL at three years of age were significantly more likely to be classified as learning-disabled than children with a BLL of 1 µg/dL.⁶

The consequences of lead exposure are clear. This code change proposal seeks to reduce the risk of lead exposure during and after work performed on a pre-1978 home – and level the playing field among contractors working on pre-1978 properties.

The EPA 40 CFR 745 standard is available at <http://www.gpo.gov/fdsys/pkg/CFR-2012-title40-vol32/xml/CFR-2012-title40-vol32-part745.xml>.

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R106.1.4 (NEW)-RB-MORLEY

RB9 – 13

R109.1.4.1 (New)

Proponent: Andrew Herseth, US Dept of Homeland Security, Federal Emergency Management Agency (FEMA); Glenn Overcash, URS Corporation representing FEMA

Revise as follows:

R109.1.4.1 High wind region sheathing inspection. Where wind design is required in accordance with Section R301.2.1.1, inspection of the roof sheathing, wall sheathing and sheathing fasteners shall be made after all roof sheathing, wall sheathing and sheathing fasteners are in place. The sheathing inspection shall be permitted to coincide with the frame inspection, and shall be made prior to the dry-in inspection.

Reason: The purpose of this proposal is to ensure design-intended performance of roof and wall sheathing in hurricane prone regions by requiring inspection to verify those elements are installed as specified. As summarized in Fact Sheet 1.1 of FEMA P-499, *Home Builder's Guide to Coastal Construction* (FEMA, 2010), "construction inspections and quality control are essential for building success (as even) "minor" construction errors and defects can lead to major damage during high-wind or flood events." The need for roof and wall sheathing inspection is supported by post-disaster investigations. Numerous FEMA-sponsored MAT observations have documented failed sheathing installations resulting from inadequate connections to framing, as shown on pages 4-58 (wall) and 4-59 (roof) of *Hurricane Katrina in the Gulf Coast* (2006, FEMA). Hurricane Recovery Advisory No. 1 from FEMA 488, *Hurricane Charley in Florida* (2004), further identifies the verification of proper roof sheathing attachment as a key issue in the installation of roof underlayment in hurricane-prone regions. Failed sheathing attachments can lead to water intrusion, loss of roof structure, and wall collapse.

Cost Impact: The code change proposal will not increase the cost of construction since inspections will be through building code official.

R109.1.4.1 (NEW)-RB-HERSETH-OVERCASH

RB10 – 13

R202

Proponent: Tim Pate, City and County of Broomfield, CO, representing Colorado Chapter Code Change Committee

Revise as follows:

R202 DEFINITIONS

Accessory Structure. A structure ~~not greater than 3,000 square feet (279 m²) in floor area, and not more than two stories in height, the use of which is customarily accessory to and incidental to that of dwelling (s) and which is located on the same lot.~~

Reason: This code change proposal will delete the limitation of an accessory structure being 3,000 square feet or less. It does not make sense to limit accessory structures to only 3,000 square feet when there is no restriction to a size of a single family dwelling. These types of structures are typically used for vehicle and farm equipment storage, shops, etc. and are still only accessory and incidental to that of a dwelling. Houses in rural areas routinely need much larger accessory structures to store farm equipment.

Cost Impact: Will not increase cost

Analysis: This term is also defined in the *International Wildland-Urban Interface Code*. The definitions were not identical and this proposal does not make them identical.

RB10-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R202-ACCESSORY STRUCTURE-RB-PATE

RB11 – 13

R202

Proponent: Mike Winkler, Chair of the IRC Interpretations Committee, representing IRC interpretations committee

Revise as follows:

R202 DEFINITIONS

ACCESSORY STRUCTURE. A structure with a total floor area not greater than 3,000 square feet (279m²) including basements in floor area, and not over two stories in height, the use of which is customarily accessory to and incidental to that of the dwelling(s) and which is located on the same *lot*.

Reason: The current language is silent on whether the 3,000 square foot limit is per floor or the total aggregate area of all floors. This oversight was the subject of a formal interpretation and the IRC interpretation committee is requesting the language be amended to reflect the committees' interpretation. The revisions only clarify the scope of the IRC relating to accessory buildings. A larger building would not be prohibited; it would simply need to comply with the IBC.

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: This term is also defined in the *International Wildland-Urban Interface Code*. The definitions were not identical and this proposal does not make them identical.

RB11-13

R202

Proponent: Rick Davidson, City of Maple Grove, Association of Minnesota Building Officials
(rdavidson@maplegrovern.gov)

Revise as follows:

SECTION R202 DEFINITIONS

ATTIC. The unfinished space between the ceiling assembly of the top story and the roof assembly.

Reason: The current definition of “attic” is insufficient in that it excludes spaces that clearly should be regulated. Attics exist at locations other than the top story. It encourages a lack of uniformity in enforcement and confusion from all users of the code.

Examples of areas where the current definition becomes problematic include rules regarding attics with limited storage, exposed foam plastics, insulation requirements, fire separations, draft stops, structural requirements, access, and ventilation. These rules are intended to apply to all attics, not just those defined as being above the top story.

Cost Impact: None

RB12-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R202-ATTIC-RB-DAVIDSON

RB13 – 13

R202

Proponent: David Hall CFM, Georgetown, Texas representing the ICC PMG Code Action Committee (Dave.Hall@georgetown.org)

Revise as follows:

SECTION R202 DEFINITIONS

BACKFLOW PREVENTER. A backflow prevention assembly, a backflow prevention device or other means or method to prevent backflow into the potable water supply.

Reason: The proposed language was approved for the 2015 IPC. This definition is used throughout the code. However, it does not define to the user of the code, how to specifically identify or apply proper “protection” to a use or connection. Industry standards differentiate between backflow prevention devices and backflow prevention assemblies. A backflow prevention assembly is a specific type of mechanical backflow prevention protection which is field testable and repairable in-line, with shutoff valves and test cock fittings.

This proposal is submitted by the ICC Plumbing, Mechanical and Fuel Gas Code Action Committee (PMGCAC). The PMGCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance an assigned International Code or portion thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the PMGCAC has held 2 open meetings, multiple conference calls and multiple workgroup calls which included members of the PMGCAC. Interested parties also participated in all of the meetings and conference calls to discuss and debate the proposed changes. For PMGCAC member reference, this was item no. X1 on the PMGCAC IRC-P list.

Cost Impact: The code change proposal will not increase the cost of construction.

Add definitions as follows:

SECTION R202 DEFINITIONS

BALCONY. An exterior floor projecting from and supported by a structure without additional independent supports.

DECK. An exterior floor system supported on at least two opposing sides by an adjoining structure and/or posts, piers, or other independent supports.

Reason: This proposal restores the definitions for “balcony” and “deck” that had previously been in the IRC. There is a need for a definition of the terms because of their frequent use in the IRC and in ICC Evaluation Service Reports that are not as easily understood with undefined terms. In fact, there is now an entire section in the IRC title “Decks”. The definitions were deleted from the IRC in the last code cycle because of structural interpretation issues that had nothing to do with the need for the definitions. The terms are frequently used in the IRC and there needs to be a means to distinguish between the terms “balcony” and “deck”, both of which are regulated. These definitions are necessary to create some uniformity in code interpretations and to prevent unnecessary regulations from being imposed.

Cost Impact: None

RB15-13

	Assembly:	ASF	AMF	DF

R202-BALCONY (NEW)-RB-DAVIDSON

RB16 – 13

R202

Proponent: David Hall CFM, Georgetown Texas representing the ICC PMG Code Action Committee (dave.hall@georgetown.org)

THIS CODE CHANGE WILL BE HEARD BY THE IRC-PLUMBING/MECHANICAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

Revise definition as follows:

R202 DEFINITIONS

CONDITIONED SPACE. For energy purposes, space within a building that is provided with heating and/or cooling *equipment* or systems capable of maintaining, through design or heat loss/gain, 50°F (10°C) during the heating season and 85°F (29°C) during the cooling season, or communicates directly with a *conditioned space*. For mechanical purposes, an area, room or space that is being heated or cooled by any equipment or appliance, enclosed within the building thermal envelope and that is directly heated or cooled or that is indirectly heated or cooled. Spaces are indirectly heated or cooled where they communicate thru openings with conditioned spaces, where they are separated from conditioned spaces by un-insulated walls, floors or ceilings or where they contain un-insulated ducts, piping or other sources of heating or cooling.

Reason: This revised language was approved for the 2015 IMC. Confusion exists between the two different definitions in the IRC and IECC. The IECC attempts to define how a space is indirectly conditioned; however, further clarification is needed. This proposed change is similar to the definition in ASHRAE 90.1 – 2010.

Cost Impact: The code change proposal will not increase the cost of construction.

RB16-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R202-CONDITIONED SPACE-RB-HALL-PMGCAC

RB17 – 13

R202

Proponent: Michael S. Moss, American Backflow Prevention Association (msmoss@utah.gov)

Revise as follows:

R202 DEFINITIONS

BACKFLOW PREVENTER. A backflow prevention assembly, a backflow prevention device or other means or methods to prevent backflow into the potable water supply.

Reason: This definition is used throughout the code. However, it does not define to the user of the code, how to specifically identify or apply proper "protection" to a use or connection. Industry standards differentiate between backflow prevention devices and backflow prevention assemblies. A backflow prevention assembly is a specific type of mechanical backflow prevention protection which is field testable and repairable in-line, with shutoff valves and test cock fittings.

Cost Impact: The code change proposal will not increase the cost of construction.

RB17-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R202-BACKFLOW PREVENTER-RB-MOSS.doc

Proponent: David Hall CFM, Georgetown Texas representing the ICC PMG Code Action Committee (dave.hall@georgetown.org)

THIS CODE CHANGE WILL BE HEARD BY THE IRC-PLUMBING/MECHANICAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

Add new definition as follows:

R202 DEFINITIONS

FACTORY MADE AIR DUCT. A listed and labeled duct manufactured in a factory and assembled in the field in accordance with the manufacturer's installation instructions and conditions of the listing.

Reason: The term is used in Sections M1601.1.1 and M1601.2 but is not defined. It is unclear if the term includes both factory-built fibrous glass ducts and flexible ducts and also any other duct material made in a factory. The IMC does not use this term which is unique to the IRC. Section M1601.2 requires that factory made ducts be listed to UL 181 and that standard does not limit the material.

This proposal is submitted by the ICC Plumbing, Mechanical and Fuel Gas Code Action Committee (PMGCAC). The PMGCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance an assigned International Code or portion thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the PMGCAC has held 2 open meetings, multiple conference calls and multiple workgroup calls which included members of the PMGCAC. Interested parties also participated in all of the meetings and conference calls to discuss and debate the proposed changes.

Cost Impact: The code change proposal will not increase the cost of construction.

RB18-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R202-FACTORY MADE AIR DUCT (NEW)-RB-HALL-PMGCAC

RB19 – 13

R202

Proponent: John Mulder, Intertek Testing Services NA, Inc., representing International Standards Organization Technical Committee 77, Products in Fibre-reinforced Cement and self

Revise as follows:

R202 DEFINITIONS

FIBER-CEMENT (BACKER BOARD, SIDING, SOFFIT, TRIM, AND UNDERLAYMENT) PRODUCTS. ~~A manufactured thin section composites of hydraulic cementitious matrices and discrete non-asbestos fibers, fiber-reinforced products made with an inorganic hydraulic or calcium silicate binder formed by chemical reaction and reinforced with discrete organic or inorganic nonasbestos fibers, or both. Additives that enhance manufacturing or product performance are permitted.~~

Reason: The current definition is limited to fiber-cement siding products. The proposal corrects the definition to that published in ASTM C1154-06, *Standard Terminology for Non-Asbestos Fiber-reinforced Cement Products* (see attached copy of ASTM C1154-06), for “fiber-cement products”. Additional text describes types of fiber-cement products to include also fiber-cement backer board, soffit, trim and underlayment products currently recognized in the Code (IRC Sections R703.10, R703.10.1, R703.10.2, Table R503.2.1.1(2), and R702.4.2) The proposed code change eliminates a barrier to trade by including other fiber-cement products currently permitted by the Code.

IBC Section 202 has, as a result of the Group A IBC Code Hearings, already been revised to this definition (see attached “Final Action Hearing” results). This proposed revision would bring the two code definitions of “Fiber-cement Products” into alignment.

Cost Impact: The code change proposal will not increase the cost of construction because the change simply corrects the current definition to be consistent with the National Standard and provides examples of the types of products covered by the definition.

RB19-13

Proponent: David Hall CFM, Georgetown Texas representing the ICC PMG Code Action Committee (dave.hall@georgetown.org)

THIS CODE CHANGE WILL BE HEARD BY THE IRC-PLUMBING/MECHANICAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

Add new definition as follows:

R202 DEFINITIONS

FLEXIBLE AIR CONNECTOR. A conduit for transferring air between an air duct or plenum and an air terminal unit, an air inlet or an air outlet. Such conduit is limited in its use, length and location.

Reason: The code does not define "flexible air connector." As seen in the field, flexible air connectors are often indistinguishable from flexible ducts and the only way to tell them apart is to look at their labels. It is the product listing and label that dictates whether the product is an air connector or an air duct. This definition was approved for the 2015 IMC.

This proposal is submitted by the ICC Plumbing, Mechanical and Fuel Gas Code Action Committee (PMGCAC). The PMGCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance an assigned International Code or portion thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the PMGCAC has held 2 open meetings, multiple conference calls and multiple workgroup calls which included members of the PMGCAC. Interested parties also participated in all of the meetings and conference calls to discuss and debate the proposed changes.

Cost Impact: The code change proposal will not increase the cost of construction.

R202-FLEXIBLE AIR CONNECTOR (NEW)-RB-HALL-PMGCAC

RB22 – 13

R202 (New)

Proponent: Michael Gardner, representing Gypsum Association (mgardner@gypsum.org)

Add new definition as follows:

R202 DEFINITIONS

GYPSUM BOARD. The generic name for a family of sheet products consisting of a noncombustible core primarily of gypsum with paper surfacing. Gypsum wallboard, gypsum sheathing, gypsum base for gypsum veneer plaster, exterior gypsum soffit board, predecorated gypsum board and water-resistant gypsum backing board complying with the standards listed in Section R702.3 and Part IX of this code are types of gypsum board.

Reason: The IRC has incorporated the term gypsum board since the creation of the first edition of the code; however, the code does not define the term. To correct this oversight, this proposal adds a definition for gypsum board.

The definition of gypsum board in the IBC was modified during the Group 'A' hearings in 2012. The proposed definition in this proposal is identical to the definition that will appear in the 2015 IBC. It is also the definition contained in the ASTM standards referenced in Section R702.3.

A separate proposal submitted by the Gypsum Association proposes to add language to Chapters 2 and 7 to define and incorporate gypsum panel products. Adding the panel product definition to the code creates the need to add a definition for gypsum board. Gypsum boards are paper-faced gypsum sheet materials. Gypsum panel products are gypsum sheet materials with facings other than paper.

Cost Impact: None.

RB23 – 13

R202

Proponent: Joseph D. Belcher, JDB Code Services, Inc, representing the International Hurricane Protection Association (joe@jdbcodeservices.com)

Add new definition as follows:

R202 DEFINITIONS

IMPACT PROTECTIVE SYSTEM: Construction that has been shown by testing to withstand the impact of test missiles and that is applied, attached, or locked over exterior glazing.

Reason: Definition is added as companion to proposed change to Section R105.1 adding impact protective systems to the permitting requirements of the code. The definition is taken from ASCE 7-10 to assure consistency.

Cost Impact: The proposal is to add a definition and will have no cost.

Staff Analysis: Mr. Belcher has a companion change for a new Section 614 that has criteria for impact protective systems. Requirements for these types of systems are in the IRC in Section R301.2.1.2 and R612.6.

RB23-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R202 IMPACT PROTECTIVE SYSTEM (NEW)-RB-BELCHER

RB24 – 13

R202

Proponent: Jason Thompson, National Concrete Masonry Association representing Masonry Alliance for Codes and Standards

Revise as follows:

R202 DEFINITIONS

MASONRY UNIT. Brick, tile, stone, architectural cast stone, glass block or concrete block conforming to the requirements specified in Section 2103 of the *International Building Code*.

Reason: In the last cycle a reference to ASTM C1364 for architectural cast stone was added to Section 2103 of the IBC. This modification clarifies that architectural cast stone materials cited within the IRC must also comply with the material requirements for these products as required by the IBC.

Cost Impact: This code change will not increase the cost of construction.

RB24-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R202-MASONRY UNIT-THOMPSON

Proponent: David Hall CFM, Georgetown Texas representing the ICC PMG Code Action Committee (dave.hall@georgetown.org)

THIS CODE CHANGE WILL BE HEARD BY THE IRC-PLUMBING/MECHANICAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

Add new definition as follows:

R202 DEFINITIONS

MECHANICAL JOINT.

1. A connection between pipes, fittings, or pipes and fittings that is not welded, brazed, caulked, soldered, solvent cemented or heat-fused.
2. A general form of gas or liquid-tight connections obtained by the joining of parts through a positive holding mechanical construction such as, but not limited to, flanged, screwed, clamped or flared connections.

Reason: This language will be the 2015 IMC. Heat fusion is now a defined type of joint for plastic piping, and is considered to be separate from welding because there is no additional filler material used in forming the joint. However, heat-fusion joints are not mechanical joints and as such should be excluded from the definition of mechanical joints.

Cost Impact: This proposal will not increase the cost of construction.

RB25-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

202-MECHANICAL JOINT (NEW)-RB-HALL-PMGCAC

Proponent: Mark S. Graham, representing National Roofing Contractors Association
(mgraham@nrca.net)

THIS CODE CHANGE WILL BE HEARD BY THE IRC-PLUMBING/MECHANICAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

Add new definitions as follows:

R202 DEFINITIONS

PHOTOVOLTAIC MODULE. A complete, environmentally-protected unit consisting of solar cells, optics and other components, exclusive of a tracker, designed to generate DC power when exposed to sunlight.

PHOTVOLTAIC PANEL. A collection of modules mechanically fastened together, wired and designed to provide a field-installable unit.

Reason: This code change proposal is intended to clarify the code by providing specific terms and definitions for photovoltaic devices already addressed in the Code.

These definitions for the terms “photovoltaic module” and photovoltaic panel” are taken from NFPA 70, “National electrical Code, 2011 Edition.”

This same code change proposal was submitted for consideration as a portion of S3-12 for Group A of the International Building Code and was Approved as Modified; the modification was to a portion of the code change proposal separate from the definitions.

Cost Impact: This code change proposal will not increase the cost of construction

RB26-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R202-PHOTOVOLTAIC MODULE (NEW)-RB-GRAHAM

RB27 – 13

R202

Proponent: Mark S. Graham, representing National Roofing Contractors Association
(mgraham@nrca.net)

THIS CODE CHANGE WILL BE HEARD BY THE IRC-PLUMBING/MECHANICAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

Add new definitions as follows:

R202 DEFINITIONS

PHOTOVOLTIAIC MODULES/SHINGLES. A roof covering ~~composed of flat-plate photovoltaic modules fabricated into that~~ resembles shingles and incorporates photovoltaic modules.

Reason: This code change proposal is intended to clarify the term and definition for “photovoltaic modules/shingles” in Chapter 2-Definitions and make it consist with that of the next edition of the International Building Code.

This same code change proposal was submitted for consideration as a portion of S2-12 for Group A of the International Building Code and was Approved as Modified; the modification was to a portion of the code change proposal separate from the definition.

Cost Impact: This code change proposal will not increase the cost of construction

RB27-13

RB28 -13

R202

Proponent: David Hall CFM, Georgetown, Texas representing the ICC PMG Code Action Committee (Dave.Hall@georgetown.org)

Revise as follows:

R202 DEFINITIONS

PLUMBING SYSTEMS. ~~Includes the water supply and distribution pipes, plumbing fixtures, supports and appurtenances; soil, waste and vent pipes; sanitary drains and building sewers to an approved point of disposal.~~ Includes the water distribution pipes; plumbing fixtures and traps; water-treating or water-using equipment; soil, waste and vent pipes; and building drains; in addition to their respective connections, devices and appurtenances within a structure or premises; and the water service, building sewer and building storm sewer serving such structure or premises.

Reason: The proposed language was approved for the 2015 IPC. There is no technical reason for the IRC and the IPC to be different for this definition.

This proposal is submitted by the ICC Plumbing, Mechanical and Fuel Gas Code Action Committee (PMGCAC). The PMGCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance an assigned International Code or portion thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the PMGCAC has held 2 open meetings, multiple conference calls and multiple workgroup calls which included members of the PMGCAC. Interested parties also participated in all of the meetings and conference calls to discuss and debate the proposed changes. For PMGCAC member reference, this was item no. X3 on the PMGCAC IRC-P list.

Cost Impact: The code change proposal will not increase the cost of construction.

RB29 – 13

R202

Proponent: Michael S. Moss, American Backflow Prevention Association (msmoss@utah.gov)

Revise as follows:

R202 DEFINITIONS

POLLUTION. ~~An~~ A low hazard or non-health hazard impairment of the quality of the potable water to a degree that does not create a hazard to the public health, but that does adversely and unreasonably affect the aesthetic qualities of such potable water supply for domestic use.

Reason: The code does not define "low hazard" or non-health, however, the term is used in Table 608.1 as a footnote. This terminology is required to more correctly determine the type of backflow prevention assembly, backflow prevention device, means or method which is required for the protection of the water system to ensure protection of public health.

Cost Impact: This code change proposal will not increase the cost of construction.

RB30 – 13

R202 (New)

Proponent: Gary J. Ehrlich, P.E., representing National Association of Home Builders (NAHB)
(gehrlich@nahb.org)

Add new text as follows:

R202 DEFINITIONS

SHINGLE FASHION. A method of installing roof or wall coverings, water-resistive barriers, flashing, or other building components such that upper layers of material are placed overlapping lower layers of material to provide for drainage via gravity and moisture control.

Reason: The purpose of this code change is to introduce to the IRC a definition for “shingle fashion”. This term is used in the IBC and IRC to describe the required method of applying moisture control layers such as roof underlayment and water-resistive barriers to the building. The intent is to direct the builder, contractor or installer to place upper layers of material lapping over lower layers of material, in the fashion of placing roof shingles, so moisture is provided with a clear path to drain down and away from the building. In field investigations of buildings with mold and moisture issues, it is frequently discovered that flashing, WRBs or underlayment have been placed in **reverse** shingle fashion, with the upper layer tucked behind the lower layer. This permits moisture to drain behind or below the intended protective layer or material where it can be trapped and lead to mold and decay of building components. The above definition was approved earlier this cycle (G21-12) for inclusion in the 2015 IBC.

Cost Impact: The code change proposal will not increase the cost of construction.

RB31– 13

R202 (New)

Proponent: David W. Cooper, Stair Manufacturing and Design Consultants, representing the Stairway Manufacturers' Association (sma@stairways.org)

Add new definition as follows:

SECTION R202 DEFINITIONS

STAIRWAY, SPIRAL. A stairway with a plan view of closed circular form and uniform section-shaped treads radiating from a minimum-diameter circle.

Reason: The IRC does not define spiral stairway however the term is defined in the IBC and consequently R201.3 states this definition would apply to spiral stairs in the IRC. The IBC definition of spiral stairway is:

STAIRWAY, SPIRAL. A stairway having a closed circular form in its plan view with uniform section-shaped treads attached to and radiating from a minimum-diameter supporting column.

This definition is flawed. The requirement of a supporting column is superfluous and restricts many safe designs that conform to the spiral stairway geometry but provide a supporting stringer and a guard with additional handrail instead of a column. These space saving stairs function as spiral stairways with the preferred walking path at the outside perimeter and enhance their safe use with handrails on both sides without intruding into the required width as when wrapping a support column with a handrail. This change would not restrict the continued use of a column or require an additional handrail.

This change is part of several related changes being proposed to clarify the regulations related to spiral stairways. In particular please see our change to R311.7.10.1 limiting the minimum diameter and defining the point at which curved stair requirements would apply.

Cost Impact: This code change will not increase the cost of construction.

RB31-13

Public Hearing:	Committee:	AS	AM	D

RB34 – 13

R301.1

Proponent: Kevin S. Moore, S.E., Chair of Seismic Subcommittee to Code Advisory Committee, National Council of Structural Engineers Associations; Matt Mlakar, Chair of General Engineering Committee, Structural Engineers Association of California

Revise as follows:

R301.1 Application. Buildings and structures, and all parts thereof, shall be constructed to safely support all loads, including dead loads, live loads, roof loads, flood loads, snow loads, wind loads and seismic loads as prescribed by this code. The construction of buildings and structures in accordance with the provisions of this code shall result in a system that provides a complete load path that meets all requirements for the transfer of all loads from their point of origin through the load-resisting elements to the foundation. ~~Buildings and structures constructed as prescribed by this code are deemed to comply with the requirements of this section.~~

Reason: Execution of prescriptive measures promulgated by the IRC may not result in a complete load path for the transfer of all loads from their point of origin through the load-resisting elements to the foundation.

Several examples include:

1. Absence of provision for connection between roof framing member perpendicular to interior braced wall lines.
2. Absence of prescriptive requirements to provide positive lateral force connection between roof trusses and top of wall.
3. Discontinuous load path from roof sheathing to top of wall where gap between roof sheathing and blocking is required per following figure R602.10.8.2(1).
4. Provision for anchorage requirement of 24" return panel for wall bracing located on second story.

Deleting the last sentence of R301.1 will better ensure complete load path is provided when using IRC.

FIGURE R602.10.8.2(1)
BRACED WALL PANEL CONNECTION TO PERPENDICULAR RAFTERS

Cost Impact: This code change proposal will not increase construction cost.

R301.1.1, R301.2.1.1, Table R602.3(1), Table R602.3(2), R803.2.3, R803.2.3.1 (New)

Proponent: T. Eric Stafford, Insurance Institute for Business and Home Safety

Revise as follows:

R301.1.1 Alternative provisions. As an alternative to the requirements in Section R301.1 the following standards are permitted subject to the limitations of this code and the limitations therein. Where engineered design is used in conjunction with these standards, the design shall comply with the *International Building Code*.

1. AF&PA *Wood Frame Construction Manual* (WFCM).
2. AISI *Standard for Cold-Formed Steel Framing—Prescriptive Method for One- and Two-Family Dwellings* (AIS S230).
3. ICC *Standard on the Design and Construction of Log Structures* (ICC 400).

Exception: Wood structural panels used as roof sheathing for wood roof framing shall be attached in accordance with Section R803.

R301.2.1.1 Wind limitations and wind design required. The wind provisions of this code shall not apply to the design of buildings where wind design is required in accordance with Figure R301.2(4)B or where the basic wind speed from Figure R301.2(4)A equals or exceeds 110 miles per hour (49 m/s).

Exceptions:

1. For concrete construction, the wind provisions of this code shall apply in accordance with the limitations of Sections R404 and R611.
2. For structural insulated panels, the wind provisions of this code shall apply in accordance with the limitations of Section R613.
3. Wood structural panels used as roof sheathing for wood roof framing shall be attached in accordance with Section R803.

TABLE R602.3(1)
FASTENER SCHEDULE FOR STRUCTURAL MEMBERS

FASTENER SCHEDULE FOR STRUCTURAL MEMBERS				
ITEM	DESCRIPTION OF BUILDING MATERIALS	DESCRIPTION OF FASTENER ^{b,c,e}	SPACING OF FASTENERS	
			Edges (inches) ⁱ	Intermediate supports ^{c,e}
Wood structural panels, subfloor, roof and interior wall sheathing to framing and particleboard wall sheathing to framing

h. Where wind design is required in accordance with Figure R301.2(4)B, wood structural panel roof sheathing shall be fastened in accordance with Section R803.2.3.1.

(Portions of table and footnotes not shown to remain unchanged.)

R803.2.3 Installation. Wood structural panel used as roof sheathing shall be installed with joints staggered or not staggered in accordance with Table R602.3(1), or APA E30 for wood roof framing or with Table R804.3 for steel roof framing. Where wind design is required in accordance with Figure R301.2(4)B, wood structural panels used as roof sheathing for wood framed roofs shall be installed with joints staggered and fastened in accordance with Section R803.2.3.1.

R803.2.3.1 Sheathing fastenings. Wood structural panel sheathing shall be fastened to roof framing with ring-shank nails spaced not more than 6 inches on center at edges and 6 inches on center at intermediate framing. Ring-shank nails shall have the following properties:

1. Not less than 0.113-inch nominal shank diameter
2. Ring diameter shall be 0.005-inch larger than nominal shank diameter
3. Rings shall be not less than 3/4-inch from the head
4. 16 to 32 rings per inch
5. 0.270 inch nominal full round head diameter; for other head shapes such as D and clipped heads, the smaller dimension shall be not less than 0.190-inches and the larger dimension shall be not less than 0.270-inches
6. Not less than 2 3/8-inch nominal nail length

Exceptions:

1. Where roof framing with a specific gravity of 0.42 to not more than 0.49 is used, ring-shank nails shall be spaced not more than 4-inches on center in Nailing Zone 3 in accordance with Figure R803.2.3.1 where the basic wind speed equals or exceeds 130 mph.
2. Where roof framing with a specific gravity of 0.42 to not more than 0.49 is used, ring-shank nails shall be spaced not more than 12 inches on center at intermediate framing in the following Nailing Zones:
 - 2.1. In nailing zone 1 in accordance with Figure R803.2.3.1 for any basic wind speed, and
 - 2.2. In nailing zone 2 in accordance with Figure R803.2.3.1 where the basic wind speed is not more than 110 mph.
3. Where roof framing with a specific gravity of 0.49 or more is used, ring-shank nails shall be spaced not more than 12 inches on center at intermediate framing in the following Nailing Zones:
 - 3.1 In nailing zone 1 in accordance with Figure R803.2.3.1 for any basic wind speed, and
 - 3.2 In nailing zone 2 in accordance with Figure R803.2.3.1 where the basic wind speed is not more than 120 mph.
4. Where roof framing with a specific gravity of 0.49 or more is used, 8d common or 8d hot dipped galvanized box nails shall be spaced not more than 6 inches on center at edges and 6 inches on center at intermediate framing where the basic wind speed is not more than 100 mph.

5. Where the roof diaphragm shear load exceeds 170 plf in the direction parallel to the ridge or 225 plf in the direction perpendicular to the ridge, the size and spacing of fasteners shall be designed to resist the applicable shear load.

FIGURE R803.2.3.1
WOOD STRUCTURAL PANEL ROOF SHEATHING NAILING ZONES

Reason: Table R602.3(1) in the IRC currently requires the use of deformed shank nails in higher wind regions and on locations of the roof where pressures are known to be the highest. Thus, the IRC currently recognizes the benefit of using deformed shank fasteners for attaching roof sheathing to resist wind loads. However, the IRC is somewhat inconsistent with the specification of the deformed shank fasteners required in Table R602.3(1). This proposal corrects that inconsistency and specifically references the nail dimensions that are consistent with tests that form the basis for this proposal.

This proposed modification, if approved, will significantly improve the performance of wood structural panel roofs when subjected to high wind loads. It does so at a minimal to negligible cost which provides an extremely generous benefit/cost ratio. The requirements are based on hundreds of true wood structural panel tests. Extensive roof sheathing fastening tests at Clemson University (Reinhold 2000 – 2002, McKinley 2001) and at the International Hurricane Center – Florida International University (Reinhold, Alvarez 2003) compared the Mean Failure Pressure in psf for roof sheathing panels using both the 8d common and the 8d ring shank nails spaced at 6 inches as prescribed by the code. Sheathing consisted of 5/8 inch thick plywood attached to nominal 2x4 Southern Yellow Pine rafters.

The results of these tests were as follows:

1. Mean ultimate uplift capacity for panels attached with 8d common nails at 6 inch spacing: 126 pounds per square foot
2. Mean ultimate uplift capacity for panels attached with 8d ring shank nails at 6 inch spacing: 292 pounds per square foot

This shows a 131% improvement in performance when 8d ring shank nails are used instead of the currently prescribed 8d common nails. The original nail specifications adopted in the Florida Building Code and submitted to the IBC have been modified based on additional tests of nail withdrawal capacities. This testing has shown that a wider variety of ring dimensions consistently produce enhanced withdrawal capacities over those of smooth shank nails. The new specifications are more inclusive of nails available from a number of manufacturers and recognize that nail head characteristics can be varied without reducing the reliability of the sheathing attachment because of the close spacing of fasteners required for higher design load situations.

Additionally, the tests showed that the mean ultimate nail pullout for the 8d common nail was 175 lbs which is about half the value given by the NDS.

Requiring the use of 8d ring shank nails would result in an almost negligible increase in cost. While variations will occur regionally, it's estimated that the cost increase will be less than \$10 for 2000 square foot roof.

This proposal is written with wind speed triggers that are consistent with the current wind speed maps in the IRC. However, the author is aware of a group developing a code change proposal to update the wind speed maps in the IRC, including applicable wind speed triggers, to be consistent with the IBC and ASCE 7-10. Therefore, a corresponding code change has been submitted that provides wind speed triggers consistent with the wind speed maps in the IBC and ASCE 7-10. If the proposal to adopt the wind speed maps from the IBC and ASCE 7-10 is approved for the IRC, it is recommended that the corresponding proposal be approved.

Cost Impact: will increase cost

RB35-13

Public Hearing: Committee: AS AM D

R301.1.1-RB-STAFFORD

RB36 – 13

R301.1.3.1 (New)

Proponent: Kevin S. Moore, S.E., Chair of Seismic Subcommittee to Code Advisory Committee, National Council of Structural Engineers Associations; Matt Mlakar, Chair of General Engineering Committee, Structural Engineers Association of California

Add new text as follows:

R301.1.3.1 Wood-frame structures. The building official shall require construction documents to be approved and stamped by a licensed architect or engineer for all dwellings of wood-frame construction more than one story in height above grade plane that are located in Seismic Design Category D₀, D₁, D₂ or E.

Reason: After the 1994 Northridge earthquake, Los Angeles City building officials and the Structural Engineers Association of Southern California Wood Frame Construction Joint Task Force recommended that the quality of wood frame construction be greatly improved for regions of significant seismic risk. For buildings or structures located in Seismic Design Category D and E, the requirement to have a California licensed architect or engineer prepare construction documents is intended to minimize or reduce structural deficiencies that may cause excessive damage or injuries in wood frame buildings. Licensed architects and engineers can reduce or eliminate the design of structural deficiencies such as plan and vertical irregularities, inadequate construction details necessary to transfer seismic shear transfer throughout the seismic force-resisting system and improper application of prescriptive requirements of the California Residential Code. This is consistent with the intent of efforts following the costly 1994 Northridge earthquake.

This proposal recommends that the use of IRC be limited to **single story buildings in SDC D and E**. This is consistent with the conventional provisions in the **2012 IBC (Section 2308.12.1)**.

Reference:

B. Schmidt, R. Harder, circa 1994, "Report on Plywood Shear Wall Performance," City of Los Angeles Department of Building and Safety and Structural Engineers Associations of Southern California Joint Task Force Plywood Shear Wall Committee

Cost Impact: This code change proposal may increase construction cost but should reduce damage after an earthquake event.

Reason: This proposal replaces the Risk-Targeted seismic design maps of the 2012 IRC with the same named figures from the previous 2009 edition, thereby deleting Risk-Targeted seismic design maps from the code.

So-called Risk-Targeted National Seismic Hazard Maps are not appropriate for protecting public safety in residential construction, because they do not realistically consider the “maximum potential earthquake” impacts and effects from known “active” earthquake source regions; in particular from the M 9 Cascadia subduction zone along coastal regions of the entire Pacific Northwest.

The NOW so-called Risk Basis is: (a) arbitrary; (b) not explicitly defined; (c) unsubstantiated by any true standards approval process; (d) not a true consensus; and (e) inappropriate for such huge inventories of residential structures (where minimal efforts in design implementation and expense for resiliency in realistic earthquake threats both can and should make major differences in the intended outcomes). Since earthquakes are by their very natures “rare events,” any perceived or assigned probabilities as to their likelihood, occurrence, reoccurrence, periodicity, frequency, return period, etc. are most assuredly “unreliable.”

Specifically, these newly derived maps are not meeting the R101.3 Intent or purpose of this code: which is to establish minimum requirements to safeguard the public safety, health and general welfare through affordability, **structural strength**, means of egress facilities, **stability, sanitation**, light and ventilation, energy conservation and **safety to life and property** from fire and other **[earthquake] hazards** attributed to the built environment and **to provide safety to fire fighters and emergency responders during emergency operations.**

- (1) Constantly changing the USGS National Seismic Hazard Maps’ “ground motion response accelerations contours” is **destabilizing** to design practice, plan review requirements, and code enforcement provisions, because such changes are:
 - (a) creating **yo-yo earthquake design standards** – “high” one code cycle and “low” the next; or vice-versa; making it, as a result, ever more difficult to develop, practice and apply “professional engineering judgment” in the design process.
 - (b) creating serious and perplexing problems for addressing seismic hazards for **existing buildings** – which must then “**benchmark**” to a specific year and to a specific version (year & edition) of seismic hazard map (for any specific public policy mandate/requirements for earthquake retrofit/mitigation ordinances or measures. These required “benchmark” seismic hazard maps will then be different (sometimes a lot different) from the current (and ever-changing and ever-evolving) USGS National Seismic Hazard Maps. This is, and will continue to be, a big source of confusion.
- (2) **RISK-TARGETED MAXIMUM CONSIDERED EARTHQUAKE (MCE_R) GROUND MOTION RESPONSE ACCELERATIONS** contours in the IBC 2012 / ASCE 7-10 are sometimes **30% lower** than previous map values of just a decade ago:
 - (a) the recent 08-23-2011 M 5.8 Mineral VA (Cuckoo) earthquake had 30% lower design values (with these new maps) than a decade ago – making the earthquake’s epicentral region **Seismic Design Category A-B**; yet the **actual intensity of earthquake ground shaking** experienced there was the “stated intensity” that could be expected for the IBC/ASCE 7-10 designation **SDC D!**. (Bela 2011)
 - (b) when the seismic hazard maps **depict such low hazard ground motion response accelerations** and their corresponding **low** Seismic Design Categories, they both foster and create the “circumstances” for “**comfortable inaction**,” and, unfortunately, this feeling of “comfortable inaction” easily transfers to the arena of public policy.
 - (c) The condition of “comfortable inaction” (due to perceived low hazard - depicted on the seismic hazard map) was cited as perhaps the main culprit in Christchurch, New Zealand’s lack of adequate preparedness during its recent hammering by a “pair” of earthquakes – which killed around 200 people in unsafe “**Killer Buildings**” in the M 6.3 Feb. 22, 2011 event.
- (3) The basic underlying methodology for preparing the USGS National Seismic Hazard Maps (and their derivative so-called Risk-Targeted Maximum Considered Earthquake (MCE_R) Ground Motion Response Accelerations contours); i.e., probabilistic seismic hazard assessment (or psha) is fatally “**flawed**” – due to systemic “errors” in the applied mathematics which both create and define it. And it is, unfortunately, these same flawed “mathematics” that are prescribing how these psha-determined ground motion contours are ultimately derived, computed . . . and then finally codified.
- (4) Errors in its methodology aside, the basic problems, difficulties and really insurmountable obstacles to performing a psha seismic hazard assessment (*Mualchin, 2010; Bela and Mualchin 2011*) have **never** actually been “solved.” And they still remain unsolved! These problems involve data-driven earth-science requirements for a knowledge and understanding of:
 - (a) **fault slip rates**;
 - (b) **frequency** of occurrence of earthquakes (and their known magnitudes); and
 - (c) **earthquake source mechanisms** – specifically, (i) the style of faulting; and (ii) the hypocentral depth (or where exactly the earthquake rupture process begins).
- (5) The psha methodology is easily “manipulated,” particularly in the sense that: (i) selecting the probabilistic hazard level is a totally **arbitrary** process; and (ii) changing the hazard level (higher hazard or lower hazard) gives a completely different ground motion response acceleration contour – and consequently, then, different code requirements!
- (6) These very real and insurmountable problems with psha’s methodology have been swept away by its proponents: by convoluted (and mostly unintelligible) efforts and preoccupations with “logic trees,” “quantifying uncertainties,” etc. These efforts proceed busily ahead; but, meanwhile, they are “neglecting baseline principles” (of “what” the earthquake can do to you – and “how” it can do it – and the maximum Magnitude it could be). All that mathematical busywork, logic-tree accounting, and so-called “expert opinion” built the “better model” (or -- so the proponents believe). Unfortunately, that “better model” then:
 - (a) has become “**substituted**” for “reality” by its creators;
 - (b) has dismissed criticisms of it -- by claiming (itself) to be “best available science;” and
 - (c) has become ultimately so “**complicated**” -- that not even its proponents now can logically and successfully explain how it came to be (Hamburger et. al., 2010; Bela, 2011); nor can they effectively explain how to apply it to the real world of earthquake engineering, public safety, and socioeconomic issues of community resiliency.
- (7) The ground motion accelerations, and their probabilities for exceeding them, are combined and co-mingled in such a way that the actual sources (or **earthquake magnitudes, frequency content of earthquake ground motions, and duration** of strong ground shaking) are treated more-or-less equally—and they are most certainly not!
- (8) The “**Maximum Credible Earthquake**” (**MCE**) or “Maximum Capable Earthquake” or “Maximum Possible Earthquake” (within ¼ unit of Magnitude, M) is never explicitly stated. And it’s really “Magnitude, Magnitude,

Magnitude!" (and for the same reasons previously stated in (4)) – that has everything to do with building performance (damage and repair costs) and, more importantly, public safety and community resilience.

- (9) **R-Factors, or Response Modification Factors**, that are used in design provisions in the IBC become **less reliable** in ascertaining/predicting the “**end result**” (or the building’s actual performance in an earthquake). And, “**an earthquake**” really needs to explicitly consider the full suite of earthquake possibilities that the regional tectonics forewarn us can occur (including MCE = Maximum Credible Earthquake, or Maximum Possible Earthquake). “R-Factors” have become less reliable primarily because:
- (a) quite a lot of the “ductility” or building “toughness” that the code relies upon to: (i) ride out the earthquake (by bending, not breaking, and absorbing energy); and (ii) remain standing (without killing the occupants) -- is due to “over-strength;” and. (b) when the code design “strength” is systematically diminished (weakened) or reduced (over several-to-many iterations of seismic hazard mapping --by lowering (yo-yo effect) the “numerator” quantity in the design strength equation; then when dividing this numerator (now smaller number) by the same “large” number (R-Factor in denominator) – we have now “lost” perhaps a good portion of our “over-strength” – that was implicit in selecting the weights of the various R-Factors in the first place! Basically, with RISK-TARGETED (MCE_R), the code is now dividing an ever-decreasing and now smaller number (perhaps by 30%) by the same “large” number (R-Factor denominator) -- with the result that the buildings’ performances and outcomes are really now much less certain . . . and also now much more problematical.
- (10) The psha methodology has been shown in dramatic and tragic fashion to be not only “misleading”, but also deadly, in the last decade or so of the “**Eleven of the World’s Deadliest Earthquakes.**” (Panza et. al. 2011, Table 1) In example after example, and all across the globe (where now more than 700, 000 people have perished); the psha-methodology “prescribed” seismic hazard: was determined to be either low or very low – but was “disproved” in these many cases by earthquakes that were “surprises” from what psha had determined could be expected. In too many of these deadly “surprises”, the actual intensities of ground shaking experienced were greater by factors of 2X to 4X – than what psha had predicted. (Bela 2010; Bela and Mualchin, 2011; Kossobokov and Nekrasova, 2010;) It is clear that this is an unsafe situation (to general public) that must **not** continue; but it does continue for some of these following main reasons:
- (a) the psha methodology is “anonymous,” so when there is clear evidence (> 700,000 casualties) that it is “not working;” no one is accountable for its: (i) external failures (mass casualties); and/or (ii) internal failures (very real errors in its “applied mathematics” derivations).
- (b) the psha methodology has a hierarchial and powerful elite behind its influence and continued use.
- (c) the psha methodology has a pedigree of high sounding terms (like “quantifying uncertainty,” “logic-tree”, “expert opinion,” “best science,” etc.) -- all purporting to increase the method’s “**precision**.” But the end result, as these Eleven Deadliest Earthquakes” have shown us, is, unfortunately, still too “**inaccurate**” and “too deadly” for protecting the public safety. And in this regard, it is clearly missing its target!

Table R301.2(1)

Proponent: Matthew L. Mlakar, Barrish Pelham & Associates, Inc., representing Structural Engineers Association of California

Revise as follows:

TABLE R301.2(1)
CLIMATIC AND GEOGRAPHIC DESIGN CRITERIA

GROUND SNOW LOAD	WIND DESIGN			SEISMIC DESIGN CATEGORY ^f
	Speed ^d (mph)	Topographic effects ^k	Special wind region ^l	Wind-borne debris zone ^m

(Portions of table not shown to remain unchanged.)

a through k (No changes to text)

l. In accordance with Table R301.2(4)B, where there is local historical data documenting unusual wind conditions, the jurisdiction shall fill in this part of the table with "YES" and identify any specific requirements. Otherwise, the jurisdiction shall indicate "NO" in this part of the table.

m. In accordance with Table R301.2(4)C, the jurisdiction shall indicate the wind-borne debris wind zone(s). Otherwise, the jurisdiction shall indicate "NO" in this part of the table.

Reason: Currently, the special wind regions in Table R301.2(4)B and the wind-borne debris regions in Table R301.2(4)C are shown on a single map for the entire continental United States. Attempting to interpret the map in areas where the contour lines occur can be difficult and may lead to mis-application of the tables especially since the contour lines do not follow county lines or readily identifiable borders. The identification of the transitions should be provided by the local *jurisdiction* to ensure that the proper coefficients are used.

Cost Impact: The proposed change will not impact the cost of construction.

Proponent: Gary J. Ehrlich, P.E., National Association of Home Builders (NAHB);

Revise definitions as follows:

SECTION R202 DEFINITIONS

HURRICANE-PRONE REGIONS. Areas vulnerable to hurricanes, defined as the U.S. Atlantic Ocean and Gulf of Mexico coasts where the ultimate design wind speed, V_{ult} , basic wind speed is greater than 115 90 miles per hour (5140 m/s), and Hawaii, Puerto Rico, Guam, Virgin Islands, and America Samoa.

WIND-BORNE DEBRIS REGION. Areas within *hurricane-prone regions* located as designated in accordance with Figure R302.1(4)C. :

1. Within 1 mile (1.61 km) of the coastal mean high water line where the ultimate design wind speed, V_{ult} , is 130 mph (58 m/s) or greater; or
2. In areas where the ultimate design wind speed, V_{ult} , is 140 mph (63.6 m/s) or greater; or Hawaii.

Revise as follows:

R301.2.1 Wind design criteria. Buildings and portions thereof shall be constructed in accordance with the wind provisions of this code using the ultimate design ~~basic~~ wind speed in Table R301.2(1) as determined from Figure R301.2(4)A. The structural provisions of this code for wind loads are not permitted where wind design is required as specified in Section R301.2.1.1. Where different construction methods and structural materials are used for various portions of a building, the applicable requirements of this section for each portion shall apply. Where not otherwise specified, the wind loads listed in Table R301.2(2) adjusted for height and exposure using Table R301.2(3) shall be used to determine design load performance requirements for wall coverings, curtain walls, roof coverings, exterior windows, skylights, garage doors and exterior doors. Asphalt shingles shall be designed for wind speeds in accordance with Section R905.2.4. A continuous load path shall be provided to transmit the applicable uplift forces in Section R802.11.1 from the roof assembly to the foundation.

R301.2.1.1 Wind limitations and wind design required. The wind provisions of this code shall not apply to the design of buildings where wind design is required in accordance with Figure R301.2(4)B ~~or where the basic wind speed from Figure R301.2(4)A equals or exceeds 110 miles per hour (49 m/s).~~

Exceptions:

1. For concrete construction, the wind provisions of this code shall apply in accordance with the limitations of Sections R404 and R611.
2. For structural insulated panels, the wind provisions of this code shall apply in accordance with the limitations of Section R613.

In regions where wind design is required in accordance with Figure R301.2(4)B ~~or where the basic wind speed shown on Figure R301.2(4)A equals or exceeds 110 miles per hour (49 m/s)~~, the design of buildings for wind loads shall be in accordance with one or more of the following methods:

1. AF&PA *Wood Frame Construction Manual* (WFCM); or

2. ICC *Standard for Residential Construction in High-Wind Regions* (ICC 600); or
3. ASCE *Minimum Design Loads for Buildings and Other Structures* (ASCE 7); or
4. AISI *Standard for Cold-Formed Steel Framing—Prescriptive Method For One- and Two-Family Dwellings* (AISI S230); or
5. *International Building Code*.

The elements of design not addressed by the methods in Items 1 through 5 shall be in accordance with the provisions of this code. When ASCE 7 or the *International Building Code* is used for the design of the building, the wind speed map and exposure category requirements as specified in ASCE 7 and the *International Building Code* shall be used.

R301.2.1.2 Protection of openings. Exterior glazing in buildings located in windborne debris regions shall be protected from windborne debris. Glazed opening protection for windborne debris shall meet the requirements of the Large Missile Test of ASTM E 1996 and ASTM E 1886 as modified in Section R301.2.1.2.1 referenced therein. ~~The applicable wind zones for establishing missile types in ASTM E 1996 are shown on Figure R301.2(4)C.~~ Garage door glazed opening protection for windborne debris shall meet the requirements of an *approved* impact-resisting standard or ANSI/DASMA 115.

Exception: Wood structural panels with a minimum thickness of 7/16 inch (11 mm) and a maximum span of 8 feet (2438 mm) shall be permitted for opening protection in one- and two-story buildings. Panels shall be precut and attached to the framing surrounding the opening containing the product with the glazed opening. Panels shall be predrilled as required for the anchorage method and shall be secured with the attachment hardware provided. Attachments shall be designed to resist the component and cladding loads determined in accordance with either Table R301.2(2) or ASCE 7, with the permanent corrosion-resistant attachment hardware provided and anchors permanently installed on the building. Attachment in accordance with Table R301.2.1.2 is permitted for buildings with a mean roof height of 45 33 feet (10 058 mm) or less where the ultimate design wind speed, V_{ult} is 180 mph or less, ~~located in Wind Zones 1 and 2 in accordance with Figure R301.2(4)C.~~

SCHEDULE FOR WOOD STRUCTURAL PANELS^{a,b,c,d}

a. This table is based on 430 180 mph ultimate design wind speeds, V_{ult} and a 45 33-foot mean roof height.

(Table and footnotes not shown to remain unchanged.)

R301.2.1.2.1. Application of ASTM E 1996. The text of Section 2.2 of ASTM E 1996 shall be substituted as follows:

2.2 ASCE Standard:

ASCE 7-10 American Society of Civil Engineers Minimum Design Loads for Buildings and Other Structures

The text of Section 6.2.2 of ASTM E 1996 shall be substituted as follows:

6.2.2 Unless otherwise specified, select the wind zone based on the strength design wind speed, V_{ult} , as follows:

6.2.2.1 Wind Zone 1—130 mph \leq ultimate design wind speed, $V_{ult} < 140$ mph.

6.2.2.2 Wind Zone 2—140 mph \leq ultimate design wind speed, $V_{ult} < 150$ mph at greater than one mile (1.6 km) from the coastline. The coastline shall be measured from the mean high water mark.

6.2.2.3 Wind Zone 3—150 mph (58 m/s) \leq ultimate design wind speed, $V_{ult} \leq 160$ mph (63 m/s), or 140 mph (54 m/s) \leq ultimate design wind speed, $V_{ult} \leq 160$ mph (63 m/s) and within one mile (1.6 km) of the coastline. The coastline shall be measured from the mean high water mark.

6.2.2.4 Wind Zone 4—ultimate design wind speed, $V_{ult} > 160$ mph (63 m/s).

R301.2.1.3 Wind speed conversion. When referenced documents are based on nominal design-fastest mile wind speeds, the ultimate design-three-second gust basic wind speeds, $V_{ult}-V_{3s}$, of Figure R301.2(4)A shall be converted to nominal design-fastest mile wind speeds, $V_{asd}-V_{fm}$, using Table R301.2.1.3.

**TABLE R301.2.1.3
EQUIVALENT BASIC WIND SPEEDS**

WIND SPEED CONVERSIONS^a**

V_{ult}	110	115	120	130	140	150	160	170	180	190	200
V_{asd}	85	89	93	101	108	116	124	132	139	147	155

a. Linear interpolation is permitted

R301.2.1.4 Exposure category. For each wind direction considered, an exposure category that adequately reflects the characteristics of ground surface irregularities shall be determined for the site at which the building or structure is to be constructed. For a site located in the transition zone between categories, the category resulting in the largest wind forces shall apply. Account shall be taken of variations in ground surface roughness that arise from natural topography and vegetation as well as from constructed features. For a site where multiple detached one- and two-family dwellings, townhouses or other structures are to be constructed as part of a subdivision, master-planned community, or otherwise designated as a developed area by the authority having jurisdiction, the exposure category for an individual structure shall be based upon the site conditions that will exist at the time when all adjacent structures on the site have been constructed, provided their construction is expected to begin within one year of the start of construction for the structure for which the exposure category is determined. For any given wind direction, the exposure in which a specific building or other structure is sited shall be assessed as being one of the following categories:

1. Exposure A. Large city centers with at least 50 percent of the buildings having a height in excess of 70 feet (21 336 mm). Use of this exposure category shall be limited to those areas for which terrain representative of Exposure A prevails in the upwind direction for a distance of at least 0.5 mile (0.8 km) or 10 times the height of the building or other structure, whichever is greater. Possible channeling effects or increased velocity pressures due to the building or structure being located in the wake of adjacent buildings shall be taken into account.
12. Exposure B. Urban and suburban areas, wooded areas, or other terrain with numerous closely spaced obstructions having the size of single-family dwellings or larger. Exposure B shall be assumed unless the site meets the definition of another type exposure.
23. Exposure C. Open terrain with scattered obstructions, including surface undulations or other irregularities, having heights generally less than 30 feet (9144 mm) extending more than 1,500

feet (457 m) from the building site in any quadrant. This exposure shall also apply to any building located within Exposure B type terrain where the building is directly adjacent to open areas of Exposure C type terrain in any quadrant for a distance of more than 600 feet (183 m). This category includes flat, open country and grasslands.

34. Exposure D. Flat, unobstructed areas exposed to wind flowing over open water for a distance of at least 5000 feet (1,524 m) ~~1 mile (1.61 km)~~. ~~Shorelines in Exposure D include inland waterways, the Great Lakes, and coastal areas of California, Oregon, Washington and Alaska.~~ This exposure shall apply only to those buildings and other structures exposed to the wind coming from over the water. Exposure D extends inland from the shoreline a distance of 600 feet (183 m) ~~4500 feet (457 m)~~ or 20-40 times the height of the building or structure, whichever is greater. This category includes smooth mud flats, salt flats and unbroken ice.

For SI: 1 foot = 304.8 mm, 1 square foot = 0.0929 m², 1 mile per hour = 0.447 m/s, 1 pound per square foot = 0.0479 kPa.

Notes:

- The effective wind area shall be equal to the span length multiplied by an effective width. This width shall be permitted to be not be less than one-third the span length. For cladding fasteners, the effective wind area shall not be greater than the area that is tributary to an individual fastener.
- For effective areas between those given above, the load may be interpolated; otherwise, use the load associated with the lower effective area.
- Table values shall be adjusted for height and exposure by multiplying by the adjustment coefficient in Table R301.2(3).
- See Figure R301.2(7) for location of zones.
- Plus and minus signs signify pressures acting toward and away from the building surfaces.

Notes:

1. Values are nominal design 3-second gust wind speeds in miles per hour (m/s) at 33 ft (10m) above ground for Exposure C category.
2. Linear interpolation between contours is permitted.
3. Islands and coastal areas outside the last contour shall use the last wind speed contour of the coastal area.
4. Mountainous terrain, gorges, ocean promontories, and special wind regions shall be examined for unusual wind conditions.
5. Wind speeds correspond to approximately a 7% probability of exceedance in 50 years (Annual Exceedance Probability = 0.00143, MRI = 700 Years).

FIGURE R301.2(4)A
ULTIMATE DESIGN WIND SPEEDS

Notes:

1. Values are nominal design 3-second gust wind speeds in miles per hour (m/s) at 33 ft (10m) above ground for Exposure C category.
2. Linear interpolation between contours is permitted.
3. Islands and coastal areas outside the last contour shall use the last wind speed contour of the coastal area.
4. Mountainous terrain, gorges, ocean promontories, and special wind regions shall be examined for unusual wind conditions.
5. Wind speeds correspond to approximately a 7% probability of exceedance in 50 years.

TABLE R301.7
ALLOWABLE DEFLECTION OF STRUCTURAL MEMBERS^{a, b, c, d, e}

STRUCTURAL MEMBER	ALLOWABLE DEFLECTION
Exterior walls ^a — wind loads ^a with plaster or stucco finish	H/360
Exterior walls ^a with other brittle finishes	H/240
Exterior walls ^a with flexible finishes	H/120 ^d
Lintels supporting masonry veneer walls ^e	L/600

Note: L = span length, H = span height.

a. The wind load shall be permitted to be taken as 0.7 times the Component and Cladding (ASD) loads obtained from Table R301.2(2) for the purpose of determining deflection limits herein.

(Footnotes not shown to remain unchanged.)

Reason: The purpose of this code change is to bring the wind provisions of the IRC in line with the 2012 IBC and ASCE 7-10. As a result of the schedule changes implemented during the 2009-2010 ICC code development cycle changes, there was not sufficient time to revise the IRC to fully implement the new ultimate wind speed basis of ASCE 7-10 and the 2012 IBC, due to the extent of prescriptive IRC provisions and tables which are directly related to basic wind speed. New maps based on the ASCE 7-10 ultimate wind speed data but converted back down to nominal (ASD) basis were provided in the IRC. This has led to a fair amount of confusion among those stakeholders who work with both codes.

A working group of stakeholders including NAHB, the major material associations, ASCE, and the Insurance Institute for Business and Home Safety developed a series of IRC proposals to implement the new ultimate wind speed basis. This proposal updates the Chapter 3 design criteria, including definitions, a new ultimate wind speed map, a new map of the regions where special high-wind design is required, a conversion table to the nominal (ASD) wind speed basis for use with those standards which have not updated their provisions, and a revised table of component and cladding pressures.

It is noted the component and cladding pressure table is set up using the ultimate design wind speed, but reports pressures at an ASD level. That is, the listed pressures incorporate the 0.6 multiplier on wind loads per the allowable stress design load combinations shown in Section 1605.3 of the *International Building Code* and Section 2.3.2 of ASCE 7-10. This is done here and throughout this series of proposals to allow for easy adaptation of existing stock designs, construction documents and guidelines to the 2015 IRC, as the loads and pressures will be comparable to previous editions of the IRC for most sites.

The region in revised Figure R301.2(4)B where the use of alternate prescriptive high-wind standards or engineered design is required is defined using the 130mph contour along the Gulf Coast and along the southern portions of the Atlantic coast from Florida up to North Carolina. The 140mph contour is used for the northern portions of the Atlantic coast from Virginia up to Maine, and for Alaska. A 130mph trigger is also used for the assorted Caribbean and Pacific islands that are also considered part of the "hurricane-prone" region. This creates a region that approximately equals the region defined by the 110mph contour under the wind map used in the 2000 through 2009 IRC, maintains areas of Florida and the Gulf Coast traditionally outside of the prescriptive limits of the IRC, and maintains areas of New England traditionally included within the prescriptive limits of the IRC.

Code users desiring a more accurate determination in areas near or along a particular contour (or in general) can make use of the Applied Technology Council's Windspeed by Location web site (<http://www.atcouncil.org/windspeed/>) to obtain site-specific wind speeds using latitude/longitude or site address. This site was developed by ATC using the same data used to develop the wind maps for ASCE 7, the IBC and the IRC. As the site is not a reference standard or maintained by a government agency, we could not make a direct reference in the code figures. However, we include mention of the Windspeed by Location web site here to draw code users' attention to its existence and in hopes that mention of the web site could become part of the IRC Commentary.

Cost Impact: The code change proposal will not increase the cost of construction.

R301.2.1-RB-EHRLICH

RB40 – 13

R301.2.1.1.1 (New), Chapter 44

Proponent: Julie Ruth, P.E., JRuth Code Consulting, representing the American Architectural Manufacturers Association (julruth@aol.com); Daniel J. Walker, P.E., Thomas Associates, representing the National Sunroom Association

Add new text as follows:

R301.2.1.1.1 Sunrooms. Sunrooms shall comply with the wind loads, structural requirements and testing provisions of Section 5.2.1 of AAMA/NPEA/NSA 2100, with the following modifications:

1. Basic wind speed in miles per hour (mph) shall be determined in accordance with Section R301.2.1 of this code; and
2. Sunrooms including exposed structure, components, cladding, and roof covering shall be designed to resist the wind loads as established in Section R301.2.1 of this code.

For the purpose of applying the criteria of AAMA/NPEA/NSA-2100 based on the intended use, sunrooms shall be identified as one of the following categories by the permit applicant, design professional or the property owner in the construction documents. Component and Cladding pressures shall be used for the design of elements that do not qualify as main wind force resisting systems. Main wind force resisting systems pressures shall be used for the design of elements assigned to provide support and stability for the overall sunroom.

Category I: A Thermally Isolated Sunroom with walls that are open or enclosed with insect screening or 0.5 mm (20 mil) maximum thickness plastic film. The space is nonhabitable and unconditioned.

Category II: A Thermally Isolated Sunroom with enclosed walls. The openings are enclosed with translucent or transparent plastic or glass. The space is nonhabitable and unconditioned.

Category III: A Thermally Isolated Sunroom with enclosed walls. The openings are enclosed with translucent or transparent plastic or glass. The sunroom fenestration complies with additional requirements for air infiltration resistance and water-penetration resistance. The space is nonhabitable and unconditioned.

Category IV: A Thermally Isolated Sunroom with enclosed walls. The sunroom is designed to be heated or cooled by a separate temperature control or system and is thermally isolated from the primary structure. The sunroom fenestration complies with additional requirements for water penetration resistance, air infiltration resistance, and thermal performance. The space is nonhabitable and conditioned.

Category V: A Sunroom with enclosed walls. The sunroom is designed to be heated or cooled and is open to the main structure. The sunroom fenestration complies with additional requirements for water-penetration resistance, air infiltration resistance, and thermal performance. The space is habitable and conditioned.

Add standards to Chapter 44 as follows:

AAMA American Architectural Manufacturers Association
1827 Walden Office Square, Suite 550
Schaumburg, IL 60173

AAMA/NSA/NPEA 2100-12 Specifications for Sunrooms

NSA National Sunroom Association
1300 Sumner Ave.
Cleveland, OH 44115-2851

AAMA/NSA/NPEA 2100-12 Specifications for Sunrooms

NPEA National Sunroom Association
1300 Sumner Ave.
Cleveland, OH 44115-2851

AAMA/NSA/NPEA 2100-12 Specifications for Sunrooms

Reason: The 2012 *International Residential Code* defines a sunroom as "A one-story structure attached to a *dwelling* with a *glazing area* in excess of 40 percent of the gross area of the structure's *exterior walls* and roof." These structures are typically constructed in one of two manners: 1) using typical wood framing techniques, or 2) using a stick system that consists of prefabricated framing of aluminum, fiberglass, wood or other materials, with glass or opaque wall or roof panels, and steel or aluminum connections.

The first technique can be done in accordance with the current provisions of the IRC for wood framed construction. There are no provisions in the IRC for the second method of constructing a sunroom other than by engineering analysis or demonstrating equivalence to the current provisions of the *International Residential Code* by some other means.

This proposal seeks to clarify the requirements for sunrooms under the IRC by adding reference to the provisions of AAMA/NPEA/NSA 2100 - 12 *Specifications for Sunrooms* to the available options for approval of sunroom construction in the IRC. Sunrooms designed and constructed in accordance with AAMA/NPEA/NSA 2100 are required within the standard to meet the structural provisions of the IRC or the IBC. Therefore, the appropriate engineering analysis has already been conducted for these structures. In addition, the standard establishes the specific requirements for these unique structures based upon their designated Category.

In 2002 the American Architectural Manufacturers Association (AAMA), the National Sunroom Association (NSA) and the National Patio Enclosure Association (NPEA) published the first U.S. standard for the design and specification of sunrooms – AAMA/NPEA/NSA 2100 – 02. The standard established five categories of sunrooms based upon the intended use of the space, and established specific design and performance criteria for them based on the end use.

As the document began to be used and referenced in various local codes (such as the Florida Building Code) the members of the AAMA Sunroom Council and NSA became aware that improvements and updates were needed. These improvements included revisions that would bring the document in line with the requirements of AAMA/WDMA/CSA 101/I.S.2/A440 for the design, testing and labeling of windows, glass doors and skylights, and revisions that would bring the foundation requirements more closely in line with the requirements of the *International Residential Code*. The most recent edition of the standard is AAMA/NPEA/NSA 2100-12. The table below provides an overview of the requirements of AAMA/NPEA/NSA 2100-12, as they apply to the various categories of sunrooms.

Minimum Requirements	Cat. I	Cat. II	Cat. III	Cat. IV	Cat. V
Structural Design in accordance with IRC or IBC.	x	x	x	x	x
Fenestration products comply with AAMA/WDMA/CSA 101/I.S.2/A440 (includes resistance to air leakage, water penetration, forced entry, etc. as well as structural design pressure rating).		x	x	x	x
Comply with IECC or IRC Chapter 11.				x	x
Comply with the Foundation/footings, site location, and emergency escape and rescue openings requirements of the IRC or local code.	x	x	x	x	x
Emergency escape and rescue openings are permitted to open onto sunroom.	x				
Comply with the natural lighting requirements of the IRC or local code.	x	x	x	x	x
Openings for natural lighting are permitted to open onto sunroom.	x				
Comply with the requirements of the IRC or local code for stairway and egress illumination.	x	x	x	x	x
Required to have exit lighting.		x	x	x	x
Receptacle outlets as required by NFPA 70, Article 314.				x	x

The 2002 edition of AAMA/NPEA/NSA 2100 has been used successfully in previous editions of the Florida Building Code. Reference to the 2012 edition in the 2015 IRC to facilitate its use on a nationwide basis is appropriate at this time.

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: A review of the standard proposed for inclusion in the code, [AAMA/NSA/NPEA 2100-12] with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 1, 2013.

R301.2.1.1.1 (NEW)-RB-RUTH-WALKER

RB41 – 13

R301.2.1.2

Proponent: Edward L. Keith, APA, representing The Engineered Wood Association
(ed.keith@apawood.org)

Revise as follows:

R301.2.1.2 Protection of openings. ~~Exterior openings in buildings located in windborne debris regions shall be protected from windborne debris. Windows in buildings located in windborne debris regions shall have glazed openings protected from windborne debris.~~ Glazed opening protection for windborne debris shall meet the requirements of the Large Missile Test of ASTM E 1996 and ASTM E 1886 referenced therein. ~~The applicable wind Zones for establishing missile types in ASTM E 1996 are shown on Figure R301.2(4)C.~~ Garage door glazed opening protection for windborne debris shall meet the requirements of an *approved* impact resisting standard or ANSI/DASMA 115.

Exception: Wood structural panels with a minimum thickness of 7/16 inch (11 mm) and a maximum span of 8 feet (2438 mm) shall be permitted for opening protection in buildings with a mean roof height of 33 feet (10 058 mm) or less, one- and two-story buildings. Panels shall be precut and attached to the framing surrounding the opening containing the product with the glazed opening. Panels shall be predrilled as required for the anchorage method and shall be secured with the attachment hardware provided. Attachments shall be designed to resist the component and cladding loads determined in accordance with either Table R301.2(2) or ASCE 7, with the permanent corrosion resistant attachment hardware provided and anchors permanently installed on the building. Attachment in accordance with Table R301.2.1.2 is permitted for buildings with a mean roof height of 33 feet (10 058 mm) or less where wind speeds do not exceed 130 miles per hour (58 m/s) located in Wind Zones 1 and 2 in accordance with Figure R301.2(4)G.

Reason: This is a companion item to S99-12/13 adopted in Portland in the October Final Action Hearing.

In the early development of the SBCCI Deemed to Comply document (The precursor to the SBCCI Standard for Hurricane Resistant Residential Construction (SSTD-10) and ultimately the ICC Standard for Residential Construction in High Wind Regions (ICC 600).) limits were developed to the geometry of the structures covered by the standard. These limits included a height limit of 33 feet mean roof height. The 33 feet was based on then-current height zoning regulations, the referenced wind speed height in the contemporary ASTM wind standard, as well as height of most anemometers (wind measuring devices). As the Deemed to Comply and later documents were limited for wood buildings to two stories in height, as the standards evolved the height limit was changed from 33 feet mean roof height to simply two stories. Note that the information in the code is based on a mean roof height of 33 feet and NOT two stories. APA developed this information and it is based on 33 feet mean roof height. (APA Form Number T450, free PDF download at www.apawood.org.)

From a wind perspective only the geometry of the structure matters. Its internal make-up of floors and walls affect the *resistance* of the structure to the wind but has no impact on the load on the structure. The reason for this change is that the “two story-only” requirement puts artificial limitations on the use of the shutter provisions. This requirement has been used to limit the use of the shutter provisions from 3-story residential structures built on sloped surfaces or with the first story partially embedded in the ground. In either of the cases the mean roof height may be 33 feet or less.

From the other perspective, the geometry of a two-story house could be such that the mean roof height exceeds 33 feet. This would make the analytical basis for the shutter design incorrect.

This proposal will also eliminate the confusion in the provision that first limits the exception to two-stories and then in the last sentence of the paragraph limits it to a 33 foot mean roof height.

The provisions in the code were originally based on a mean roof height of 33 feet; the shift to two-story was an unfortunate attempt at simplifying the provisions of the early high-wind prescriptive publications. Approval of this change will correct an unintended consequence of this attempt at simplification. Please vote for approval of this provision.

Cost Impact: The code change proposal will not increase the cost of construction.

RB41-13

	Assembly:	ASF	AMF	DF

R301.2.1.2-RB-KEITH

RB42 – 13

R301.2.1.2

Proponent: Julie Ruth, P.E., JRuth Code Consulting, representing the American Architectural Manufacturers Association (julruth@aol.com); Daniel J. Walker, P.E., Thomas Associates, representing the National Sunroom Association

Revise as follows:

R301.2.1.2 Protection of openings. Exterior glazing in buildings located in windborne debris regions shall be protected from windborne debris. Glazed opening protection for windborne debris shall meet the requirements of the Large Missile Test of ASTM E 1996 and ASTM E 1886 referenced therein. The applicable wind zones for establishing missile types in ASTM E 1996 are shown on Figure R301.2(4)C. Garage door glazed opening protection for windborne debris shall meet the requirements of an *approved* impact-resisting standard or ANSI/DASMA 115.

Exceptions:

1. Wood structural panels with a minimum thickness of 7/16 inch (11 mm) and a maximum span of 8 feet (2438 mm) shall be permitted for opening protection in one- and two-story buildings. Panels shall be precut and attached to the framing surrounding the opening containing the product with the glazed opening. Panels shall be predrilled as required for the anchorage method and shall be secured with the attachment hardware provided. Attachments shall be designed to resist the component and cladding loads determined in accordance with either Table R301.2(2) or ASCE 7 with the permanent corrosion-resistant attachment hardware provided and anchors permanently installed on the building. Attachment in accordance with Table R301.2.1.2 is permitted for buildings with a mean roof height of 33 feet (10 058 mm) or less where located in Wind Zones 1 and 2 in accordance with Figure R301.2(4)C.
2. Openings in walls enclosing sunrooms, balconies or porches constructed under existing roofs or decks are not required to be protected provided that the spaces are separated from the building interior by a wall and all openings in that separating wall are protected in accordance with this section. Such spaces shall be permitted to be designed as either partially enclosed or enclosed structures.

Reason: Frequently spaces such as sunrooms, balconies or porches that are separated from the interior of a building by an exterior wall will be constructed under existing roofs or decks. There may or may not be walls enclosing these spaces, or there may only be walls on one, two or three sides of the space. Or the space may be enclosed on all four sides, but still separated from the interior space by an exterior wall.

Although the spaces are provided some degree of protection from exterior elements such as sun, wind, rain or snow by the overhead assembly, and possibly by one or more enclosure walls, they are outside the building envelope and not completely protected from the exterior elements. They are not treated as interior, habitable spaces. They are exterior spaces.

It is not appropriate to require openings in the walls that may partially or completely enclose these spaces to be protected from wind borne debris, since these are exterior spaces, the walls themselves are not required and these spaces might otherwise be subject to wind borne debris regardless of whether or not openings in any enclosing walls are breached.

This proposal adds an exception for these spaces to the existing protection of opening requirements of the IRC. The exception is limited to spaces that are separated from the building interior by a wall whose openings are protected from wind borne debris. For the purposes of the application of ASCE 7, the enclosures of these spaces are to be designed as either partially or completely enclosed structures.

Cost Impact: None.

(Portions of table not shown remain unchanged.)

R602.10.6.5.1 Length of bracing. The length of bracing along each braced wall line shall be the greater of that required by the basic design wind speed and braced wall line spacing in accordance with Table R602.10.3(1) as adjusted by the factors in the Table R602.10.3(2) or the Seismic Design Category and braced wall line length in accordance with Table R602.10.6.5. Angled walls shall be permitted to be counted in accordance with Section R602.10.1.4, and braced wall panel location shall be in accordance with Section R602.10.2.2. The seismic adjustment factors in Table R602.10.3(4) shall not be applied to the length of bracing determined using Table R602.10.6.5. In no case shall the minimum total length of bracing in a braced wall line, after all adjustments have been taken, be less than 48 inches (1219 mm) total.

R602.10.8.2 Connections to roof framing. Top plates of exterior braced wall panels shall be attached to rafters or roof trusses above in accordance with Table R602.3(1) and this section. Where required by this section, blocking between rafters or roof trusses shall be attached to top plates of braced wall panels and to rafters and roof trusses in accordance with Table R602.3(1). A continuous band, rim, or header joist or roof truss parallel to the braced wall panels shall be permitted to replace the blocking required by this section. Blocking shall not be required over openings in continuously-sheathed braced wall lines. In addition to the requirements of this section, lateral support shall be provided for rafters and ceiling joists in accordance with Section R802.8 and for trusses in accordance with Section R802.10.3. Roof ventilation shall be provided in accordance with Section R806.1.

1. For Seismic Design Categories A, B and C and basic wind speeds less than 100 mph (45 m/s) where the distance from the top of the braced wall panel to the top of the rafters or roof trusses above is 91/4 inches (235 mm) or less, blocking between rafters or roof trusses shall not be required. Where the distance from the top of the braced wall panel to the top of the rafters or roof trusses above is between 91/4 inches (235 mm) and 151/4 inches (387 mm), blocking between rafters or roof trusses shall be provided above the braced wall panel in accordance with Figure R602.10.8.2(1).
2. For Seismic Design Categories D0, D1 and D2 or basic wind speeds of 100 mph (45 m/s) or greater, where the distance from the top of the braced wall panel to the top of the rafters or roof trusses is 151/4 inches (387 mm) or less, blocking between rafters or roof trusses shall be provided above the braced wall panel in accordance with Figure R602.10.8.2(1).
3. Where the distance from the top of the *braced wall panel* to the top of rafters or roof trusses exceeds 15¹/₄ inches (387 mm), the top plates of the *braced wall panel* shall be connected to perpendicular rafters or roof trusses above in accordance with one or more of the following methods:
 - 3.1. Soffit blocking panels constructed in accordance with Figure R602.10.8.2(2);
 - 3.2. Vertical blocking panels constructed in accordance with Figure R602.10.8.2(3);
 - 3.3. Full-height engineered blocking panels designed in accordance with the AF&PA WFCM; or
 - 3.4. Blocking, blocking panels, or other methods of lateral load transfer designed in accordance with accepted engineering practice.

R603.1.1 Applicability limits. The provisions of this section shall control the construction of exterior cold-formed steel wall framing and interior load-bearing cold-formed steel wall framing for buildings not more than 60 feet (18 288 mm) long perpendicular to the joist or truss span, not more than 40 feet (12 192 mm) wide parallel to the joist or truss span, and less than or equal to three stories above *grade plane*. All exterior walls installed in accordance with the provisions of this section shall be considered as load-bearing walls. Cold-formed steel walls constructed in accordance with the provisions of this section shall be limited to sites ~~subjected to a maximum~~ where the basic design wind speed is not greater than ~~of~~ 110 miles per hour (49 m/s), the Exposure Category is B or C, and ~~the a maximum~~ ground snow load is not greater than ~~of~~ 70 pounds per square foot (3.35 kPa).

TABLE R603.8
HEAD AND SILL TRACK SPAN

(Portions of table not shown remain unchanged.)

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 mile per hour = 0.447 m/s.

- Deflection limit: $L/240$.
- Head and sill track spans are based on components and cladding wind pressures speeds and 48 inch tributary span.
- For openings less than 4 feet in height that have both a head track and sill track, the above spans are permitted to be multiplied by 1.75. For openings less than or equal to 6 feet in height that have both a head track and a sill track, the above spans are permitted to be multiplied by a factor of 1.5.

R603.9.4.1 Wind speeds greater than 100 mph. Where ~~the basic wind speeds are in excess of~~ exceeds 100 miles per hour (45 m/s) ~~and, Exposure C or D applies,~~ walls shall be provided with ~~wind~~ direct uplift connections in accordance with AISI S230, Section E13.3, and AISI S230, Section F7.2, as required for 110 miles per hour (49 m/s), Exposure C.

R611.2 Applicability limits. The provisions of this section shall apply to the construction of exterior concrete walls for buildings not greater than 60 feet (18 288 mm) in plan dimensions, floors with clear spans not greater than 32 feet (9754 mm) and roofs with clear spans not greater than 40 feet (12 192 mm). Buildings shall not exceed 35 feet (10 668 mm) in mean roof height or two stories in height above-grade. Floor/ceiling dead loads shall not exceed 10 pounds per square foot (479 Pa), roof/ceiling dead loads shall not exceed 15 pounds per square foot (718 Pa) and *attic* live loads shall not exceed 20 pounds per square foot (958 Pa). Roof overhangs shall not exceed 2 feet (610 mm) of horizontal projection beyond the exterior wall and the dead load of the overhangs shall not exceed 8 pounds per square foot (383 Pa).

Walls constructed in accordance with the provisions of this section shall be limited to buildings ~~subjected to a maximum~~ where the basic design wind speed is not greater than ~~of~~ 130 miles per hour (58 m/s) Exposure B, 110 miles per hour (49 m/s) Exposure C and 100 miles per hour (45 m/s) Exposure D. Walls constructed in accordance with the provisions of this section shall be limited to detached one- and two-family *dwellings* and townhouses assigned to Seismic Design Category A or B, and detached one- and two-family *dwellings* assigned to Seismic Design Category C.

R613.2 Applicability limits. The provisions of this section shall control the construction of exterior structural insulated panel walls and interior load-bearing structural insulated panel walls for buildings not greater than 60 feet (18 288 mm) in length perpendicular to the joist or truss span, not greater than 40 feet (12 192 mm) in width parallel to the joist or truss span and not greater than two stories in height with each wall not greater than 10 feet (3048 mm) high. All exterior walls installed in accordance with the provisions of this section shall be considered as load-bearing walls. Structural insulated panel walls constructed in accordance with the provisions of this section shall be limited to sites where the basic ~~subjected to a maximum design~~ wind speed is not greater than ~~of~~ 130 miles per hour (58 m/s), the

Exposure Category is A, B or C, and a ~~maximum~~ the ground snow load is not greater than of 70 pounds per foot (3.35 kPa), and the Seismic Design Category is ~~Categories~~ A, B, or and C.

(Portions of table not shown remain unchanged.)

Revise as follows:

R802.10.2.1 Applicability limits. The provisions of this section shall control the design of truss roof framing when snow controls for buildings not greater than 60 feet (18 288 mm) in length perpendicular to the joist, rafter or truss span, not greater than 36 feet (10 973 mm) in width parallel to the joist, rafter or truss span, not greater than two stories in height with each *story* not greater than 10 feet (3048 mm) high, and roof slopes not smaller than 3:12 (25-percent slope) or greater than 12:12 (100-percent slope). Truss roof framing constructed in accordance with the provisions of this section shall be limited to sites ~~subjected to a maximum~~ where the basic design wind speed is not greater than of 110 miles per hour (49 m/s), the Exposure Category is A, B or C, and the ~~a maximum~~ ground snow load is not greater than of 70 pounds per square foot (3.35 kPa). For consistent loading of all truss types, roof snow load is to be computed as: 0.7 *pg*.

R804.1.1 Applicability limits. The provisions of this section shall control the construction of cold-formed steel roof framing for buildings not greater than 60 feet (18 288 mm) perpendicular to the joist, rafter or truss span, not greater than 40 feet (12 192 mm) in width parallel to the joist span or truss, less than or equal to three stories above *grade* plane and with roof slopes not less than 3:12 (25-percent slope) or greater than 12:12 (100 percent slope). Cold-formed steel roof framing constructed in accordance with the provisions of this section shall be limited to sites ~~subjected to a maximum~~ where the basic design wind speed is not greater than of 110 miles per hour (49 m/s), the Exposure Category is B or C, and the ~~a maximum~~ ground snow load is not greater than of 70 pounds per square foot (3.35 kPa).

R804.3.2.1 Minimum roof rafter sizes. Roof rafter size and thickness shall be determined in accordance with the limits set forth in Tables R804.3.2.1(1) and R804.3.2.1(2) based on the horizontal projection of the roof rafter span. For determination of roof rafter sizes, reduction of roof spans shall be permitted when a roof rafter support brace is installed in accordance with Section R804.3.2.2. The reduced roof rafter span shall be taken as the larger of the distance from the roof rafter support brace to the ridge or to the heel measured horizontally.

For the purpose of determining roof rafter sizes in Tables R804.3.2.1(1) and R804.3.2.1(2), basic wind speeds shall be converted to equivalent ground snow loads in accordance with Table R804.3.2.1(3). Roof rafter sizes shall be based on the higher of the ground snow load or the equivalent snow load converted from the basic wind speed.

R804.3.3 Hip framing. Hip framing shall consist of jack-rafters, hip members, hip support columns and connections in accordance with this section, or shall be in accordance with an *approved* design. The provisions of this section for hip members and hip support columns shall apply only where the jack rafter slope is greater than or equal to the roof slope. For the purposes of determining member sizes in this section, basic wind speeds shall be converted to equivalent ground snow load in accordance with Table R804.3.2.1(3).

Revise as follows:

R905.3.7 Application. Tile shall be applied in accordance with this chapter and the manufacturer's installation instructions, based on the following:

Clay and concrete roof tiles shall be fastened in accordance with this section and the manufacturer's installation instructions. Perimeter tiles shall be fastened with a minimum of one fastener per tile. Tiles with installed weight less than 9 pounds per square foot (0.4 kg/m²) require a minimum of one fastener per tile regardless of roof slope. Clay and concrete roof tile attachment shall be in accordance with the manufacturer's installation instructions where applied in areas where the basic wind speed exceeds 100 miles per hour (45 m/s) and on buildings where the roof is located more than 40 feet (12 192 mm) above *grade*. In areas subject to snow, a minimum of two fasteners per tile is required. In all other areas, clay and concrete roof tiles shall be attached in accordance with Table R905.3.7.

Reason: This proposal is submitted by the ICC Building Code Action Committee (BCAC). The BCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance an assigned International Code or portion thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the BCAC has held 6 open meetings and numerous workgroup calls which included members of the BCAC as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: <http://www.iccsafe.org/cs/BCAC/Pages/default.aspx>.

The purpose of this proposal is to coordinate terminology in the code. Figure R301.2.4(A) supplies the "basic wind speed", defined as the "three-second gust speed at 33 feet (10 058 mm) above the ground in Exposure C (see Section R301.2.1). This wind speed, derived from ASCE 7, is a design wind speed based on an extensive modeling process using historical data, wind characteristics and computer simulations. It is not necessarily the "maximum" wind speed that can be experienced by a site, nor does it suggest the "maximum" wind speed an element is capable of resisting due to factors of safety in material standards and design procedures. This proposal corrects references throughout the IRC to properly refer to "basic wind speed."

Cost Impact: None

R301.2.1.4, R603.3.2, R613.2, Table R613.5(1), Table R613.5(2), R802.10.2.1

Proponent: Matthew L. Mlakar, Barrish Pelham and Associates, Inc., representing Structural Engineers Association of California

Revise as follows:

R301.2.1.4 Exposure category. For each wind direction considered, an exposure category that adequately reflects the characteristics of ground surface irregularities shall be determined for the site at which the building or structure is to be constructed. For a site located in the transition zone between categories, the category resulting in the largest wind forces shall apply. Account shall be taken of variations in ground surface roughness that arise from natural topography and vegetation as well as from constructed features. For a site where multiple detached one- and two-family dwellings, *townhouses* or other structures are to be constructed as part of a subdivision, master-planned community, or otherwise designated as a developed area by the authority having jurisdiction, the exposure category for an individual structure shall be based upon the site conditions that will exist at the time when all adjacent structures on the site have been constructed, provided their construction is expected to begin within one year of the start of construction for the structure for which the exposure category is determined. For any given wind direction, the exposure in which a specific building or other structure is sited shall be assessed as being one of the following categories:

- ~~1. Exposure A. Large city centers with at least 50 percent of the buildings having a height in excess of 70 feet (21 336 mm). Use of this exposure category shall be limited to those areas for which terrain representative of Exposure A prevails in the upwind direction for a distance of at least 0.5 mile (0.8 km) or 10 times the height of the building or other structure, whichever is greater. Possible channeling effects or increased velocity pressures due to the building or structure being located in the wake of adjacent buildings shall be taken into account.~~
12. Exposure B. Urban and suburban areas, wooded areas, or other terrain with numerous closely spaced obstructions having the size of single-family dwellings or larger. Exposure B shall be assumed unless the site meets the definition of another type exposure.
23. Exposure C. Open terrain with scattered obstructions, including surface undulations or other irregularities, having heights generally less than 30 feet (9144 mm) extending more than 1,500 feet (457 m) from the building site in any quadrant. This exposure shall also apply to any building located within Exposure B type terrain where the building is directly adjacent to open areas of Exposure C type terrain in any quadrant for a distance of more than 600 feet (183 m). This category includes flat open country and grasslands.
34. Exposure D. Flat, unobstructed areas exposed to wind flowing over open water for a distance of at least 1 mile (1.61 km). Shorelines in Exposure D include inland waterways, the Great Lakes, and coastal areas of California, Oregon, Washington and Alaska. This exposure shall apply only to those buildings and other structures exposed to the wind coming from over the water. Exposure D extends inland from the shoreline a distance of 1500 feet (457 m) or 10 times the height of the building or structure, whichever is greater.

Revise as follows:

R603.3.2 Minimum stud sizes. Cold-formed steel walls shall be constructed in accordance with Figures R603.3.1(1), R603.3.1(2), or R603.3.1(3), as applicable. Exterior wall stud size and thickness shall be determined in accordance with the limits set forth in Tables R603.3.2(2) through R603.3.2(31). Interior load-bearing wall stud size and thickness shall be determined in accordance with the limits set forth in Tables R603.3.2(2) through R603.3.2(31) based upon an 85 miles per hour (38 m/s) Exposure A/B wind value and the building width, stud spacing and snow load, as appropriate. Fastening requirements shall be in accordance with Section R603.2.4 and Table R603.3.2(1). Top and bottom tracks shall have the same minimum thickness as the wall studs.

(No change to remaining text)

R613.2 Applicability limits. The provisions of this section shall control the construction of exterior structural insulated panel walls and interior load-bearing structural insulated panel walls for buildings not greater than 60 feet (18 288 mm) in length perpendicular to the joist or truss span, not greater than 40 feet (12 192 mm) in width parallel to the joist or truss span and not greater than two stories in height with each wall not greater than 10 feet (3048 mm) high. All exterior walls installed in accordance with the provisions of this section shall be considered as load-bearing walls. Structural insulated panel walls constructed in accordance with the provisions of this section shall be limited to sites subjected to a maximum design wind speed of 120 miles per hour (54 m/s), Exposure A or B or, 110 miles per hour (49 m/s) Exposure C, and a maximum ground snow load of 70 pounds per foot (3.35 kPa), and Seismic Design Categories A, B, and C.

TABLE R613.5(1)
MINIMUM THICKNESS FOR SIP WALL SUPPORTING SIP LIGHT-FRAME ROOF ONLY (inches)^a

Building Width (ft)							
Wind Speed (3-sec gust)		Snow Load (psf)	24	28	32	36	40
Exp A/B	Exp. C		Wall Height (feet)	Wall Height (feet)	Wall Height (feet)	Wall Height (feet)	Wall Height (feet)

(Portions of table not shown to remain unchanged.)

TABLE R613.5(2)
MINIMUM THICKNESS FOR SIP WALLS SUPPORTING SIP OR LIGHT-FRAME ONE STORY AND ROOF (inches)^a

Building Width (ft)							
Wind Speed (3 –sec gust)		Snow Load (psf)	24	28	32	36	40
Exp A/B	Exp. C		Wall Height (feet)	Wall Height (feet)	Wall Height (feet)	Wall Height (feet)	Wall Height (feet)

(Portions of table not shown to remain unchanged.)

Revise as follows:

R802.10.2.1 Applicability limits. The provisions of this section shall control the design of truss roof framing when snow controls for buildings not greater than 60 feet (18 288 mm) in length perpendicular to the joist, rafter or truss span, not greater than 36 feet (10 973 mm) in width parallel to the joist, rafter or truss span, not more than three stories above *grade plane* in height, and roof slopes not smaller than 3:12 (25-percent slope) or greater than 12:12 (100-percent slope). Truss roof framing constructed in accordance with the provisions of this section shall be limited to sites subjected to a maximum design wind speed of 110 miles per hour (49 m/s), Exposure A, B or C, and a maximum ground snow load of 70 psf (3352 Pa). For consistent loading of all truss types, roof snow load is to be computed as: $0.7 p_g$.

Reason: Exposure category A is no longer listed as an exposure category under ASCE 7-10 section 26.7.3, nor is it used in the current edition of the IBC. Most of the references to Exposure A have been removed from the IRC, however, a few still remain. The four sections and two tables included in this proposal represent the remaining locations where Exposure A is referenced. The removal of Exposure A will bring the IRC in line with the IBC and industry standards.

Cost Impact: The proposed code change will not change the cost of construction.

R301.2.1.4 #1-RB-MLAKAR

RB45 – 13

R301.2.1.4

Proponent: Matthew L. Mlakar, Barrish Pelham and Associates, Inc., representing Structural Engineers Association of California

Revise as follows:

R301.2.1.4 Exposure category. For each wind direction considered, an exposure category that adequately reflects the characteristics of ground surface irregularities shall be determined for the site at which the building or structure is to be constructed. For a site located in the transition zone between categories, the category resulting in the largest wind forces shall apply. Account shall be taken of variations in ground surface roughness that arise from natural topography and vegetation as well as from constructed features. For a site where multiple detached one- and two-family dwellings, *townhouses* or other structures are to be constructed as part of a subdivision, master-planned community, or otherwise designated as a developed area by the authority having jurisdiction, the exposure category for an individual structure shall be based upon the site conditions that will exist at the time when all adjacent structures on the site have been constructed, provided their construction is expected to begin within one year of the start of construction for the structure for which the exposure category is determined. For any given wind direction, the exposure in which a specific building or other structure is sited shall be assessed as being one of the following categories:

1. Exposure A. Large city centers with at least 50 percent of the buildings having a height in excess of 70 feet (21 336 mm). Use of this exposure category shall be limited to those areas for which terrain representative of Exposure A prevails in the upwind direction for a distance of at least 0.5 mile (0.8 km) or 10 times the height of the building or other structure, whichever is greater. Possible channeling effects or increased velocity pressures due to the building or structure being located in the wake of adjacent buildings shall be taken into account.
2. Exposure B. Urban and suburban areas, wooded areas, or other terrain with numerous closely spaced obstructions having the size of single-family dwellings or larger. Exposure B shall be assumed unless the site meets the definition of another type exposure.
3. Exposure C. Open terrain with scattered obstructions, including surface undulations or other irregularities, having heights generally less than 30 feet (9144 mm) extending more than 1,500 feet (457 m) from the building site in any quadrant. This exposure shall also apply to any building located within Exposure B type terrain where the building is directly adjacent to open areas of Exposure C type terrain in any quadrant for a distance of more than 600 feet (183 m). This category includes flat open country and grasslands.
4. Exposure D. Flat, unobstructed areas exposed to wind flowing over open water, smooth mud flats, salt flats and unbroken ice for a distance of at least 1 mile (1.61 km) 5000 feet (1,524m). ~~Shorelines in Exposure D include inland waterways, the Great Lakes, and coastal areas of California, Oregon, Washington and Alaska.~~ This exposure shall apply only to those buildings and other structures exposed to the wind coming from over the water unobstructed area. Exposure D extends ~~inland~~ downwind from the ~~shoreline~~ edge of the unobstructed area a distance of ~~1500 feet (457 m)~~ 600 feet (183 m) or ~~10-20~~ times the height of the building or structure, whichever is greater.

Reason: The 2012 IRC definition for wind exposure category D does not match the definition in either the 2012 IBC or ASCE 7-10. Under ICC CP#28 policy section 1.3.1 the provisions of all codes shall be consistent with one another so that conflicts between codes do not occur. The proposed change is to incorporate the language of ASCE 7-10 section 26.7.3 into the IRC. It should be noted that ASCE 7-10 now requires the use of exposure D along hurricane coastlines. ASCE 7-10 commentary section C26.7, cites recent research which provides data showing that the surface roughness over the ocean in a hurricane is consistent with that of exposure D rather than exposure C.

The change to the exposure categories will bring the IRC in line with the IBC and industry standards.

Cost Impact: The proposal is editorial and will not impact the cost of construction.

:

RB46 – 13

R301.2.1.4

Proponent: Andrew Herseth, US Dept of Homeland Security, Federal Emergency Management Agency (FEMA) and Glenn Overcash, URS Corporation representing FEMA

Revise as follows:

R301.2.1.4 Exposure category. For each wind direction considered, an exposure category that adequately reflects the characteristics of ground surface irregularities shall be determined for the site at which the building or structure is to be constructed. For a site located in the transition zone between categories, the category resulting in the largest wind forces shall apply. Account shall be taken of variations in ground surface roughness that arise from natural topography and vegetation as well as from constructed features. For a site where multiple detached one- and two-family dwellings, *townhouses* or other structures are to be constructed as part of a subdivision, master-planned community, or otherwise designated as a developed area by the authority having jurisdiction, the exposure category for an individual structure shall be based upon the site conditions that will exist at the time when all adjacent structures on the site have been constructed, provided their construction is expected to begin within one year of the start of construction for the structure for which the exposure category is determined. For any given wind direction, the exposure in which a specific building or other structure is sited shall be assessed as being one of the following categories:

- ~~1. Exposure A. Large city centers with at least 50 percent of the buildings having a height in excess of 70 feet (21 336 mm). Use of this exposure category shall be limited to those areas for which terrain representative of Exposure A prevails in the upwind direction for a distance of at least 0.5 mile (0.8 km) or 10 times the height of the building or other structure, whichever is greater. Possible channeling effects or increased velocity pressures due to the building or structure being located in the wake of adjacent buildings shall be taken into account.~~
- ~~2.1.~~ Exposure B. Urban and suburban areas, wooded areas, or other terrain with numerous closely spaced obstructions having the size of single family dwellings or larger. Use of this exposure category shall be limited to those areas for which terrain representative of Exposure B prevails in the upwind direction for a distance of at least 1,500 feet (460 m). Exposure B shall be assumed unless the site meets the definition of another type exposure.
- ~~3.2.~~ Exposure C. Open terrain with scattered obstructions, including surface undulations or other irregularities, having heights generally less than 30 feet (9144 mm) ~~extending more than 1,500 feet (457 m) from the building site in any quadrant.~~ This exposure shall also apply to any building located within Exposure B type terrain where the building is directly adjacent to open areas of Exposure C type terrain in any quadrant for a distance of more than 600 feet (183 m). This category includes flat, open country and grasslands. Exposure C shall be assumed unless the site meets the definition of another type exposure.
- ~~4.3.~~ Exposure D. Flat, unobstructed areas and areas exposed to wind flowing over open water for a distance of at least 5000 feet (1524 m) ~~1 mile (1.61 km).~~ Shorelines in Exposure D include inland waterways, the Great Lakes, and coastal areas of California, Oregon, Washington and Alaska. This exposure shall apply only to those buildings and other structures exposed to the wind coming from over the water. Exposure D extends inland from the shoreline a distance of 600 feet 1500 feet (457 m) or 20 ~~10~~ times the height of the building or structure, whichever is greater.

Reason: The purpose of this proposal is simply to update the methodology in the IRC for assigning an Exposure Category to a site, so that it is consistent with ASCE 7 and the IBC. The Exposure Category definitions in the IRC are essentially described in the same way that they were in the first version (2000) of the IRC. The Exposure Category definitions in ASCE 7 were substantially updated in the 2002 to include surface roughness concepts. These changes were subsequently incorporated in the 2006 IBC. Additionally, ASCE 7 and the IBC no longer refer to Exposure A. This proposal represents a simplified approach to bring the IRC up to date with some of the more substantial changes in site Exposure determination by maintaining language consistent with earlier versions of the code.

Exposure Categories provide a way of establishing the roughness of the terrain surrounding a building. The amount and type of roughness surrounding a building can significantly impact the applicable design wind loads. All things being equal, a building sited in Exposure C would have to be designed for wind loads that are approximately 20% higher than for the same building sited in

Exposure B. Similarly, a building sited in Exposure D would have to be designed for wind loads that are approximately 20% higher than for the same building sited in Exposure C. Therefore, the determination of the most likely Exposure at the site is essential to the determination of the appropriate wind loads for a building.

More importantly, the current Exposure Category definitions result in some anomalies related to Exposure Categories B and C. For example, consider a building that had a 100 ft buffer of trees on the north face of the building. Beyond the 100 ft buffer is completely open terrain. ASCE 7 and the IBC would clearly define the Exposure Category for this site as C. However, the IRC would define this site as Exposure B. Additionally, if the north side of the building was subject to wind blowing over a length of open water that was $\frac{3}{4}$ of a mile, the code is not very clear which Exposure Category would apply. However, Exposure D would not apply to the site because the length of the water Exposure is less than 1 mile. As such, the described Exposure condition doesn't fit within the description for Exposure C as currently established by the code. Therefore, the user may default to Exposure B, when ASCE 7 and IBC would be clear that situation would qualify as Exposure C.

Lastly, ASCE 7 and the IBC differ from the IRC with regard to Exposure D. The IRC requires Exposure D to extend inland from the shoreline 1500 ft or 10 times the height of the building, whichever is greater. ASCE 7 and the IBC essentially require Exposure D to extend inland from the shoreline 600 feet or 20 times the height of the building, whichever is greater. .

Eight years ago, FEMA P-488, *Mitigation Assessment Team Report: Hurricane Charley in Florida* (FEMA, 2004), recommended that Exposure Categories used in design be defined in a manner consistent with ASCE 7-02. It noted specifically that the refinements to design guidance for Exposure Categories included in ASCE 7-02 would help ensure that full-wind loads are calculated in open areas (Exposure C) where speed reductions are not appropriate. As previously noted, while the IBC adopted the updated ASCE 7 methodology for assigning Exposure Categories in the 2006 edition, the IRC has yet to move forward and risks underestimation of wind pressure as a result.

Cost Impact: The code change proposal will not increase the cost of construction.

RB46-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R301.2.1.4-RB-HERSETH-OVERCASH

RB47 – 13

R301.2.2.2.1, Table R301.2.2.2.1

Proponent: Edward L. Keith, APA, representing The Engineered Wood Association
(ed.keith@apawood.org)

Revise as follows:

R301.2.2.2.1 Weights of materials. Average dead loads shall not exceed 15 pounds per square foot (720 Pa) for the combined roof and ceiling assemblies (on a horizontal projection) or 10 pounds per square foot (480 Pa) for floor assemblies, except as further limited by Section R301.2.2. Dead loads for walls above grade shall not exceed:

1. Fifteen pounds per square foot (720 Pa) for exterior light-frame wood walls.
2. Fourteen pounds per square foot (670 Pa) for exterior light-frame cold-formed steel walls.
3. Ten pounds per square foot (480 Pa) for interior light-frame wood walls.
4. Five pounds per square foot (240 Pa) for interior light-frame cold-formed steel walls.
5. Eighty pounds per square foot (3830 Pa) for 8-inch-thick (203 mm) masonry walls.
6. Eighty-five pounds per square foot (4070 Pa) for 6-inch-thick (152 mm) concrete walls.
7. Ten pounds per square foot (480 Pa) for SIP walls.

Exceptions:

- ~~1. Roof and ceiling dead loads not exceeding 25 pounds per square foot (1190 Pa) shall be permitted provided the wall bracing amounts in Chapter 6 are increased in accordance with Table R301.2.2.2.1.~~
12. Light-frame walls with stone or masonry veneer shall be permitted in accordance with the provisions of Sections R702.1 and R703.
23. Fireplaces and chimneys shall be permitted in accordance with Chapter 10.

TABLE R301.2.2.2.1
WALL BRACING ADJUSTMENT FACTORS BY
ROOF COVERING DEAD LOAD^a

WALL SUPPORTING	ROOF/CEILING DEAD LOAD	
	15 psf or less	25 psf
Roof only	1.0	1.2
Roof plus one or two stories	1.0	1.1

For SI: 1 pound per square foot = 0.0479 kPa

a. Linear interpolation shall be permitted.

Reason: Exception 1 proposed for deletion in this proposal calls for the adjustment of the bracing amount in Chapter 6 to be increased by the Table R301.2.2.2.1 amounts. Currently the same adjustments are duplicated in Chapter 6 in Table R602.10.3(4) for the adjustment based on: "Roof/ceiling dead load for wall supporting". The way the exception is written could require the same adjustments be applied twice; once when determining Chapter 6 bracing, and once again it comply with Section R301.2.2.2.1. Deleting the requirement in Section R301.2.2.2.1 would eliminate the potential for "double dipping" and eliminate the resulting unnecessary construction costs.

Cost Impact: This code change proposal will not increase the cost of construction.

R301.2.2.2.5, R301.2.2.1.2, R502.2.2 (New), R502.3.3.1 (New), Table R502.3.3(1), R502.10.1 (New), R602.10, R602.10.9, R603.1.1, R802.9.1, AJ104.1

Proponent: Charles S. Bajnai, Chesterfield County, VA, ICC Building Code Action Committee (bajnaic@chesterfield.gov)

Revise as follows:

~~R301.2.2.2.5 Irregular buildings.~~ The seismic provisions of this code shall not be used for irregular structures located in Seismic Design Categories C, D0, D1 and D2. Irregular portions of structures shall be designed in accordance with accepted engineering practice to the extent the irregular features affect the performance of the remaining structural system. When the forces associated with the irregularity are resisted by a structural system designed in accordance with accepted engineering practice, design of the remainder of the building shall be permitted using the provisions of this code. A building or portion of a building shall be considered to be irregular when one or more of the following conditions occur:

- ~~1. When exterior shear wall lines or *braced wall panels* are not in one plane vertically from the foundation to the uppermost story in which they are required.~~

Exception: For wood light frame construction, floors with cantilevers or setbacks not exceeding four times the nominal depth of the wood floor joists are permitted to support *braced wall panels* that are out of plane with *braced wall panels* below provided that:

- ~~1. Floor joists are nominal 2 inches by 10 inches (51 mm by 254 mm) or larger and spaced not more than 16 inches (406 mm) on center.~~
- ~~2. The ratio of the back span to the cantilever is at least 2 to 1.~~
- ~~3. Floor joists at ends of *braced wall panels* are doubled.~~
- ~~4. For wood frame construction, a continuous rim joist is connected to ends of all cantilever joists. When spliced, the rim joists shall be spliced using a galvanized metal tie not less than 0.058 inch (1.5 mm) (16 gage) and 1 1/2 inches (38 mm) wide fastened with six 16d nails on each side of the splice or a block of the same size as the rim joist of sufficient length to fit securely between the joist space at which the splice occurs fastened with eight 16d nails on each side of the splice; and 5. Gravity loads carried at the end of cantilevered joists are limited to uniform wall and roof loads and the reactions from headers having a span of 8 feet (2438 mm) or less.~~

- ~~2. When a section of floor or roof is not laterally supported by shear walls or *braced wall lines* on all edges.~~

Exception: Portions of floors that do not support shear walls or *braced wall panels* above, or roofs, shall be permitted to extend no more than 6 feet (1829 mm) beyond a shear wall or *braced wall line*.

- ~~3. When the end of a *braced wall panel* occurs over an opening in the wall below and ends at a horizontal distance greater than 1 foot (305 mm) from the edge of the opening. This provision is applicable to shear walls and *braced wall panels* offset in plane and to *braced wall panels* offset out of plane as permitted by the exception to Item 1 above.~~

Exception: For wood light frame wall construction, one end of a *braced wall panel* shall be permitted to extend more than 1 foot (305 mm) over an opening not more than 8 feet (2438 mm) wide in the wall below provided that the opening includes a header in accordance with the following:

- ~~1. The building width, loading condition and framing member species limitations of Table R502.5(1) shall apply; and~~

- ~~2. Not less than one 2 × 12 or two 2 × 10 for an opening not more than 4 feet (1219 mm) wide;
or~~
- ~~3. Not less than two 2 × 12 or three 2 × 10 for an opening not more than 6 feet (1829 mm) wide;
or~~
- ~~4. Not less than three 2 × 12 or four 2 × 10 for an opening not more than 8 feet (2438 mm) wide;
and~~
- ~~5. The entire length of the *braced wall panel* does not occur over an opening in the wall below.~~
- ~~4. When an opening in a floor or roof exceeds the lesser of 12 feet (3658 mm) or 50 percent of the least floor or roof dimension.~~
- ~~5. When portions of a floor level are vertically offset.~~

Exceptions:

- ~~1. Framing supported directly by continuous foundations at the perimeter of the building.~~
- ~~2. For wood light-frame construction, floors shall be permitted to be vertically offset when the floor framing is lapped or tied together as required by Section R502.6.1.~~
- ~~6. When shear walls and *braced wall lines* do not occur in two perpendicular directions.~~
- ~~7. When stories above *grade* plane partially or completely braced by wood wall framing in accordance with Section R602 or steel wall framing in accordance with Section R603 include masonry or concrete construction.~~

Exception: ~~Fireplaces, chimneys and masonry veneer as permitted by this code. When this irregularity applies, the entire story shall be designed in accordance with accepted engineering practice.~~

R301.2.2.1.2 Alternative determination of Seismic Design Category E. Buildings located in Seismic Design Category E in accordance with Figure R301.2(2) are permitted to be reclassified as being in Seismic Design Category D 2 provided one of the following is done:

1. A more detailed evaluation of the seismic design category is made in accordance with the provisions and maps of the International Building Code. Buildings located in Seismic Design Category E per Table R301.2.2.1.1, but located in Seismic Design Category D per the International Building Code, may be designed using the Seismic Design Category D2 requirements of this code.
2. Buildings located in Seismic Design Category E that conform to the following additional restrictions are permitted to be constructed in accordance with the provisions for Seismic Design Category D2 of this code:
 - 2.1. All exterior shear wall lines or braced wall panels are in one plane vertically from the foundation to the uppermost story.
 - 2.2. Floors shall not cantilever past the exterior walls.
 - 2.3. The building or portions of the building are constructed in accordance with the requirements for structures assigned to Seismic Design Category D2 elsewhere in this code. ~~is within all of the requirements of Section R301.2.2.2.5 for being considered as regular.~~

Revise as follows:

R502.2 Design and construction. Floors shall be designed and constructed in accordance with the provisions of this chapter, Figure R502.2 and Sections R317 and R318 or in accordance with AF&PA/NDS.

R502.2.1 Framing at braced wall lines. A load path for lateral forces shall be provided between floor framing and *braced wall panels* located above or below a floor, as specified in Section R602.10.8.

R502.2.2 Vertically offset floor diaphragms in Seismic Design Category C, D0, D1 and D2. In structures or portions of structures in Seismic Design Category C, D0, D1 and D2, floor diaphragms or portions of floor diaphragms shall not be vertically offset.

Exceptions:

1. Framing supported directly by continuous foundations at the perimeter of the building.
2. For wood light-frame construction, floors shall be permitted to be vertically offset when the floor framing is lapped or tied together as required by Section R502.6.1.

R502.3.3 Floor cantilevers. Floor cantilever spans shall not exceed the nominal depth of the wood floor joist. Floor cantilevers constructed in accordance with Table R502.3.3(1) shall be permitted when supporting a light frame bearing wall and roof only. Floor cantilevers supporting an exterior balcony are permitted to be constructed in accordance with Table R502.3.3(2).

R502.3.3.1 Floor cantilevers in Seismic Design Categories D0, D1 or D2. Floor cantilevers supporting *braced wall panels* in all structures assigned to *Seismic Design Categories* D0, D1 or D2 and in townhouses in Seismic Design Category C shall be constructed in accordance with Section R602.10.9.

TABLE R502.3.3(1)
CANTILEVER SPANS FOR FLOOR JOISTS SUPPORTING LIGHT-FRAME EXTERIOR BEARING
WALL AND ROOF ONLY^{a, b, c, f, g, h}
(Floor Live Load 540 psf, Roof Live Load)

(Portions of table not shown remain unchanged)

a through e (No changes to text)

f. See Section R301.2.2.2.5 R602.10.9, Item 1, for additional limitations on cantilevered floor joists for detached one- and two-family dwellings in Seismic Design Category D0, D1, or D2 and townhouses in Seismic Design Category C, D0, D1 or D2.

g through h (No change to text)

R502.10 Framing of openings. Openings in floor framing shall be framed with a header and trimmer joists. When the header joist span does not exceed 4 feet (1219 mm), the header joist may be a single member the same size as the floor joist. Single trimmer joists may be used to carry a single header joist that is located within 3 feet (914 mm) of the trimmer joist bearing. When the header joist span exceeds 4 feet (1219 mm), the trimmer joists and the header joist shall be doubled and of sufficient cross section to support the floor joists framing into the header. *Approved* hangers shall be used for the header joist to trimmer joist connections when the header joist span exceeds 6 feet (1829 mm). Tail joists over 12 feet (3658 mm) long shall be supported at the header by framing anchors or on ledger strips not less than 2 inches by 2 inches (51 mm by 51 mm).

R502.10.1 Framing of openings in Seismic Design Categories C, D0, D1 and D2. In structures in Seismic Design Category D0, D1 or D2 and in townhouses in Seismic Design Category C, where an opening in a floor exceeds the lesser of 12 feet (3658 mm) or 50 percent of the least floor dimension, that portion of the structure shall be designed in accordance with accepted engineering practice to the extent that the opening affects the performance of the remaining structural system.

Revise as follows:

R602.10 Wall bracing. Buildings shall be braced in accordance with this section or, when applicable, Section R602.12. Where a building, or portion thereof, does not comply with one or more of the bracing requirements in this section, those portions shall be designed and constructed in accordance with Section R301.1.

For all structures in Seismic Design Category D0, D1 or D2 and in townhouses in Seismic Design Category C, stories above grade plane partially or completely braced by wood wall framing in accordance with this section shall not include masonry or concrete construction or the entire story shall be designed in accordance with accepted engineering practice.

Exception: Fireplaces, chimneys and masonry veneer as permitted by this code.

R602.10.9 Braced wall panel support. *Braced wall panel* support shall be provided as follows:

1. Cantilevered floor joists complying with Section R502.3.3 shall be permitted to support *braced wall panels*.

For structures in Seismic Design Category D0, D1 and D2 and in townhouses in Seismic Design Category C, cantilevered floor joists supporting braced wall panels shall also comply with all of the following:

1. Floor joists shall be nominal 2 inches by 10 inches (51 mm by 254 mm) or larger and spaced not more than 16 inches (406 mm) on center.
 2. The ratio of the back span to the cantilever shall be at least 2 to 1.
 3. Floor joists at ends of *braced wall panels* shall be doubled.
 4. For wood-frame construction, a continuous rim joist shall be connected to ends of all cantilever joists. When spliced, the rim joists shall be spliced using a galvanized metal tie not less than 0.058 inch (1.5 mm) (16 gage) in thickness and 1 1/2 inches (38 mm) in width fastened with six 16d nails on each side of the splice or a block of the same size as the rim joist of sufficient length to fit securely between the joist space at which the splice occurs fastened with eight 16d nails on each side of the splice; and
 5. Gravity loads carried at the end of cantilevered joists shall be limited to uniform wall and roof loads and the reactions from headers having a span of 8 feet (2438 mm) or less.
2. Elevated post or pier foundations supporting *braced wall panels* shall be designed in accordance with accepted engineering practice.
 3. Masonry stem walls with a length of 48 inches (1219 mm) or less supporting *braced wall panels* shall be reinforced in accordance with Figure R602.10.9. Masonry stem walls with a length greater than 48 inches (1219 mm) supporting *braced wall panels* shall be constructed in accordance with Section R403.1 Methods ABW and PFH shall not be permitted to attach to masonry stem walls.
 4. Concrete stem walls with a length of 48 inches (1219 mm) or less, greater than 12 inches (305 mm) tall and less than 6 inches (152 mm) thick shall have reinforcement sized and located in accordance with Figure R602.10.9.
 5. For all structures in Seismic Design Category D0, D1 or D2 and in townhouses in Seismic Design Category C, the end of a *braced wall panel* over an opening in the wall below shall not extend a horizontal distance greater than 1 foot (305 mm) from the end of the panel to the edge of the opening. This provision is applicable to *braced wall panels* offset in plane and to *braced wall panels* offset out of plane as permitted by the exception to Item 1 above.

Exception: For wood light-frame wall construction, one end of a *braced wall panel* shall be permitted to extend more than 1 foot (305 mm) over an opening not more than 8 feet (2438 mm) wide in the wall below provided that the opening includes a header in accordance with the following:

1. The building width, loading condition and framing member species limitations of Table R502.5(1) shall apply; and
2. Not less than one 2 × 12 or two 2 × 10 for an opening not more than 4 feet (1219 mm) wide; or
3. Not less than two 2 × 12 or three 2 × 10 for an opening not more than 6 feet (1829 mm) wide; or
4. Not less than three 2 × 12 or four 2 × 10 for an opening not more than 8 feet (2438 mm) wide; and
5. The entire length of the *braced wall panel* does not occur over an opening in the wall below.

R603.1.1 Applicability limits. The provisions of this section shall control the construction of exterior cold-formed steel wall framing and interior load-bearing cold-formed steel wall framing for buildings not more than 60 feet (18 288 mm) long perpendicular to the joist or truss span, not more than 40 feet (12 192 mm) wide parallel to the joist or truss span, and less than or equal to three stories above *grade plane*. All exterior walls installed in accordance with the provisions of this section shall be considered as load-bearing walls. Cold-formed steel walls constructed in accordance with the provisions of this section shall be limited to sites subjected to a maximum design wind speed of 110 miles per hour (49 m/s) Exposure B or C and a maximum ground snow load of 70 pounds per square foot (3.35 kPa).

For all structures in Seismic Design Category D0, D1 or D2 and in townhouses in Seismic Design Category C, stories above grade plane walls partially or completely braced by cold-formed wall framing in accordance with this section shall not include masonry or concrete construction or the entire story shall be designed in accordance with accepted engineering practice.

Exception: Fireplaces, chimneys and masonry veneer as permitted by this code.

Revise as follows:

R802.9 Framing of openings. Openings in roof and ceiling framing shall be framed with header and trimmer joists. When the header joist span does not exceed 4 feet (1219 mm), the header joist may be a single member the same size as the ceiling joist or rafter. Single trimmer joists may be used to carry a single header joist that is located within 3 feet (914 mm) of the trimmer joist bearing. When the header joist span exceeds 4 feet (1219 mm), the trimmer joists and the header joist shall be doubled and of sufficient cross section to support the ceiling joists or rafter framing into the header. *Approved* hangers shall be used for the header joist to trimmer joist connections when the header joist span exceeds 6 feet (1829 mm). Tail joists over 12 feet (3658 mm) long shall be supported at the header by framing anchors or on ledger strips not less than 2 inches by 2 inches (51 mm by 51 mm).

R802.9.1 Framing of openings in Seismic Design Categories C, D0, D1 and D2. For structures or portions of structures in Seismic Design Category C, D0, D1 or D2 when an opening in a roof exceeds the lesser of 12 feet (3658 mm) or 50 percent of the least roof dimension, that portion of the structure shall be designed in accordance with accepted engineering practice to the extent the opening affects the performance of the remaining structural system.

Revise as follows:

SECTION AJ104 EVALUATION OF AN EXISTING BUILDING

AJ104.1 General. The *building official* may require an existing building to be investigated and evaluated by a registered design professional in the case of proposed reconstruction of any portion of a building. The evaluation shall determine the existence of any potential non-conformities to these provisions, and shall provide a basis for determining the impact of the proposed changes on the performance of the building. The evaluation shall use the following sources of information, as applicable:

1. Available documentation of the existing building.
 - 1.1. Field surveys.
 - 1.2. Tests (nondestructive and destructive).
 - 1.3. Laboratory analysis.

Exception: Detached one- or two-family dwellings that comply with Section R102.7. ~~are not irregular buildings under Section R301.2.2.2.5 and~~ are not undergoing an extensive reconstruction shall not be required to be evaluated.

Reason: This proposal is submitted by the ICC Building Code Action Committee (BCAC). The BCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance an assigned International Code or portion thereof. This includes

both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the BCAC has held 6 open meetings and numerous workgroup calls which included members of the BCAC as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: <http://www.iccsafe.org/cs/BCAC/Pages/default.aspx>.

This proposal is to delete the concept of "Irregular Structures" from Section R301.2.2.2.5 from the code and relocate the specific construction requirements of the irregular structures into the applicable sections of the code where they are relevant. As currently written, the list of items defining "Irregular Structures" in high seismic categories is a laundry list of items that cause the structure to be outside of the scope of this code. Then, for most of the defined irregularities there is an exception including technical construction requirements that, when done, allow the structure to not be classified as "Irregular". So, in essence, the current section of "Irregular structures" items are exceptions to the code. Then the exceptions to each item are exceptions to the exception. This makes poor code language.

In addition, many code users are not aware of these requirements because they are located in Chapter 3. As an example, when a code user is looking to the code to determine how to construct cantilever floor joists, they would go to Chapter 5, "Floor Framing". There is a section addressing cantilevers. However, in this section in Chapter 3 it says when a floor cantilevers and supports a wall above (not in the same vertical plane) it is irregular. Then the exception to the exception defines how to construct the floor so that it will not be considered irregular. The BCAC determined that it would be much better to actually include the cantilever construction requirements in the actual section in Chapter 5 that describes cantilevered floor construction.

This proposal does not make any technical changes to the code. It merely moves the construction requirements and limitations therein to the applicable sections that already exist in Chapter 5, Floor framing, Chapter 6, Wall framing and Chapter 8 Roof framing. The limitations are still applicable and by relocating them they will be more noticeable and apparent. The current code already has language and provisions to cover construction that exceeds the limitations of this code.

As shown below, R301.1 states that when, "... construction is in accordance with the provision of this code..." it is deemed to comply and the converse is true as well. When construction is NOT in accordance with the provisions it does not comply. Further, Section R301.1.3 it states that, "...elements exceeding the limits of Section R301 or otherwise not conforming to this code." shall require an engineered design. With the specific construction requirements now in the applicable code sections, those two provisions already exist and adequately address the cases when mandatory code requirements are exceeded.

R301.1 Application. *Buildings and structures, and all parts thereof, shall be constructed to safely support all loads, including dead loads, live loads, roof loads, flood loads, snow loads, wind loads and seismic loads as prescribed by this code. The construction of buildings and structures in accordance with the provisions of this code shall result in a system that provides a complete load path that meets all requirements for the transfer of all loads from their point of origin through the load-resisting elements to the foundation. Buildings and structures constructed as prescribed by this code are deemed to comply with the requirements of this section.*

R301.1.3 Engineered design. *When a building of otherwise conventional construction contains structural elements exceeding the limits of Section R301 or otherwise not conforming to this code, these elements shall be designed in accordance with accepted engineering practice. The extent of such design need only demonstrate compliance of nonconventional elements with other applicable provisions and shall be compatible with the performance of the conventional framed system. Engineered design in accordance with the International Building Code is permitted for all buildings and structures, and parts thereof, included in the scope of this code.*

The existing Section R301.2.2.2 defines limitations for the use and scope of this code for structures in Seismic Design Category C such as weights of materials, stone and masonry veneer, masonry and concrete construction. The existing Section R301.2.2.3 defines further limitations for Seismic Design Category D0, D1 and D2 in addition to the Seismic Design Category C limitations such as height limitations. These two sections remain as is and the current limitations apply. The net effect is the same and proposal makes the code much more user friendly and will prevent the oversight of the specific construction requirements and limitations that now exist in Chapter 3.

Cost Impact: The code change does not change the existing requirements of the code and will not increase the cost of construction.

RB48-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R301.2.2.2.5-RB-BAJNAI-BCAC

RB49 – 13

R301.2.2.2.5, R301.3, R803.2.3

Proponent: Bonnie Manley, P.E., American Iron and Steel Institute (bmanley@steel.org)

Revise as follows:

R301.2.2.2.5 Irregular buildings. The seismic provisions of this code shall not be used for irregular structures located in Seismic Design Categories C, D0, D1 and D2. Irregular portions of structures shall be designed in accordance with accepted engineering practice to the extent the irregular features affect the performance of the remaining structural system. When the forces associated with the irregularity are resisted by a structural system designed in accordance with accepted engineering practice, design of the remainder of the building shall be permitted using the provisions of this code. A building or portion of a building shall be considered to be irregular when one or more of the following conditions occur:

1 through 6 *(No changes to current text)*

7. When stories above *grade* plane partially or completely braced by wood wall framing in accordance with Section R602 or cold-formed steel wall framing in accordance with Section R603 include masonry or concrete construction.

Exception: Fireplaces, chimneys and masonry veneer as permitted by this code. When this irregularity applies, the entire *story* shall be designed in accordance with accepted engineering practice.

R301.3 Story height. The wind and seismic provisions of this code shall apply to buildings with story heights not exceeding the following:

1. *(No changes to current text)*

2. For cold-formed steel wall framing, a stud height of 10 feet (3048 mm), plus a height of floor framing not to exceed 16 inches (406 mm).

3 through 5 *(No changes to current text)*

Individual walls or walls studs shall be permitted to exceed these limits as permitted by Chapter 6 provisions, provided story heights are not exceeded. Floor framing height shall be permitted to exceed these limits provided the story height does not exceed 11 feet 7 inches (3531 mm). An engineered design shall be provided for the wall or wall framing members when they exceed the limits of Chapter 6. Where the story height limits of this section are exceeded, the design of the building, or the non-compliant portions thereof, to resist wind and seismic loads shall be in accordance with the International Building Code.

R803.2.3 Installation. Wood structural panel used as roof sheathing shall be installed with joints staggered or not staggered in accordance with Table R602.3(1), or APA E30 for wood roof framing or with Table R804.3 for cold-formed steel roof framing.

Reason: These editorial modifications correct the terminology to reflect what is adopted throughout the IRC and the IBC.

Cost Impact: No impact to the cost of construction is anticipated.

<p><u>3.</u></p>	<p>Where the end of a braced wall panel occurs over an opening in the wall below and ends at a horizontal distance greater than one (1) foot from the edge of the opening. This provision is applicable to shear walls and braced wall panels offset out of plane in accordance with Exception to Item 1 of Section R301.2.2.2.5 of this code.</p>	 <p>REQUIRED BRACED WALL PANEL</p> <p>MORE THAN 1'-0"</p> <p>EXTERIOR ELEVATION</p>
<p><u>4</u></p>	<p>Where an opening in a floor or roof exceeds the lesser of 12 feet or 50 percent of the least floor or roof dimension.</p>	 <p>MORE THAN $b/2$ IS IRREGULAR</p> <p>b</p> <p>PLAN VIEW</p>
<p><u>5</u></p>	<p>Where portions of a floor level are vertically offset. Also called "split level" irregularity.</p>	 <p>STRAP FOR TENSION TIE</p> <p>COMMON WALL</p> <p>OFFSET IN FLOOR LEVEL</p> <p>IRC MAY BE USED</p> <p>FLOOR OFFSET TOO LARGE FOR DIRECT TENSION TIE</p> <p>ENGINEERED DESIGN REQUIRED</p>
<p><u>6</u></p>	<p>Where shear walls and braced wall lines do not occur in two perpendicular directions.</p>	 <p>ANGLED WALL NOT PERMITTED AS REQUIRED BRACING</p> <p>ROOF PLAN</p>

Reason: Exceptions listed under R301.2.2.2.5 "irregular buildings" lacks clarification and requires engineering judgment commonly missing by most non-engineer users. Illustrations on configuration irregularity are added similar to those used in Section 2.3 of FEMA 232, one of the source documents for IRC.

Cost Impact: This code change proposal will not increase construction cost.

RB50-13

	Assembly:	ASF	AMF	DF

R301.2.2.2.5-RB-MLAKAR-MORE

RB51 – 13

R301.2.4, R322.1

Proponent: Gregory Wilson, representing Department of Homeland Security, Federal Emergency Management Agency (Gregory.wilson2@fema.dhs.gov); Rebecca Quinn, RCQuinn Consulting, Inc., representing Federal Emergency Management Agency (rcquinn@earthlink.net).

Add new text as follows:

R301.2.4 Floodplain construction. Buildings and structures constructed in whole or in part in flood hazard areas (including A or V Zones) as established in Table R301.2(1) shall be designed and constructed in accordance with Section R322. Buildings and structures that are located in more than one flood hazard area shall comply with the provisions associated with the most restrictive flood hazard area. Buildings and structures located in whole or in part in identified floodways shall be designed and constructed in accordance with ASCE 24.

R322.1 General. Buildings and structures constructed in whole or in part in flood hazard areas (including A or V Zones) as established in Table R301.2(1) shall be designed and constructed in accordance with the provisions contained in this section. Buildings and structures that are located in more than one flood hazard area shall comply with the provisions associated with the most restrictive flood hazard area. Buildings and structures located in whole or in part in identified floodways shall be designed and constructed in accordance with ASCE 24.

Reason: General requirements for all dwellings in flood hazard area are in R322.1. Then specific requirements are in R322.2 (Zone A) or R322.3 (Zone V), depending on the nature of the flood hazard area. This proposal clarifies that buildings that are located such they are affected by more than one of these areas ("flood zones" on Flood Insurance Rate Maps) must comply with the provisions that take into account flood loads and conditions of the area that requires the more restrictive design. For example, a dwelling that straddles the line that separates Zone A from Zone V must comply with the requirements for Zone V. The IBC has the same phrasing in 1612.1.

Cost Impact: None. It has always been an NFIP requirement that buildings that are in more than one zone have to meet the requirements of the more restrictive zone.

R301.2.4-RB-QUINN-WILSON

RB52 – 13

R301.2.4.1, R322.1.1

Proponent: Gregory Wilson, representing Department of Homeland Security, Federal Emergency Management Agency (Gregory.wilson2@fema.dhs.gov); Rebecca Quinn, RCQuinn Consulting, Inc., representing Federal Emergency Management Agency (rcquinn@earthlink.net).

Revise as follows

R301.2.4.1 Alternative provisions. As an alternative to the requirements in Section ~~R322, R322.3~~ for buildings and structures located in whole or in part in coastal high-hazard areas (V Zones) and Coastal A Zones, if delineated, ASCE 24 is permitted subject to the limitations of this code and the limitations therein.

R322.1.1 Alternative provisions. As an alternative to the requirements in Section ~~R322, R322.3~~ for buildings and structures located in whole or in part in coastal high-hazard areas (V Zones) and Coastal A Zones, if delineated, ASCE 24 is permitted subject to the limitations of this code and the limitations therein.

Reason: This code change provides an alternative for buildings and structures in any flood hazard areas to be designed and constructed according to the standard ASCE 24 *Flood Resistant Design and Construction*. There is no reason to limit use of ASCE 24 as an alternative. There are many flood hazard areas where the builder, designer or building official may deem it appropriate to not use prescriptive foundations, such as along riverine waterways and some coastal areas (inland of Zone V) where flood depths are significant and dwellings would need very tall foundations or in riverine floodplains where flood velocities are very fast which suggests it is appropriate to specifically consider hydrodynamic loads.

Another situation where use of ASCE 24 is appropriate is for dwellings in flood hazard areas on alluvial fans. The IBC, by reference to ASCE 24, has specific limitations for buildings on alluvial fans. The fact that the IRC does not have explicit provisions for alluvial fans does not mean code officials should ignore credible information on Flood Insurance Rate Maps or other sources that identifies flood hazard areas subject to high risk conditions, including alluvial fans. Specifying that ASCE 24 is an alternative allows its use where the prescriptive provisions of the IRC may not adequately account for flood risks.

Cost Impact: Use of ASCE 24 is an alternative; there are no cost impacts imposed by providing an alternative.

R301.2.4.1-RB-QUINN-WILSON

RB53 – 13

R301.3

Proponent: Charles S. Bajnai, Chesterfield County, VA, ICC Building Code Action Committee and Virginia Building and Code Officials Association (bajnaic@chesterfield.gov)

Revise as follows:

R301.3 Story height. The wind and seismic provisions of this code shall apply to buildings with story heights not exceeding the following:

1. For wood wall framing, the maximum story height shall not exceed 11 feet 7 inches (3531 mm) and the laterally unsupported bearing wall stud height shall not exceed that permitted by Table R602.3(5) plus a height of floor framing not to exceed 16 inches (406 mm).

Exception: ~~For wood-framed wall buildings with bracing in accordance with Tables R602.10.3(1) and R602.10.3(3), the wall stud clear height used to determine the maximum permitted story height may be increased to 12 feet (3658 mm) without requiring an engineered design for the building wind and seismic force-resisting systems provided that the length of bracing required by Table R602.10.3(1) is increased by multiplying by a factor of 1.10 and the length of bracing required by Table R602.10.3(3) is increased by multiplying by a factor of 1.20. Wall studs are still subject to the requirements of this section.~~

2. For steel wall framing, the maximum story height shall not exceed 11 feet 7 inches (3531 mm) and the a maximum unsupported bearing wall stud height shall not exceed of 10 feet (3048 mm), plus a height of floor framing not to exceed 16 inches (406 mm).
3. For masonry walls, the maximum story height shall not exceed 13 feet 7 inches (4140 mm) and the a maximum bearing wall clear height shall not exceed of 12 feet (3658 mm) plus a height of floor framing not to exceed 16 inches (406 mm).

Exception: An additional 8 feet (2438 mm) of bearing wall clear height is permitted for gable end walls.

4. For insulating concrete form walls, the maximum story height shall not exceed 11 feet 7 inches (3531 mm) and the maximum unsupported bearing wall height per story as permitted by Section R611 tables shall not exceed 10 feet (3048 mm) plus a height of floor framing not to exceed 16 inches (406 mm).
5. For structural insulated panel (SIP) walls, the maximum story height shall not exceed 11 feet 7 inches (3531 mm) and the maximum bearing wall height per story as permitted by Section R613 tables shall not exceed 10 feet (3048 mm) plus a height of floor framing not to exceed 16 inches (406 mm).

Individual walls or walls studs shall be permitted to exceed these limits as permitted by Chapter 6 provisions, provided *story heights* are not exceeded. ~~Floor framing height shall be permitted to exceed these limits provided the story height does not exceed 11 feet 7 inches (3531 mm).~~ An engineered design shall be provided for the wall or wall framing members when they exceed the limits of Chapter 6. Where the *story height* limits of this section are exceeded, the design of the building, or the noncompliant portions thereof, to resist wind and seismic loads shall be in accordance with the *International Building Code*.

Reason: This proposal is submitted by the ICC Building Code Action Committee (BCAC). The BCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance an assigned International Code or portion thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the BCAC has held 6 open meetings and numerous workgroup calls which included members of the

BCAC as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: <http://www.iccsafe.org/cs/BCAC/Pages/default.aspx>.

The purpose of this proposal is to revise the story height limits. Proposal S100-06/07 introduced the 11'-7" story height limit into the IBC and IRC as an alternative to limiting the floor framing height to 16" where wall stud heights were less than 10'-0". In the IBC this change was implemented directly into the equivalent provision under Section 2308 to Item #1 above. In the IRC, the exception was added to the paragraph following the five individual limits. This has led to confusion with Chapter 6 provisions including stud size/height and wall bracing. This revision relocates the story height limit to each of the individual material limits and coordinates it with the material-specific provisions.

The current exception for wood wall studs is deleted as it is redundant with other provisions of Chapter 6 and not necessary. Table R602.3(5) covers when studs in non-bearing walls can exceed 10'-0". Table R602.3.1 provides limited cases when studs in bearing walls can exceed 10'-0". The wall bracing section provides adjustments to wind and seismic bracing amounts for heights up to 12'-0". It is not necessary to repeat that requirement here, in fact that could result in an accidental double-application of the increase factors. Finally, simply applying the wall bracing provisions for walls permitted to be 12'-0" high does not automatically address other structural concerns resulting from an overall increase in story height. This is why only the limited conditions in Table R602.3.1 are allowed for studs greater than 10' in height and supporting floor or roof loads.

Cost Impact: None

Public Hearing:	Committee:	AS	M	D
	Assembly:	ASF	AMF	DF

R301.3-RB-BAJNAI-BCAC

RB54 – 13

R301.3

Proponent: Edward L. Keith, APA, representing The Engineered Wood Association
(ed.keith@apawood.org)

Revise as follows:

R301.3 Story height. The wind and seismic provisions of this code shall apply to buildings with story heights not exceeding the following:

1. For wood wall framing, the laterally unsupported bearing wall stud height permitted by Table R602.3(5) plus a height of floor framing not to exceed 16 inches (406 mm).

Exception: For wood-framed wall buildings with bracing in accordance with Tables R602.10.3(1) and R602.10.3(3), the wall stud clear height used to determine the maximum permitted *story height* may be increased to 12 feet (3658 mm) without requiring an engineered design for the building wind and seismic force-resisting systems provided that the length of bracing required is increased in accordance with Tables R602.10.3(2) and R602.10.3(4) for wind and seismic, respectively. ~~by Table R602.10.3(1) is increased by multiplying by a factor of 1.10 and the length of bracing required by Table R602.10.3(3) is increased by multiplying by a factor of 1.20.~~ Wall studs are still subject to the requirements of this section.

2 through 5 *(No changes to current text)*

Individual walls or walls studs shall be permitted to exceed these limits as permitted by Chapter 6 provisions, provided story heights are not exceeded. Floor framing height shall be permitted to exceed these limits provided the story height does not exceed 11 feet 7 inches (3531 mm). An engineered design shall be provided for the wall or wall framing members when they exceed the limits of Chapter 6. Where the story height limits of this section are exceeded, the design of the building, or the non-compliant portions thereof, to resist wind and seismic loads shall be in accordance with the International Building Code.

Reason: The original exception proposed for modification requires an increase in the amount of bracing for wind and/or seismic application when the maximum story height is increased from 10 to 12 feet. The factors given in this original section are duplicated in Tables R602.10.3(2) and R602.10.3(4). As it is written it is unclear that the adjustments must only be applied once. Replacing the requirements in Section R301.2.2.2.1 with a reference to the tables in Chapter 6 would make it clear that the adjustments are to be applied only once and eliminate the potential for “double dipping” along with the unnecessary construction costs.

Cost Impact: This code change proposal will not increase the cost of construction.

R301.4 (New), R301.6 (New), R301.7 (New), R318.1, R505.2, R603.2, R804.2, M1308.1, M2101.6, P2603.2

Proponent: Bonnie Manley, P.E., American Iron and Steel Institute (bmanley@steel.org)

Add new text as follows:

R301.4 Additional design loads. In addition to the requirements of Section R301.2, additional design loads for buildings and structures, and all parts thereof, shall be in accordance with this section.

R301.4.1 ~~R301.4~~ Dead load. The actual weights of materials and construction shall be used for determining dead load with consideration for the dead load of fixed service *equipment*.

R301.4.2 ~~R301.5~~ Live load. The minimum uniformly distributed live load shall be as provided in Table R301.5.

R301.4.3 ~~R301.6~~ Roof load. The roof shall be designed for the live load indicated in Table R301.6 or the snow load indicated in Table R301.2(1), whichever is greater.

R301.5 ~~R301.7~~ Deflection. The allowable deflection of any structural member under the live load listed in Sections R301.4.2~~5~~ and R301.4.3~~6~~ or wind loads determined by Section R301.2.1 shall not exceed the values in Table R301.5~~7~~.

R301.6 Material requirements. The general material requirements set forth in this section shall apply to the use of load-bearing materials in buildings and structures, and all parts thereof.

R301.6.1 Wood framing. Load-bearing wood-wood frame members shall be designed in accordance with Sections R502, R602, R802 and this section.

R301.6.1.1 ~~R301.8~~ Nominal sizes. For the purposes of this code, where dimensions of lumber are specified, they shall be deemed to be nominal dimensions unless specifically designated as actual dimensions.

R301.6.2 Cold-formed steel framing. Load-bearing cold-formed steel framing members designed in accordance with Sections R505, R603 or R804 shall be in accordance with this section.

R301.6.2.1 Material. Load-bearing cold-formed steel framing members shall be cold formed to shape from structural quality sheet steel complying with the requirements of ASTM A 1003, Structural Grades 33 Type H and 50 Type H.

R301.6.2.2 Corrosion protection. Load-bearing cold-formed steel framing shall have a metallic coating complying with ASTM A 1003 and one of the following:

1. A minimum of G 60 in accordance with ASTM A 653.
2. A minimum of AZ 50 in accordance with ASTM A 792.

R301.6.2.3 Dimension, thickness and material grade. Load-bearing cold-formed steel framing members shall comply with Figure R301.6.2.3(1) and with the dimensional and thickness requirements specified in Table R301.6.2.3. Additionally, all c-shaped sections shall have a minimum flange width of 1.625 inches (41 mm) and a maximum flange width of 2 inches (51 mm). The minimum lip size for c-shaped sections shall be 0.5 inches (13 mm). Track sections shall comply with Figure R301.6.2.3(2) and shall have a minimum flange width of 1¹/₄ inches (32 mm). Minimum Grade 33 ksi steel shall be used wherever 33 mil and 43 mil thicknesses are specified. Minimum Grade 50 ksi steel shall be used wherever 54 and 68 mil thicknesses are specified.

TABLE R301.6.2.3
LOAD-BEARING COLD-FORMED STEEL FRAMING MEMBER SIZES AND THICKNESSES

MEMBER DESIGNATION^a	WEB DEPTH (inches)	MINIMUM BASE STEEL THICKNESS mil (inches)
350S162-t	3.5	33 (0.0329), 43 (0.0428), 54 (0.0538)
550S162-t	5.5	33 (0.0329), 43 (0.0428), 54 (0.0538), 68 (0.0677)
800S162-t	8	33 (0.0329), 43 (0.0428), 54 (0.0538), 68 (0.0677)
1000S162-t	10	43 (0.0428), 54 (0.0538), 68 (0.0677)
1200S162-t	12	43 (0.0428), 54 (0.0538), 68 (0.0677)

For SI: 1 inch = 25.4 mm

a. The member designation is defined by the first number representing the member depth in hundredths of an inch, the letter "s" representing a stud or joist member, the second number representing the flange width in hundredths of an inch, and the letter "t" shall be a number representing the minimum base metal thickness in mils.

FIGURE R301.6.2.3(1)
C-SHAPED SECTION

FIGURE R301.6.2.3(2)
TRACK SECTION

R301.6.2.4 Identification. Load-bearing cold-formed steel framing members shall have a legible *label*, stencil, stamp or embossment with the following information as a minimum:

1. Manufacturer's identification.
2. Minimum base steel thickness in inches (mm).
3. Minimum coating designation.
4. Minimum yield strength, in kips per square inch (ksi) (MPa).

R301.6.2.5 Fastening. Screws for steel-to-steel connections shall be installed with a minimum edge distance and center-to-center spacing of $\frac{1}{2}$ inch (12.7 mm), shall be self-drilling tapping, and shall conform to ASTM C 1513. Structural sheathing shall be attached to cold-formed steel framing members with minimum No. 8 self-drilling tapping screws that conform to ASTM C 1513. Screws attaching structural-sheathing to cold-formed steel framing members shall have a minimum head diameter of 0.292 inch (7.4 mm) with countersunk heads and shall be installed with a minimum edge distance of $\frac{3}{8}$ inch (9.5 mm). Gypsum board shall be attached to cold-formed steel framing members with minimum No. 6 screws conforming to ASTM C 954 or ASTM C 1513 with a bugle head style and shall be installed in accordance with Section R702. For all connections, screws shall extend through the steel a minimum of three exposed threads. All fasteners shall have a rust inhibitive coating suitable for the installation in which they are being used, or shall be manufactured from material not susceptible to corrosion.

R301.6.2.6 Web holes, web hole reinforcing and web hole patching. Web holes, web hole reinforcing, and web hole patching shall be in accordance with this section.

R301.6.2.6.1 Web holes. Web holes in load-bearing cold-formed steel framing members shall comply with all of the following conditions:

1. Holes shall conform to Figure R301.6.2.6.1(1) for floor and ceiling joists and Figure R301.6.2.6.1(2) for wall studs;
2. Holes shall be permitted only along the centerline of the web of the framing member;
3. Holes shall have a center-to-center spacing of not less than 24 inches (610 mm);
4. Holes shall have a web hole width not greater than 0.5 times the member depth, or $1\frac{1}{2}$ inches (38 mm) for wall studs and $2\frac{1}{2}$ inches (64.5 mm) for floor joists and roof framing members;
5. Holes shall have a web hole length not exceeding $4\frac{1}{2}$ inches (114 mm); and
6. Holes shall have a minimum distance between the edge of the bearing surface and the edge of the web hole of not less than 10 inches (254 mm).

Framing members with web holes not conforming to the above requirements shall be reinforced in accordance with Section R301.6.2.6.2, patched in accordance with Section R301.6.2.6.3 or designed in accordance with accepted engineering practices.

For SI: 1 inch = 25.4 mm.

FIGURE R301.6.2.6.1(1)
FLOOR AND CEILING JOIST WEB HOLES

For SI: 1 inch = 25.4 mm.

FIGURE R301.6.2.6.1(2)
WALL STUD WEB HOLES

R301.6.2.6.2 Web hole reinforcing. Reinforcement of web holes in floor joists, gable endwall studs, and ceiling joists not conforming to the requirements of Section R301.6.2.6.1 shall be permitted if the hole is located fully within the center 40 percent of the span and the depth and length of the hole does not exceed 65 percent of the flat width of the web. The reinforcing shall be a steel plate or C-shape section with a hole that does not exceed the web hole size limitations of Section R301.6.2.6.1 for the member being reinforced. The steel reinforcing shall be the same thickness as the receiving member and shall extend at least 1 inch (25.4 mm) beyond all edges of the hole. The steel reinforcing shall be fastened to the web of the receiving member with No. 8 screws spaced not more than 1 inch (25.4 mm) center-to-center along the edges of the patch with minimum edge distance of $\frac{1}{2}$ inch (12.7 mm).

R301.6.2.6.3 Hole patching. Patching of web holes in cold-formed steel framing members not conforming to the requirements in Section R301.6.2.6.1 shall be permitted in accordance with either of the following methods:

1. Framing members shall be replaced or designed in accordance with accepted engineering practices where web holes exceed the following size limits:
 - 1.1. The depth of the hole, measured across the web, exceeds 70 percent of the flat width of the web; or
 - 1.2. The length of the hole measured along the web, exceeds 10 inches (254 mm) or the depth of the web, whichever is greater.
2. Web holes not exceeding the dimensional requirements in Section R301.6.2.6.3, Item 1, shall be patched with a solid steel plate, stud section, or track section in accordance with Figure R301.6.2.6.3(1) for floor and ceiling joists and Figure R301.6.2.6.3(2) for wall studs. The steel patch shall, as a minimum, be of the same thickness as the receiving member and shall extend at least 1 inch (25 mm) beyond all edges of the hole. The steel patch shall be fastened to the web of the receiving member with No. 8 screws spaced no more than 1 inch (25 mm) center-to-center along the edges of the patch with minimum edge distance of $\frac{1}{2}$ inch (13 mm).

FIGURE R301.6.2.6.3(1)
FLOOR AND CEILING JOIST WEB HOLE PATCH

For SI: 1 inch = 25.4 mm.

FIGURE R301.6.2.6.3(2)
WALL STUD WEB HOLE PATCH

Revise as follows:

R318.1 Subterranean termite control methods. In areas subject to damage from termites as indicated by Table R301.2(1), methods of protection shall be one of the following methods or a combination of these methods:

1. Chemical termiticide treatment, as provided in Section R318.2.
2. Termite baiting system installed and maintained according to the *label*.
3. Pressure-preservative-treated wood in accordance with the provisions of Section R317.1.
4. Naturally durable termite-resistant wood.
5. Physical barriers as provided in Section R318.3 and used in locations as specified in Section R317.1.
6. Cold-formed steel framing in accordance with Sections ~~R301.6.2.1 and R603.2.1~~.

Delete and substitute as follows:

~~**R505.2 Structural framing.** Load-bearing cold-formed steel floor framing members shall comply with Figure R505.2(1) and with the dimensional and minimum thickness requirements specified in Tables R505.2(1) and R505.2(2). Tracks shall comply with Figure R505.2(2) and shall have a minimum flange width of 11/4 inches (32 mm).~~

R505.2 Structural framing. Load-bearing cold formed steel floor framing members shall comply with Section R301.6.2

Delete and substitute as follows:

~~**R603.2 Structural framing.** Load-bearing cold-formed steel wall framing members shall comply with Figure R603.2(1) and with the dimensional and minimum thickness requirements specified in Tables R603.2(1) and R603.2(2). Tracks shall comply with Figure R603.2(2) and shall have a minimum flange width of 11/4 inches (32 mm).~~

R603.2 Structural framing. Load-bearing cold formed steel wall framing members shall comply with Section R301.6.2

Delete and substitute as follows:

~~**R804.2 Structural framing.** Load-bearing, cold-formed steel roof framing members shall comply with Figure R804.2(1) and with the dimensional and minimum thickness requirements specified in Tables R804.2(1) and R804.2(2). Tracks shall comply with Figure R804.2(2) and shall have a minimum flange width of 11/4 inches (32 mm).~~

R804.2 Structural framing. Load-bearing cold formed steel roof framing members shall comply with Section R301.6.2

Revise as follows:

M1308.1 Drilling and notching. Wood-framed structural members shall be drilled, notched or altered in accordance with the provisions of Sections R502.8, R602.6, R602.6.1 and R802.7. Holes in load-bearing members of cold-formed steel light-frame construction shall be permitted only in accordance with Sections ~~R301.6.2.6~~ R505.2.5, R603.2.5 and R804.2.5. In accordance with the provisions of Sections R505.3.5, R603.3.4 and R804.3.4, cutting and notching of flanges and lips of load-bearing members of cold-formed steel light frame construction shall not be permitted. Structural insulated panels (SIPs) shall be drilled and notched or altered in accordance with the provisions of Section R613.7.

Revise as follows:

M2101.6 Drilling and notching. Wood-framed structural members shall be drilled, notched or altered in accordance with the provisions of Sections R502.8, R602.6, R602.6.1 and R802.7. Holes in load bearing members of cold-formed steel light-frame construction shall be permitted only in accordance with Sections ~~R301.6.2.6~~ R505.2.5, R603.2.5 and R804.2.5. In accordance with the provisions of Sections R505.3.5, R603.3.4 and R804.3.4, cutting and notching of flanges and lips of load-bearing members of cold-formed steel light frame construction shall not be permitted.

Structural insulated panels (SIPs) shall be drilled and notched or altered in accordance with the provisions of Section R613.

Revise as follows:

P2603.2 Drilling and notching. Wood-framed structural members shall not be drilled, notched or altered in any manner except as provided in Sections R502.8, R602.6, R802.7 and R802.7.1. Holes in load-bearing members of cold-formed steel light-frame construction shall be permitted only in accordance with Sections ~~R301.6.2.6~~~~R505.2.5~~, ~~R603.2.5~~ and ~~R804.2.5~~. In accordance with the provisions in Sections R505.3.5, R603.3.4 and R804.3.4, cutting and notching of flanges and lips of load-bearing members of cold-formed steel light frame construction shall not be permitted. Structural insulated panels (SIPs) shall be drilled and notched or altered in accordance with the provisions of Section R613.7.

Reason: This proposal represents a trial balloon, which was developed in the process of updating and streamlining the cold-formed steel framing (CFSF) provisions of the IRC. Rather than repeat the CFSF material requirements in Sections R505, R603 and R804, it was suggested that the material requirements be stated once in Chapter 3. This proposal incorporates the CFSF provisions in a new Section R301.6 on load-bearing material requirements.

In order for this new section to work as fully intended, it is expected that general requirements for the other load-bearing materials in the IRC would be incorporated into this new section as well. For example, in the case of wood frame construction, that would involve moving and combining requirements from Sections R502.1, R602.1 and R802.1. We believe that this could go a long way towards streamlining the IRC. Additionally, the section numbering changes recommended for design loads (Section R301.4) is editorial in nature and an attempt to better organize the chapter. It would be ideal to move the wind load and seismic load requirements under this section as well. However, that was deemed too ambitious for this code change without the general consent of the many affected parties.

Please note that the provisions recommended for Section R301.6.2 are not extracted directly from the 2012 IRC; rather, they reflect a generalized version of the language recommended in AISI's separate proposals on Section R505, R603 and R804. If this proposal is successful, it is intended to build on top of those proposals. See their reason statements for additional information on the specific changes to the section from the 2012 IRC.

Cost Impact: No impact to the cost of construction is anticipated.

RB55-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R301.4-RB-MANLEY

RB56 – 13

R301.5, Table R301.5

Proponent: Stephen Kerr, S.E., Josephson Werdowatz and Associates Inc., representing self (skerr@jwa-se.com)

Revise as follows:

R301.5 Live load. The minimum uniformly distributed and concentrated live loads shall be as provided in Table R301.5.

TABLE R301.5
MINIMUM UNIFORMLY DISTRIBUTED LIVE LOADS
AND MINIMUM CONCENTRATED LIVE LOADS
(in pounds per square foot)

<u>OCCUPANCY OR USE</u>	<u>LIVE LOAD UNIFORM</u> <u>(psf)</u>	<u>CONCENTRATED</u> <u>(lbs.)</u>
Uninhabitable attics without storage ^b	10	-
Uninhabitable attics with limited storage ^{b,g}	20	-
Habitable attics and attics served with fixed stairs	30	-
Balconies (exterior) and decks ^e	40	-
Fire escapes	40	-
Guardrails and handrails ^d	- 200 ^h	<u>200</u> ^h
Guardrail in-fill components ^f	- 50 ^h	<u>50</u> ^h
Passenger vehicle garages ^a	40 <u>50</u> ^a	<u>Note a</u>
Rooms other than sleeping room	40	-
Sleeping rooms	30	-
Stairs	40 ^e	<u>300</u> ^c

- a. Elevated garage floors shall be capable of supporting a 3,000 ~~2,000~~-pound load applied on an area of over a 20 square inches area.
- b. *(No change to current text)*
- c. The minimum concentrated load on stair treads shall be applied on individual stair treads shall be designed for the uniformly distributed live load or a 300-pound concentrated load acting over an area of 4 square inches. This load need not be assumed to act concurrently with the uniform load, whichever produces the greater stresses.
- d through h *(No change to current text)*

Reason: As currently presented, the title of Table R301.5 states that the loads are uniformly distributed and that the loads are in pounds per square foot. However, this is incorrect, since the guardrail and handrail loads shown are concentrated loads. By splitting the loads into two columns, the Live Load table will accurately represent what type of live load is shown. The passenger vehicle garage loads were also changed to reflect the changes that occurred to the live load in the 2012 IBC.

These changes will make the IRC Live Load table match the format and values of the IBC and ASCE 7 Live Load tables.

Cost Impact: This code change proposal will not increase construction cost.

RB56-13

Public Hearing: Committee: AS AM D
Assembly: ASF AMF DF

R301.5-RB-KERR

RB57 – 13

Table R301.5

Proponent: Larry Wainright, Qualtim, representing the Structural Building Components Association (lwainright@qualtim.com)

Revise as follows:

TABLE R301.5 MINIMUM UNIFORMLY DISTRIBUTED LIVE LOADS (in pounds per square foot)

(Portions of table not shown remain unchanged)

a through f (No change to current text)

g. Uninhabitable attics with limited storage are those where the maximum clear height between joists and rafters is 42 inches or greater, or where there are two or more adjacent trusses with web configurations capable of accommodating an assumed rectangle 42 inches in height by 24 inches in width, or greater, within the plane of the trusses. The live load need only be applied to those portions of the joists or truss bottom chords where all of the following conditions are met:

1. The attic area is accessible from an opening not less than 20 inches in width by 30 inches in length that is located where the clear height in the attic is a minimum of 30 inches.
2. The slopes of the joists or truss bottom chords are no greater than 2 inches vertical to 12 units horizontal.
3. Required insulation depth is less than the joist or truss bottom chord member depth.

The remaining portions of the joists or truss bottom chords shall be designed for a uniformly distributed non-concurrent live load of not less than 10 lb/ft².

h. (No change to current text)

Reason The intent of this proposal is to bring the IRC into agreement with the IBC, Table 1607.1, footnote "i"; ASCE 7, Table 4-1, footnotes "l" and "m" and the IRC Table R301.5, footnote "b".

The requirement for the 10 PSF live load on those portions of the bottom chords not serving as storage areas was originally intended to reflect the requirement to provide a 10 PSF load per Table R301.5, footnote "b" for uninhabitable attics without storage on those portions of the joist or truss where a storage load is not applied. Footnote b clearly indicates that this is a non-concurrent load (intended for occasional access for maintenance). This is confirmed by the Commentary to the 2012 IBC, Table 1607.1 which states in part, "...Historically, a minimum load of 10 psf (0.48 kN/m²) has been viewed as appropriate where occasional access to the attic is anticipated for maintenance purposes, but significant storage is restricted by physical constraints, such as low clearance or the configuration of truss webs. It provides a minimum degree of structural integrity, allowing for occasional access to an attic space for maintenance purposes. ***Allowing the application of this load to be independent of other live loads is deemed appropriate, since it would be rare for this load and other maximum live loads to occur at once.***"[emphasis added]

Current truss design methodology also treats this 10 PSF non-storage load as a non-concurrent live load intended for occasional access for maintenance purposes. Furthermore, the change to this section (S57-09/10) was intended to coordinate the language with the ASCE 7-10 which was in draft form at the time the original proposal was submitted. During the public comment period, ASCE 7 was corrected to show that this is a non-concurrent load but the change was not picked up in the IRC. This code change simply coordinates this footnote with Table 1607.1, Table R301.5 footnote b, ASCE 7, and with the original intent of S57-09/10.

For reference, Table R301.5, footnote "b" states:

b. Uninhabitable attics without storage are those where the maximum clear height between the joist and rafter is less than 42 inches, or where there are not two or more adjacent trusses with web configurations capable of accommodating an assumed rectangle 42 inches in height by 24 inches in width, or greater, within the plane of the trusses. **This live load need not be assumed to act concurrently with any other live load requirements.**

ASCE 7-10, Table 4-1, footnotes "l" and "m" state:

^l Uninhabitable attic areas without storage are those where the maximum clear height between the joist and rafter is less than 42 in. (1,067 mm), or where there are not two or more adjacent trusses with web configurations capable of accommodating an assumed rectangle 42 in. (1,067 mm) in height by 24 in. (610 mm) in width, or greater, within the plane of the trusses. **This live load need not be assumed to act concurrently with any other live load requirement.**

^m Uninhabitable attic areas with storage are those where the maximum clear height between the joist and rafter is 42 in. (1,067 mm) or greater, or where there are two or more adjacent trusses with web configurations capable of accommodating an assumed rectangle 42 in. (1,067 mm) in height by 24 in. (610 mm) in width, or greater, within the plane of the trusses. At the trusses, the live load need only be applied to those portions of the bottom chords where both of the following conditions are met:

- i. The attic area is accessible from an opening not less than 20 in. (508 mm) in width by 30 in. (762 mm) in length that is located where the clear height in the attic is a minimum of 30 in. (762 mm); and

- ii. The slope of the truss bottom chord is no greater than 2 units vertical to 12 units horizontal (9.5% slope).

The remaining portions of the bottom chords shall be designed for a uniformly distributed nonconcurrent live load of not less than 10 lb/ft² (0.48 kN/m²).

IBC Table 1607.1, footnote "i" states:

- i. Uninhabitable attics without storage are those where the maximum clear height between the joists and rafters is less than 42 inches, or where there are not two or more adjacent trusses with web configurations capable of accommodating an assumed rectangle 42 inches in height by 24 inches in width, or greater, within the plane of the trusses. **This live load need not be assumed to act concurrently with any other live load requirements.**

Note that the IBC, Table 1607.1 footnote "j" is also inconsistent with ASCE 7, the IRC and the IBC, table 1607.1, footnote "i".

Cost Impact: This code change will not increase the cost of construction.

RB58 – 13

Table R301.5, R311.7.8.1, R317.4, R317.4.1, R507.3

Proponent: Glenn Mathewson, MCP, representing the North American Deck and Railing Association (GlennMathewson@nadra.org)

Revise as follows:

TABLE R301.5
MINIMUM UNIFORMLY DISTRIBUTED LIVE LOADS
(in pounds per square foot)

USE	LIVE LOAD
Uninhabitable attics without storage ^b	10
Uninhabitable attics with limited storage ^{b, g}	20
Habitable attics and attics served with fixed stairs	30
Balconies (exterior) and decks ^e	40
Fire escapes	40
Guardrails and handrails ^d	200 ^h
Guardrail in-fill components ^f	50 ^h
Passenger vehicle garages ^a	50 ^a
Rooms other than sleeping room	40
Sleeping rooms	30
Stairs	40 ^c

R311.7.8.1 Height. Handrail height, measured vertically from the sloped plane adjoining the tread nosing, or finish surface of ramp slope, shall be not less than 34 inches (864 mm) and not more than 38 inches (965 mm).

Exceptions:

1. The use of a volute, turnout or starting easing shall be allowed over the lowest tread.
2. When handrail fittings or bending are used to provide continuous transition between flights, transitions at winder treads, the transition from handrail to guardrail or used at the start of a flight, the handrail height at the fittings or bending shall be permitted to exceed the maximum height.

R317.4 Wood/plastic composites. Wood/plastic composites used in exterior deck boards, stair treads, handrails and guardrail systems shall bear a *label* indicating the required performance levels and demonstrating compliance with the provisions of ASTM D 7032.

R317.4.1 Labeling. Deck boards and stair treads shall bear a label that indicates compliance to ASTM D 7032 and includes the allowable load and maximum allowable span. Handrails and guardrail systems or their packaging shall bear a label that indicates compliance to ASTM D 7032 and includes the maximum allowable span.

R507.3 Wood/plastic composites. Wood/plastic composites used in exterior deck boards, stair treads, handrails, and guardrail systems shall bear a label indicating the required performance levels and demonstrating compliance with the provisions of ASTM D 7032.

Reason: There is no construction component recognized or required by the IRC called a “guardrail”. A “guard” is clearly defined by the IRC in chapter two and does not in anyway require the presence of a “rail”. In the decking industry, it is quite common to see guards constructed as outdoor kitchen counters, benches, planter boxes and numerous other architectural elements. Use of the term “guardrail” inappropriately implies that a “rail” must be present in guard assemblies, and has been known to unnecessarily restrict design freedom in the decking industry. Note that footnote “d”, associated with the term “guardrail” uses the correct term “guard” within its text. The use of appropriate, IRC-defined terms clarifies the intent of the provisions.

Cost Impact: The code change proposal will not increase the cost of construction.

R301.5T-RB-MATHEWSON

RB59 – 13

Table R301.5

Proponent: Dennis Pitts, American Wood Council, representing American Wood Council
(dpitts@awc.org)

Revise as follows:

TABLE R301.5 MINIMUM UNIFORMLY DISTRIBUTED LIVE LOADS (in pounds per square foot)

(Portions of table not shown remain unchanged.)

- a *(No change to current text)*
- b. Uninhabitable attics without storage are those where the maximum clear height between joists and rafters is less than 42 inches, or where there are not two or more adjacent trusses with web configurations capable of accommodating an assumed rectangle 42 inches high by 24 inches in width, or greater, within the plane of the trusses. This live load need not be assumed to act concurrently with any other live load requirements.
- c through f *(No change to current text)*
- g. Uninhabitable attics with limited storage are those where the maximum clear height between joists and rafters is 42 inches or greater, or where there are two or more adjacent trusses with web configurations capable of accommodating an assumed rectangle 42 inches in height by 24 inches in width, or greater, within the plane of the trusses. The live load need only be applied to those portions of the joists or truss bottom chords where all of the following conditions are met:
 - 1. The attic area is accessible from an opening not less than 20 inches in width by 30 inches in length that is located where the clear height in the attic is a minimum of 30 inches.
 - 2. The slopes of the joists or truss bottom chords are no greater than 2 inches vertical to 12 units horizontal.
 - 3. Required insulation depth is less than the joist or truss bottom chord member depth.

The remaining portions of the joists or truss bottom chords shall be designed for a uniformly distributed ~~concurrent~~ live load of not less than 10 lb/ft². This live load need not be assumed to act concurrently with any other live load requirements.

- h *(No change to current text)*

Reason: In ASCE 7-10, uninhabited attics without storage are assigned a 10 psf live load for design of ceiling joists and truss bottom chords. This live load is intended to address occasional access of the space and wording in ASCE 7-10 footnote "l" does not require this live load to be applied concurrently with other live loads when designing the full roof assembly or supporting members such as headers and studs.

Similarly in ASCE 7-10, uninhabited attics with limited storage are also assigned a 10 psf live load in the portions of the attic above ceiling joists and truss bottom chords where significant storage is not possible. As with uninhabited attics without storage, ASCE 7-10 footnote "m" does not require the 10 psf live load to be applied concurrently with other live loads when designing the full roof assembly or supporting members such as headers and studs. However, the current wording in the IRC dropped the prefix "non" from "nonconcurrent" when these new provisions from ASCE 7-10 were incorporated. This change returns the wording to the ASCE 7-10 intent.

Cost Impact: No increase in cost of construction.

RB60 – 13

Table R301.7

Proponent: Charles S. Bajnai, Chesterfield County, VA, ICC Building Code Action Committee and Virginia Building and Code Officials Association (bajnaic@chesterfield.gov)

Revise as follows:

TABLE R301.7
ALLOWABLE DEFLECTION OF STRUCTURAL MEMBERS ^{b,c}

STRUCTURAL MEMBER	ALLOWABLE DEFLECTION
Rafters having slopes greater than 3:12 with no finished ceiling attached to rafters	L/180
Interior walls and partitions	H/180
Floors/ ceilings with plaster or stucco finish (including deck floors)	L/360
<u>Ceilings with brittle finishes (plaster, stucco, etc)</u>	<u>L/360</u>
<u>Ceilings with flexible finishes (gypsum board, etc)</u>	<u>L/240</u>
All other structural members	L/240
Exterior walls—wind loads ^a with plaster or stucco finish	H/360
Exterior walls with other brittle finishes	H/240
Exterior walls with flexible finishes	H/120 ^d
Lintels supporting masonry veneer walls ^e	L/600

Note: *L* = span length, *H* = span height.

- The wind load shall be permitted to be taken as 0.7 times the Component and Cladding loads for the purpose of the determining deflection limits herein.
- For cantilever members, *L* shall be taken as twice the length of the cantilever.
- For aluminum structural members or panels used in roofs or walls of sunroom additions or patio covers, not supporting edge of glass or sandwich panels, the total load deflection shall not exceed *L*/60. For continuous aluminum structural members supporting edge of glass, the total load deflection shall not exceed *L*/175 for each glass lite or *L*/60 for the entire length of the member, whichever is more stringent. For sandwich panels used in roofs or walls of sunroom additions or patio covers, the total load deflection shall not exceed *L*/120.
- Deflection for exterior walls with interior gypsum board finish shall be limited to an allowable deflection of *H*/180.
- Refer to Section R703.7.2.

Reason: This proposal is submitted by the ICC Building Code Action Committee (BCAC). The BCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance an assigned International Code or portion thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the BCAC has held 6 open meetings and numerous workgroup calls which included members of the BCAC as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: <http://www.iccsafe.org/cs/BCAC/Pages/default.aspx>.

This code change was intended to clarify two issues.

1. There is confusion regarding the deflection allowed for deck joists. It was not clear if the original authors intended deck joists to be considered as a floor joist (L/360) or as "other structural members" (L/240). This clarifies the intention.
2. The other significant change addresses the flexibility/stiffness of gypsum board which is a lot more common than either plaster or stucco in most parts of the country. There is now cleaner differentiation between materials and is consistent with the allowable deflection limits in Table R802.4(1) and R802.4(2).

Cost Impact: None.

RB60-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R301.7T-RB-BAJNAI-BCAC

RB61 – 13

Table R301.7

Proponent: Cole Graveen PE, SE, Rath, Rath & Johnson, Inc., representing self (cwgraveen@rrj.com)

Revise as follows:

TABLE R301.7
ALLOWABLE DEFLECTION OF STRUCTURAL MEMBERS^{b,c}

STRUCTURAL MEMBER	ALLOWABLE DEFLECTION
All other structural members	L/240
<u>Guards^{f,g}</u>	
<u>Post (horizontal deflection)</u>	$\frac{H}{12}$
<u>Top Rail (horizontal deflection)</u>	$\frac{H}{24} + \frac{L}{96}$
<u>Top Rail (vertical deflection)</u>	$\frac{L}{96}$

(Portions of table not shown remain unchanged)

a through e *(No change to current text)*

f. For the guard post, H shall be taken as the distance from the top of the top rail to the first point of support.

g. For the guard top rail, H shall be taken as the height of the rail and L shall be taken as the distance between edges of the post supports. The deflection of the top rail is measured relative to the center of the two posts.

Reason: Specific deflection limits for guards are proposed to clarify serviceability requirements and to help ensure occupant safety and comfort.

The serviceability requirements for guards in both the IBC and IRC are vague and open to interpretation. The IBC requires all structural systems and members to have adequate stiffness to limit deflections and lateral drift, Section 1604.3, however it contains no specific deflection limits for guards. The IRC contains a general deflection limit of L/240 in Table R301.7 for all structural members not otherwise listed in the table. However, it is not likely that this limit was originally intended to apply to guards nor does it appear that this limit is commonly applied to guards in design or code enforcement.

The deflection limits proposed in this code change are based upon existing requirements in ASTM E985, *Standard Specification for Permanent Metal Railing Systems and Rails for Buildings*, ASTM D7032, *Standard Specification for Establishing Performance Ratings for Wood-Plastic Composite Deck Boards and Guardrail Systems (Guards or Handrails)*, and ICC-ES AC273, *Acceptance Criteria for Handrails and Guards*. The proposed limits allow reasonable deflection of the guard post and top rail while still ensuring that the guard will perform its intended function of preventing accidental falls. It is important to note that while excessive deflection is undesirable, some deflection is desirable⁴ as it can provide warning to the occupant that they are at an edge of an elevated surface and may be unduly loading the guard.

Specific deflection limits are needed not only for clarity, but also to establish acceptable performance. Guards are provided to minimize the possibility of occupants accidentally falling from an elevated surface. The ability of a guard to prevent such an accidental fall depends on its stiffness as well as its height and strength. Guards that meet the strength and height requirements of the code but that move excessively under load could potentially not prevent an accidental fall. Limiting guard deflections to appropriate amounts will help protect occupants against accidentally falling from an elevated surface.

In addition, specific deflection limits are also necessary to help ensure that occupants are comfortable and feel safe. Similar to floor deflection limits that ensure that occupants are not uncomfortable or annoyed with bouncy floors or building drift limits that ensure that occupants are not uncomfortable or sick due to the swaying motion of tall buildings, reasonable lateral deflection limits for guards will help ensure that occupants do not feel that the guard is unsafe.

Example: Under the proposed deflection provisions, the post for a residential guard with a top rail height of 36" above the walking surface and a point of support 3' below the walking surface would have a deflection limit of $(36 + 3)/12 = 3.25$ inches. The top rail spanning between 4" wide posts that are spaced 4' apart would have a horizontal deflection limit of $(48 - 4)/96 + (36 + 3)/24 = 2.10$ inches.

References:

1. ASTM E985-00(2006), Standard Specification for Permanent Metal Railing Systems and Rails for Buildings
2. ASTM D7032-08, Standard Specification for Establishing Performance Ratings for Wood-Plastic Composite Deck Boards and Guardrail Systems (Guards or Handrails)
3. ICC-ES AC273, Acceptance Criteria for Handrails and Guards, Corrected January 2009
4. Loferski, J., Albright, D., and Woeste, F. (July 2007) Tested Guardrail Post Connections for Residential Decks, Structure Magazine

Cost Impact: This code change proposal may increase the cost of construction by increasing the design costs. Designers may have to perform additional serviceability calculations.

RB61-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R301.7T-RB-GRAVEEN

RB62 – 13

Table R301.7

Proponent: Edward L. Keith, APA, representing The Engineered Wood Association
(ed.keith@apawood.org)

Revise as follows:

TABLE R301.7
ALLOWABLE DEFLECTION OF STRUCTURAL MEMBERS^{b,c}

STRUCTURAL MEMBERS	ALLOWABLE DEFLECTION
Rafters having slopes greater than 3:12 with no finished ceiling attached to rafters	<i>L/180</i>
Interior walls and partitions	<i>H/180</i>
Floors/ceilings with plaster or stucco finish	<i>L/360</i>
All other structural members	<i>L/240</i>
Exterior walls – wind loads ^a with plaster or stucco finish	<i>H/360</i>
Exterior walls - <u>wind loads^a</u> with other brittle finishes	<i>H/240</i>
Exterior walls - <u>wind loads^a</u> with flexible finishes	<i>H/120^d</i>
Lintels supporting masonry veneer walls ^e	<i>L/600</i>

(Portions of table not shown remain unchanged)

Reason: The proposed changes may be considered editorial. When the current table was put into the 2012 IRC the proposed changes above were inadvertently left out of the table when the changes approved in RB18-09/10 were incorporated.

Cost Impact: The code change proposal will not increase the cost of construction.

RB62-13

Public Hearing: Committee: AS AM D
Assembly: ASF AMF DF

R301.7T-RB-KEITH

RB63 – 13

R302.1

Proponent: Charles S. Bajnai, Chesterfield County, VA, ICC Building Code Action Committee
(bajnaic@chesterfield.gov)

Revise as follows:

SECTION R302 FIRE-RESISTANT CONSTRUCTION

R302.1 Exterior walls. ~~Construction-Walls~~, projections, openings and penetrations of *exterior walls* of *dwelling*s and accessory buildings shall comply with Table R302.1(1); or *dwelling*s equipped throughout with an *automatic sprinkler system* installed in accordance with Section P2904 shall comply with Table R302.1(2). The minimum fire separation distance shall be measured at right angles from the face of the wall.

Exceptions:

1. Walls, projections, openings or penetrations in walls perpendicular to the line used to determine the *fire separation distance*.
2. Walls of *dwelling*s and their *accessory structures* located on the same *lot*.

Reason: This proposal is submitted by the ICC Building Code Action Committee (BCAC). The BCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance an assigned International Code or portion thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the BCAC has held 6 open meetings and numerous workgroup calls which included members of the BCAC as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: <http://www.iccsafe.org/cs/BCAC/Pages/default.aspx>.

Fire Separation distance is among many of the code requirements that is often misinterpreted or is improperly enforced. To minimize the confusion, the BCAC decided that the best way to clarify how the fire separation distance is measured would be to incorporate language in Section 302.1 that restates the portion of the definition for fire separation distance that explains how it is measured.

The word "Construction" was deleted to correspond with the term "Wall" used in Tables R302.1(1) and R302.1(2).

Exception #1: the requirement for protecting walls, projections and openings does NOT apply when the walls, projections or opening are perpendicular to the line- no matter how close it is to the lot line.

Conversely Exception #1: the requirements for protecting walls, projections and openings applies to all walls, projections or openings NOT perpendicular to the lot line. To determine the degree that the walls, projections or openings have to be protected, use the *fire separation distance* (as measured perpendicular to the wall)

Fire separation distance is ALWAYS measured perpendicular to the face of the wall.

Cost Impact: None

RB63-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R302.1-RB-BAJNAI-BCAC

RB64 – 13

R302.1

Proponent: Ali M. Fattah, P.E., City of San Diego, representing the San Diego Area Chapter of ICC
(afattah@sandiego.gov)

Revise as follows:

R302.1 Exterior walls. Construction, projections, openings and penetrations of *exterior walls* of *dwelling*s and accessory buildings shall comply with Table R302.1(1); or *dwelling*s equipped throughout with an *automatic sprinkler system* installed in accordance with Section P2904 shall comply with Table R302.1(2).

Where non-residential buildings are located on the same lot containing dwellings and their accessory structures, exterior wall and opening protection and the protection of projections based on fire separation distance shall be determined in accordance with the *International Building Code*.

Exceptions:

1. Walls, projections, openings or penetrations in walls perpendicular to the line used to determine the *fire separation distance*.
2. Walls of *dwelling*s and *accessory structures* located on the same *lot*.
3. Detached tool sheds and storage sheds, playhouses and similar structures exempted from permits are not required to provide wall protection based on location on the *lot*. Projections beyond the *exterior wall* shall not extend over the *lot line*.
4. Detached garages accessory to a *dwelling* located within 2 feet (610 mm) of a *lot line* are permitted to have roof eave projections not exceeding 4 inches (102 mm).
5. Foundation vents installed in compliance with this code are permitted.

Reason: Section R302.1 of the IRC is not clear as to when an imaginary line shall be used to determine protection due fire separation distance between dwellings and buildings other than dwellings or accessory structures thereto located on the same lot. Furthermore, the IBC in Chapter 5 allows for options other than assuming an imaginary line when determining fire separation distance.

The IBC Section 503.1.2 exempts multiple buildings located on the same lot from exterior fire protection due to fire separation distance when the when considered as portions of one building. Since the IRC does not limit the area of a building and does not require fire sprinkler protection for additions, the equivalent of Section 503.1.2 does not exist in the IRC.

This code change makes a reference to the IBC to make clear that the protection due to fire separation distance shall be determined based on the requirements of the IBC for both a dwelling and the non-residential building that is regulated by the IBC. Without this code change IBC Section 503.1.2 may be construed to not apply. While the IRC has been designed to be a standalone code, the building official will be regulating the non-residential building based on the IBC and this code change provides a clear reference.

Cost Impact: None. This code change will not increase the cost of construction.

R302.1 #1-RB-FATTAH

RB65 – 13

R302.1

Proponent: Ali M. Fattah, P.E., City of San Diego, representing the San Diego Area Chapter of ICC
(afattah@sandiego.gov)

Revise as follows:

R302.1 Exterior walls. Construction, projections, openings and penetrations of *exterior walls* of *dwelling*s and accessory buildings shall comply with Table R302.1(1); or *dwelling*s equipped throughout with an *automatic sprinkler system* installed in accordance with Section P2904 shall comply with Table R302.1(2).

Exceptions:

1. Walls, projections, openings or penetrations in walls perpendicular to the line used to determine the *fire separation distance*.
2. Walls of *dwelling*s shall not be separated from ~~and~~ accessory structures located on the same lot.
3. Detached tool sheds and storage sheds, playhouses and similar structures exempted from permits are not required to provide wall protection based on location on the lot. Projections beyond the *exterior wall* shall not extend over the *lot line*.
4. Detached garages accessory to a *dwelling* located within 2 feet (610 mm) of a *lot line* are permitted to have roof eave projections not exceeding 4 inches (102 mm).
5. Foundation vents installed in compliance with this code are permitted.

Reason: Exception 2 of Section R302.1 of the IRC is not clear and can be read in two different ways. It may be read to exempt only accessory structures other than those discussed in exception 3 and 4 or all dwellings and structures accessory to any of them from the fire separation distance requirements. The IBC Section 503.1.2 exempts multiple buildings located on the same lot from exterior fire protection due to fire separation distance when the when considered as portions of one building. Since the IRC does not limit the area of a building and does not require fire sprinkler protection for additions, the equivalent of Section 503.1.2 does not exist in the IRC.

The National Institutes for Standards and Technology (NIST) has performed full scale fire testing on the fire exposure between buildings of light framed construction and in "NIST Technical Note 1600 - Residential Structure Separation Fire Experiments" (<http://www.fire.nist.gov/bfrlpubs/fire08/PDF/f08034.pdf>) concludes that "... an adjacent structure can be ignited if flames from a fire inside a house exit through window openings. The experiments illustrated how a fire resistant barrier can, in the scenario tested, slow down flame spread between two structures separated by 1.8 m (6 ft)." The full scale testing demonstrates the benefits of fire separation and the need to limit exterior wall openings and to protect exterior walls.

It is not clear why the IBC and IRC are different with respect to the issue of fire separation. Neither IBC Chapter 6 nor Chapter 7 exempts structures from protections due to fire separation distance, however the IRC through this exception 2 can be construed to exempt a dwelling from being protected relative to an adjacent dwelling owned and operated by a different owner. The definition of fire separation distance in Section R202 includes the use of an imaginary line between buildings, and without this proposed code change the IRC may only require fire separation distance to buildings on the same lot that are not dwellings or accessory structures.

Cost Impact: This code change will have a minimal increase to the cost of construction since land use regulations may restrict the separation between buildings on the same lot due to zoning and other considerations.

RB65-13

R302.1 #2-RB-FATTAH

RB66 – 13

R302.1

Proponent: Ali M. Fattah, P.E., City of San Diego, representing the San Diego Area Chapter of ICC
(afattah@sandiego.gov)

Revise as follows:

R302.1 Exterior walls. Construction, projections, openings and penetrations of exterior walls of dwellings and accessory buildings shall comply with Table R302.1(1); or dwellings equipped throughout with an automatic sprinkler system installed in accordance with Section P2904 shall comply with Table R302.1(2).

Exceptions:

1. Walls, projections, openings or penetrations in walls perpendicular to the line used to determine the fire separation distance.
2. Walls of dwellings and accessory structures located on the same lot.
3. Detached tool sheds and storage sheds, playhouses and similar structures exempted from permits are not required to provide wall protection based on location on the lot. Projections beyond the exterior wall shall not extend over the lot line.
4. Detached garages accessory to a dwelling located within 2 feet (610 mm) of a lot line are permitted to have roof eave projections not exceeding 4 inches (102 mm).
5. Foundation vents installed in compliance with this code are permitted.
6. Detached patio covers and deck structures located greater than 5 feet from dwellings or lot lines.

Reason: Section R302.1 of the IRC is not clear insofar as detached patio covers and deck structures are concerned and can be read in two different ways. It may be read to exempt the detached accessory structures listed in exception 3 and require that detached patio covers and deck structures comply with fire separation distance requirements. The IBC does not regulate these accessory structures when associated with residential construction and does not exempt them either when associated with non-residential construction.

The IBC Section 503.1.2 exempts multiple buildings located on the same lot from exterior fire protection due to fire separation distance when the when considered as portions of one building. Since the IRC does not limit the area of a building and does not require fire sprinkler protection for additions, the equivalent of Section 503.1.2 does not exist in the IRC.

The National Institutes for Standards and Technology (NIST) has performed full scale fire testing on the fire exposure between buildings of light framed construction and in "NIST Technical Note 1600 - Residential Structure Separation Fire Experiments" (<http://www.fire.nist.gov/bfrlpubs/fire08/PDF/f08034.pdf>) concludes that "... an adjacent structure can be ignited if flames from a fire inside a house exit through window openings. The experiments illustrated how a fire resistant barrier can, in the scenario tested, slow down flame spread between two structures separated by 1.8 m (6 ft)." The full scale testing demonstrates the benefits of fire separation and the need to limit exterior wall openings and to protect exterior walls.

The proposed code change clarifies that if it is the intent of the IRC not to regulate the fire separation between accessory structures and between accessory structures and dwellings on the same lot that those accessory structures should at least be separated from lot lines as if they were dwellings.

Cost Impact: This code change will have a minimal increase to the cost of construction since land use regulations may restrict the separation between buildings on the same lot due to zoning and other considerations.

R302.1 #3-RB-FATTAH

RB67 – 13

Table R302.1(1), Table R302.1(2)

Proponent: C. Ray Allshouse AIA, CBO, City of Shoreline, WA, representing the Washington Association of Building Officials Technical Code Development Committee (rallshouse@shorelinewa.gov)

Revise as follows:

R302.1 Exterior walls. Construction, projections, openings and penetrations of *exterior walls* of *dwelling*s and accessory buildings shall comply with Table R302.1(1); or *dwelling*s equipped throughout with an *automatic sprinkler system* installed in accordance with Section P2904 shall comply with Table R302.1(2).

Exceptions:

1. Walls, projections, openings or penetrations in walls perpendicular to the line used to determine the *fire separation distance*.
2. Walls of *dwelling*s and *accessory structures* located on the same *lot*.
3. Detached tool sheds and storage sheds, playhouses and similar structures exempted from permits are not required to provide wall protection based on location on the *lot*. Projections beyond the *exterior wall* shall not extend over the *lot line*.
4. Detached garages accessory to a *dwelling* located within 2 feet (610 mm) of a *lot line* are permitted to have roof eave projections not exceeding 4 inches (102 mm).
5. Foundation vents installed in compliance with this code are permitted.

**TABLE R302.1(1)
EXTERIOR WALLS**

EXTERIOR WALL ELEMENT		MINIMUM FIRE-RESISTANCE RATING	MINIMUM FIRE SEPARATION DISTANCE
Walls	Fire-resistance rated	1 hour—tested in accordance with ASTM E 119 or UL 263 with exposure from both sides	< 5 feet
	Not fire-resistance rated	0 hours	³ 5 feet
Projections	Fire-resistance rated	1 hour on the underside ^{a, b}	³ 2 feet to < 5 feet
	Not fire-resistance rated	0 hours	³ 5 feet
Openings in walls	Not allowed	N/A	< 3 feet
	25% maximum of wall area	0 hours	3 feet
	Unlimited	0 hours	5 feet
Penetrations	All	Comply with Section R302.4	< 5 feet
		None required	5 feet

For SI: 1 foot = 304.8 mm.

N/A = Not Applicable

a. Roof eave fire-resistance rating shall be permitted to be reduced to 0 hours on the underside of the eave if fire blocking is provided from the wall top plate to the underside of the roof sheathing.

b. Roof eave fire-resistance rating shall be permitted to be reduced to 0 hours on the underside of the eave provided no gable vent openings are installed.

TABLE R302.1(2)
EXTERIOR WALLS-DWELLINGS WITH FIRE SPRINKLERS

EXTERIOR WALL ELEMENT		MINIMUM FIRE-RESISTANCE RATING	MINIMUM FIRE SEPARATION DISTANCE
Walls	Fire-resistance rated	1 hour—tested in accordance with ASTM E 119 or UL 263 with exposure from the outside	0 feet
	Not fire-resistance rated	0 hours	3 feet ^a
Projections	Fire-resistance rated	1 hour on the underside ^{b,c}	2 feet ^a
	Not fire-resistance rated	0 hours	3 feet
Openings in walls	Not allowed	N/A	< 3 feet
	Unlimited	0 hours	3 feet ^a
Penetrations	All	Comply with Section R302.4	< 3 feet
		None required	3 feet ^a

For SI: 1 foot = 304.8 mm.

N/A = Not Applicable

- a. For residential subdivisions where all dwellings are equipped throughout with an automatic sprinkler system installed in accordance with P2904, the fire separation distance for nonrated exterior walls and rated projections shall be permitted to be reduced to 0 feet, and unlimited unprotected openings and penetrations shall be permitted, where the adjoining lot provides an open setback yard that is 6 feet or more in width on the opposite side of the property line
- b. The roof eave fire-resistance rating shall be permitted to be reduced to 0 hours on the underside of the eave if fire blocking is provided from the wall top plate to the underside of the roof sheathing.
- c. The roof eave fire-resistance rating shall be permitted to be reduced to 0 hours on the underside of the eave provided gable vent openings are not installed.

Reason: This change is primarily intended to address construction problems associated with having to simultaneously provide fire-resistive eave projections and adequate roof ventilation vents. In addition, current code language is silent on a potential problem of fire-spread to unprotected attics from exterior sources through roof vents where residential structures are built tight to fire separation requirements. Roof ventilation, typically handled by the installation of “bird block” vents under roof eave projections, unfortunately serve as a path for fire spread from adjacent structures. This problem is further aggravated by the fact that NFPA 13D Fire Sprinkler Systems do not require sprinklers in attic spaces. The proposed change provides a builder's option to mitigate this situation by providing for the installation of a top-side roof vent in lieu of fire-resistance treatment of the eave projection. The resulting solid wood fire-block in place of the otherwise required eave vents protects the attic from fire intrusion. Under this scenario, the unprotected eave is viewed to be expendable and therefore need not be fire rated.

Cost Impact: The code change proposal will not increase the cost of construction.

RB67-13

Public Hearing: Committee: AS AM D
Assembly: ASF AMF DF

R302.1 (1)T-RB-ALLSHOUSE

RB68 – 13

Table R302.1(1)

Proponent: Rick Davidson, City of Maple Grove, Association of Minnesota Building Officials
(rdavidson@maplegrovern.gov)

Revise as follows:

**TABLE R302.1(1)
EXTERIOR WALLS**

EXTERIOR WALL ELEMENT		MINIMUM FIRE-RESISTANCE RATING	MINIMUM FIRE SEPARATION DISTANCE
Walls	Fire-resistance rated	1 hour—tested in accordance with ASTM E 119 or UL 263 with exposure from both sides	< 5 feet
	Not fire-resistance rated	0 hours	³ 5 feet
Projections	Fire-resistance rated	1 hour on the underside	³ 2 feet to < 5 feet
	Not fire-resistance rated	0 hours	³ 5 feet
Openings in walls	Not allowed	N/A	< 3 feet
	25% maximum of wall area	0 hours	3 feet
	Unlimited	0 hours	5 feet
Penetrations	All	Comply with Section R302.4	< 5 <u>3</u> feet
		None required	5 <u>3</u> feet

For SI: 1 foot = 304.8 mm.

N/A = Not Applicable.

Reason: This proposal reduces the penetration protection requirements for non sprinklered buildings to the same level as sprinklered buildings. The code currently allows walls 3 feet from a lot line to have openings up to 25% of the wall area but penetrations are required to be protected. This is senseless. The code overreacts to penetration protection. Foundation vents can be installed without limitation up to a lot line. Walls can have openings up to 25% of the area of the wall at 3 feet from the lot line. But install a penetration for a sill cock at 4 feet and it needs protection! This proposal creates some sense of reason to this section of the code.

Cost Impact: None

Walls	Fire-resistance rated	1 hour—tested in accordance with ASTM E 119 or UL 263 with exposure from the outside	0 feet
	Not fire-resistance rated	0 hours	3 feet ^a
Projections	Fire-resistance rated	1 hour on the underside	2 feet ^a <u>distance to projection</u>
	Not fire-resistance rated	0 hours	3 feet <u>distance to projection</u>
Openings in walls	Not allowed	N/A	< 3 feet
	Unlimited	0 hours	3 feet ^a
Penetrations	All	Comply with Section R302.4	< 3 feet
		None required	3 feet ^a

For SI: 1 foot = 304.8 mm.

N/A = Not Applicable

- a. For residential subdivisions where all dwellings are equipped throughout with an automatic sprinkler system installed in accordance with P2904, the fire separation distance for nonrated exterior walls and rated projections shall be permitted to be reduced to 0 feet, and unlimited unprotected openings and penetrations shall be permitted, where the adjoining lot provides an open setback yard that is 6 feet or more in width on the opposite side of the property line.

Reason: Table R302.1(1) and Table R302.1(2) are not clear when restrictions on projections are concerned. The term fire separation distance is defined in Section R202 clarifies that the fire separation distance is established by measuring “from the building face” to an imaginary line, lot line or the center line of a street. As a result once a fire separation distance is established the exterior wall elements shown in column 1 of both tables are restricted or protected based on their location. Projections however are regulated by the amount that they encroach into the fire separation distance. This code change updates the table for consistency with the TABLE 705.2 of the IBC that limits the distance from the line used to determine fire separation distance to the projection. The IRC and IBC editions preceding the 2012 edition included regulations restricting the length of projections encroaching into the fire separation distance, the famous 1/3 to 1/2 the fire separation distance approach. This editorial code change proposes to clarify the table and to assist the user.

This code change is being offered in a text format or tabular format in separate code changes to allow the membership a choice in the way that the regulations are adopted into the 2015 IBC.

Cost Impact: None. This code change will not increase the cost of construction.

Table R302.1(1), Table R302.1(2)

Proponent: Steve Orlowski, representing National Association of Home Builders (NAHB)
(sorlowski@nahb.org)

Revise as follows:

**TABLE R302.1(1)
EXTERIOR WALLS**

EXTERIOR WALL ELEMENT		MINIMUM FIRE-RESISTANCE RATING <u>Fire Protection</u>	MINIMUM FIRE SEPARATION DISTANCE
Walls	Fire-resistance rated	1 hour—tested in accordance with ASTM E 119 or UL 263 with exposure from both sides	< 5 feet
	Not fire-resistance rated	0 hours	≥5 feet
Projections	Fire-resistance rated	1 hour <u>1 layer of 5/8 inch (mm) Type X gypsum board or equivalent^a</u> on the underside	≥2 feet to < 5 feet
	Not fire-resistance	0 hours	≥5 feet
Openings in walls	Not allowed	N/A	< 3 feet
	25% maximum of wall area	0 hours	3 feet
	Unlimited	0 hours	5 feet
Penetrations	All	Comply with Section R302.4	< 5 feet
		None required	5 feet

For SI: 1 foot = 304.8 mm.

N/A = Not Applicable.

a. Attic and crawlspace ventilation shall be permitted in projections, provided such vents are covered with noncombustible corrosion-resistant mesh with openings not to exceed ¼ inch (6.4mm).

**TABLE R302.1(2)
EXTERIOR WALLS—DWELLINGS WITH FIRE SPRINKLERS**

EXTERIOR WALL ELEMENT		MINIMUM FIRE-RESISTANCE RATING <u>FIRE PROTECTION</u>	MINIMUM FIRE SEPARATION DISTANCE
Walls	Fire-resistance rated	1 hour—tested in accordance with ASTM E 119 or UL 263 with exposure from both sides	0 feet
	Not fire-resistance rated	0 hours	3 feet ^a
Projections	Fire-resistance rated	1 hour <u>1 layer of 5/8 inch (mm) Type X gypsum board or equivalent^b</u> on the underside ^b	2 feet ^a

EXTERIOR WALL ELEMENT		MINIMUM FIRE-RESISTANCE RATING <u>FIRE PROTECTION</u>	MINIMUM FIRE SEPARATION DISTANCE
	Not fire-resistance	rated 0 hours	3 feet
Openings in walls	Not allowed	N/A	< 3 feet
	Unlimited	0 hours	3 feet ^a
Penetrations	All	Comply with Section R302.4	< 3 feet
		None required	3 feet

For SI: 1 foot = 304.8 mm.

N/A = Not Applicable

- a. For residential subdivisions where all dwellings are equipped throughout with an automatic sprinkler systems installed in accordance with Section P2904, the fire separation distance for nonrated exterior walls and rated projections shall be permitted to be reduced to 0 feet, and unlimited unprotected openings and penetrations shall be permitted, where the adjoining lot provides an open setback yard that is 6 feet or more in width on the opposite side of the property line.
- b. Attic and crawlspace ventilation in projections required to be fire protected shall be covered with noncombustible corrosion-resistant mesh with openings not to exceed ¼ inch (6.4mm).

Reason: After reviewing several UL listed fire-resistant rated assemblies, the NAHB discovered a problem between attempting to provide adequate attic ventilation to certain roof types (hip roofs, cathedral ceilings, etc) and achieving the one-hour fire resistance rating. The UL listed roof assemblies do not allow for any openings in the rated assembly for roofs, thereby creating a problem for proper roof ventilation as required in section R806. The NAHB proposes this code change to balance the needs of both adequate fire protection for exposure fires and proper ventilation of the attic. Under the 2012 IRC, projections are not permitted within two feet of the fire separation distance and the required ventilation opening for attics are minimal, 1/150 of the area of the vented space. The IRC also currently allows 25% of the wall space to be occupied by windows in exterior walls that are within 3'-0" of the fire separation distance. The IRC currently exempt foundation vents from being protected. NAHB suggests that due to the minimal openings required to provide ventilation in the attic, these openings should also be exempted. This proposal suggests removing the current performance requirement of providing a one hour fire-resistant rating on the underside of projections and replacing the language with a prescriptive method which achieves the same performance and allows for minimal openings for ventilation.

Cost Impact: The code change proposal will not increase the cost of construction.

Reason: There is currently no specific language that states that projections cannot be any closer to a property line than 2 feet. Table 302.1 infers it, but it is not clear. It appears that this requirement was lost when we put the projection requirements into the table format in the 2009 IRC. Our proposal clears up this hole in the code and provides specific language stating that projections are not permitted within 2 feet of the line used to determine the fire separation distance.

Cost Impact: Construction costs will not be affected by this proposal.

R302.1(1)T-RB-THOMAS

RB72 – 13

Table R302.1(1)

Proponent: Maureen Traxler, Washington Association of Building Officials Technical Code Development Committee (maureen.traxler@seattle.gov)

Revise as follows:

**TABLE R302.1(1)
EXTERIOR WALLS**

EXTERIOR WALL ELEMENT		MINIMUM FIRE-RESISTANCE RATING	MINIMUM FIRE SEPARATION DISTANCE
Walls	Fire-resistance rated	1 hour—tested in accordance with ASTM E 119 or UL 263 with exposure from both sides	< 5 feet
	Not fire-resistance rated	0 hours	≥ 5 feet
Projections	Fire-resistance rated	1 hour on the underside	≥ 2 feet to < 5 feet
	Not fire-resistance rated	0 hours	≥ 5 feet
Openings in walls	Not allowed	N/A	< 3 feet
	25% maximum of wall area <u>per story</u>	0 hours	3 feet
	Unlimited	0 hours	5 feet
Penetrations	All	Comply with Section R302.4	< 5 feet
		None required	5 feet

For SI: 1 foot = 304.8 mm.

N/A = Not Applicable.

Reason: The IRC is ambiguous about how to calculate the percentage of openings allowed in exterior walls. The limitation could be calculated either as a percentage of the area of the entire exterior wall, or as a percentage of each story. This proposal requires that openings in exterior walls be calculated for each story. This method is consistent with IBC Section 705.8.1. Consider this example of the potential consequence of not using the proposed interpretation. If the area of openings was allowed to be calculated based on the entire face of the wall, on a 3-story building the first story of a building 3 feet from a property line could have 75% openings if there were no openings in the other 2 stories.

Cost Impact: None

Assembly: ASF AMF DF

R302.1(1)T-RB-TRAXLER

RB73 – 13

Table R302.1(2), R309.5

Proponent: Rick Davidson, City of Maple Grove, Association of Minnesota Building Officials
(rdavidson@maplegrovern.gov)

Revise as follows:

TABLE R302.1(2) EXTERIOR WALLS—DWELLINGS WITH FIRE SPRINKLERS

(Portions of table not shown remain unchanged.)

- a. ~~For residential subdivisions where all dwellings are equipped throughout with an automatic sprinkler systems installed in accordance with Section P2904, the fire separation distance for nonrated exterior walls and rated projections shall be permitted to be reduced to 0 feet, and unlimited unprotected openings and penetrations shall be permitted, where the adjoining lot provides an open setback yard that is 6 feet or more in width on the opposite side of the property line.~~

~~R309.5 Fire sprinklers.~~ ~~Private garages shall be protected by fire sprinklers where the garage wall has been designed based on Table R302.1(2), Footnote a. Sprinklers in garages shall be connected to an automatic sprinkler system that complies with Section P2904. Garage sprinklers shall be residential sprinklers or quick-response sprinklers, designed to provide a density of 0.05 gpm/ft². Garage doors shall not be considered obstructions with respect to sprinkler placement.~~

Reason: It is reasonable to delete this footnote and related section R309.5 because the code doesn't define what a "subdivision" is and there is no way to apply this footnote in a fair manner. Because it only applies to "subdivisions" where **all** dwellings are equipped with sprinklers and because there are huge numbers of undeveloped lots scattered throughout existing "subdivisions" in this country because of the financial crises, there is an incentive for lot owners to replat their lots, even single lots, to a separate "subdivision" to take advantage of this exception. It then gives special treatment to a lot owner if there is open space on an adjoining lot by allowing them to construct to a lot line and effectively requiring the adjoining owner to maintain a six foot setback. This effectively limits what that adjoining lot owner can do based on "the neighbor got there first" and can have an impact on the value of the properties.

How do you deny a permit to a homeowner because of something an adjoining owner did? Code philosophy has always been based on the correlation of a building located on its own lot with no credit being given for space on an adjoining lot that is not under the control of the jurisdiction or the owner in question. This code section is so confusing that it will result in a lack of uniformity where ever it is used.

Additionally, as it now stands, this requirement will require record keeping and plan submittals that would not have been necessary previously and require some surveys and site plans to include information on the adjoining lot. For example, if one lot owner exercised this option and placed their building two feet from a lot line, this would require the adjoining owner to maintain a 4 foot setback. Site plans would need to indicate the setback of adjoining lots in order for this to be properly enforced. This will increase the cost of site plan/survey preparation. It also assumes that ready access to adjoining properties will be permitted. This code change is necessary to avoid confusion and treat all property owners equally.

Cost Impact: None

R302.1(2)T-RB_DAVIDSON

RB74 – 13

R302.1.1 (New)

Proponent: Ali M. Fattah, P.E., City of San Diego, representing the San Diego Area Chapter of ICC
(afattah@sandiego.gov)

Add new text as follows:

R302.1 Exterior walls. Construction, projections, openings and penetrations of *exterior walls* of *dwellings* and accessory buildings shall comply with Table R302.1(1); or dwellings equipped throughout with an automatic sprinkler system installed in accordance with Section P2904 shall comply with Table R302.1(2).

Exceptions:

1. Walls, projections, openings or penetrations in walls perpendicular to the line used to determine the fire separation distance.
2. Walls of dwellings and accessory structures located on the same lot.
3. Detached tool sheds and storage sheds, playhouses and similar structures exempted from permits are not required to provide wall protection based on location on the lot. Projections beyond the exterior wall shall not extend over the lot line.
4. Detached garages accessory to a dwelling located within 2 feet (610 mm) of a lot line are permitted to have roof eave projections not exceeding 4 inches (102 mm).
5. Foundation vents installed in compliance with this code are permitted.

R302.1.1 Exterior stairways. Exterior stairways located above grade shall have a minimum fire separation distance of 5 feet (1524 mm) as measured from the exterior edge of the *stairway*, including landings, to adjacent *lot lines* and from other buildings on the same lot.

Exception: Where the *exterior walls* and openings on the adjacent building on the same lot are protected in accordance with Table R302.1(1) based on *fire separation distance*.

Reason: Section R302.1 of the IRC is not clear insofar as exterior stairways located in close proximity to lot lines. The IBC Section 1026.5 requires a fire separation distance of not less than 10 ft since it considers exterior stairways to be exits. The IRC does not fire protection for stairways and as a consequence a dwelling unit located on the second floor served independently with an exterior stairway can be served with a stairway located at a fire separation distance of 0 ft. This lack of protection to a combustible exterior exit element is not prudent as has been demonstrated by full scale fire testing for building exposures.

The National Institutes for Standards and Technology (NIST) has performed full scale fire testing on the fire exposure between buildings of light framed construction and in "NIST Technical Note 1600 - Residential Structure Separation Fire Experiments" (<http://www.fire.nist.gov/bfrlpubs/fire08/PDF/f08034.pdf>) concludes that "... an adjacent structure can be ignited if flames from a fire inside a house exit through window openings. The experiments illustrated how a fire resistant barrier can, in the scenario tested, slow down flame spread between two structures separated by 1.8 m (6 ft)." The full scale testing demonstrates the benefits of fire separation and the need to limit exterior wall openings and to protect exterior walls and by extension the reason that it is necessary to protect or separate elevated exterior exit ways.

Cost Impact: This code change will have a minimal increase to the code of construction since local use regulations may restrict the separation between buildings on the same lot due to zoning and other considerations.

R302.1.1 (NEW) #1-RB-FATTAH

RB75 – 13

R302.1.1 (New)

Proponent: Ali M. Fattah, P.E., City of San Diego, representing the San Diego Area Chapter of ICC
(afattah@sandiego.gov)

Add new text as follows:

R302.1 Exterior walls. Construction, projections, openings and penetrations of exterior walls of dwellings and accessory buildings shall comply with Table R302.1(1); or dwellings equipped throughout with an automatic sprinkler system installed in accordance with Section P2904 shall comply with Table R302.1(2).

Exceptions:

1. Walls, projections, openings or penetrations in walls perpendicular to the line used to determine the fire separation distance.
2. Walls of dwellings and accessory structures located on the same lot.
3. Detached tool sheds and storage sheds, playhouses and similar structures exempted from permits are not required to provide wall protection based on location on the lot. Projections beyond the exterior wall shall not extend over the lot line.
4. Detached garages accessory to a dwelling located within 2 feet (610 mm) of a lot line are permitted to have roof eave projections not exceeding 4 inches (102 mm).
5. Foundation vents installed in compliance with this code are permitted.

R302.1.1 Attached and detached accessory structures. Accessory structures such as patio covers and deck structures, whether attached or detached, shall be located not less than a fire separation distance of 5 ft or more from lot lines.

Reason: Section R302.1 of the IRC is not clear insofar as detached patio covers and deck structures are concerned and can be read in two different ways. It may be read to exempt the detached accessory structures listed in exception 3 and require that detached patio covers and deck structures comply with fire separation distance requirements. The IBC does not regulate these accessory structures when associated with residential construction and does not exempt them either when associated with non-residential construction.

The IBC Section 503.1.2 exempts multiple buildings located on the same lot from exterior fire protection due to fire separation distance when the when considered as portions of one building. Since the IRC does not limit the area of a building and does not require fire sprinkler protection for additions, the equivalent of Section 503.1.2 does not exist in the IRC.

The National Institutes for Standards and Technology (NIST) has performed full scale fire testing on the fire exposure between buildings of light framed construction and in "NIST Technical Note 1600 - Residential Structure Separation Fire Experiments" (<http://www.fire.nist.gov/bfrlpubs/fire08/PDF/f08034.pdf>) concludes that "... an adjacent structure can be ignited if flames from a fire inside a house exit through window openings. The experiments illustrated how a fire resistant barrier can, in the scenario tested, slow down flame spread between two structures separated by 1.8 m (6 ft)." The full scale testing demonstrates the benefits of fire separation and the need to limit exterior wall openings and to protect exterior walls.

The proposed code change clarifies that if it is the intent of the IRC not to regulate the fire separation between accessory structures and between accessory structures and dwellings on the same lot that those accessory structures should at least be separated from lot lines as if they were dwellings.

Cost Impact: This code change will have a minimal increase to the cost of construction since land use regulations may restrict the separation between buildings on the same lot due to zoning and other considerations.

RB75-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

(NEW) #2-RB-FATTAH

RB76 – 13

R302.1.1 (New)

Proponent: Ali M. Fattah, P.E., City of San Diego, representing the San Diego Area Chapter of ICC(afattah@sandiego.gov)

Add new text as follows:

R302.1 Exterior walls. Construction, projections, openings and penetrations of exterior walls of dwellings and accessory buildings shall comply with Table R302.1(1); or dwellings equipped throughout with an automatic sprinkler system installed in accordance with Section P2904 shall comply with Table R302.1(2).

Exceptions:

1. Walls, projections, openings or penetrations in walls perpendicular to the line used to determine the fire separation distance.
2. Walls of dwellings and accessory structures located on the same lot.
3. Detached tool sheds and storage sheds, playhouses and similar structures exempted from permits are not required to provide wall protection based on location on the lot. Projections beyond the exterior wall shall not extend over the lot line.
4. Detached garages accessory to a dwelling located within 2 feet (610 mm) of a lot line are permitted to have roof eave projections not exceeding 4 inches (102 mm).
5. Foundation vents installed in compliance with this code are permitted.

R302.1.1 Projections. Projections shall be located a minimum distance from the line used to determine fire separation distance based on Table R302.1(1) and Table R302.1(2). Projections shall be fire resistance rated where required by Table R302.1(1) and Table R302.1(2).

Reason: Table R302.1(1) and Table R302.1(2) are not clear when restrictions on projections are concerned. The term fire separation distance is defined in Section R202 clarifies that the fire separation distance is established by measuring "from the building face" to an imaginary line, lot line or the center line of a street. As a result once a fire separation distance is established the exterior wall elements shown in column 1 of both tables are restricted or protected based on their location. Projections however are regulated by the amount that they encroach into the fire separation distance. This code change updates the table for consistency with the TABLE 705.2 of the IBC that limits the distance from the line used to determine fire separation distance to the projection. The IRC and IBC editions preceding the 2012 edition included regulations restricting the length of projections encroaching into the fire separation distance, the famous 1/3 to 1/2 the fire separation distance approach. This editorial code change proposes to clarify the table and to assist the user.

This code change is being offered in a text format or tabular format in separate code changes to allow the membership a choice in the way that the regulations are adopted into the 2015 IBC.

Cost Impact: None. This code change will not increase the cost of construction.

R302.1.1 (NEW) #3-RB-FATTAH

RB77 – 13

R302.2

Proponent: Matt Archer, Douglas County, CO representing Colorado Chapter Code Change Committee (marcher@douglas.co.us)

Revise as follows:

R302.2 Townhouses. Each *townhouse* shall be considered a separate building and shall be separated by fire-resistance-rated wall assemblies meeting the requirements of Section R302.1 for exterior walls.

Exception: A common 1-hour fire-resistance-rated wall assembly tested in accordance with ASTM E 119 or UL 263 is permitted for townhouses if such walls do not contain plumbing or mechanical equipment, ducts or vents in the cavity of the common wall. ~~The wall shall be rated for fire exposure from both sides, and shall extend to and be tight against exterior walls and the underside of the roof sheathing. Electrical installations shall be installed in accordance with Chapters 34 through 43. Penetrations of electrical outlet boxes shall be in accordance with Section R302.4.~~

Reason: This language is redundant and needs to be deleted because it is already covered in the next section, R302.2.1, Continuity.

"The fire-resistance-rated wall or assembly separating *townhouses* shall be continuous from the foundation to the underside of the roof sheathing, deck or slab. The fire-resistance rating shall extend the full length of the wall or assembly, including wall extensions through and separating attached enclosed *accessory structures*."

The language about electrical installations is not needed. This section is about fire-resistance-rated construction, not about how to wire a home.

Cost Impact: None

RB77-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R302.2-RB-ARCHER

RB78 – 13

R302.2

Proponent: Michael Gardner, representing Gypsum Association (mgardner@gypsum.org); Jeffrey Hugo, representing National Fire Sprinkler Association (hugo@nfsa.org)

Revise as follows:

R302.2 Townhouses. Each *townhouse* shall be considered a separate building and shall be separated by fire-resistance rated wall assemblies meeting the requirements of Section R302.1 for exterior walls-

Exception: A common ~~1-hour~~ fire-resistance-rated wall assembly tested in accordance with ASTM E 119 or UL 263 is permitted for townhouses if such walls do not contain plumbing or mechanical equipment, ducts or vents in the cavity of the common wall. The wall shall be rated for fire exposure from both sides and shall extend to and be tight against exterior walls and the underside of the roof sheathing. Electrical installations shall be installed in accordance with Chapters 34 through 43. Penetrations of electrical outlet boxes shall be in accordance with Section R302.4. The common wall shall be 1-hour-fire-resistance-rated for townhouses complying with Section R313.1 and 2-hour-fire-resistance-rated in all other installations.

Reason: A number of governmental entities, primarily local jurisdictions in states where a state-wide code does not exist, are electing to eliminate the residential sprinkler requirement when adopting a new version of the IRC. In so doing, the jurisdiction runs the risk of overlooking the need to re-insert the language that requires the townhouse separation wall to have a two-hour fire rating if the option to use a common wall is chosen.

This proposal addresses this potential oversight. By reference to Section R313.1, it re-establishes the 2-hour common wall requirement only in the instance where adjacent townhouse units are not sprinklered. If sprinkler systems that meet the requirements of Section R313.1 are installed in adjacent townhouse units, the common wall rating remains 1- hour.

Cost Impact: None

RB78-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R302.2-RB-HUGO-GARDNER

RB79 – 13

R302.2, R302.2.4

Proponent: Jeffrey M. Shapiro, representing IRC Fire Sprinkler Coalition
(jeff.shapiro@intlcodeconsultants.com)

Revise as follows:

R302.2 Townhouses. Each *townhouse* shall be considered a separate building and shall be separated by fire-resistance rated wall assemblies meeting the requirements of Section R302.1 for exterior walls.

Exceptions:

1. Where a fire sprinkler system in accordance with Section P2904 is provided, a common 1-hour-fire-resistance-rated wall assembly tested in accordance with ASTM E 119 or UL 263 is permitted for townhouses if such walls do not contain plumbing or mechanical equipment, ducts or vents in the cavity of the common wall. The wall shall be rated for fire exposure from both sides and shall extend to and be tight against exterior walls and the underside of the roof sheathing. Electrical installations shall be installed in accordance with Chapters 34 through 43. Penetrations of electrical outlet boxes shall be in accordance with Section R302.4.
2. Where a fire sprinkler system in accordance with Section P2904 is not provided, a common 2-hour fire-resistance-rated wall assembly tested in accordance with ASTM E 119 or UL 263 is permitted for townhouses where such walls do not contain plumbing or mechanical equipment, ducts or vents in the cavity of the common wall. The wall shall be rated for fire exposure from both sides and shall extend to and be tight against exterior walls and the underside of the roof sheathing. Electrical installations shall be installed in accordance with Chapters 34 through 43. Penetrations of electrical outlet boxes shall be in accordance with Section R302.4.

R302.2.4 Structural independence. Each individual *townhouse* shall be structurally independent.

Exceptions:

1. Foundations supporting *exterior walls* or common walls.
2. Structural roof and wall sheathing from each unit may fasten to the common wall framing.
3. Nonstructural wall and roof coverings.
4. Flashing at termination of roof covering over common wall.
5. *Townhouses* separated by a common ~~4-hour fire resistance-rated~~ wall as provided in Section R302.2, Exceptions 1 or 2.

Reason: The 1-hour separation requirements in these sections were reduced from 2-hour ratings in prior editions of the IRC based on the assumption that fire sprinklers mandated by the IRC would be present in all townhouses. Because some jurisdictions are amending the IRC to remove the fire sprinkler requirement, it is essential that the IRC provide for townhouse separation fire ratings to be returned to 2-hours if sprinklers are not provided. No justification, other than sprinklers, was ever provided for allowing a 1-hour separation, and this reduced rating is inappropriate for non-sprinklered buildings.

Cost Impact: The code change proposal will not increase the cost of construction.

RB79-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R302.2-RB-SHAPIRO

RB80 – 13

R302.2, R302.2.4

Proponent: Jason Thompson, National Concrete Masonry Association representing Masonry Alliance for Codes and Standards (jthompson@ncma.org)

Revise as follows:

R302.2 Townhouses. Each *townhouse* shall be considered a separate building and shall be separated by fire-resistance-rated wall assemblies meeting the requirements of Section R302.1 for exterior walls.

Exception: A common ~~1-hour fire-resistance-rated~~ wall assembly with a minimum 1-hour fire-resistance-rating as tested in accordance with ASTM E 119 or UL 263 is permitted for *townhouses* if such walls do not contain plumbing or mechanical equipment, ducts or vents in the cavity of the common wall. The wall shall be rated for fire exposure from both sides and shall extend to and be tight against exterior walls and the underside of the roof sheathing. Electrical installations shall be installed in accordance with Chapters 34 through 43. Penetrations of electrical outlet boxes shall be in accordance with Section R302.4.

R302.2.4 Structural independence. Each individual townhouse shall be structurally independent.

Exceptions:

1. Foundations supporting exterior walls or common walls.
2. Structural roof and wall sheathing from each unit may fasten to the common wall framing.
3. Nonstructural wall coverings.
4. Flashing at termination of roof covering over common wall.
5. Townhouses separated by a common ~~1-hour fire-resistance-rated~~ wall as provided in Section R302.2.

Reason: The present language in R302.2 specifically requires a 1-hour fire resistance rating for common walls between townhouses. It is unclear if the code user could specify and construct a 2-hour or 3-hour fire rated wall assembly if they wanted to though common walls with a higher fire resistance rating should be allowed. This proposal is intended to allow the code user to construct common walls between townhouses with a fire resistance rating of 1-hour or greater.

As a corollary change Exception No. 5 to Section 302.2.4 applies to the common walls between townhouses that have a 1-hour fire resistance rating as specified in R302.2. The exception permits these common walls to be shared by townhouses without having to provide structural independence. However, the wording in the exception also prevents a person who may want to use a common wall with a fire resistance rating that is more than 1-hour from applying the structural independence exemption. This proposal deletes the hourly fire resistance rating from Exception No. 5 so the "common wall" is only required to meet the provisions in accordance with Section R302.2, which includes the requirement for a fire resistance rating of at least 1-hour. The use of the term "common wall" in Exception No. 5 is also consistent with the "common wall" terminology in Exceptions 1, 2 and 4 to Section R302.2.4.

Cost Impact: This proposal will not increase the cost of construction.

RB80-13

	Assembly:	ASF	AMF	DF

R302.2 #1-RB-THOMPSON

RB81 – 13

R302.2, R302.2.4, R313.1, R313.2 and R313.3 (New)

Proponent: Jason Thompson, P.E., National Concrete Masonry Association representing Masonry Alliance for Codes and Standards (jthompson@ncma.org)

Revise as follows:

R302.2 Townhouses. Each *townhouse* shall be considered a separate building and shall be separated by fire-resistance-rated wall assemblies meeting the requirements of Section R302.1 for exterior walls.

Exception: A common 1-hour fire-resistance-rated wall assembly tested in accordance with ASTM E 119 or UL 263 is permitted for *townhouses* with automatic fire sprinkler systems in accordance with Section R313.1 if such walls do not contain plumbing or mechanical equipment, ducts or vents in the cavity of the common wall. The wall shall be rated for fire exposure from both sides and shall extend to and be tight against exterior walls and the underside of the roof sheathing. Electrical installations shall be installed in accordance with Chapters 34 through 43. Penetrations of electrical outlet boxes shall be in accordance with Section R302.4.

R302.2.4 Structural independence. Each individual townhouse shall be structurally independent.

Exceptions:

1. Foundations supporting exterior walls or common walls.
2. Structural roof and wall sheathing from each unit may fasten to the common wall framing.
3. Nonstructural wall coverings.
4. Flashing at termination of roof covering over common wall.
5. Townhouses separated by a common ~~1-hour fire-resistance-rated~~ wall as provided in Section R302.2 or Section R313.3.

R313.1 Townhouse automatic fire sprinkler systems. Except as provided in Section R313.3, A ~~an~~ automatic residential fire sprinkler system shall be installed in *townhouses*.

Exception: An automatic residential fire sprinkler system shall not be required when *additions* or *alterations* are made to existing *townhouses* that do not have an automatic residential fire sprinkler system installed.

R313.1.1 Design and installation. Automatic residential fire sprinkler systems for *townhouses* shall be designed and installed in accordance with Section P2904.

R313.2 One- and two-family dwellings automatic fire systems. Except as provided in Section R313.3, A ~~an~~ automatic residential fire sprinkler system shall be installed in one- and two-family *dwellings*.

Exception: An automatic residential fire sprinkler system shall not be required for *additions* or *alterations* to existing buildings that are not already provided with an automatic residential sprinkler system.

R313.2.1 Design and installation. Automatic residential fire sprinkler systems shall be designed and installed in accordance with Section P2904 or NFPA 13D.

R313.3 Automatic fire sprinkler system alternative. Where an automatic fire sprinkler system is not required to be installed by the adopting authority, the following requirements shall be met.

1. Construction, projections, openings and penetrations of exterior walls of dwellings shall comply with Table R302.1(1);

2. Townhouses constructed with a common wall assembly in accordance with the exception to Section R302.2 shall have a minimum 2-hour fire-resistance-rating. The common wall shall not contain plumbing or mechanical equipment, ducts or vents in the cavity of the common wall. The wall shall be rated for fire exposure from both sides and shall extend to and be tight against exterior walls and the underside of the roof sheathing. Electrical installations shall be installed in accordance with Chapters 34 through 43. Penetrations for electrical outlet boxes shall be in accordance with Section R302.4.

Reason: Where adoption of the 2009 and 2012 editions of the International Residential Building Code have been considered, many adopting authorities have made modifications to negate the requirement for mandatory automatic fire sprinkler protection. In some instances the adopting authorities have re-instated the previous requirements for the fire resistance for exterior walls for dwellings and the fire resistance for common walls separating townhouses to those established in the 2006 edition. However, some jurisdictions negated the mandatory automatic fire sprinkler protection but did not require the previous fire resistance requirements for these exterior walls and common walls resulting in reduced fire safety for the occupants and property.

This proposal provides an alternative within the code to permit adopting authorities an option to permit townhouses and one- and two-family dwellings to be unsprinklered provided the fire resistance rating for exterior walls and common walls are established at the code prescribed levels prior to the 2009 IRC.

Cost Impact: This proposal will not increase the cost of construction.

RB81-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R302.2 #2-RB-THOMPSON

RB82 – 13

R302.2, R302.2.4

Proponent: Jason Thompson, National Concrete Masonry Association representing Masonry Alliance for Codes and Standards (jthompson@ncma.org)

Revise as follows:

R302.2 Townhouses. Each *townhouse* shall be considered a separate building and shall be separated by fire-resistance-rated wall assemblies meeting the requirements of Section R302.1 for exterior walls.

Exception: A common ~~1-hour fire-resistance-rated~~ wall assembly with a minimum 2-hour fire-resistance-rating as tested in accordance with ASTM E 119 or UL 263 is permitted for townhouses if such walls do not contain plumbing or mechanical equipment, ducts or vents in the cavity of the common wall. The wall shall be rated for fire exposure from both sides and shall extend to and be tight against exterior walls and the underside of the roof sheathing. Electrical installations shall be installed in accordance with Chapters 34 through 43. Penetrations of electrical outlet boxes shall be in accordance with Section R302.4.

R302.2.4 Structural independence. Each individual townhouse shall be structurally independent.

Exceptions:

1. Foundations supporting exterior walls or common walls.
2. Structural roof and wall sheathing from each unit may fasten to the common wall framing.
3. Nonstructural wall coverings.
4. Flashing at termination of roof covering over common wall.
5. Townhouses separated by a common ~~1-hour fire-resistance-rated~~ wall as provided in Section R302.2.

Reason: Code change RB66-07/08 required townhouses constructed in accordance with the International Residential Code to be provided with automatic sprinkler protection. While this new requirement added a fire safety feature to townhouses the code change also reduced the level of fire safety that existed in the code by reducing the fire resistance rating required for the common wall separating dwelling units in townhouses. The first part of this code change to Section R302.2 will restore the previous IRC code requirement that the common wall separating dwelling units in townhouses shall have a minimum fire resistance rating of 2-hours. There are two reasons for this part of the change.

First, Code Change RB66-07/08 justified the addition of mandatory sprinkler protection for townhouses based on sprinklers being the best tool for providing additional fire safety in residential occupancies. Given that the 2006 IRC already had an established level of fire safety for residential occupancies utilizing townhouse construction with 2-hour fire rated construction for the common wall, the goal for improving fire safety with the addition of sprinkler protection was not fully achieved. The existing level of fire safety was diminished by the reduction in the fire resistance rating of the common wall from 2-hours to 1-hour.

Second, Code Change RB66-07/08 created an inconsistency in the IRC. If two separate one and two family dwellings are constructed on individual lots and each built less than 3 feet from the property line, Section R302.1 and Tables R302.1(1) and R302.1(2) will require the exterior wall of each dwelling to be built with a 1-hour fire resistance rating using a fire exposure from both sides. The net result is that both dwellings are separated from the other adjacent, closely located dwelling by wall construction with a total cumulative fire resistance of 2-hours. Yet, if these same two individual dwellings are physically connected at the property line by a common wall the code permits the fire resistance rating between the townhouse dwelling units to be reduced to 1-hour. The level of fire safety for dwellings with these two configurations is not consistent.

Part 2 of the change modifies Exception No. 5 to Section R302.2.4 by deleting any reference to an hourly fire resistance rating. Presently Exception No. 5 to Section 302.2.4 applies to the common walls between townhouses that have a 1-hour fire resistance rating as specified in R302.2. The exception permits these common walls to be shared by townhouses without having to provide structural independence. However, the wording in the exception also prevents a person who may want to use a common wall with a fire resistance rating that is more than 1-hour from applying the structural independence exemption. This proposal deletes the hourly fire resistance rating from Exception No. 5 so the "common wall" is only required to meet the provisions in accordance with Section R302.2, which includes the requirement for a fire resistance rating. The use of the term "common wall" in Exception No. 5 is also consistent with the "common wall" terminology in Exceptions 1, 2 and 4 to Section R302.2.4.

This code change achieves the full level of fire safety provided for in residential occupancies through the use of sprinkler protection and built-in fire resistant construction. It will also eliminate the fire safety inconsistency in the IRC between dwelling units built with small fire separation distances to property lines and dwelling units constructed as townhouses and connected at property lines by a common wall.

Cost Impact: This proposal will not increase the cost of construction.

RB82-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R302.2 #3-RB-THOMPSON

RB83 – 13

302.2.1

Proponent: C. Ray Allshouse AIA, CBO, City of Shoreline, WA, representing the Washington Association of Building Officials Technical Code Development Committee (rallshouse@shorelinewa.gov)

Revise as follows:

R302.2.1 Continuity. The fire-resistance-rated wall or assembly separating *townhouses* shall be continuous from the foundation to the underside of the roof sheathing, deck or slab. The fire-resistance rating shall extend the full length of the wall or assembly, including wall extensions through and separating attached enclosed *accessory structures*. Where a story extends beyond the exterior wall of a story below, one of the following shall apply:

1. The fire-resistance-rated wall or assembly shall extend to the outside edge of the upper story; or
2. The underside of the exposed floor-ceiling assembly shall be protected as required for projections in Section R302.

Reason: Current townhouse code language is vague regarding the continuity of fire-resistance-rated assemblies, specifically in those instances where an upper story extends beyond the face of the wall immediately below. This represents a potential breach in the integrity of the fire resistance rated construction deemed necessary to ensure full dwelling unit separation in townhouse configured construction. This change clarifies the needed protection requirements. It is not uncommon for local zoning ordinances to include provisions specifically intended to break up continuous building facades as well as the large scale presentation of multifamily buildings. Developers typically utilize offsets between units to achieve these building modulation requirements that frequently result in this configuration. This proposed change provides language to cover this condition thereby helping ensure that the required dwelling separation is achieved.

Cost Impact: The code change proposal will not increase the cost of construction.

RB83-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R302.2.1-RB-ALLSHOUSE

RB84 – 13

R302.1

Proponent: Steve Orlowski, representing National Association of Home Builders (NAHB)
(sorlowski@nahb.org)

Revise as follows:

R302.1 Exterior walls. Construction, projections, openings and penetrations of *exterior walls* of *dwelling*s and accessory buildings shall comply with Table R302.1(1); or *dwelling*s equipped throughout with an *automatic sprinkler system* installed in accordance with Section P2904 shall comply with Table R302.1(2).

Exceptions:

1. Walls, projections, openings or penetrations in walls perpendicular to the line used to determine the *fire separation distance*.
2. Walls of *dwelling*s and *accessory structures* located on the same *lot*.
3. Detached tool sheds and storage sheds, playhouses and similar structures exempted from permits are not required to provide wall protection based on location on the *lot*. Projections beyond the *exterior wall* shall not extend over the *lot line*.
4. Detached garages accessory to a *dwelling* located within 2 feet (610 mm) of a *lot line* are permitted to have roof eave projections not exceeding 4 inches (102 mm).
5. Foundation and attic vents installed in compliance with this code are permitted.

Reason: After reviewing several UL listed fire-resistant rated assemblies, the NAHB discovered a problem between attempting to provide adequate attic ventilation to certain roof types (hip roofs, cathedral ceilings, etc) and achieving the one-hour fire resistance rating. The UL listed roof assemblies do not allow for any openings in the rated assembly for roofs, thereby creating a problem for proper roof ventilation as required in section R806. The NAHB proposes this code change to balance the needs of both adequate fire protection for exposure fires and proper ventilation of the attic. Under the 2012 IRC, projections are not permitted within two feet of the fire separation distance and the required ventilation opening for attics are minimal, 1/150 of the area of the vented space. The IRC also currently allows 25% of the wall space to be occupied by windows in exterior walls that are within 3'-0" of the fire separation distance. The IRC currently exempt foundation vents from being protected. NAHB suggest that due to the minimal openings required to provide ventilation in the attic, these openings should also be exempted.

Cost Impact: The code change proposal will not increase the cost of construction.

R302.1-RB-ORLOWSKI

RB85 – 13

R302.2.2, R302.2.3

Proponent: Rick Davidson, City of Maple Grove, Association of Minnesota Building Officials
(rdavidson@maplegrovern.gov)

Delete without substitution:

R302.2.2 Parapets. ~~Parapets constructed in accordance with Section R302.2.3 shall be constructed for townhouses as an extension of exterior walls or common walls in accordance with the following:~~

- ~~1. Where roof surfaces adjacent to the wall or walls are at the same elevation, the parapet shall extend not less than 30 inches (762 mm) above the roof surfaces.~~
- ~~2. Where roof surfaces adjacent to the wall or walls are at different elevations and the higher roof is not more than 30 inches (762 mm) above the lower roof, the parapet shall extend not less than 30 inches (762 mm) above the lower roof surface.~~

Exception: ~~A parapet is not required in the two cases above when the roof is covered with a minimum class C roof covering, and the roof decking or sheathing is of noncombustible materials or approved fire-retardant-treated wood for a distance of 4 feet (1219 mm) on each side of the wall or walls, or one layer of 5/8-inch (15.9 mm) Type X gypsum board is installed directly beneath the roof decking or sheathing, supported by a minimum of nominal 2-inch (51 mm) ledgers attached to the sides of the roof framing members, for a minimum distance of 4 feet (1219 mm) on each side of the wall or walls and there are no openings or penetrations in the roof within 4 feet (1219 mm) of the common walls.~~

- ~~3. A parapet is not required where roof surfaces adjacent to the wall or walls are at different elevations and the higher roof is more than 30 inches (762 mm) above the lower roof. The common wall construction from the lower roof to the underside of the higher roof deck shall have not less than a 1-hour fire-resistance rating. The wall shall be rated for exposure from both sides.~~

R302.2.3 Parapet construction. ~~Parapets shall have the same fire-resistance rating as that required for the supporting wall or walls. On any side adjacent to a roof surface, the parapet shall have noncombustible faces for the uppermost 18 inches (457 mm), to include counterflashing and coping materials. Where the roof slopes toward a parapet at slopes greater than 2 units vertical in 12 units horizontal (16.7-percent slope), the parapet shall extend to the same height as any portion of the roof within a distance of 3 feet (914 mm), but in no case shall the height be less than 30 inches (762 mm).~~

Reason: At first one might think of this as a huge leap in eliminating passive fire protection but it isn't. It is recognition of existing rules and the use of residential fire sprinklers. In fact, it is a "tradeoff" if you will.

There are two separate sections of the IRC dealing with buildings adjacent lot lines and the end result is two completely different sets of requirements. Section R302.1 and Table R302.1(1) provide requirements for all buildings regulated under the IRC including dwellings, accessory structures, and townhouses. There are no requirements for parapets for these structures and they apply to dwellings that may be permitted to be constructed to all four lot lines, be of unlimited area, be unlimited in number, and may be constructed side by side for miles.

But, R302.2.2 requires a parapet for a building defined by the building official as a townhouse at the very location where it is not required for any other structure. Townhouses are required to have sprinkler systems. Unlike dwellings, they are required to have open space on at least two sides. It is reasonable for some relaxation of passive fire protection when active fire protection systems are required. It is inconsistent to require parapets for townhouses and not for dwellings. The proposal is to delete the parapet requirements for townhouses to bring the rules in line with those for all other structures regulated in the IRC.

Cost Impact: None

R302.2.2-RB-DAVIDSON

RB86 – 13

R302.2.2

Proponent: Rick Davidson, City of Maple Grove, Association of Minnesota Building Officials
(rdavidson@maplegrovern.gov)

Revise as follows:

R302.2.2 Parapets. Parapets constructed in accordance with Section R302.2.3 shall be constructed for *townhouses* as an extension of exterior walls or common walls in accordance with the following:

1. Where roof surfaces adjacent to the wall or walls are at the same elevation, the parapet shall extend not less than 30 inches (762 mm) above the roof surfaces.
2. Where roof surfaces adjacent to the wall or walls are at different elevations and the higher roof is not more than 30 inches (762 mm) above the lower roof, the parapet shall extend not less than 30 inches (762 mm) above the lower roof surface.

Exception: A parapet is not required in the two cases above when the roof is covered with a minimum class C roof covering, and the roof decking or sheathing is of noncombustible materials or *approved* fire-retardant treated wood for a distance of 4 feet (1219 mm) on each side of the wall or walls, or one layer of 5/8-inch (15.9 mm) Type X gypsum board is installed directly beneath the roof decking or sheathing, supported by a minimum of nominal 2-inch (51 mm) ledgers attached to the sides of the roof framing members, for a minimum distance of 4 feet (1219 mm) on each side of the wall or walls ~~and there are no openings or penetrations in the roof within 4 feet (1219 mm) of the exterior or common walls.~~

3. A parapet is not required where roof surfaces adjacent to the wall or walls are at different elevations and the higher roof is more than 30 inches (762 mm) above the lower roof. The common wall construction from the lower roof to the underside of the higher roof deck shall have not less than a 1-hour fire-resistance rating. The wall shall be rated for exposure from both sides.

Reason: The language proposed to be deleted was added in last code cycle and it was argued by the proponent that the change put the IRC in sync with the IBC. That is, it was argued that openings were not permitted within a certain distance of a townhouse separation wall in the IBC and the proposal made the IRC consistent with the IBC. This proposal was disapproved by the ICC IRC Committee with the following comment: "**Committee Reason:** This change would impose severe restrictions on penetrations at the roof. This does not mirror the IBC requirement on this issue." The IRC Committee action was right. However the membership approved the code change anyway.

The result is a more restrictive requirement in the IRC than in the IBC for the exact same application. This proposal deletes the conflicting language so that the IRC and IBC rules are again the same.

This proposal is necessary to maintain equivalencies for the same type of structures regulated by the IBC and IRC. The following language is from the IBC for information only (note the bold italicized text). Note that there is no regulation of openings under method 5.

2012 IBC

705.11 Parapets. Parapets shall be provided on *exterior walls* of buildings.

Exceptions: A parapet need not be provided on an *exterior wall* where any of the following conditions exist:

1. The wall is not required to be fire-resistance rated in accordance with Table 602 because of *fire separation distance*.
2. The building has an area of not more than 1,000 square feet (93 m²) on any floor.
3. Walls that terminate at roofs of not less than 2-hour fire-resistance-rated construction or where the roof, including the deck or slab and supporting construction, is constructed entirely of noncombustible materials.
4. One-hour fire-resistance-rated *exterior walls* that terminate at the underside of the roof sheathing, deck or slab, provided:
 - 4.1. Where the roof/ceiling framing elements are parallel to the walls, such framing and elements supporting such framing shall not be of less than 1-hour fire-resistance-rated construction for a width of 4 feet (1220 mm) for Groups R and U and 10 feet (3048 mm) for other occupancies, measured from the interior side of the wall.

- 4.2. Where roof/ceiling framing elements are not parallel to the wall, the entire span of such framing and elements supporting such framing shall not be of less than 1-hour fire-resistance-rated construction.
- 4.3. Openings in the roof shall not be located within 5 feet (1524 mm) of the 1-hour fire resistance-rated exterior wall for Groups R and U and 10 feet (3048 mm) for other occupancies, measured from the interior side of the wall.
- 4.4. The entire building shall be provided with not less than a Class B roof covering.
5. *In Groups R-2 and R-3 where the entire building is provided with a Class C roof covering, the exterior wall shall be permitted to terminate at the underside of the roof sheathing or deck in Type III, IV and V construction, provided:*
 - 5.1. *The roof sheathing or deck is constructed of approved noncombustible materials or of fire-retardant-treated wood for a distance of 4 feet (1220 mm); or*
 - 5.2. *The roof is protected with 0.625-inch (16 mm) Type X gypsum board directly beneath the underside of the roof sheathing or deck, supported by a minimum of nominal 2-inch (51 mm) ledgers attached to the sides of the roof framing members for a minimum distance of 4 feet (1220 mm).*
6. Where the wall is permitted to have at least 25 percent of the exterior wall areas containing unprotected openings based on fire separation distance as determined in accordance with Section 705.8.

There are no restrictions on openings in the roof under item #5 in the IBC. The IRC should follow suit.

Cost Impact: None

RB86-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R302.2.2.2-RB-DAVIDSON

RB87 – 13

R302.3, R302.4, R302.7, R302.9, R302.11, R302.12, R310.1, R314.5

Proponent: Rick Davidson, City of Maple Grove, Association of Minnesota Building Officials
(rdavidson@maplegrovern.gov)

Revise as follows:

R302.3 Two-family dwellings. *Dwelling units* in two-family dwellings shall be separated from each other by wall and/or floor assemblies having not less than a 1-hour fire-resistance rating when tested in accordance with ASTM E 119 or UL 263. Fire-resistance-rated floor-ceiling and wall assemblies shall extend to and be tight against the *exterior wall*, and wall assemblies shall extend from the foundation to the underside of the roof sheathing.

Exceptions:

1. ~~A fire-resistance rating of 1/2 hour shall be permitted in buildings equipped throughout with an automatic sprinkler system installed in accordance with NFPA 13.~~ Dwellings provided with an automatic fire sprinkler system complying with the requirements of Section R313.
2. Wall assemblies need not extend through *attic* spaces when the ceiling is protected by not less than 5/8-inch (15.9 mm) Type X gypsum board and an *attic* draft stop constructed as specified in Section R302.12.1 is provided above and along the wall assembly separating the *dwellings*. The structural framing supporting the ceiling shall also be protected by not less than 1/2-inch (12.7 mm) gypsum board or equivalent.

R302.4 Dwelling unit rated penetrations. Penetrations of wall or floor/ceiling assemblies required to be fire-resistance rated in accordance with Section R302.2 or R302.3 shall be protected in accordance with this section.

Exception: Dwellings provided with an automatic fire sprinkler system complying with the requirements of Section R313.

R302.7 Under-stair protection. Enclosed accessible space under stairs shall have walls, under-stair surface and any soffits protected on the enclosed side with 1/2-inch (12.7 mm) gypsum board.

Exception: Dwellings provided with an automatic fire sprinkler system complying with the requirements of Section R313 and a minimum of one sprinkler head is installed in the enclosed space.

R302.9 Flame spread index and smoke-developed index for wall and ceiling finishes. Flame spread and smoke index for wall and ceiling finishes shall be in accordance with Sections R302.9.1 through R302.9.4.

Exception: Dwellings provided with an automatic fire sprinkler system complying with the requirements of Section R313.

R302.11 Fireblocking. In combustible construction, fireblocking shall be provided to cut off all concealed draft openings (both vertical and horizontal) and to form an effective fire barrier between stories, and between a top *story* and the roof space.

Exception: Dwellings provided with an automatic fire sprinkler system complying with the requirements of Section R313 and a minimum of one sprinkler head is installed in the enclosed space.

Where required, fireblocking shall be provided in wood-frame construction in the following locations:

1. In concealed spaces of stud walls and partitions, including furred spaces and parallel rows of studs or staggered studs, as follows:
 - 1.1. Vertically at the ceiling and floor levels.
 - 1.2. Horizontally at intervals not exceeding 10 feet (3048 mm).
2. At all interconnections between concealed vertical and horizontal spaces such as occur at soffits, drop ceilings and cove ceilings.
3. In concealed spaces between stair stringers at the top and bottom of the run. Enclosed spaces under stairs shall comply with Section R302.7.
4. At openings around vents, pipes, ducts, cables and wires at ceiling and floor level, with an *approved* material to resist the free passage of flame and products of combustion. The material filling this annular space shall not be required to meet the ASTM E 136 requirements.
5. For the fireblocking of chimneys and fireplaces, see Section R1003.19.
6. Fireblocking of cornices of a two-family *dwelling* is required at the line of *dwelling unit* separation.

R302.12 Draftstopping. In combustible construction where there is usable space both above and below the concealed space of a floor/ceiling assembly, draftstops shall be installed so that the area of the concealed space does not exceed 1,000 square feet (92.9 m²). Draftstopping shall divide the concealed space into approximately equal areas.

Exception: Dwellings provided with an automatic fire sprinkler system complying with the requirements of Section R313.

Where draftstopping is required and where the assembly is enclosed by a floor membrane above and a ceiling membrane below, draftstopping shall be provided in floor/ceiling assemblies under the following circumstances:

1. Ceiling is suspended under the floor framing.
2. Floor framing is constructed of truss-type open-web or perforated members.

R310.1 Emergency escape and rescue required. *Basements*, habitable attics and every sleeping room shall have at least one operable emergency escape and rescue opening. Where *basements* contain one or more sleeping rooms, emergency egress and rescue openings shall be required in each sleeping room. Where emergency escape and rescue openings are provided they shall have a sill height of not more than 44 inches (1118 mm) measured from the finished floor to the bottom of the clear opening. Where a door opening having a threshold below the adjacent ground elevation serves as an emergency escape and rescue opening and is provided with a bulkhead enclosure, the bulkhead enclosure shall comply with section R310.3. The net clear opening dimensions required by this code shall be obtained by the normal operation of the emergency escape and rescue opening from the inside. Emergency escape and rescue openings with a finished sill height below the adjacent ground elevation shall be provided with a window well in accordance with Section R310.2. Emergency escape and rescue openings shall open directly into a public way, or to a yard or court that opens to a public way.

Exception Exceptions:

1. Basements used only to house mechanical equipment and not exceeding total floor area of 200 square feet (18.58 m²).
2. Dwellings provided with an automatic fire sprinkler system complying with the requirements of Section R313 shall not be required to comply with this section.

R314.5 Interconnection. Where more than one smoke alarm is required to be installed within an individual dwelling unit in accordance with Section R314.3, the alarm devices shall be interconnected in such a manner that the actuation of one alarm will activate all of the alarms in the individual unit. Physical interconnection shall not be required where listed wireless alarms are installed and all alarms sound upon activation of one alarm.

Exception Exceptions:

1. Interconnection of smoke alarms in existing areas shall not be required where alterations or repairs do not result in removal of interior wall or ceiling finishes exposing the structure, unless there is attic, crawl space or basement available which could provide access for interconnection without the removal of interior finishes.
2. Interconnection of smoke alarms shall not be required in dwellings provided with an automatic fire sprinkler system complying with the requirements of Section R313.

Reason: The purpose of this proposal is to provide reductions in code requirements related to fire protection for various components of a dwelling when fire sprinklers are installed, to offset costs created by the installation of fire sprinklers, and to fulfill the scoping provisions to maintain minimum code requirements.

Proponents of residential fire sprinklers have consistently touted the increased safety levels that sprinkler systems bring to new dwellings. That provides the opportunity to eliminate passive systems as unnecessarily redundant and costly. Many similar exceptions are granted buildings in the IBC for sprinkler installation (fire-resistive substitution, reductions in separation requirements, increased travel distance, reduction in exiting requirements, and exclusion of emergency exit windows) so there is ample justification for doing the same in dwellings. While not all of the exceptions granted to buildings constructed under the IBC have an application in residential construction, there are many that do. Similar additional reductions are proposed. Fire sprinkler advocates repeatedly touted the high degree of reliability and effectiveness of residential sprinklers during numerous hearings on sprinkler requirements for dwellings. Based on that testimony, fires will be extinguished when they are small and before they have an opportunity to spread

**TABLE R302.1(2)
EXTERIOR WALLS—DWELLINGS WITH FIRE SPRINKLERS**

EXTERIOR WALL ELEMENT		MINIMUM FIRE-RESISTANCE RATING	MINIMUM FIRE SEPARATION DISTANCE
Walls	Fire-resistance rated	1 hour—tested in accordance with ASTM E 119 or UL 263 with exposure from the outside	0 feet
	Not fire-resistance rated	0 hours	3 feet ^a
Projections	Fire-resistance rated	1 hour on the underside	2 feet ^a
	Not fire-resistance rated	0 hours	3 feet
Openings in walls	Not allowed	N/A	< 3 feet
	Unlimited	0 hours	3 feet ^a
Penetrations	All	Comply with Section R302.4	< 3 feet
		None required	3 feet ^a

For SI: 1 foot = 304.8 mm.

N/A = Not Applicable

- a. For residential subdivisions where all dwellings are equipped throughout with an automatic sprinkler systems installed in accordance with Section P2904, the fire separation distance for nonrated exterior walls and rated projections shall be permitted to be reduced to 0 feet, and unlimited unprotected openings and penetrations shall be permitted, where the adjoining lot provides an open setback yard that is 6 feet or more in width on the opposite side of the property line.

2012 INTERNATIONAL RESIDENTIAL CODE*

and thereby further justifying the proposed tradeoffs.

There is precedent for reductions in code requirements related to fire protection in the IRC already so this is not something new to the IRC. Table R302.1(2) (provided below for information) provides reductions for exterior wall and opening protection for exterior walls required to have a fire protection rating due to proximity to a lot line for sprinklered buildings.

And, IRC Section 501.3 allows the fire resistive membrane for floors to be eliminated in sprinklered buildings.

There are a host of reductions in the IBC. The IBC permits sprinklers to be installed as a substitution for one-hour fire-resistive construction. Table 601 from the IBC is provided for information purposes. See Foot note D.

**TABLE 601
FIRE-RESISTANCE RATING REQUIREMENTS FOR BUILDING ELEMENTS (HOURS)**

BUILDING ELEMENT	TYPE I		TYPE II		TYPE III		TYPE IV	TYPE V	
	A	B	A ^d	B	A ^d	B	HT	A ^d	B
Primary structural frame ^e (see Section 202)	3 ^a	2 ^a	1	0	1	0	HT	1	0
Bearing walls									
Exterior ^{f, g}	3	2	1	0	2	2	2	1	0
Interior	3 ^a	2 ^a	1	0	1	0	1/HT	1	0
Nonbearing walls and partitions	See Table 602								
Exterior									
Nonbearing walls and partitions							See		
Interior ^c	0	0	0	0	0	0	Section	0	0
602.4.6									
Floor construction and associated secondary members (see Section 202)	2	2	1	0	1	0	HT	1	0
Roof construction and associated secondary members (see Section 202)	1 ^{1/2} ^b	1 ^{b, c}	1 ^{b, c}	0 ^c	1 ^{b, c}	0	HT	1 ^{b, c}	0

For SI: 1 foot = 304.8 mm.

- a. Roof supports: Fire-resistance ratings of primary structural frame and bearing walls are permitted to be reduced by 1 hour where supporting a roof only.
- b. Except in Group F-1, H, M and S-1 occupancies, fire protection of structural members shall not be required, including protection of roof framing and decking where every part of the roof construction is 20 feet or more above any floor immediately below. Fire-retardant-treated wood members shall be allowed to be used for such unprotected members.
- c. In all occupancies, heavy timber shall be allowed where a 1-hour or less fire-resistance rating is required.
- d. An approved automatic sprinkler system in accordance with Section 903.3.1.1 shall be allowed to be substituted for 1-hour fire-resistance-rated construction, provided such system is not otherwise required by other provisions of the code or used for an allowable area increase in accordance with Section 506.3 or an allowable height increase in accordance with Section 504.2. The 1-hour substitution for the fire resistance of exterior walls shall not be permitted.
- e. Not less than the fire-resistance rating required by other sections of this code.
- f. Not less than the fire-resistance rating based on fire separation distance (see Table 602).
- g. Not less than the fire-resistance rating as referenced in Section 704.10

2012 INTERNATIONAL BUILDING CODE®

107

IBC Section 508.4 requires that separation of occupancy requirements may be reduced by one hour in buildings with sprinkler systems.

Table 803.9 permits the reduction in class of wall and ceiling finishes in sprinklered buildings.

IBC section 907.2.9 allows reductions in fire alarm systems in sprinklered buildings.

IBC Chapter 26 allows reductions in protection of plastics in sprinklered buildings.

IBC section 3004 exempts the venting of elevator hoistways in sprinklered buildings.

IBC Chapters 5 and 10 have literally dozens of reductions in construction and exiting requirements in sprinklered buildings.

It is reasonable to provide the same benefits that come with sprinkler systems to residential occupancies constructed under the IRC as similar occupancies would receive under the IBC.

This proposal eliminates a host of fire related requirements based on superior protection provided by fire sprinklers as stated by fire sprinkler proponents and on equivalencies currently afforded buildings built under the IBC.

Cost Impact: None

RB87-13

Public Hearing: Committee: AS AM D
Assembly: ASF AMF DF

R302.3-RB-DAVIDSON

RB88 – 13

R302.4.2

Proponent: Mark Nowak, M Nowak Consulting LLC, representing Steel Framing Alliance

Revise as follows:

R302.4.2 Membrane penetrations. Membrane penetrations shall comply with Section R302.4.1. Where walls are required to have a fire-resistance rating, recessed fixtures shall be installed so that the required fire-resistance rating will not be reduced.

Exceptions:

1. Membrane penetrations of maximum 2-hour fire-resistance-rated walls and partitions by steel electrical boxes that do not exceed 16 square inches (0.0103 m²) in area provided the aggregate area of the openings through the membrane does not exceed 100 square inches (0.0645 m²) in any 100 square feet (9.29 m)² of wall area. The annular space between the wall membrane and the box shall not exceed $\frac{1}{8}$ inch (3.1 mm). Such boxes on opposite sides of the wall shall be separated by one of the following:
 - 1.1. By a horizontal distance of not less than 24 inches (610 mm) where the wall or partition is constructed with individual noncommunicating stud cavities;
 - 1.2. By a horizontal distance of not less than the depth of the wall cavity when the wall cavity is filled with cellulose loose-fill, rockwool or slag mineral wool insulation;
 - 1.3. By solid fire blocking in accordance with Section R302.11;
 - 1.4. By protecting both boxes with listed putty pads; or
 - 1.5. By other listed materials and methods.
2. Membrane penetrations by listed electrical boxes of any materials provided the boxes have been tested for use in fire-resistance-rated assemblies and are installed in accordance with the instructions included in the listing. The annular space between the wall membrane and the box shall not exceed $\frac{1}{8}$ inch (3.1 mm) unless listed otherwise. Such boxes on opposite sides of the wall shall be separated by one of the following:
 - 2.1. By the horizontal distance specified in the listing of the electrical boxes;
 - 2.2. By solid fireblocking in accordance with Section R302.11;
 - 2.3. By protecting both boxes with listed putty pads; or
 - 2.4. By other listed materials and methods.
3. The annular space created by the penetration of a fire sprinkler provided it is covered by a metal escutcheon plate.
4. Ceiling membranes of 1- and 2-hour fire-resistant assemblies are permitted to be interrupted by wall assembly double wood top plates, or steel top tracks complying with Sections 702.3.3 or R603.2.1, where the wall assembly complies with all of the following:
 - 4.1 The wall assembly is sheathed with Type X gypsum board.
 - 4.2 All penetrations through the top plate or track are protected in accordance with Section R302.4.1 and
 - 4.3 The ceiling membrane is installed tight to the top plate or track.

Reason: This proposal is consistent with approved proposal FS76-12 for the 2015 IBC. However, it is inclusive of both wood top plates and steel top tracks. This proposal is needed only for the stacked duplex case in the IRC where the floor may be supported by a wall having at least equivalent fire resistance (R302.3.1) or where non-loadbearing walls are framed prior to installation of the membrane as is often necessary to route mechanical and electrical equipment. Thus, penetrations through the top plate or track are required to be protected per Section R302.4.1 to maintain the integrity and intent of the fire resistance requirement of floors separating stacked duplexes.

Cost Impact: The code change proposal will not increase the cost of construction.

RB88-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R302.4.2-RB-NOWAK

RB89 – 13

R302.4.3 (New)

Proponent: Larry Wainright, Qualtim, representing the Structural Building Components Association (lwainright@qualtim.com)

Add new text as follows:

R302.4.3 Penetration of fire-resistance rated wall assemblies by structural members. Penetration of wall assemblies required to be fire-resistance rated in accordance with sections R302.2 or R302.3, by roof and floor structural members shall be permitted, provided that the fire-resistance rating, the structural integrity of the wall, and structural independence is maintained.

Reason: The purpose of this code change proposal is to clarify that the fire-resistance rating and the structural integrity of wall assemblies separating townhouses and two family dwellings needs to be maintained when they are penetrated by other structural members. The most common application is where a floor or roof assembly is supported by the separation wall. The code is currently silent on this type of penetration while other types of penetrations are addressed in sections R302.4.1 and R302.4.2. This change makes it clear that when supporting these assemblies, some means of maintaining the fire-resistance and integrity of the separation wall is required.

Cost Impact: This code change will not increase the cost of construction.

RB89-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R302.4.3 (NEW)-RB-WAINRIGHT

RB90 – 13

R302.5.1

Proponent: Rick Davidson, City of Maple Grove, Association of Minnesota Building Officials
(rdavidson@maplegrovern.gov)

Revise as follows:

R302.5.1 Opening protection. Openings from a private garage directly into a room used for sleeping purposes shall not be permitted. Other openings between the garage and residence shall be equipped with solid wood doors not less than 1-3/8 inches (35 mm) in thickness, solid or honeycomb core steel doors not less than 1-3/8 inches (35 mm) thick, or 20-minute fire-rated doors, ~~equipped with a self-closing device.~~

Reason: The IRC Committee and the ICC membership has consistently opposed closers on the door between a garage and dwelling in the past for a number of legitimate reasons not the least of which is the danger the closers pose to small children.

The effort to require closers on garage doors continued at the national level every year for perhaps fifteen years or more. Each year the membership denied the request because there was no statistical data to support the requirement and there had been no equivalent requirement in several of the legacy codes without an apparent problem.

During the last code cycle, this proposal was approved but again with erroneous and irrelevant arguments. There was no justification for the change and no evidence that a problem exists. Following is the justification from the fire service for the change published in the monograph during the last cycle.

***Reason:** There are times when proposed code submittals require a very lengthy substantiation, and then there are times when code change proposals just make sense. I would believe this is one of those times where a code change proposal makes a lot of sense. We are seeking a requirement to install items for very minimal costs yet great life saving potentials.*

If it "just makes sense", then there should be a justifiable reason for the requirement. If there is no reason, then it is overregulation. The presumption that the door between the house and garage will be left open is not rational. There is no evidence that the cost is minimal, that the benefit is real, or that any life saving would occur. Closers require maintenance and can easily be defeated by the homeowner. There is no standard specified in the code. It is obvious that there was no thought put into the proposal regarding the practicality, the need, or the ability to enforce. The closing force to engage the lock on a gasketed door can potentially be a hazard to young children who may get knocked over by the door or get fingers pinched in the closing side of the door or the latch side of the door upon closing. The vague language provides little guidance to install or approve these devices which can result in greater liability for the builder. Closers on these doors have not been required in many parts of the country for decades and there is no indication that it has created any hazard to life safety in those regions. This is a non-rated door in a non-rated frame in a non-rated wall.

Furthermore, there is no similar requirement for car ports. In fact, the code requires no protection of the wall between a dwelling and a carport. Windows are permitted. Hollow doors with glazing are permitted. Both structures house the same items including motor vehicles. A carport is enclosed on two or fewer sides. A garage is enclosed on more than two sides but one side can be completely open. And no vehicle door is required in either.

This amendment is necessary because it eliminates a potential for injury to small children, there is no data to support that there is a need for this rule, and it eliminates a source of potential liability for builders.

Cost Impact: None

	Assembly:	ASF	AMF	DF

R302.5.1-RB-DAVIDSON

RB91 – 13

R302.6, Table 302.6

Proponent: Homer Maiel, PE, CBO, 4LEAF, Inc., representing self

Revise as follows:

R302.6 Dwelling/garage and dwelling/carport fire separation. The garage and carport shall be separated as required by Table R302.6. Openings in garage walls shall comply with Section R302.5.

Exceptions:

1. This provision does not apply to garage walls that are perpendicular to the adjacent dwelling unit wall.
2. A separation is not required between the dwelling and carport, provided the carport is entirely open on not less than two sides and there are not enclosed areas above.

TABLE R302.6
DWELLING/GARAGE AND DWELLING/ CARPORT SEPARATION

SEPARATION	MATERIAL
From the residence and attics	Not less than 1/2-inch gypsum board or equivalent applied to the garage side
From all habitable rooms above the garage or carport	Not less than 5/8-inch Type X gypsum board or equivalent
Structure(s) supporting floor/ceiling assemblies used for separation required by this section	Not less than 1/2-inch gypsum board or equivalent
Garages located less than 3 feet from a dwelling unit on the same lot	Not less than 1/2-inch gypsum board or equivalent applied to the interior side of exterior walls that are within this area

Reason: A carport usually poses the same level of hazard to a dwelling unit as a garage does. Currently the code is silent about carport. This revision addresses that deficiency.

Cost Impact: The code change proposal will increase the cost of construction.

RB91-13

Public Hearing: Committee: AS AM D
Assembly: ASF AMF DF

R302.6-RB-MAIEL

RB92 – 13

R302.10.1, R302.10.2, R302.10.3

Proponent: Rick Thornberry, P.E., representing Cellulose Insulation Manufacturers Association (CIMA)

Revise as follows:

R302.10.1 Insulation. Insulation materials, including facings, such as vapor retarders and vapor-permeable membranes, installed within floor-ceiling assemblies, roof-ceiling assemblies, wall assemblies, crawl spaces and attics shall have a flame spread index not to exceed 25 with an accompanying smoke-developed index not to exceed 450 when tested in accordance with ASTM E 84 or UL 723.

Exceptions:

1. When such materials are installed in concealed spaces, the flame spread index and smoke-developed index limitations do not apply to the facings, provided that the facing is installed in substantial contact with the unexposed surface of the ceiling, floor or wall finish.
2. ~~Cellulose~~ Cellulosic fiber loose-fill insulation, ~~which is not spray applied~~, complying with the requirements of Section R302.10.3, shall only be required to meet the smoke-developed index of not more than 450.
3. Foam plastic insulation shall comply with Section R316.

R302.10.2 Loose-fill insulation. Loose-fill insulation materials that cannot be mounted in the ASTM E 84 or UL 723 apparatus without a screen or artificial supports shall comply with the flame spread and smoke-developed limits of Section R302.10.1 when tested in accordance with CAN/ULC S102.2.

Exception: ~~Cellulose~~ Cellulosic fiber loose-fill insulation shall not be required to be tested in accordance with CAN/ULC S102.2, provided such insulation has a smoke-developed index of not more than 450 and complies with the requirements of ~~Section R302.10.1 and~~ Section R302.10.3.

R302.10.3 ~~Cellulose~~ Cellulosic fiber loose-fill insulation and self-supported spray applied cellulosic insulation. ~~Cellulose~~ Cellulosic fiber loose-fill insulation and self-supported spray applied cellulosic insulation shall comply with CPSC 16 CFR, Parts 1209 and 1404. Each package of such insulating material shall be clearly *labeled* in accordance with CPSC 16 CFR, Parts 1209 and 1404.

Reason: The purpose of this code change proposal is to clarify the requirements for cellulose insulation by substituting the industry terms for the two types of cellulose insulation commonly used: cellulosic fiber loose-fill insulation and self-supported spray applied cellulosic insulation. These two terms are taken from ASTM C 739, Standard Specification for Cellulosic Fiber Loose-Fill Thermal Insulation and ASTM C 1149, Standard Specification for Self-Supported Spray Applied Cellulosic Thermal Insulation, respectively. The application of the Exception to Section R302.10.2 is also simplified and made more user friendly by including the smoke-developed index requirement and deleting the reference to Section R302.10.1 where that requirement is specified by the Exceptions to those sections. This saves the code user a step in the process of applying Section R302.10.2 and avoids potential misapplications and misinterpretations that often occur when dealing with multiple Exceptions.

Cost Impact: This code change proposal will not increase the cost of construction.

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R302.10-RB-THORNBERRY

RB93 – 13

R302.11.1

Proponent: Tony Crimi, A.C. Consulting Solutions, Inc., representing North American Insulation Manufacturer's Association (NAIMA) (tcrimi@sympatico.ca)

Revise as follows:

R302.11.1 Fireblocking materials. Except as provided in Section R302.11, Item 4, fireblocking shall consist of the following materials.

1. Two-inch (51 mm) nominal lumber.
2. Two thicknesses of 1-inch (25.4 mm) nominal lumber with broken lap joints.
3. One thickness of 23/32-inch (18.3 mm) wood structural panels with joints backed by 23/32-inch (18.3 mm) wood structural panels.
4. One thickness of 3/4-inch (19.1 mm) particleboard with joints backed by 3/4-inch (19.1 mm) particleboard.
5. One-half-inch (12.7 mm) gypsum board.
6. One-quarter-inch (6.4 mm) cement-based millboard.
7. Batts or blankets of mineral wool or glass fiber or other *approved* materials installed in such a manner as to be securely retained in place.
8. Cellulose insulation installed as tested in accordance with ASTM E 119 or UL 263, for the specific application.

Reason: This proposal clarifies the code requirement and prevents potentially unintended test methods from being used for these purposes. The proposal aims to provide more detail to the requirement to test cellulose insulation in accordance with the appropriate fire test standards. During the last cycle, FS118-09/10 added spray-applied cellulose to the list of acceptable fireblocking materials. The proponent's statement does identify ASTM E119 as the test standard used by the Cellulose Insulation Manufacturers Association (CIMA) to conduct a variety of fireblocking fire tests.

Cost Impact: This code change proposal will not increase the cost of construction.

R302.11.1-RB-CRIMI.doc

RB94 – 13

R 302.12, R302.12.2 (New)

Proponent: Sean DeCrane, Battalion Chief, representing Cleveland Division of Fire, International Association of Fire Fighters (rovloc93@aol.com)

Revise as follows:

R302.12 Draftstopping. Draftstopping shall be provided in construction in accordance with this section.

R302.12.1 Concealed spaces. In combustible construction where there is usable space both above and below the concealed space of a floor/ceiling assembly, draftstops shall be installed so that the area of the concealed space does not exceed 1,000 square feet (92.9 m²). Draftstopping shall divide the concealed space into approximately equal areas. Where the assembly is enclosed by a floor membrane above and a ceiling membrane below, draftstopping shall be provided in floor/ceiling assemblies under the following circumstances:

1. Ceiling is suspended under the floor framing.
2. Floor framing is constructed of truss-type open-web or perforated members.

R302.12.2. Attics. Draftstopping shall be provided in attics with an area that exceeds 1,500 square feet (92.9 m²). The draftstopping shall be installed such that each draftstopped area of the attic does not exceed 1,500 square feet (92.9 m²).

Reason: Void spaces, are areas of potentially large fire growth that can have explosive results for responding and operating fire fighters. We have seen multiple incidents where large single-family residences can simulate commercial size fires due to the large open areas. Modern construction techniques are providing home owners with a number of options including large open spaces. These large floor plans lead to increased amounts of void spaces in the attic and floor systems. When fire travels into these attic spaces, they are fuel enriched by the combustible wood truss and in many instances the sprayed insulation. With large amounts of oxygen the fire can grow unchecked and on many occasions showing very little evidence on the exterior of amount of fire present. One side discovery of the original Underwriters Laboratories studies on lightweight construction in 2006, was the performance of the plastic ridge vent which when subjected to elevated temperatures would melt and create a seal at the peak of the ridge causing the increased pressures from the fires to push downward on top of operating fire fighters. We have seen instances where fire fighters have been killed or injured. In 2010 Fire Fighter Kyle Wilson, of Price William County, was killed while performing Search and Rescue operations from a wind driven exterior fire that accumulated in the attic space until it exploded downward trapping Fire Fighter Wilson in the Master Bedroom causing him to burn to death. In 2012 in Huntington, MD, ten fire fighters were injured, two seriously, when they were investigating the smell of smoke on the second floor. The fire originated in the chimney and travelled into the attic space where it had plenty of air to grow uncontrolled until the building pressure caused the fire to explosively escape from the attic downward on the fire fighters. Fire fighters were forced to dive down the stairwell and out the second story windows causing one fire fighter to break his back. The author will acknowledge the lack of technical justification at the time of submission. There is current testing being conducted at Underwriters Laboratories and NIST and we hope to have additional test data available at the code hearing in Dallas.

Cost Impact: This proposal will increase the cost of construction

RB94-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R302.12-RB-DECRANE

RB95 – 13

R302.12

Proponent: Wesley Walters, Clark County Nevada Development Services, representing self

Revise as follows:

R502.12 Draftstopping. In combustible construction where there is ~~usable~~ occupied space both above and below the concealed space of a floor/ceiling assembly, draftstops shall be installed so that the area of the concealed space does not exceed 1,000 square feet (92.9 m²). Draftstopping shall divide the concealed space into approximately equal areas. Where the assembly is enclosed by a floor membrane above and a ceiling membrane below draftstopping shall be provided in floor/ceiling assemblies under the following circumstances:

1. Ceiling is suspended under the floor framing.
2. Floor framing is constructed of truss-type open-web or perforated members.

Reason: Usable is an undefined term within the code. The term occupied is defined and describes the whole area of the house.

Cost Impact: The code change proposal will not increase the cost of construction.

RB95-13

R302.12-RB-WALTERS

RB96 – 13

R302.13 (New), Table N1102.4.1.1 (R402.4.1.1)

THIS IS A 2 PART CODE CHANGE. PART I WILL BE HEARD BY THE IRC COMMITTEE. PART II WILL BE HEARD BY THE IECC COMMITTEE. SEE THE TENTATIVE HEARING ORDERS FOR THESE COMMITTEES.

Proponent: Duncan Prael, IBACOS Inc, representing self (dprahl@ibacos.com)

PART I - IRC-RB

Add new Text as follows:

R302.13 Sealants. In combustible construction, sealants that are used to limit air leakage in accordance with Section N1102.4 and Table N1102.4.1.1 shall not be required to comply with ASTM E 136 and shall not be required to be included in the fire tests required in association with the following:

1. Fire resistant assemblies where required by Sections R302.1, R302.2, R302.4, and R302.6;
 2. Fireblocking where required by Section R302.11 and
 3. Draftstopping where required by Section R302.12.
- (Existing Section R302.13 to be renumbered.)

PART II - IECC-RE

Revise as follows:

**TABLE R402.4.1.1
AIR BARRIER AND INSULATION INSTALLATION**

Fire separation assemblies in accordance with <i>International Residential Code</i> Sections R302.1, R302.2, R302.4, and R302.6, and fireblocking and draftstopping in accordance with <i>International Residential Code</i> Sections R302.11 and R302.12, respectively.	Air sealing shall be provided in all fire separation assemblies where the assembly, fireblocking or draftstopping is part of or intersects the thermal enclosure.
Garage separation	Air sealing shall be provided between the garage and conditioned spaces

(Portions of table not shown to remain unchanged)

Reason: Many ASTM E119 tested assemblies do not include any sealant materials for airtightness at the location where the assembly intersects the thermal enclosure of the building in the real world. Builders and code officials should be guided specifically on the airsealing that should be included at these locations. The materials used for sealing this location fall under the same criteria as sealants that the committee approved in for sealants used to fireblock annular spaces per R302.11. Many common sealants have an auto ignition temperature that is the same as or higher than the wood framing within the assembly and, as such, would only burn if the wood in the assembly was already on fire.

Examples of locations that are indicative of the need for sealants within fire separation assemblies follow. The heavy dotted line indicated the desired location of the airtightness layer within the constructed assembly as it appears in some typical details:

Two hour separation, plan view at garage

Two hour separation, plan view at exterior wall

Cost Impact:

The code change proposal will not increase the cost of construction

RB97 – 13

R303.1, R303.4, M1507.1

THIS IS A 2 PART CODE CHANGE. PART I WILL BE HEARD BY THE IRC-RB COMMITTEE. PART II WILL BE HEARD BY THE IRC-PM COMMITTEE. SEE THE TENTATIVE HEARING ORDERS FOR THESE COMMITTEES.

Proponent: Joe Lstiburek, Building Science Corporation; Mike Moore, P.E., Newport Ventures, representing Broan-NuTone (mmoore@newportpartnersllc.com); Thomas D. Culp, Birch Point Consulting, representing the Glazing Industry Code Committee

PART I-IRC-RB

Revise as follows:

R303.1 Habitable rooms. All habitable rooms shall have an aggregate glazing area of not less than 8 percent of the floor area of such rooms. Natural *ventilation* shall be through windows, doors, louvers or other *approved* openings to the outdoor air. Such openings shall be provided with ready access or shall otherwise be readily controllable by the building occupants. The minimum openable area to the outdoors shall be 4 percent of the floor area being ventilated.

Exceptions:

- ~~1. The glazed areas need not be openable where the opening is not required by Section R310 and a whole-house mechanical ventilation system is installed in accordance with Section M1507.~~
21. The glazed areas need not be installed in habitable rooms without exterior walls, where an opening is not required by Section R310, mechanical ventilation is installed in accordance with Section M1507, and Exception 1 above is satisfied and artificial light is provided capable of producing an average illumination of 6 footcandles (65 lux) over the area of the room at a height of 30 inches (762 mm) above the floor level.
32. Use of sunroom and patio covers, as defined in Section R202, shall be permitted for natural *ventilation* if in excess of 40 percent of the exterior sunroom walls are open, or are enclosed only by insect screening.

PART II-IRC-RM

Revise as follows:

R303.4 Mechanical ventilation. ~~Where the air infiltration rate of a dwelling unit is less than 5 air changes per hour when tested with a blower door at a pressure of 0.2 inch w.c (50 Pa) in accordance with Section N1102.4.1.2, the dwelling units shall be provided with local exhaust and whole-house mechanical ventilation in accordance with Section M1507-3.~~

M1507.1 General. ~~Where Local exhaust or and whole-house mechanical ventilation is provided, the equipment systems shall be designed and installed in accordance with this section.~~

Reason: Experience from decades of work with builders confirms that achieving a home air tightness of around 3 to 5 ACH 50 is not difficult if the builder just addresses the “big holes” during construction.¹ The practice of addressing big holes was initially tackled by builders to reduce call backs associated with comfort complaints from homebuyers. Once builders figured out that plugging the big holes reduced callbacks, the practice went mainstream. In 2009, the steps required to plug the big holes were codified in the mandatory air barrier table (IRC Table N1102.4.2; IECC Table R402.4.1.1). At the end of 2012, 55% of the states had adopted the 2009 IECC or more stringent. Fast forward to 2015, and 76% of states (which accounted for 86% of the single family starts in 2011) are expected to have adopted the 2009 IECC or more stringent.²

This timeline shows that building tight (3 to 5 ACH 50) has become the new standard, regardless of whether or not a builder confirms the tightness with a blower door test. Of course, the one potential problem with building tight is the negative impact it can

have on indoor air quality if mechanical ventilation is not provided; and there is broad consensus that air quality begins to be compromised at or below 5 ACH 50 if mechanical ventilation is not provided. Without mechanical ventilation, tight homes can experience elevated humidity levels; increased condensation potential on windows; higher concentrations of dust mites and allergens; and higher concentrations of pollutants such as chloroform, formaldehyde, acetaldehyde, and other VOCs that have negative health impacts.

With today's typical, code-minimum construction resulting in homes that easily achieve 3 to 5 ACH 50, a blower door test is not needed to confirm that these homes are less than 5 ACH 50 and in need of mechanical ventilation. At this point, mechanical ventilation is needed to provide minimum acceptable air quality for code-minimum construction. This change will ensure that the comfortable, energy efficient homes that builders are now building are also provided with minimum indoor air quality.

At the same time, we do not want to discourage the use of operable windows, which offer natural ventilation in addition to daylight and egress. Even with mechanical ventilation, a home occupant needs to be able to control their own environment, particularly in the case of an emergency such as a power failure (e.g. being able to open windows for airflow in the aftermath of a storm or blackout). As such, this proposal deletes exception 1 and modifies exception 2 of R303.1 to ensure operable windows in habitable rooms are still installed even with mechanical ventilation, only keeping the exception for interior rooms with no exterior walls. Note that the IRC still permits bathrooms and water closets to use local exhaust instead of windows, as per the exception to R303.3.

References:

1. J.W. Lstiburek, "Just Right and Airtight" ASHRAE Journal, May 2011.
2. U.S. DOE Building Energy Codes Program, "Status of State Energy Code Adoption, Residential: Projected" accessed from <http://www.energycodes.gov/adoption/states> on Nov 29, 2012.

Cost Impact: Because new standard construction practices will typically result in building envelope tightness levels of 3 to 5 ACH 50, these dwellings should already be provided with mechanical ventilation (based on R303.4). So, no additional costs should be incurred for mechanical ventilation systems. Also, removing the loophole of trading off windows for mechanical ventilation in habitable rooms is not expected to affect the practice of the overwhelming majority of builders who tend towards more windows, versus less, based on consumer demand.

PART II

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R303.1-RB-CULP-LSTIBUREK-MOORE

RB98 – 13

R303.1

Proponent: Jeff Inks, representing the Window & Door Manufacturers Association.

Revise as follows:

R303.1 Habitable rooms. All habitable rooms shall have an aggregate glazing area of not less than 8 percent of the floor area of such rooms. Natural *ventilation* shall be through windows, skylights, doors, louvers or other *approved* openings to the outdoor air. Such openings shall be provided with ready access or shall otherwise be readily controllable by the building occupants. The minimum openable area to the outdoors shall be 4 percent of the floor area being ventilated.

Exceptions:

1. The glazed areas need not be openable where the opening is not required by Section R310 and a whole-house mechanical *ventilation* system is installed in accordance with Section M1507.
2. The glazed areas need not be installed in rooms where Exception 1 above is satisfied and artificial light is provided capable of producing an average illumination of 6 footcandles (65 lux) over the area of the room at a height of 30 inches (762 mm) above the floor level.
3. Use of sunroom and patio covers, as defined in Section R202, shall be permitted for natural *ventilation* if in excess of 40 percent of the exterior sunroom walls are open, or are enclosed only by insect screening.

Reason: Openable skylights are intended to provide natural ventilation and should also be expressly included with other fenestration approved for meeting this requirement.

Cost Impact: This code change will not increase the cost of construction.

RB98-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R303.1 #1-RB-INKS

RB99 – 13

R303.1

Proponent: Jeff Inks, representing the Window & Door Manufacturers Association.

Revise as follows:

R303.1 Habitable rooms. All habitable rooms shall have an aggregate glazing area of not less than 8 percent of the floor area of such rooms. Natural *ventilation* shall be through windows, doors, louvers or other *approved* openings to the outdoor air. Such openings shall be provided with ready access or shall otherwise be readily controllable by the building occupants. The minimum openable area to the outdoors shall be 4 percent of the floor area being ventilated.

Exceptions:

- ~~1. The glazed areas need not be openable where the opening is not required by Section R310 and a whole-house mechanical *ventilation* system is installed in accordance with Section M1507.~~
- ~~21. The glazed areas need not be installed in rooms where Exception 1 above is satisfied and without *exterior walls* where all of the following conditions are met:~~
 - ~~1.1 An opening is not required by Section R310.~~
 - ~~1.2 Artificial light is provided capable of producing an average illumination of 6 footcandles (65 lux) over the area of the room at a height of 30 inches (762 mm) above the floor level.~~
 - ~~1.3 A whole-house mechanical *ventilation* system is installed in accordance with Section M1507.~~
- ~~32. Use of sunroom and patio covers, as defined in Section R202, shall be permitted for natural *ventilation* if in excess of 40 percent of the exterior sunroom walls are open, or are enclosed only by insect screening.~~

Reason: While whole-house mechanical ventilation systems can provide adequate ventilation when in operation, natural ventilation should still be provided as an option and more importantly, needs to be provided as a back-up in the event of power outages, especially when power outages can be prolonged for many hours or many days, or for problems that may occur with the ventilation system, or for in-home events such as cooking or burning food when supplemental natural ventilation may be needed or desired. Therefore, a blanket exception should not be provided.

The amendment to Exception 2 is proposed to maintain an exception for providing glazed areas in rooms (such as certain basement rooms) with no *exterior walls* as defined by the IRC provided they meet all of the same conditions required by the current provisions in order for the exception to R303.1 to apply.

Cost Impact: This code change may increase the cost of construction in some cases where fixed glazing may have been used in lieu of openable glazing and then depending on the glazing options being considered.

RB99-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R303.1 #4-RB-INKS

RB100 – 13

R303.4

Proponent: Mike Moore, P.E., Newport Ventures, representing Broan-NuTone (mmoore@newportpartnersllc.com), Jeremiah Williams representing U.S. Department of Energy (jeremiah.williams@ee.doe.gov)

THIS CODE CHANGE WILL BE HEARD BY THE IRC-PLUMBING/MECHANICAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

Revise as follows:

R303.4 Mechanical ventilation. Where the air infiltration rate of a dwelling unit is ~~less than~~ 5 air changes per hour or less when tested with a blower door at a pressure of 0.2 inch w.c (50 Pa) in accordance with Section N1102.4.1.2, the dwelling unit shall be provided with whole-house mechanical ventilation in accordance with Section M1507.3.

Reason (Moore): The current language is inconsistent with N1103.5, which requires mechanical ventilation for all dwellings, and also requires dwellings in climate zone 1 and 2 to have an air tightness "not exceeding" 5 ACH 50. By changing this language to 5 ACH or less, "the two sections are brought closer into alignment.

Reason (Williams) : Chapter R4 of the International Energy Conservation Code and Chapter 11 of the IRC require air leakage to be equal or less than 5 air changes per hour in climate zones 1 and 2, with lower rates required in other climate zones. This minor code change creates consistency where all buildings constructed to the air tightness levels of the IECC and IRC must have whole house mechanical ventilation systems.

Cost Impact (Moore): There is no additional cost, as mechanical ventilation is already required for these dwellings based on section N1103.5.

Cost Impact (Williams): The code change proposal will increase the cost of construction only if tested air leakage in climate zones 1 and 2 is exactly 5 air changes per hour.

RB100-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R303.4-RB-MOORE

RB101 – 13

R303.5.1

Proponent: David Hall, CFM, Georgetown Texas representing the ICC PMG Code Action Committee (dave.hall@georgetown.org)

THIS CODE CHANGE WILL BE HEARD BY THE IRC-PLUMBING/MECHANICAL COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THIS COMMITTEE.

Revise text as follows:

R303.5.1 Intake openings. Mechanical and gravity outdoor air intake openings shall be located a minimum of 10 feet (3048 mm) from any hazardous or noxious contaminant, such as vents, chimneys, plumbing vents, streets, alleys, parking lots and loading docks, ~~except as otherwise specified in this code.~~ ~~Where a source of contaminant is located within 10 feet (3048 mm) of an intake opening, such opening shall be located a minimum of 3 feet (914 mm) below the contaminant source.~~

For the purpose of this section, the exhaust from *dwelling* unit toilet rooms, bathrooms and kitchens shall not be considered as hazardous or noxious.

Exceptions:

1. The 10 foot (3048 mm) separation is not required where the intake opening is located 3 feet (914 mm) or greater below the contaminant source.
2. Separation distances for appliance vents shall be as allowed in Chapters 18 and 24.

Reason: This proposal is text cleanup. The phrase “except as otherwise specified in this code” is not user-friendly since it offers no guidance as to where something else is specified. The new exception # 2 provides the exact text for what is otherwise specified. New exception # 1 is just the original last sentence of this section reworded into an exception format, because it is actually an exception to the 10 foot rule.

This proposal is submitted by the ICC Plumbing, Mechanical and Fuel Gas Code Action Committee (PMGCAC). The PMGCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance an assigned International Code or portion thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the PMGCAC has held 2 open meetings, multiple conference calls and multiple workgroup calls which included members of the PMGCAC. Interested parties also participated in all of the meetings and conference calls to discuss and debate the proposed changes.

Cost Impact: The code change proposal will not increase the cost of construction.

RB101-13

Public Hearing:	Committee:	AS	AM	D

R303.5.1-RB-HALL-PMGCAC

RB102 – 13

R303.7, R303.7 (New), R303.7.1, R303.8 (New)

Proponent: Rick Davidson, City of Maple Grove, Association of Minnesota Building Officials
(rdavidson@maplegrovern.gov)

Revise as follows:

~~R303.7 Stairway illumination.~~ All interior and exterior stairways shall be provided with a means to illuminate the stairs, including the landings and treads. Interior stairways shall be provided with an artificial light source located in the immediate vicinity of each landing of the stairway. For interior stairs the artificial light sources shall be capable of illuminating treads and landings to levels not less than 1 foot-candle (11 lux) measured at the center of treads and landings. Exterior stairways shall be provided with an artificial light source located in the immediate vicinity of the top landing of the stairway. Exterior stairways providing access to a ~~basement~~ from the outside grade level shall be provided with an artificial light source located in the immediate vicinity of the bottom landing of the stairway.

~~Exception:~~ An artificial light source is not required at the top and bottom landing, provided an artificial light source is located directly over each stairway section.

~~R303.7.1 Light activation.~~ Where lighting outlets are installed in interior stairways, there shall be a wall switch at each floor level to control the lighting outlet where the stairway has six or more risers. The illumination of exterior stairways shall be controlled from inside the ~~dwelling~~ unit.

~~Exception:~~ Lights that are continuously illuminated or automatically controlled.

R303.7 Interior stairway illumination. Interior stairways shall be provided with an artificial light source to illuminate the landings and treads. The light source shall be capable of illuminating treads and landings to levels of not less than 1 foot-candle (11 lux) as measured at the center of treads and landings. There shall be a wall switch at each floor level to control the light source where the stairway has six or more risers.

Exception: A switch is not required where remote, central, or automatic control of lighting is provided.

R303.8 Exterior door illumination. At least one wall-switch-controlled lighting outlet shall be installed to provide illumination on the exterior side of each exterior door having grade level access, including exterior stairways providing access to a basement.

Exception: A switch is not required where remote, central, or automatic control of lighting is provided.

(Renumber subsequent sections)

Reason: This section is proposed for revision for one reason – it is confusing. The first sentence says that all interior and exterior stairways, including treads and landings, shall be illuminated. The next two sentences state that interior stairs must have lights near the landings and provide a minimum of 1 foot-candle of light. Then the next sentence states that exterior stairs must be provided with a light source in the immediate vicinity of the top landing but seems to exclude treads and landings. So, going back to the first sentence, the code says exterior stairs need landings and tread illuminated. Now just the top landing is illuminated for exterior stairs. Which one is it? The reference to 1 foot-candle of light is only applicable to interior stairs. It seems there is no standard for exterior stairs. But some code officials apply the 1 foot-candle standard to exterior stairs and others do not. Some code officials require exterior stairs to be illuminated along their entire length. Others only require light at the top landing. Then there is the exception that appears to apply only to interior stairs but can be misconstrued to support the contention that exterior stairs must be lit for their entire length.

Furthermore, the code requires the light source be in specific locations and meet certain intensities. If the intensity is met, what difference does it make where the light source is? The text referencing the location of the light source for interior stairs is proposed for deletion since the interest is in the amount of light on the walking surface, not on the light location.

The electrical code will require a switched light at exterior doors but that may not illuminate exterior stairs. This proposal would not waive any requirement found in the electrical code but there seems to be a conflict between what could be argued is the intent of R303.7, which is to illuminate exterior stairs, and the electrical code which only requires illumination of the exterior side of exterior doors having access to grade.

E3903.3 Additional locations. *At least one wall-switch-controlled lighting outlet shall be installed in hallways, stairways, attached garages, and detached garages with electric power. At least one wall-switch-controlled lighting outlet shall be installed to provide illumination on the exterior side of each outdoor egress door having grade level access, including outdoor egress doors for attached garages and detached garages with electric power. A vehicle door in a garage shall not be considered as an outdoor egress door. Where one or more lighting outlets are installed for interior stairways, there shall be a wall switch at each floor level and landing level that includes an entryway to control the lighting outlets where the stairway between floor levels has six or more risers.*

Exception: *In hallways, stairways, and at outdoor egress doors, remote, central, or automatic control of lighting shall be permitted.*

The proposed revisions create separate sections for interior stairways and exterior doorways. It eliminates a term that is difficult to enforce - "immediate vicinity". It uses the same text found in the electrical code to identify the light location at exterior doors and the exception addressing controls. Some text is editorially revised to eliminate repetitive language but the basic intent is left unchanged. The light levels and exceptions are retained as they are in the current rule. It is believed that this change helps to eliminate some confusion and improve uniformity of application and creates consistency between the building and electrical portions of the IRC.

Cost Impact: None

	Assembly:	ASF	AMF	DF

R303.7-RB-DAVIDSON

RB103 – 13

R303.7

Proponent: Wesley Walters, Clark County Nevada Development Services, representing self

Revise as follows:

R303.7 Stairway illumination. All interior and exterior stairways shall be provided with a means to illuminate the stairs, including the landings and treads. Interior stairways shall be provided with an artificial light source located in the immediate vicinity of each landing of the stairway. For interior stairs the artificial light sources shall be capable of illuminating treads and landings to levels not less than 1 footcandle (11 lux) measured at the center of treads and landings. Exterior stairways shall be provided with an artificial light source located in the immediate vicinity of the top landing of the stairway. Exterior stairways providing access to a *basement* from the outside *grade* level shall be provided with an artificial light source located in the immediate vicinity of the bottom landing of the stairway.

Exception: An artificial light source is not required at the top and bottom landing, provided an artificial light source is located directly over each ~~stairway~~ stair section.

Reason: Stairway defines the whole area including the landings. The commentary shows the light source centered over each flight of stairs so the proper definition word choice would be "stair" not stairway.

Cost Impact: The code change proposal will not increase the cost of construction.

R303.7-RB-WALTERS

RB104 – 13

R202, R303.8

Proponent: Jonathan Siu, representing City of Seattle Department of Planning & Development
(jon.siu@seattle.gov)

Revise as follows:

SECTION R202 DEFINITIONS

COURT. A minimum 3-foot wide space on the lot on which a building is situated, open and unobstructed to the sky, located at or above grade level on a lot and bounded on three or more sides by walls or a building. The distance shall be measured at a right angle from the face of the walls.

YARD. A minimum 3-foot wide open space, other than a court, unobstructed from the ground to the sky, except where specifically provided by this code, on the lot on which a building is situated. The distance shall be measured at a right angle from the face of the wall.

Revise as follows:

R303.8 Required glazed openings. Required glazed openings shall open directly onto a street or public alley, or a yard or court ~~located on the same lot as the building.~~

Exceptions:

1. Required glazed openings may face into a roofed porch where the porch abuts a street, yard or court and the longer side of the porch is at least 65 percent unobstructed and the ceiling height is not less than 7 feet (2134 mm).
2. Eave projections shall not be considered as obstructing the clear open space of a yard or court.
3. Required glazed openings may face into the area under a deck, balcony, bay or floor cantilever provided a clear vertical space at least 36 inches (914 mm) in height is provided.

Reason:

1. The intent of the proposed change to the definition of "court" is to clarify that the court must be on the same property as the building under consideration. This aligns its definition with that for "yard", since "court" only appears in conjunction with "yard" in this code. This proposal also reinforces a general (but unstated) principle in all the I-codes that a building cannot rely on features on an adjacent property to demonstrate compliance with the code. That is, each building must demonstrate compliance within its own property lines unless specifically provided for in the code, such as in Footnote a to Table R302.1(2), or for spaces such as rights-of way.
2. The reason for adding the 3-foot dimension to the definitions for "yard" and "court" is that their minimum dimension is not defined. The 3-foot dimension was chosen because it is consistent with the requirements for minimum separation distance for walls (Table R302.1(2)) and for minimum width of a window well for emergency escape windows (Section R310.2). The requirement to measure the 3 feet perpendicular to the wall is copied from the definition for "Fire Separation Distance" in Chapter 2.

Such a minimum dimension is needed to define what size yard or court is eligible for consideration of:

- A. What can be called a townhouse. The definition for "townhouse" states the dwelling unit must have a yard or public way on at least two sides. However, because the code does not define a minimum dimension for the yard, a designer can argue that a 1-foot or even a 1-inch distance constitutes a yard, and therefore, dwelling units close to the property line may be considered townhouses. (See Figure 1 below.) That interpretation does not agree with the commonly understood concept of what constitutes a townhouse, so this proposal provides clear guidance to the designer and the building official.
- B. What can be used for light and ventilation. Section 303.8 requires that glazed openings used for light and ventilation open into a yard or court. Similar to the argument for "townhouse," a minimum dimension is necessary because the current code provisions could be construed to allow these openings to comply by receiving light and ventilation from a very small

space. It stands to reason that some minimum space is required in order to allow sufficient light and ventilation to enter through the opening.

- C. What can be used for a pathway to get to a right-of-way from an emergency escape and rescue opening. Section 310.1 requires emergency escape and rescue openings to open “directly into a public way, or to a yard or court that opens to a public way.” However, an inadequate width of yard or court would render the emergency escape opening useless. Section R310.2 requires a minimum 3-foot wide window well for below-grade emergency escape and rescue openings, and if at least 3 feet is required for a window well, it stands to reason a yard or court should be at least 3 feet wide as well, in order to provide an adequate pathway to the right-of-way.

It is to be noted that defining a yard as having a width of at least 3 feet will not adversely affect sections different from those mentioned above where “yard” is used (Table R302.1(2), Section R303.8.1, and in Appendix M, Sections AM103.1.1 and AM103.1.3). “Court” is not used in any sections other than those mentioned above.

3. The text being proposed for deletion in Section R303.8 is redundant with the proposed definition of “court” and the existing definition of “yard.”

FIGURE 1 – PLAN VIEW

Cost Impact: Minimal, if any, increase to the cost of construction.

RB105 – 13

R304, R305.1, R202

Proponent: Rick Davidson, City of Maple Grove, Association of Minnesota Building Officials
(rdavidson@maplegrovern.gov)

Revise as follows:

SECTION R202 DEFINITIONS

ATTIC, HABITABLE. A finished or unfinished area, not considered a *story*, complying with all of the following requirements:

- ~~1. The occupiable floor area is at least 70 square feet (17 m²), in accordance with Section R304,~~
- ~~1.2 The occupiable floor area has a ceiling height in accordance with Section R305, and~~
- ~~2.3 The occupiable space is enclosed by the roof assembly above, knee walls (if applicable) on the sides and the floor-ceiling assembly below.~~

SECTION R304 MINIMUM ROOM AREAS

~~**R304.1 Minimum area.** Every dwelling unit shall have at least one habitable room that shall have not less than 120 square feet (11 m²) of gross floor area.~~

~~**R304.2 Other rooms.** Other habitable rooms shall have a floor area of not less than 70 square feet (6.5 m²).~~

~~**Exception:** Kitchens.~~

~~**R304.3 Minimum dimensions.** Habitable rooms shall not be less than 7 feet (2134 mm) in any horizontal dimension.~~

~~**Exception:** Kitchens.~~

~~**R304.4 Height effect on room area.** Portions of a room with a sloping ceiling measuring less than 5 feet (1524 mm) or a furred ceiling measuring less than 7 feet (2134 mm) from the finished floor to the finished ceiling shall not be considered as contributing to the minimum required habitable area for that room.~~

SECTION R305 CEILING HEIGHT

R305.1 Minimum height. *Habitable space*, hallways, bathrooms, toilet rooms, laundry rooms and portions of *basements* containing these spaces shall have a ceiling height of not less than 7 feet (2134 mm).

Exceptions:

1. For rooms with sloped ceilings, at least ~~50 percent of the required floor area~~ 35 square feet of floor area of the room must have a ceiling height of at least 7 feet (2134 mm) and no portion of the required floor area may have a ceiling height of less than 5 feet (1524 mm).
2. Bathrooms shall have a minimum ceiling height of 6 feet 8 inches (2032 mm) at the center of the front clearance area for fixtures as shown in Figure R307.1. The ceiling height above fixtures shall be such that the fixture is capable of being used for its intended purpose. A shower or tub equipped with a showerhead shall have a minimum ceiling height of 6 feet 8

inches (2032 mm) above a minimum area 30 inches (762 mm) by 30 inches (762 mm) at the showerhead.

R305.1.1 Basements. Portions of *basements* that do not contain *habitable space*, hallways, bathrooms, toilet rooms and laundry rooms shall have a ceiling height of not less than 6 feet 8 inches (2032 mm).

Exception: Beams, girders, ducts or other obstructions may project to within 6 feet 4 inches (1931 mm) of the finished floor.

Reason: Minimum room sizes began to appear in model codes around the time of WWII. But their origin traces back to the tenement regulations in larger cities in the late 1800's. These room sizes are of necessity arbitrary because they were not based on any scientific studies. They are not based on the number of people who may safely occupy a space. The rules have outlived their usefulness and are no longer necessary. People occupy spaces considered small for all or portions of their day including work cubicles and vehicles. And, it isn't hard to find news articles about small trendy dwelling units that exist due to costs caused by both construction and demand. These are no longer considered unsafe.

The market drives room sizes in large part for new construction. It is unlikely that there are many homebuyers that would opt for a living room or bedroom of 50 square feet. But even if they did, would that create a hazardous, unhealthy, or dangerous situation?

Considering that required ceiling heights are only required in 35 square feet of a room with a sloped ceiling, one wonders if enforcing the rule is worth it. It is doubtful that plan reviewers ever calculate room sizes during a plan review.

And as the rule applies to existing dwellings, installation of rooms in unfinished basements (where this is most likely to come into play) will only result in rooms being identified as non-habitable or work will be done without permits. Then other safety features such as smoke alarms and egress windows may be avoided.

It is time to focus resources on requirements that are more beneficial to the public and eliminate the micromanaging.

Cost Impact: None

RB304-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R304-RB-DAVIDSON

RB106 – 13

R304.1, R304.2

Proponent: Thomas Meyers, CBO representing self (Codeconsultant@gmail.com)

Revise as follows:

R304.1 Minimum area. ~~Every dwelling unit shall have at least one habitable room that shall have not less than 120 square feet (11 m2) of gross floor area.~~

R304.2 Other rooms. ~~Other~~ Habitable rooms shall have a floor area of not less than 70 square feet (6.5 m2).

Exception: Kitchens.

Reason: The code has long provided a minimum room area that was historically accommodated by market expectation. Recently, proponents of minimalist living have advocated living in smaller dwellings to reduce environmental impact and provide for lower living costs through reduced mortgage and maintenance expenses. These dwellings are intended to allow for a minimalist lifestyle that doesn't demand large volumes of living space. Extreme examples of these "minimalist" dwellings may be found by using search engine term "tiny house".

During the past three years, I have attempted to research the basis of the requirement for the minimum room area. There is little, if any, documentation on the life safety benefit of having a certain area provided as a minimum. Logically, there is no real benefit to a minimum area provided that the activities necessary in "dwelling" may be accommodated within the space provided. The code has previously set a minimum of 70sf to perform any "habitable" use. Therefore, that is the value that should be applicable throughout.

Removal of this requirement may provide for a gain in overall life safety. My research indicates that a considerable number of these structures are purposefully built to evade building code oversight. The main reason cited is the minimum area provisions. If the code reduced the minimum area to 70sf, the main objective would be removed.

Consumers make a purposeful and informed decision as to the appropriateness of the housing they choose to live in. It isn't appropriate that the code place arbitrary restrictions that have no demonstrable life-safety benefit.

Cost Impact: Proposed change will reduce the cost of construction

R304.1-RB-MEYERS

RB107 – 13

R305.1, R305.1.1

Proponent: Charles S. Bajnai, Chesterfield County, VA, ICC Building Code Action Committee and Virginia Building and Code Officials Association (bajnaic@chesterfield.gov)

Revise as follows:

SECTION R305 CEILING HEIGHT

R305.1 Minimum height. *Habitable space*, hallways, bathrooms, toilet rooms, laundry rooms and portions of *basements* containing these spaces shall have a ceiling height of not less than 7 feet (2134 mm).

Exceptions:

1. For rooms with sloped ceilings, at least 50 percent of the required floor area of the room must have a ceiling height of at least 7 feet (2134 mm) and no portion of the required floor area may have a ceiling height of less than 5 feet (1524 mm).
2. Bathrooms shall have a minimum ceiling height of 6 feet 8 inches (2032 mm) at the center of the front clearance area for fixtures as shown in Figure R307.1. The ceiling height above fixtures shall be such that the fixture is capable of being used for its intended purpose. A shower or tub equipped with a showerhead shall have a minimum ceiling height of 6 feet 8 inches (2032 mm) above a minimum area 30 inches (762 mm) by 30 inches (762 mm) at the showerhead.
3. In portions of basements and detached accessory structures not containing habitable space, the spaces shall have a minimum headroom of 6 feet 8 inches (2032 mm). Beams, girders, ducts or other obstructions may project to within 6 feet 4 inches (1931 mm) of the finished floor.

~~**R305.1.1 Basements.** Portions of *basements* that do not contain *habitable space*, hallways, bathrooms, toilet rooms and laundry rooms shall have a ceiling height of not less than 6 feet 8 inches (2032 mm).~~

~~**Exception:** Beams, girders, ducts or other obstructions may project to within 6 feet 4 inches (1931 mm) of the finished floor.~~

Reason: This proposal is submitted by the ICC Building Code Action Committee (BCAC). The BCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance an assigned International Code or portion thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the BCAC has held 6 open meetings and numerous workgroup calls which included members of the BCAC as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: <http://www.iccsafe.org/cs/BCAC/Pages/default.aspx>.

The BCAC decided that the current language for basement ceiling heights created some confusion with the double negative. In addition, the BCAC decided that requiring a minimum 7 foot ceiling clearance in non-habitable portions of basements containing mechanical rooms, bathrooms and laundry rooms was overly restrictive.

Cost Impact: None

RB107-13

Public Hearing:	Committee: AS	AM	D
	Assembly: ASF	AMF	DF

R305.1-RB-BAJNAI-BCAC

RB108 – 13

R305.1, R305.1.1

Proponent: Rick Davidson, City of Maple Grove, Association of Minnesota Building Officials
(rdavidson@maplegrovern.gov)

Revise as follows:

SECTION R305 CEILING HEIGHT

R305.1 Minimum height. *Habitable space*, hallways, ~~bathrooms, toilet rooms, laundry rooms~~ and portions of *basements* containing these spaces shall have a ceiling height of not less than 7 feet (2134 mm). Bathrooms, toilet rooms and laundry rooms shall have a ceiling height of not less than 6 feet 8 inches (2032 mm).

Exceptions:

1. For rooms with sloped ceilings, at least 50 percent of the required floor area of the room must have a ceiling height of at least 7 feet (2134 mm) and no portion of the required floor area may have a ceiling height of less than 5 feet (1524 mm).
2. ~~Bathrooms shall have a minimum ceiling height of 6 feet 8 inches (2032 mm) at the center of the front clearance area for fixtures as shown in Figure R307.1.~~ The ceiling height above bathroom and toilet room fixtures shall be such that the fixture is capable of being used for its intended purpose. A shower or tub equipped with a showerhead shall have a minimum ceiling height of 6 feet 8 inches (2032 mm) above a minimum area 30 inches (762 mm) by 30 inches (762 mm) at the showerhead.

R305.1.1 Basements. Portions of *basements* that do not contain *habitable space*, ~~or hallways, bathrooms, toilet rooms and laundry rooms~~ shall have a ceiling height of not less than 6 feet 8 inches (2032 mm).

Exception: Beams, girders, ducts or other obstructions may project to within 6 feet 4 inches (1931 mm) of the finished floor.

Reason: This proposal sets the required ceiling height for bathrooms, toilet rooms, and laundry rooms at 6 feet 8 inches. The current language requires ceiling heights in these spaces to be 7 feet. Then the exception allows the ceiling height to be 6 feet 8 inches in front of the fixtures (the most used area of the space) so the exception is really the rule. It only makes sense that the entire room be permitted to be 6 feet 8 inches, not just the most used areas of the room.

- 7" Ceiling height required.
- 6' 8" Ceiling height permitted.
- Fixture capable of being used.

Cost Impact: None

RB108-13

Public Hearing: Committee: AS AM D
 Assembly: ASF AMF DF

R305.1-RB-DAVIDSON

RB109 – 13

R307.2

Proponent: David Hall CFM, Georgetown, Texas representing the ICC PMG Code Action Committee (Dave.Hall@georgetown.org); Roger Harper, Louisa County, VA, representing Virginia Plumbing and Mechanical Inspectors Association (VPMIA), Virginia Building Code Officials Association (VBCOA) and ICC Region 7 (sharper@louisa.org); Richard Grace of Fairfax County representing Virginia Plumbing and Mechanical Inspectors Association and Virginia Building and Code Officials Association (Richard.Grace@fairfaxcounty.gov)

Delete and substitute as follows:

~~**R307.2 Bathtub and shower spaces.** Bathtub and shower floors and walls above bathtubs with installed shower heads and in shower compartments shall be finished with a nonabsorbent surface. Such wall surfaces shall extend to a height of not less than 6 feet (1829 mm) above the floor.~~

R307.2 Bathtub and shower floors and walls. Bathtub floors, shower floors, wall areas above built-in tubs that have installed shower heads and walls in shower compartments shall be constructed of smooth, corrosion-resistant and nonabsorbent waterproof materials. Wall materials shall extend to a height of not less than 6 feet (1829 mm) above the room floor level and not less than 70 inches (1778 mm) above the drain of the tub or shower. Such walls shall form a water-tight joint with each other and with either the tub or shower floor.

Reason: This revised language was approved for the 2015 IPC. There is no reason for the two codes to have different language.

This proposal is submitted by the ICC Plumbing, Mechanical and Fuel Gas Code Action Committee (PMGCAC). The PMGCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance an assigned International Code or portion thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the PMGCAC has held 2 open meetings, multiple conference calls and multiple workgroup calls which included members of the PMGCAC. Interested parties also participated in all of the meetings and conference calls to discuss and debate the proposed changes. For PMGCAC member reference, this was Item no. X8 on the PMGCAC IRC-P list.

Cost Impact: The code change proposal will not increase the cost of construction.

RB110 – 13

R308.1, R308.1.1, R308.3, R308.4

Proponent: Rick Davidson, City of Maple Grove, Association of Minnesota Building Officials
(rdavidson@maplegrovern.gov)

Revise as follows:

R308.1 Identification. ~~Except as indicated in Section R308.1.1 each~~ **Required.** Every pane of glazing installed in hazardous locations ~~as defined in Section R308.4~~ shall meet the requirements of R308.3.1 and shall be provided with a manufacturer's designation specifying who applied the designation, designating the type of glass and the safety glazing standard with which it complies, which is visible in the final installation. The designation shall be acid etched, sandblasted, ceramic-fired, laser etched, embossed, or be of a type which once applied cannot be removed without being destroyed. ~~A label shall be permitted in lieu of the manufacturer's designation.~~

Exceptions:

- ~~1. For other than tempered glass, manufacturer's designations are not required provided the building official approves the use of a certificate, affidavit or other evidence confirming compliance with this code.~~
2. Tempered spandrel glass is permitted to be identified by the manufacturer with a removable paper designation.

R308.1.1 Identification of multiple assemblies. ~~Multipane assemblies having individual panes not exceeding 1 square foot (0.09 m²) in exposed area shall have at least one pane in the assembly identified in accordance with Section R308.1. All other panes in the assembly shall be labeled "CPSC 16 CFR 1201" or "ANSI Z97.1" as appropriate.~~

R308.2 Louvered windows or жалousies. Regular, float, wired or patterned glass in жалousies and louvered windows shall be no thinner than nominal 3/16 inch (5 mm) and no longer than 48 inches (1219 mm). Exposed glass edges shall be smooth.

R308.2.1 Wired glass prohibited. Wired glass with wire exposed on longitudinal edges shall not be used in жалousies or louvered windows.

R308.3 Human impact loads. Individual glazed areas, including glass mirrors ~~in hazardous locations such as those indicated as defined in Section R308.4~~, shall pass the test requirements of Section R308.3.1.

Exceptions:

1. Louvered windows and жалousies shall comply with Section R308.2.
2. Mirrors and other glass panels mounted or hung on a surface that provides a continuous backing support.
3. Glass unit masonry complying with Section R610.

R308.3.1 Impact test. Where required by other sections of the code, glazing shall be tested in accordance with CPSC 16 CFR 1201. Glazing shall comply with the test criteria for Category I or II as indicated in Table R308.3.1(1).

Exception: Glazing not in doors or enclosures for hot tubs, whirlpools, saunas, steam rooms, bathtubs and showers shall be permitted to be tested in accordance with ANSI Z97.1. Glazing shall comply with the test criteria for Class A or B as indicated in Table R308.3.1 (2).

R308.4 Hazardous locations. The locations specified in Sections R308.4.1 through R308.4.7 shall be considered specific hazardous locations for the purposes of glazing.

R308.4.1 Glazing in doors. Glazing in all fixed and operable panels of swinging, sliding and bifold doors shall be considered a hazardous location.

Exceptions:

1. ~~Glazed openings of a size through which a 3-inch-diameter (76 mm) sphere is unable to pass.~~
2. ~~Decorative glazing.~~

R308.4.2 Glazing adjacent doors. Glazing in an individual fixed or operable panel adjacent to a door where the nearest vertical edge of the glazing is within a 24-inch (610 mm) arc of either vertical edge of the door in a closed position and where the bottom exposed edge of the glazing is less than 60 inches (1524 mm) above the floor or walking surface shall be considered a hazardous location.

Exceptions:

1. ~~Decorative glazing.~~
2. ~~When there is an intervening wall or other permanent barrier between the door and the glazing.~~
3. ~~Glazing in walls on the latch side of and perpendicular to the plane of the door in a closed position.~~
4. ~~Where access through the door is to a closet or storage area 3 feet (914 mm) or less in depth. Glazing in this application shall comply with section R308.4.3.~~
5. ~~Glazing that is adjacent to the fixed panel of patio doors.~~

R308.4.3 Glazing in windows. Glazing in an individual fixed or operable panel that meets all of the following conditions shall be considered a hazardous location:

1. ~~The exposed area of an individual pane is larger than 9 square feet (0.836 m²);~~
2. ~~The bottom edge of the glazing is less than 18 inches (457 mm) above the floor;~~
3. ~~The top edge of the glazing is more than 36 inches (914 mm) above the floor; and~~
4. ~~One or more walking surfaces are within 36 inches (914 mm), measured horizontally and in a straight line, of the glazing.~~

Exceptions:

1. ~~Decorative glazing.~~
2. ~~When a horizontal rail is installed on the accessible side(s) of the glazing 34 to 38 inches (864 to 965 mm) above the walking surface. The rail shall be capable of withstanding a horizontal load of 50 pounds per linear foot (730 N/m) without contacting the glass and be a minimum of 1¹/₂ inches (38 mm) in cross sectional height.~~
3. ~~Outboard panes in insulating glass units and other multiple glazed panels when the bottom edge of the glass is 25 feet (7620 mm) or more above grade, a roof, walking surfaces or other horizontal [within 45 degrees (0.79 rad) of horizontal] surface adjacent to the glass exterior.~~

R308.4.4 Glazing in guards and railings. Glazing in guards and railings, including structural baluster panels and nonstructural in-fill panels, regardless of area or height above a walking surface shall be considered a hazardous location.

R308.4.5 Glazing and wet surfaces. Glazing in walls, enclosures or fences containing or facing hot tubs, spas, whirlpools, saunas, steam rooms, bathtubs, showers and indoor or outdoor swimming pools where

~~the bottom exposed edge of the glazing is less than 60 inches (1524 mm) measured vertically above any standing or walking surface shall be considered a hazardous location. This shall apply to single glazing and all panes in multiple glazing.~~

Exception: ~~Glazing that is more than 60 inches (1524 mm), measured horizontally and in a straight line, from the water's edge of a bathtub, hot tub, spa, whirlpool, or swimming pool.~~

R308.4.6 Glazing adjacent stairs and ramps. ~~Glazing where the bottom exposed edge of the glazing is less than 36 inches (914 mm) above the plane of the adjacent walking surface of stairways, landings between flights of stairs and ramps shall be considered a hazardous location.~~

Exceptions:

- ~~1. When a rail is installed on the accessible side(s) of the glazing 34 to 38 inches (864 to 965 mm) above the walking surface. The rail shall be capable of withstanding a horizontal load of 50 pounds per linear foot (730 N/m) without contacting the glass and be a minimum of 1 1/2 inches (38 mm) in cross sectional height.~~
- ~~2. Glazing 36 inches (914 mm) or more measured horizontally from the walking surface.~~

R308.4.7 Glazing adjacent to the bottom stair landing. ~~Glazing adjacent to the landing at the bottom of a stairway where the glazing is less than 36 inches (914 mm) above the landing and within 60 inches (1524 mm) horizontally of the bottom tread shall be considered a hazardous location.~~

Exception: ~~The glazing is protected by a guard complying with Section R312 and the plane of the glass is more than 18 inches (457 mm) from the guard.~~

Reason: We have all heard the warnings from the media and the National Weather Service during certain weather events asking people to take shelter and "stay away from windows". Why? Windows are the weak link in protection from flying debris and hail. Windows allow debris to enter homes. Windows can be a danger in certain weather conditions and from certain common everyday events. Occupants are put at risk from this flying debris or from flying glass. Flying shards of glass can become deadly missiles. Homes with shattered windows are more susceptible to interior damage and greater wind damage increasing repair costs and insurance premiums.

Tempered glass is 4-5 times stronger than non-tempered glass. Using tempered glass or other safety glazing products will increase the safety of homes during certain weather events by reducing the amount of flying debris entering the home, reducing flying glass, and adding greater protection against the elements for the home.

But weather events aren't the only reason to require all glazing to be safety glazing. In earthquake prone areas, shattered glass is a reality and a safety hazard.

And, normal activities in the home can quickly turn tragic and involve serious injury. In the last code cycle, Thomas S. Zaremba, Roetzel & Andress, representing Glazing Industry Code Committee stated during the ICC hearings: "The assumption that people are familiar with their home environment does not take into consideration guests, rental units, or accidental impacts, for example, resulting from horseplay, that can result in human impact with glazing ..." Children playing in or about the home can come into contact with glazing that is not now required to be safety glazed resulting in serious injuries. Children and adults can accidentally fall into window wells contacting the glass in a downward fall. News reports periodically highlight these events such as the Oklahoma lady who was cut by flying glass when a neighbor child's baseball hit her window or of the children in Ohio that were cut by flying glass when a tree fell against their home in a storm.

Because of its added strength, safety glazing creates more of a barrier to intruders which in turn increases the personal safety level in the home.

There are significant benefits to be had by requiring all glass in a home to be safety glazed. They can reduce injuries and related health care costs and because of the increased strength, may help to reduce break-ins.

The rules themselves as they are currently written are full of arbitrary limitations. Consider this: A window that is at floor level and that is 8.9 square feet need not be safety glazed while a window that is .1 sq feet larger and 17 inches off the floor must be safety glazed. Children are just as likely to run into and be harmed regardless the size. Flying shards of glass are dangerous no matter what size window they come out of or no matter how high off the floor they fall from. Windows can be struck by flying debris at any height. The higher the glass is off the floor, the more dangerous it is when it falls.

Entire industries have popped up that provide various films for placement over windows to make the glass safer from the standpoint of intrusion, damage from weather, and other safety glazing reasons. Why not just require safety glazing to begin with. Tempered glass is even more resistant to breakage from fire in an adjoining building.

It is amazing that with all of the news articles written about the dangers of glass that industry hasn't taken on the responsibility of installing safety glazing in all of their products. The technology is there. The cost is minimal compared to the many code changes that have been approved in recent years to prevent incidents that by any means would be rare; the underfloor fire protection to protect fire fighters comes immediately to mind. Accidents related to breaking glass could occur at any time in any

dwelling with any occupant. And unlike a fire, are more likely to involve entire communities. It is time to make homes safer for the occupants.

Cost Impact: This proposal will increase the cost of construction.

R308.1-RB-DAVIDSON

RB11 – 13

R308.4.2

Proponent: Charles S. Bajnai, Chesterfield County, VA, ICC Building Code Action Committee and Virginia Building and Code Officials Association (bajnaic@chesterfield.gov)

Revise as follows:

R308.4.2 Glazing adjacent doors. Glazing in an individual fixed or operable panel adjacent to a door shall be considered a hazardous location ~~where the nearest vertical edge of the glazing is within a 24-inch (610 mm) arc of either vertical edge of the door in a closed position and where if the bottom exposed edge of the glazing is less than 60 inches (1524 mm) above the floor or walking surface shall be considered a hazardous location~~ and it meets either of the following conditions:

1. Where the glazing is within 24" of either side of the door in the plane of the door in a closed position.
2. Where the glazing is on a wall perpendicular to the plane of the door in a closed position and within 24" of the hinge side of an in-swinging door.

Exceptions:

1. Decorative glazing.
2. When there is an intervening wall or other permanent barrier between the door and the glazing.
3. ~~Glazing in walls on the latch side of and perpendicular to the plane of the door in a closed position~~
4. Where access through the door is to a closet or storage area 3 feet (914 mm) or less in depth. Glazing in this application shall comply with section R308.4.3.
5. Glazing that is adjacent to the fixed panel of patio doors.

Reason: This proposal is submitted by the ICC Building Code Action Committee (BCAC). The BCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance an assigned International Code or portion thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the BCAC has held 6 open meetings and numerous workgroup calls which included members of the BCAC as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: <http://www.iccsafe.org/cs/BCAC/Pages/default.aspx>.

Exception 3: Currently the code requires safety glazing for windows on the hinge side of walls perpendicular to the door plane – regardless of the door swing. See sketch below.

These are the four possible configurations of windows adjacent/perpendicular to a door. Only the one with an in-swinging door on the hinge side would be required to be safety glazed.

Cost Impact: This proposal may decrease the cost of construction.

R308.4.2

Proponent: Charles S. Bajnai, Chesterfield County, VA, ICC Building Code Action Committee
(bajnaic@chesterfield.gov)

Revise as follows:

R308.4.2 Glazing adjacent doors. Glazing in an individual fixed or operable panel adjacent to a door where the nearest vertical edge of the glazing is within a 24-inch (610 mm) arc of either vertical edge of the door in a closed position and where the bottom exposed edge of the glazing is less than 60 inches (1524 mm) above the floor or walking surface shall be considered a hazardous location.

Exceptions:

1. Decorative glazing.
2. When there is an intervening wall or other permanent barrier between the door and the glazing.
3. Glazing in walls on the latch side of and perpendicular to the plane of the door in a closed position
4. Where access through the door is to a closet or bathroom or storage area 3 feet (914 mm) or less in depth. Glazing in this application shall comply with section R308.4.3.
5. Glazing that is adjacent to the fixed panel of patio doors.

Reason: This proposal is submitted by the ICC Building Code Action Committee (BCAC). The BCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance an assigned International Code or portion thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the BCAC has held 6 open meetings and numerous workgroup calls which included members of the BCAC as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: <http://www.iccsafe.org/cs/BCAC/Pages/default.aspx>.

1. There is some confusing language in this section trying to acknowledge that the requirements in Section R308.4 may overlap and how to handle them. Adding this sentence in R308.4 says that you have to comply with all of the requirements in this section – even if you get an exception in one part, you might still have to comply by a different rule. That is what the second sentence in Exception 4 of R308.4.2 is trying to do.
2. Currently the code requires safety glazing in windows within 24" arc of the hinge side of a door for walls perpendicular to the door swing.

Currently both of these windows would have to be safety glazed. By this proposed code change, neither window would have to be safety glazed because the door is to a bathroom

Because the situation is familiar to the home occupants, and most of the time the bathroom or closet would be serving one or two people on a very limited basis, the threat of danger is not present.

Cost Impact: This proposal may decrease the cost of construction.

R308.4.2 #2-RB-BAJNAI-BCAC

RB113 – 13

R308.4.5

Proponent: Tim Pate, City and County of Broomfield, CO, representing the Colorado Chapter Code Change Committee

Revise as follows:

R308.4.5 Glazing and wet surfaces. Glazing in walls, enclosures or fences containing or facing hot tubs, spas, whirlpools, saunas, steam rooms, bathtubs, showers and indoor or outdoor swimming pools where the bottom exposed edge of the glazing is less than 60 inches (1524 mm) measured vertically above any standing or walking surface shall be considered a hazardous location. This shall apply to single glazing and all panes in multiple glazing.

Exception: Glazing that is more than 60 inches (1524 mm), measured horizontally and in a straight line, from the ~~water's~~ edge of a bathtub, hot tub, spa, whirlpool, or swimming pool or from the edge of a shower, sauna, or steam room.

Reason: This code change is proposing to add the language "shower, sauna, steam room" to the laundry list in the exception to require safety glazing in locations within and adjacent to areas with wet surfaces. The laundry list should match what is in the main section R308.4.5. This code change will also delete the word "water's" so that it will make sense with the added items. There will typically not be any depth of water in a shower, sauna, or steam room.

This will help provide clarity to the code user to show that if you have glazing at any height above floor and it is at least 60" away from edge of these items it would be exempt from the requirement to have glass be safety glazing. All of these items will potentially have very slippery floor surfaces and if one were to fall down the person would not extend out past 60" with their arms and hands or bodies when falling. This will match the requirements and concept for exception for safety glazing measured from bottom tread of stairs.

Cost Impact: This code change will not increase the cost of construction.

RB113-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R308.4.5-RB-PATE

RB114 – 13

R308.4.6, R308.4.7

Proponent: Tim Pate, City and County of Broomfield, CO representing Colorado Chapter Code Change Committee

Revise as follows:

R308.4.6 Glazing adjacent to stairs and ramps. Glazing where the bottom exposed edge of the glazing is less than ~~36 inches (914 mm)~~ 60 inches (1524 mm) above the plane of the adjacent walking surface of stairways, landings between flights of stairs and ramps shall be considered a hazardous location.

Exceptions:

1. When a rail is installed on the accessible side(s) of the glazing 34 to 38 inches (864 to 965 mm) above walking surface. The rail shall be capable of withstanding a horizontal load of 50 pounds per linear foot (730 N/m) without contacting the glass and be a minimum of 1 ½ inches (38 mm) in cross sectional height and the plane of glass is more than 18 inches (457 mm) horizontally from the rail.
2. Glazing 36 inches (914 mm) or more measured horizontally from the walking surface.

R308.4.7 Glazing adjacent to the bottom stair landing. Glazing adjacent to the landing at the bottom of a stairway where the glazing is less than ~~36 inches (914 mm)~~ 60 inches (1524 mm) above the landing and within 60 inches (1524 mm) horizontally of the bottom tread shall be considered a hazardous location.

Exception: The glazing is protected by a guard complying with Section 312 and the plane of the glass is more than 18 inches (457 mm) from the guard.

Reason: All of the previous editions of the IRC required glazing that was had bottom edge below 60 inches above the plane of walking surfaces of stairways, landings between flights of stairs and ramps, and adjacent to stair landings to be approved safety glazing. Code change was approved which changed the 36 inches back to 60 inches. There was a comprehensive code change (S218 09/10) that reformatted the entire safety glazing section and also changed the dimension from 60 inches down to 36 inches. This was approved and overrode my code change.

My reason statement for the code change during the 2009/2010 cycle was very clear in helping clean up the inconsistencies in the earlier codes. As you can see it specifically required the wall with glazing to be at least 18 inches away. The reason statement that the IRC change committee gave in approving the comprehensive change was that it should be lowered to 36" which would match the exception. I could never find a good reason as to why my code change that was approved by the IRC committee did not stand and get incorporated into the overall change also approved by the IRC code change committee.

I am copying my code change (RB40-09/10) and reason statement that the 2009/2010 IRC committee agreed with:

Revise as follows:

R308.4 The following shall be considered specific hazardous locations for the purposes of glazing:

Items 1 through 6 remain unchanged

7. Glazing adjacent to stairways, landings, and ramps within 36 inches (914 mm) horizontally of a walking surface when the exposed surface of the glazing is less than 60 inches (1524 mm) above the plane of the adjacent walking surface.

Exceptions:

1. ~~When a rail is installed on the accessible side(s) of the glazing 34 to 38 inches (864 to 965 mm) above the walking surface. The rail shall be capable of withstanding a horizontal load of 50 pounds per lineal foot (730 N/m) without contacting the glass and be a minimum of 1 ½ inches (38 mm) in cross sectional height.~~
2. The side of the stairway has a guardrail or handrail, including balusters or in-fill panels, complying with Sections R311.7.6 and R312 and the plane of the glazing is more than 18 inches (457 mm) from the railing; or
3. When a solid wall or panel extends from the plane of adjacent walking surface to 34 inches (863 mm) to 36 inches (914 mm) above the walking surface and the construction at the top of that wall or panel is capable of withstanding the same horizontal load as a guard and the plane of the glazing is more than 18 inches (457 mm) from the wall or panel.

8. Glazing adjacent to stairways within 60 inches (1524 mm) horizontally of the bottom tread of a stairway in any direction when the exposed surface of the glazing is less than 60 inches (1524 mm) above the nose of the tread.

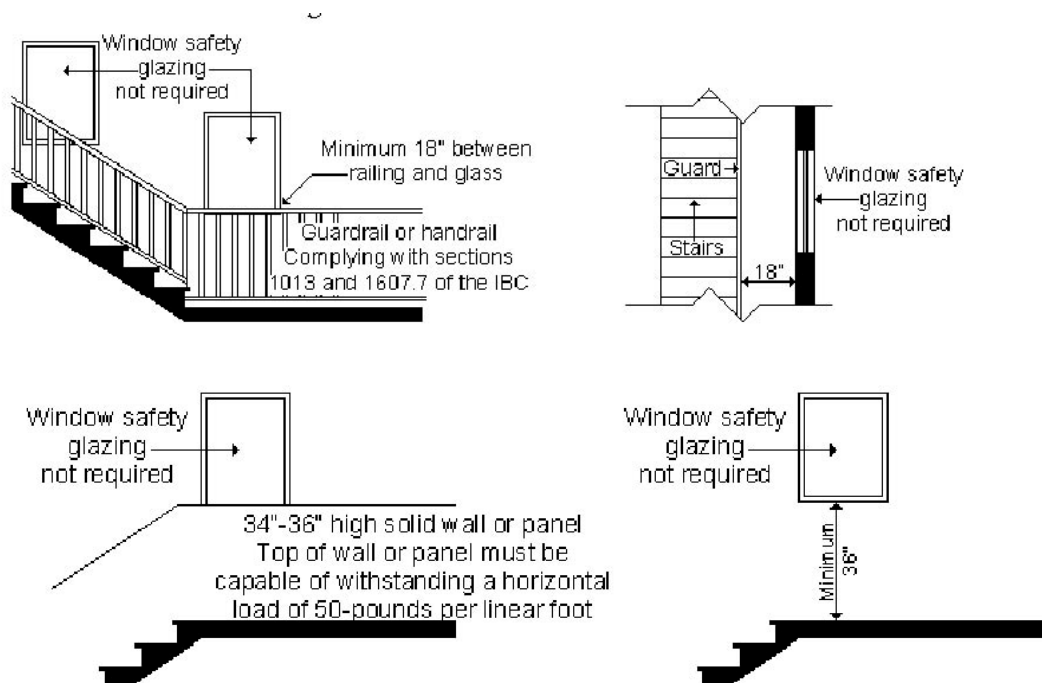

Exceptions:

1. The side of the stairway has a guardrail or handrail, including balusters or in-fill panels, complying with Sections R311.7.6 and R312 and the plane of the glazing is more than 18 inches (457 mm) from the railing; or
2. When a solid wall or panel extends from the plane of adjacent walking surface to 34 inches (863 mm) to 36 inches (914 mm) above the walking surface and the construction at the top of that wall or panel is capable of withstanding the same horizontal load as a guard and the plane of the glazing is more than 18 inches (457 mm) from the wall or panel.

Reason: Code change RB15-00 added exception 9 (9.1 and 9.2) which allowed the protective bar but also required the glazing to be at least 18" away from the stair and bar. Code change RB16-00 was also approved in the same code change cycle which added the reference in exception #5 which would allow the protective bar but not require the 18" separation. This created a direct conflict between the two exceptions in the 2003 IRC and the 2006 IRC. IRC Section R308.4 was modified for the 2009 IRC by reformatting the requirements and exceptions in order to make it more user friendly but no technical changes were made.

Stairs are inherently more dangerous for tripping hazards than normal walking surfaces. It does not make sense to allow a 1 1/2" wide bar or a solid wall directly adjacent to stairs and landings and think this gives adequate protection for someone falling into glazing that is not safety glazing. Requiring the glazing to be at least 18" away would provide better protection if someone trips and falls which is exactly what 2009 IRC section R308.4 #7 Exception 2 requires.

The following diagrams illustrate what R308.4 #7 exception 2 allows which is the guard or handrail but also the 18" separation which is in conflict with what is allowed in #7 exception 1 or 3 which allows a rail or solid wall but does not require the 18" separation.

I was also successful in having the IBC safety glazing section changed back to 60 inches during the past Code Change Hearing in Dallas for the 2015 IBC. Here is the code change (S297-12) to IBC along with the reason statement – this code change was approved by Structural Code Change Committee and was not challenged at Final Action Hearings and therefore was approved on the consent agenda:

Revise as follows:

2406.4.7 Glazing adjacent to the bottom stair landing. Glazing adjacent to the landing at the bottom of a stairway where the glazing is less than 36 inches (914 mm) 60 inches (1524 mm) above the landing and within a 60 inches (1524 mm) horizontally of the bottom tread shall be considered a hazardous location.

Reason: Previous editions of the IBC before the 2012 required glazing that is less than 60" above the landing to be approved safety glazing. It is not clear why this requirement was changed in the 2012. It does not make sense that section 2406.4.6 applies to glazing that is less than 60" above the stairs and intermediate landings but the glazing at bottom landing is treated differently – only when below 36" The potential for falling through the glazing at bottom landing is the same. This change will bring back the 60" height which will then match the requirement at intermediate landings and stairs.

Both 2012 IBC sections 2406.4.6 and 2406.4.7 have exceptions which allow a guard but require the plane of glass to be at least 18" away from the guard.

This code change should be approved in order to make sure that people who use stairs, ramps, and landings remain safe in case they trip and fall and potentially fall through windows adjacent to the stairs and ramps. I do not feel that only protecting glazing that is below 36" above walking surface is adequate but that all glazing below 60" should be protected. The vast majority of people will have their hands and arms outstretched if falling at 48" or so high and would be falling through glass at this height or somewhat higher. Approving this code change will get both the IRC and IBC to match which is extremely important.

Cost Impact: **Cost Impact:** This code change will increase the cost of construction.

RB114-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R308.4.6-RB-PATE

RB115 – 13

R308.4.7

Proponent: Tim Pate, City and County of Broomfield, CO representing Colorado Chapter Code Change Committee

Revise as follows:

R308.4.7 Glazing adjacent to the bottom stair landing. Glazing adjacent to the landing at the bottom of a stairway where the glazing is less than 36 inches (914 mm) above the landing and within a 60 inches (1524 mm) ~~horizontally of horizontal arc less than 180 degrees from the bottom tread nosing~~ shall be considered a hazardous location.

Exception: The glazing is protected by a guard complying with Section 312 and the plane of the glass is more than 18 inches (457 mm) from the guard.

Reason: Previous editions of the IRC before the 2012 required glazing that is 60" horizontally in any direction to be approved safety glazing. It is not clear why this requirement was changed in the 2012. The previous editions had the additional wording "in any direction" when applying the 60" horizontal rule. This is due to the "splay" factor for when someone gets to the last tread and falls. The tendency is for someone to flail out in any direction.

This added wording will make this section only apply to any glazing that is in a wall that is less than 180 degrees from the bottom tread nosing. I believe that adding the wording which would limit the area needing safety glazing to any glazing that falls within a 180 degree arc from bottom tread nosing and extending out 60" makes more sense since it is extremely unlikely that someone will fall out and backwards. I have added an illustration which should help everyone see what this changed wording will do.

Please note that there is still a requirement to provide approved safety glazing when located within 36" horizontally of the sides of the stairs.

The new code language will incorporate the areas shown in the following diagram:

The current code language incorporates the area shown below in the diagram:

This same code change proposal was reviewed and approved at the Final Action Hearings for the 2015 IBC – therefore this proposal for the IRC will get the two code sections to match which is important for consistency.

Cost Impact: This code change will reduce construction cost.

RB115-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R308.4.7-RB-PATE

RB116 – 13

R308.6.9.1 (New), Chapter 44

Proponent: Jeff Inks, Window and Door Manufacturers Association, representing the Window & Door Manufacturers Association.

Add new text as follows:

R308.6.9 Testing and labeling. Unit skylights and tubular daylighting devices shall be tested by an approved independent laboratory, and bear a label identifying manufacturer, performance grade rating and approved inspection agency to indicate compliance with the requirements of AAMA/WDMA/CSA 101/I.S.2/A440.

R308.6.9.1 Comparative analysis for glass-glazed unit skylights. Structural wind load design pressures for glass-glazed unit skylights different than the size tested in accordance with Section R308.6.9 shall be permitted to be different than the design value of the tested unit when determined in accordance with one of the following comparative analysis methods:

1. Structural wind load design pressures for glass-glazed unit skylights smaller than the size tested in accordance with Section 308.6.9 shall be permitted to be higher than the design value of the tested unit provided such higher pressures are determined by accepted engineering analysis. All components of the smaller unit shall be the same as those of the tested unit. Where such calculated design pressures are used, they shall be validated by an additional test of the glass-glazed unit skylight having the highest allowable design pressure.
2. In accordance with WDMA I.S. 11.

Add new standard to Chapter 44 as follows:

WDMA Window & Door manufacturers Association
1400 East Touhy Avenue, Suite 470
Des Plaines, IL 60018

WDMA I.S.11-13 Analytical Method for Design Pressure Rating of Fenestration Products.....R308.6.9.1

Reason: Comparative analysis based on accepted engineering methods provides a proven, accurate and reliable means for determining design pressures of different sized products within a fenestration product line based on testing of specimen unit/s from the respective line. This alleviates the need for costly testing of all sizes within the line saving considerable construction costs and providing greater design flexibility without incurring additional time and costs, especially for specialty/custom products, for testing that isn't necessary in order to determine the correct DP.

Currently the IRC only allows comparative analysis for windows and doors in Section 612.3.1 which has been and continues to be widely utilized for those products for the reasons stated above. Since comparative analysis as noted above is equally applicable to glass-glazed unit skylights, it should also be permitted by the IRC for them.

Proposed method #1 is taken verbatim from the existing comparative analysis provision in Section 612.3.1 except for substituting "glass-glazed unit skylights" for "windows and door units". However, the existing provision is limited only to allowing comparative analysis for units smaller than the unit tested, not larger. Because comparative analysis can also be effectively used to accurately determine DP ratings for fenestration products that are larger in width and/or height than the actual tested specimen/s provided proper analytical methods are followed, it should also be permitted by the IRC for glass-glazed unit skylights for that purpose as long as proper engineering analysis is required.

The intent of this proposal is to provide for that by allowing for comparative analysis to also be used on units larger than the tested unit if determined in accordance with proposed method #2 -- WDMA I.S. 11. WDMA I.S. 11 - *Industry Standard for Voluntary Analytical Method for Design Pressure (DP) Ratings of Fenestration Products*, provides more comprehensive alternative methods appropriate for using comparative analysis to determine DP of units different in size, both smaller and larger, than that of the tested unit/s within a product line. The comparative analysis methods included in WDMA I.S. 11 are based on accepted engineering analysis which must also be sealed by a licensed Professional Engineer (PE) making it technically sound for use in the IRC for this purpose. This same alternative method is also being proposed for Section 612.3.1 for windows and doors for the same reasons.

Copies of the standard are being submitted to ICC for ICC and IRC code committee review accordingly. The standard is also available on WDMA's website via the following link: <https://www.wdma.com/OnlineBookstore/tabid/61/pid/20/WDMA-I-S-11-09-Voluntary-Analytical-Method-for-Design-Pressure-Rating-of-Fenestration-Products-PDF-Download.aspx>

Cost Impact: This code change proposal will not increase the cost of construction.

Analysis: A review of the standard proposed for inclusion in the code, [WDMA I.S.11-13] with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 1, 2013.

RB117 – 13

R310

Proponent: Charles S. Bajnai, Chesterfield County, VA, ICC Building Code Action Committee
(bajnaic@chesterfield.gov)

Delete and substitute as follows:

R310 EMERGENCY ESCAPE AND RESCUE OPENINGS

~~R310.1 Emergency escape and rescue required.~~ Basements, habitable attics and every sleeping room shall have at least one operable emergency escape and rescue opening. ~~Where basements contain one or more sleeping rooms, emergency egress and rescue opening shall be required in each sleeping room. Where emergency escape and rescue openings are provided, they shall have a sill height of not more than 44 inches (1118 mm) measured from the finished floor to the bottom of the clear opening. Where a door opening having a threshold below the adjacent ground elevation serves as an emergency escape and rescue opening and is provided with a bulkhead enclosure, the bulkhead enclosure shall comply with Section R310.3. The net clear opening dimensions required by this section shall be obtained by the normal operation of the emergency escape and rescue opening from the inside. Emergency and escape rescue openings with a finished sill height below the adjacent ground elevation shall be provided with a window well in accordance with Section R310.2. Emergency escape and rescue openings shall open directly into a public way, or to a yard or court that opens to a public way.~~

~~Exception:~~ Storm shelters and basements used only to house mechanical equipment not exceeding total floor area of 200 square feet (18.58 m²)

~~R310.1.1 Minimum opening area.~~ All emergency and escape rescue openings shall have a minimum net clear opening of 5.7 square feet.

~~Exception:~~ Grade floor openings shall have a minimum net clear opening of 5 square feet.

~~R310.1.2 Minimum opening height.~~ The minimum net clear opening height shall be 24 inches.

~~R310.1.3 Minimum opening width.~~ The minimum net clear opening width shall be 20 inches (508 mm).

~~R310.1.4 Operational constraints.~~ Emergency escape and rescue openings shall be operational from the inside of the room without the use of keys, tools or special knowledge.

~~R310.2 Window wells.~~ The minimum horizontal area of the window well shall be 9 square feet (0.9 m²), with a minimum horizontal projection and width of 36 inches (914 mm). The area of the window well shall allow the emergency escape and rescue opening to be fully opened.

~~Exception:~~ The ladder or steps required by Section R310.2.1 shall be permitted to encroach a maximum of 6 inches (152mm) into the required dimensions of the window well.

~~R310.2.1 Ladder and steps.~~ Window wells with a vertical depth greater than 44 inches (1118 mm) shall be equipped with a permanently affixed ladder or steps usable with the window in the fully open position. Ladders or steps required by this section shall not be required to comply with Sections R311.7 and R311.8. Ladders or rungs shall have an inside width of at least 12 inches (305 mm), shall project at least 3 inches (76 mm) from the wall and shall be spaced not more than 18 inches (457mm) on center vertically for the full height of the window well.

R310.2.2 Drainage. Window wells shall be designed for proper drainage by connecting to the building's foundation drainage system required by Section R504.1 or by an approved alternative method.

Exception: A drainage system for window wells is not required when the foundation is on well-drained soil or sand-gravel mixture soils according to the United Soil Classification System, Group I Soils, as detailed in Table R405.1.

R310.3 Bulkhead enclosures. Bulkhead enclosures shall provide direct access to the basement. The bulkhead enclosure with the door panels in the fully open position shall provide the minimum net clear opening required by Section R310.1.1. Bulkhead enclosures shall also comply with Section R311.7.8.2.

R310.4 Bars, grilles, covers and screens. Bars, grilles, covers, screens or similar devices are permitted to be placed over emergency escape and rescue openings, bulkhead enclosures, or window wells that serve such openings, provided the minimum net clear opening size complies with Sections R310.1.1 to R310.1.3, and such devices shall be releasable or removable from the inside without the use of a key, tool, special knowledge or force greater than that which is required for normal operation of the escape and rescue opening.

R310.5 Emergency escape windows under decks and porches. Emergency escape windows are allowed to be installed under decks and porches provided the location of the deck allows the emergency escape window to be fully opened and provides a path not less than 36 inches (914 mm) in height to a yard or court.

R310.1 Emergency escape and rescue opening required. Basements, habitable attics and every sleeping room shall have at least one operable emergency escape and rescue opening. Where basements contain one or more sleeping rooms, an emergency escape and rescue opening shall be required in each sleeping room. Emergency escape and rescue openings shall open directly into a public way, or to a yard or court that opens to a public way.

Exception: Storm shelters and basements used only to house mechanical equipment not exceeding a total floor area of 200 square feet (18.58 m²)

R310. 1.1 Operational constraints. Emergency escape and rescue openings shall be operational from the inside of the room without the use of keys, tools or special knowledge.

R310.2 Emergency escape and rescue openings. Emergency and escape rescue openings shall have minimum dimensions as specified in this section.

R310.2.1 Minimum opening area. All emergency and escape rescue openings shall have a minimum net clear opening of 5.7 square feet. The net clear opening dimensions required by this section shall be obtained by the normal operation of the emergency escape and rescue opening from the inside. The minimum net clear height opening shall be 24" and the minimum net clear width shall be 20"

Exception: Grade floor or below-grade openings shall have a minimum net clear opening of 5 square feet.

R310.2.2 Window sill height. Where a window is provided as the emergency escape and rescue opening, it shall have a sill height of not more than 44 inches (1118 mm) above the floor; if the sill height is below-grade, it shall be provided with a window well in accordance with Section R310.2.3.

R310.2.3 Window wells. The minimum horizontal area of the window well shall be 9 square feet (0.9 m²), with a minimum horizontal projection and width of 36 inches (914 mm). The area of the window well shall allow the emergency escape and rescue opening to be fully opened.

Exception: The ladder or steps required by Section R310.2.1 shall be permitted to encroach a maximum of 6 inches (152mm) into the required dimensions of the window well.

R310.2.3.1 Ladder and steps. Window wells with a vertical depth greater than 44 inches (1118 mm) shall be equipped with a permanently affixed ladder or steps usable with the window in the fully open position. Ladders or steps required by this section shall not be required to comply with Sections R311.7 and R311.8. Ladders or rungs shall have an inside width of at least 12 inches (305 mm), shall project at least 3 inches (76 mm) from the wall and shall be spaced not more than 18 inches (457mm) on center vertically for the full height of the window well.

R310.2.3.2 Drainage. Window wells shall be designed for proper drainage by connecting to the building's foundation drainage system required by Section R504.1 or by an approved alternative method.

Exception: A drainage system for window wells is not required when the foundation is on well-drained soil or sand-gravel mixture soils according to the United Soil Classification System, Group I Soils, as detailed in Table R405.1.

R310.2.4 Emergency escape and rescue openings under decks and porches. Emergency escape and rescue openings shall be permitted to be installed under decks and porches provided the location of the deck allows the emergency escape and rescue openings to be fully opened and provides a path not less than 36 inches (914 mm) in height to a yard or court.

R310.3 Emergency escape and rescue doors. Where a door is provided as the required emergency escape and rescue opening, it shall be permitted to be a side hinged door or a slider. Where the opening is below the adjacent ground elevation, it shall be provided with a bulkhead enclosure.

R310.3.1 Minimum door opening size. The minimum net clear height opening for any door that serves as an emergency and escape rescue opening shall be in accordance with Section R310.2.1.

R310.3.2 Bulkhead enclosures. Bulkhead enclosures shall provide direct access from the basement. The bulkhead enclosure shall provide the minimum net clear opening equal to the door in the fully open position.

R310.3.2.1 Drainage. Bulkhead enclosures shall be designed for proper drainage by connecting to the building's foundation drainage system required by Section R504.1 or by an approved alternative method.

Exception: A drainage system for bulkhead enclosures is not required when the foundation is on well-drained soil or sand-gravel mixture soils according to the United Soil Classification System, Group I Soils, as detailed in Table R405.1.

R310.4 Bars, grilles, covers and screens. Bars, grilles, covers, screens or similar devices are permitted to be placed over emergency escape and rescue openings, bulkhead enclosures, or window wells that serve such openings, provided the minimum net clear opening size complies with Sections R310.1.1 to R310.1.3, and such devices shall be releasable or removable from the inside without the use of a key, tool, special knowledge or force greater than that which is required for normal operation of the escape and rescue opening.

Reason: This proposal is submitted by the ICC Building Code Action Committee (BCAC). The BCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance an assigned International Code or portion thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the BCAC has held 6 open meetings and numerous workgroup calls which included members of the BCAC as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: <http://www.iccsafe.org/cs/BCAC/Pages/default.aspx>.

This code change is primarily for reorganizational purposes. It separates emergency escape and rescue openings (EERO) window and door provisions, which are currently intermingled. It also says that EERO doors do not have to be "egress" doors, that is, side hinged doors. The new code language allows sliders from basements.

Most people think of emergency escape and rescue openings as windows, and in fact, the current subsections in R310 all seem to define and quantify this type of application: minimum opening height, minimum opening width, window wells, ladders and steps from window wells, drainage from window wells, bars and grilles on windows, windows under decks.

However the most basic EERO is a door. In case of a fire, would prefer to exit through a door or a window? Will a fire fighter prefer to enter through a door or a window?

This revision acknowledges doors as a viable EERO and defines the minimum requirements for EERO doors. It allows side hinged doors or sliders to be used as EEROs.

An EERO door would not have to be an egress door but an egress door would automatically be an EERO door.

R310.1-RB-BAJNAI-BCAC

RB118 – 13

R310.1

Proponent: Rick Davidson, City of Maple Grove, Association of Minnesota Building Officials
(rdavidson@maplegrovern.gov)

Revise as follows:

R310.1 Emergency escape and rescue required. *Basements*, habitable attics and every sleeping room shall have at least one operable emergency escape and rescue opening. Where *basements* contain one or more sleeping rooms, emergency egress and rescue openings shall be required in each sleeping room. Where emergency escape and rescue openings are provided they shall have a sill height of not more than 44 inches (1118 mm) above the floor. Where a door opening having a threshold below the adjacent ground elevation serves as an emergency escape and rescue opening and is provided with a bulkhead enclosure, the bulkhead enclosure shall comply with Section R310.3. The net clear opening dimensions required by this section shall be obtained by the normal operation of the emergency escape and rescue opening from the inside. Emergency escape and rescue openings with a finished sill height below the adjacent ground elevation shall be provided with a window well in accordance with Section R310.2. Emergency escape and rescue openings shall open directly into a public way, or to a *yard* or court that opens to a public way.

Exception Exceptions:

1. *Basements* used only to house mechanical *equipment* and not exceeding total floor area of 200 square feet (18.58 m²).
2. Basements and habitable attics of buildings provided with sprinkler systems installed in accordance with Section R313.

Reason: Sprinkler systems are now required in dwellings including their basements. Sprinkler systems weren't required when basement and attic emergency escape and rescue openings went into the code. It is a reasonable trade-off to eliminate emergency escape and rescue openings in basements and attics when homes have sprinkler systems. In addition to sprinklers, new homes are now required to have numerous smoke alarms, carbon monoxide alarms, self-closing fire doors to garages, and under floor fire protection that makes the added expense of these openings unnecessary.

The addition of residential sprinkler requirements added unprecedented cost to the construction of a new home. Eliminating this unnecessary window requirement can help save money that was lost to the cost of sprinklers.

Basement emergency escape and rescue openings that must be installed below grade involve window wells. Window wells add additional cost and maintenance, pose a hazard from falling into the well by persons walking around the dwelling, and are a source of drainage problems during heavy rains. They fill with snow in winter climates and are difficult to clear. Window wells are an ideal hiding place for person's intent on breaking into a home for the purposes of burglary or bodily harm.

The code is silent on the location of basement emergency escape and rescue openings which can lead to their value as an exit being diminished, if nonexistent. The openings are intended to provide a second means of escape if the primary stairs are blocked. But there is no separation requirement for these openings and they could be located at the base of the stairway to the main floor rendering them useless. This can be particularly true in townhouses when there is only one exterior wall in which to locate the opening.

Last, elimination of emergency escape and rescue openings from basements eliminates easy potential entry points for person's intent on burglary, theft, and bodily harm. Statistics show that a person is much more likely to be the target of crime than they are of a fire. This changes even more when sprinklers are installed according to sprinkler advocates. As stated earlier, window wells provide an ideal access point for criminals to access a home. According to the US Justice Department, there are nearly 1 million victimizations of violent crime in a person's own dwelling and nearly 5 million victimizations of property crimes each year.

R310.1-RB-DAVIDSON

RB119 – 13

R310.1.1, R310.1.2, R310.1.3, R310.1.5 (NEW)

Proponent: Rick Davidson, City of Maple Grove, Association of Minnesota Building Officials
(rdavidson@maplegrovern.gov)

Revise as follows:

R310.1.1 Minimum opening area unobstructed glass area for windows. All Where windows are used as emergency escape and rescue openings, they shall have a minimum ~~net clear opening~~ unobstructed glass area of 5.7 square feet (0.530 m²).

Exception: Grade floor openings windows shall have a minimum ~~net clear opening~~ unobstructed glass area of 5 square feet (0.465 m²).

R310.1.2 Minimum opening unobstructed glass height. ~~The minimum net clear opening height~~ The minimum unobstructed glass height shall be 24 inches (610 mm).

R310.1.3 Minimum opening unobstructed glass width. ~~The minimum net clear opening width~~ The minimum unobstructed glass width shall be 20 inches (508 mm).

R310.1.4 Operational constraints. Emergency escape and rescue openings shall be operational from the inside of the room without the use of keys, tools or special knowledge.

R310.1.5 Doors used as emergency escape and rescue openings. Where a door is used to meet the requirements of this section, it shall be of a size that is capable of being used for its intended purpose.

Reason: This is a different and more logical approach to dealing with the size of emergency escape and rescue openings.

The dimensions that are currently being used for egress windows have been cited in ICC Commentaries and in the UBC predecessors as being the result of a study by the San Diego Fire Department. That statement is false. The ICC offices have no copies of any study that was done by the San Diego Fire Department that establishes egress window dimensions nor is there any record of any such study existing nor is there any recollection by ICC staff that they have ever seen such a study. Discussions with long time members of the San Diego Fire Department reveal that the Department never took part in any study to determine the appropriate size of egress windows.

Therefore, it is safe to assume that the dimensions in the code for egress windows exist without any scientific basis.

However, if one is going to have emergency escape and rescue windows, one must have certain size requirements for those windows. But the rules should be reasonable and defensible.

It has been stated by some folks that the reason for the 20 inch width requirement is that it accommodates the width of a fire ladder (20 inches). The area is necessary because "the studies" indicated that such a size (5.7 square feet) is necessary to allow emergency personnel to enter the room through the window wearing necessary safety gear (24 inches of height and 5.7 square ft). I'm not sure how that justifies the 5.0 square foot openings permitted at grade.

I don't know if there is a standard width for ladders or not. But the fallacy that exists is the assumption that the window will be open when a rescue attempt is made. Isn't it more likely that the window will be closed? Isn't it more likely that the following photos depict actual conditions? Isn't it more likely that a rescue person would need to break the window to initiate a rescue? If the ladder is placed in the window opening, won't it impede access into the room, especially with a casement window? Isn't it more reasonable to regulate the rescue opening based on the glass size of the closed window rather than the openable size of the window since that is more than likely how rescue personnel will encounter the window? Won't rescue personnel break out any glass in an opening rather than try to open the window? Of course.

Therefore, it seems to make much more sense to base emergency escape and rescue window requirements on glass size rather than openable area. Even for occupants of the room, it may be more appropriate to break the glass rather than trying to reach operating hardware that may be located where the air is untenable.

Last, there is language proposed to address doors used as rescue and escape openings. The size of the door entering the room is unregulated. This is the primary exit from the room. If a door used as the primary exit is not regulated, why should a secondary door face stricter limits? The proposed language requires that the door be "capable of being used for its intended purpose". This is similar to language approved by the IRC committee in the past and gives the field inspector discretion over door sizes. The inspector may use location, size of the occupant, or whatever limitations seem reasonable to establish the opening size.

Public Hearing: Committee:
Assembly:

AS
ASF

AM
AMF

D
DF

R310.1.1-RB-DAVIDSON

RB120 – 13

R310.1.4

Proponent: Rick Davidson, City of Maple Grove, Association of Minnesota Building Officials
(rdavidson@maplegrovern.gov)

Revise as follows:

R310.1.4 Operational constraints. Emergency escape and rescue openings shall be operational from the inside of the room without the use of keys, tools or special knowledge. Hardware necessary to operate emergency escape and rescue openings shall not be located more than 48 inches above the floor and shall be operable with one hand. The force required to activate operable parts shall be not more than 5.0 pounds (22.2 N).

(Subsequent sections remain unchanged.)

Reason: The IRC goes to great lengths to regulate the size and location of emergency escape and rescue openings except for the location of operational hardware. There is nothing in the code to prevent operational hardware from being 6 feet above the floor. One of the purposes of the window is to permit emergency escape. But how do people of small stature escape through one of these openings if they cannot reach the operational hardware? This proposal places a modest and reasonable requirement in the code that operational hardware be located within 48 inches of the floor. This would apply to locks and operators. This is consistent with hardware requirements for windows required to be accessible by ANSI A117.1.

The lock location for some typical windows is about 68 inches above the floor. Physiological studies indicate that an average child would need to be at least 9 years old and 4 feet 6 inches in height to operate hardware at that height.

The proposal also includes language from ANSI A117.1 regarding the operation of the window. Difficulty in reaching and operating window hardware can prevent children from escaping a fire. A window that can't be open serves no purpose. The code should contain rules to help safeguard our children just as it has other members of society.

This should pose no hardship on window manufacturers as they are already required to produce such windows for accessibility purposes.

	Assembly:	ASF	AMF	DF

R310.1.4-RB-DAVIDSON

RB121 – 13

R310.1.5 (New)

Proponent: Rick Davidson, City of Maple Grove, Association of Minnesota Building Officials
(rdavidson@maplegrovern.gov)

Revise as follows:

R310.1.5 Identification. Where windows are used to meet the requirements of this section, they shall be provided with a manufacturer's designation or mark that provides one of the following:

1. The net clear opening area, the net clear opening height, and the net clear opening width of the window or
2. Shall be identified as meeting emergency escape and rescue requirements with a manufacturer's designation or mark that reads "Emergency Escape and Rescue Opening 5.0 sq. ft" or "Emergency Escape and Rescue Opening 5.7 sq. ft." as applicable or similar language to indicate that the window meets the requirements of this section.

The manufacturer's designation or mark shall be affixed to the window so as to be visible for inspection and shall be of a type which once applied cannot be removed without being destroyed.

Reason: This proposal was submitted for the hearings in Baltimore. Prior to the proposal being heard, I was approached by representatives of several window manufacturers' about modifications to the proposal and a promise from them to work with me if I would request the proposal be disapproved. I made the request that the proposal be disapproved and the committee did so. That is a matter of public record.

Unfortunately, this appears to have been a delay tactic by the window manufacturers. There were never any offers of alternative language. It was suggested that perhaps inspectors should carry premeasured sticks or templates to determine compliance. Then, opponents of the proposal suggested that I requested the committee overturn the proposal to avoid any discussion before the committee! This is underhanded and deceitful.

The proposal is being brought back before the committee.

Several window manufacturers' already label their windows as meeting code requirements. Examples of the labeling follow. Requiring all window manufacturers' to label their windows levels the playing field for all manufacturers. Recall that during the discussion regarding fire protection of under floor spaces that it was argued that certain materials performed better in fire situations than others and that they shouldn't warrant the additional fire protection. But several speakers stated "cover 'em all, keep the playing field level", and we did. This proposal deserves the same consideration.

Window manufacturers' already have statements in their literature that clearly indicate which of their windows meet or exceed national egress requirement. They don't need to conduct any research to comply with the rules.

Please note that the information from the manufacturers clearly states that their windows meet or exceed national egress requirements. If there truly is a concern about liability, it isn't demonstrated by the information on the manufacturer's own websites and advertising information.

The proposed amendment provides two options for identifying that the window meets egress requirements. The designation or mark may either provide the height, width, and opening dimensions or a statement that it meets either the 5.0 or 5.7 square foot opening requirements. The designation or mark is not required to be a permanent label. The label may be a paper label but must be designed so that it cannot be transferred from one window to another. This will enable the field inspector the ability to approve windows without the need to measure them with the same accuracy as the manufacturer and without the need to perform multiplication of fractional numbers in the field. The terms "manufacturer's designation" and "mark" are defined in the code. The term "once applied cannot be removed without being destroyed" is already used in the code to describe other labels, designations, or marks.

MANUFACTURER'S DESIGNATION. An identification applied on a product by the manufacturer indicating that a product or material complies with a specified standard or set of rules. (See also "Mark" and "Label.")

MARK. An identification applied on a product by the manufacturer indicating the name of the manufacturer and the function of a product or material. (See also "Manufacturer's designation" and "Label.")

Why can't the field inspector measure the windows in the field? If you review the hundreds of sizes and styles of windows available from dozens of manufacturers, it is apparent that there are thousands of windows that meet or come close to meeting egress requirements. You will find that some windows are exactly 5.7 square feet or 5.0 square feet. And there are others that are just a few hundredths of a square foot more or less. Herein lays the problem. Could a field inspector carry a calculator in the field and a binder of window catalogs? Of course they could. But they aren't expected to do that for other building components. What makes windows so special? Why can't the manufacturer just put a simple label on their product?

Manufacturers measure window openings to the 1/16th or to the hundredths of an inch. This degree of accuracy cannot be achieved in the field. Windows often have gaskets or weather stripping that interferes with measurements and can cause variations during very hot or very cold weather. Incorrectly measuring the window size by even a 1/16th of an inch can give the impression that a window meets or fails to meet egress requirements when the opposite is true. Validating this takes time and can lead to unnecessary expense and delays. And if one window brand is approved that is just short of meeting minimum standards, the door is open for every other window manufacturer who has a window just slightly below minimum to request the same treatment.

For example, Andersen Windows advertises that their CW135 casement window has a clear opening of 22-9/16 inch by 36-3/8 inch. They state the net clear openable area is 5.7 square feet. Multiplying the width times the height (try doing that in your head) actually gives an area of 5.69938151 square feet. Setting aside the arguments related to rounding, it is easy to see that if a field inspector measured one of these windows at 22-7/16 inch by 36-1/4 inch that he would likely fail the window. This will delay the construction, increase costs, and provide no increase in safety.

◆ These units meet or exceed the following dimensions: Clear Openable Area of 5.7 sq. ft., Clear Openable Width of 20" and Clear Openable Height of 24", when appropriate hardware (straight arm or split arm) is specified.

Identifying windows as meeting egress requirements will also provide consumers, contractors, sales people and others concerned about a window used as an emergency escape and rescue opening the information they need to make informed decisions regarding the window without the need to search a catalog or website. It will also help to increase awareness of egress requirements. I'm sure every building department has stories they could tell about inspections of egress windows that failed to meet the required size and had to be removed and returned to the retailer at a loss and how the sales person either wasn't aware that egress requirements existed or didn't know the details of the rule.

Most window manufacturers *do not* provide any opening dimension information on the labeling of their windows. They are often shrink wrapped which prohibits them being measured at the store. There is no way for the purchaser of a window to know if the window meets emergency escape and rescue opening requirements. Most often, they will rely on the experience, or lack thereof, of the sales person they are dealing with. Sales people in big box home improvement stores are not trained and change frequently. Likely unintentionally, they frequently give homeowners the wrong information when purchasing windows that ends up being a costly mistake.

At the hearings in Dallas, one window rep stated that most window buyers will have researched this information and know what size window they want before they ever get to the retailer. This is pure unfounded speculation. This presumes that untrained homeowners and others will be able to wade through the manufacturer's literature, know what the rules are, and how those rules apply to one of a myriad of window sizes. In the *real* world, this just doesn't happen. Window manufacturers do not work with homeowners and contractors on a daily basis. Building departments do.

Once a window is installed that is too small, it is expensive to replace and creates unnecessary conflict between the homeowner and building department.

The information that would go on the label is already in the manufacture's printed literature. It doesn't require the manufacturer to generate new information. The manufacturer need not indicate that the window complies with egress requirements if they so choose even though their catalogs may already state that certain windows meet national egress requirements. It just won't get accepted.

The code requires labels on windows for energy code compliance and compliance with safety glazing. Almost every building product used today is identified with labels, designations or marks in one way or another. Windows used for egress purposes should be no different.

What is so difficult about putting a small paper label on a window to identify if it meets opening requirements for emergencies? Nothing! Window manufacturers have objected to window fall protection requirements, flashing requirements, egress window tradeoffs for sprinkler systems, labeling requirements, and on and on. The committee needs to realize that the window industry opposes any attempt to regulate it and needs to take a hard line with respect to ignoring the needs of the public.

This proposal just asks that the information already provided in the sales brochure be transferred to the window so the purchaser of the window can make an informed decision.

Cost Impact: None

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R310.1.5 (NEW)-RB-DAVIDSON

RB122 – 13

R310.1.5 (New)

Proponent: Jeff Inks, Window and Door Manufacturers Association, representing the Window & Door Manufacturers Association.

Add new text as follows:

R310.1.5 Replacement windows. Replacement windows installed in buildings meeting the scope of this code shall be exempt from the maximum sill height requirements of Sections R310.1 and Sections R310.1.1, R310.1.2, and R310.1.3 provided the replacement window meets the following conditions:

1. The replacement window is the manufacturer's largest standard size window that will fit within the existing frame or existing rough opening. The replacement window shall be permitted to be of the same operating style as the existing window or a style that provides for an equal or greater window opening area than the existing window.
2. The replacement window is not part of a change of occupancy.

Reason: First, while this provision is applicable to existing construction (for the reasons stated below), it is being proposed for inclusion in the main body of the IRC because window replacements are more common than other significant changes made to existing one- or two-family homes and townhomes, and in addition, for consistency with what is being proposed for IRC Appendix J and IEBC Chap 7 by us and the ICC CTC.

The proposed provisions and language are also based on Minnesota's residential code which does effectively incorporate the provisions into the main body of the code in the same location (R310.1.5) being proposed above.

The provisions and language have also already been approved for IEBC Chap. 4 which occurred during the Group A proceedings. Most importantly, it's important to note that the provisions do not allow for any decrease in safety and rather will help ensure improvements in safety can be made.

More specifically, the intent of this proposal is to ensure that the IRC does not discourage or prevent improvements in emergency escape and rescue openings, especially for fire safety, in older residential occupancies by requiring replacement windows to meet all of the provisions of Section 310 when doing so can only be accomplished by increasing the size of the rough opening or altering the interior wall.

Because many of these older buildings were constructed under codes that did not include the same emergency escape and rescue opening provisions that the IRC now requires for new construction, the only way to fully meet all of the requirements of Section 310 for new construction if required when windows are replaced is to enlarge the rough opening and/or make significant alterations to the interior wall in order to accommodate any increase in window size or lowering of a sill.

At the very least, the significant cost and design challenges of altering the rough opening and/or interior wall can discourage or prevent window replacement and at worst can discourage or prevent the replacement of older windows that are harder to operate or are inoperable all together because of their age or poor maintenance and, that are significantly less energy efficient. When that happens, improvements to safety as well as energy efficiency are needlessly compromised.

Furthermore and on the whole, while some bedroom windows in older homes may not provide the full clear opening that is required for new construction or may have a sill height above 44 inches, they nonetheless still provide a viable emergency and escape rescue opening which is the primary intent of the code. Replacement of these windows with the same type of operating window or other type that can provide an equal or greater clear opening than the existing window -- even if they do not fully meet the clear opening or sill height requirements of Section 310 -- is always an improvement in safety, especially when a replacement opening can provide a larger clear opening than the existing window. Such improvements in safety should not be discouraged or prevented by overly onerous requirements for replacement windows.

This proposal will help ensure that doesn't happen by providing limited exceptions to the requirements of Section 310 that can only be applied when certain conditions are met and that as already noted, will not result in a decrease in safety.

The requirements for new construction that emergency escape and rescue openings be provided as well as the operational requirements of Section 310.1.4 are maintained and still applicable to replacement windows.

Cost Impact: This code change will not increase the cost of construction.

R310.1.5 (NEW) #1-RB-INKS

RB123 – 13

310.1.5 (New)

Proponent: Jeff Inks, Window and Door Manufacturers Association, representing the Window & Door Manufacturers Association.

Add new text as follows:

R310.1.5 Window opening control devices. Window opening control devices complying with ASTM F 2090 shall be permitted for use on windows serving as a required *emergency escape and rescue opening*.

Reason: It has been brought to our attention that the IRC needs further clarity regarding the permitted installation of window opening control devices (wocd's) compliant with ASTM F2090 on EERO windows. While that is clearly implied and intended by Section 312 and the purpose of F2090 is specifically for wocd's with emergency release mechanisms for use on EERO windows, providing express language under Section 310.1 will provide further clarification that the installation of F2090 compliant devices is permitted on EERO windows.

Cost Impact: The code change proposal will not increase the cost of construction.

RB123-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R310.1.5 (NEW) #2-RB-INKS

RB124 – 13

R310.6 (New), R310.7 (New)

Proponent: Rick Davidson, City of Maple Grove, Association of Minnesota Building Officials
(rdavidson@maplegrovern.gov)

Revise as follows:

R310.6 Dwelling additions. Where dwelling additions occur that contain sleeping rooms, an emergency escape and rescue opening shall be provided in each new sleeping room. Where dwelling additions occur that have basements, an emergency escape and rescue opening shall be provided in the new basement.

Exceptions:

1. An emergency escape and rescue opening is not required in a new basement that contains a sleeping room with an emergency escape and rescue opening.
2. An emergency escape and rescue opening is not required in a new basement where there is an emergency escape and rescue opening in an existing basement that is accessible from the new basement.

R310.7 Alterations or repairs of existing basements. An emergency escape and rescue opening is not required where existing basements undergo alterations or repairs.

Exception: New sleeping rooms created in an existing basement shall be provided with emergency escape and rescue openings in accordance with R310.1.

Reason: There continues to be confusion in the code enforcement community as to the requirements for emergency escape and rescue opening requirements as they apply to existing basements and additions. Hopefully this proposal will make it clearer that emergency escape and rescue openings are only required in additions if there are sleeping rooms and/or a basement and then only if the new basement does not have a sleeping room or access to an emergency escape and rescue opening in the existing basement. Furthermore, this amendment is intended to clarify that existing basements that do not undergo expansion and where no sleeping rooms are added need not have emergency escape and rescue openings installed when remodeling occurs. At least in our area, code officials sometimes require emergency escape and rescue openings be installed when basements are finished or remodeled even when no sleeping rooms occur. This was never the intent of the code.

Cost Impact: None

RB124-13

	Assembly:	ASF	AMF	DF

R310.6 (NEW)-RB-DAVIDSON

RB125 – 13

R311.1

Proponent: Paul Armstrong, PE, CBO; Orange Empire Chapter – Code Committee; Orange Empire Chapter

Revise as follows:

R311.1 Means of egress. All dwellings shall be provided with a means of egress as provided in this section. The means of egress shall provide a continuous and unobstructed path of vertical and horizontal egress travel from all portions of the dwelling to the ~~exterior of the dwelling at the~~ required egress door without requiring travel through a garage. The required egress door shall open to a yard or court that leads to a public way.

Reason: The purpose of this change is to clarify the means of egress from dwellings under the IRC. The proposal attempts to split the egress path into two simpler sentences. The original sentence has been revised to address interior path of egress travel up to the required egress door. The new sentence addresses the exterior area from the required egress door and also clarifies that the required egress door opens to a yard or court that leads to a public way. The new text is consistent with the requirement for emergency escape and rescue openings in Section R310.1.

Cost Impact: The code change proposal will not increase the cost of construction.

RB125-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R311.1-RB-ARMSTRONG

RB126 – 13

R311.3.2

Proponent: Wesley Walters, Clark County Nevada Development Services, representing self

Revise as follows:

R311.3.2 Floor elevations for other exterior doors. Doors other than the required egress door shall be provided with landings or floors not more than 7 ¾ inches (196 mm) below the top of the threshold.

Exception: A top landing is not required where a stairway of two or fewer risers is located on the exterior side of the door, provided the door does not swing over the stairway.

Reason: The code does not define which landing is not required, this will clarify that it is only the top one being eliminated.

Cost Impact: The code change proposal will not increase the cost of construction.

RB126-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R311.3.2-RB-WALTERS

RB127 – 13

R311.4

Proponent: Homer Maiel, PE, CBO, 4LEAF, Inc., representing self

Revise as follows:

R311.4 Vertical egress. Egress from habitable levels including habitable attics and basements not provided with an egress door in accordance with Section R311.2 shall be by a one or more ramps in accordance with Section R311.8 or a one or more stairways in accordance with Section R311.7 or both. For habitable levels or basements located more than one story above or more than one story below an egress door, the maximum travel distance from any occupied point to a stairway or ramp that provides egress from such habitable level or basement, shall not exceed 50 feet (15 240 mm).

Reason: In the legacy codes, one exit from the third floor within an individual dwelling unit or a Group R, Division 3 congregate residence was allowed as long as the third story area did not exceed 500 square feet. Currently, IRC has no limitations on the stories above the second floor. This addition that limits the travel distance on the floors above the second floor to 50 feet or less addresses that concern. Same applies when there are more than one level of basement below the first floor.

Cost Impact: The code change proposal will not increase the cost of construction.

RB177-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R311.4-RB-MAIEL

RB128 – 13

R311. 6

Proponent: Rick Davidson, City of Maple Grove, Association of Minnesota Building Officials
(rdavidson@maplegrovern.gov)

Revise as follows:

R311.6 Hallways. The minimum width of a hallway shall be not less than ~~3 feet (914 mm)~~ 32 inches (812 mm).

Reason: The International Residential Code Commentary states the following in regards to hallways:

R311.3 Hallways. The minimum width of a hallway shall be not less than 3 feet (914 mm).

❖ **Hallways must be a minimum of 3 feet (914 mm) wide to accommodate moving furniture into rooms off the hallway and for safe egress from the structure.**

So the hallway width is necessary to accommodate moving furniture and for safe egress. Why should the code be concerned about moving furniture? In fact the scoping and purpose of the code say nothing about moving furniture. And if the concern was genuine, hallways would need to be wider given the size of some furniture. Clearly, the width of a hallway is an arbitrary dimension not based on safety but likely based on convenience.

Regarding safe egress, if this were truly a concern about safe egress, why wouldn't we specify the minimum door sizes from bedrooms, bathrooms, and other occupied spaces? As it is, the only thing we have to hang out hats on is the 20 inch minimum openable width of an emergency escape and rescue opening.

This is one of those code requirements that people seem to think is necessary but when push comes to shove, it doesn't get enforced.

For example, a plan review is done on a new home and the hallway is noted to be 36 inches wide. The framer then either frames the hallway at 36 inches or works from the exterior walls in to frame the various rooms. In either case, the potential exists that the hallway may be something less than 36 inches. This isn't something that many field inspectors will check at the framing inspection. Then during the final inspection the hall is determined to be 35 inches wide. What do you do? You ignore it of course. The cost to correct it is much too high given the benefit.

In another example, we have a home built with an unfinished basement. There is a center bearing wall with the furnace located a short distance from the wall. The mechanical contractor does not check the distance from the furnace to the bearing wall when installing the furnace. The basement is unfinished so the field inspector doesn't anticipate future finishing problems. Then, when the homeowner finishes the basement, the location of the furnace results in a hallway that is only 32 inches wide. They can't move the bearing wall. The cost to move the furnace and alter the ductwork, gas piping, and wiring is expensive. And what is to be gained? If the building department denies the permit, the basement will be finished at some point without permits. Do we want to encourage this?

These circumstances do occur. They are dealt with by building departments all the time. It is necessary to provide a better and more reasonable solution for this problem.

Furthermore, this will be regulated by the market place in new construction. If a homeowner views a new home for sale and they wish the hallway to be wider, they can make the decision to buy or not to buy.

The basic stair width requirement is 36 inches. But that can be reduced by 4.5 inches on each side for handrails. And the code only requires that the width of stairways below the handrails be 27 inches. Spiral stairways are permitted to be 26 inches.

R311.7 Stairways.

R311.7.1 Width. Stairways shall not be less than 36 inches (914 mm) in clear width at all points above the permitted handrail height and below the required headroom height. Handrails shall not project more than 4.5 inches (114 mm) on either side of the stairway and the minimum clear width of the stairway at and below the handrail height, including treads and landings, shall not be less than 31½ inches (787 mm) where a handrail is installed on one side and 27 inches (698 mm) where handrails are provided on both sides.

Exception: The width of spiral stairways shall be in accordance with Section R311.7.9.1.

R311.7.10.1 Spiral stairways. Spiral stairways are permitted, provided the minimum clear width at and below the handrail shall be **26 inches** (660 mm) with each tread having a 7½-inch (190 mm) minimum tread depth at 12 inches (914 mm) from the narrower edge. All treads shall be identical, and the rise shall be no more than 9½ inches (241 mm). A minimum headroom of 6 feet 6 inches (1982 mm) shall be provided.

The only required egress door, need only provide 32 inches of clear width. A 36 inch wide hallway seems to be an anomaly.

R311.2 Egress door. At least one egress door shall be provided for each *dwelling* unit. The egress door shall be side hinged, and shall provide a minimum clear width of 32 inches (813 mm) when measured between the face of the door and the stop, with the door open 90 degrees (1.57 rad).

This proposal reduces the required hallway width to 32 inches consistent with the main egress door and wider than what is required for stairs. If 27 inches is safe for egress in a stair and if I can move furniture up and down a stair that is 27 inches wide, I should be able to do the same in a hall.

Cost Impact: None

RB128-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R311.6-RB-DAVIDSON

RB129 – 13

R311.7

Proponent: Rick Davidson, City of Maple Grove, Association of Minnesota Building Officials
(rdavidson@maplegrovern.gov)

Add new text as follows:

R311.7 Stairways. Stairways serving a dwelling or accessory structure shall comply with this section. This shall include, but shall not be limited to, exterior stairs from a dwelling or garage to grade and those stairs serving decks, porches, balconies, sun rooms, and similar structures.

Exceptions:

1. Stairs serving attics or crawl spaces.
2. Stairs that only provide access to plumbing, mechanical, or electrical equipment.
3. Stairs that serve structures or spaces used by children as play areas.

Reason: When reading Section R311 of the IRC regarding stairs, the language supports only two interpretations on how stairs are regulated. Those two interpretations are that either all stairs must comply with the section or only those stairs that are a part of the means of egress should comply. There is no other language that allows vacillation between those interpretations.

The title of the section is "Means of Egress". R311.1 requires a means of egress from "all portions of the dwelling to the exterior of the dwelling..." R311.4 qualifies the charging language by stating that every habitable level including basements must either have an exterior exit door meeting the requirements of R311.2 or have a stair or ramp connecting that level to a level that has such a door. Note that it does not say "stairs" or "ramps" but "stair" or "ramp" (singular).

The text of the code does not support regulating stairs that are not a part of the "means of egress". This theory is apparently wide spread because many building officials are of the opinion that stairs used in landscaping are not regulated. Also, attempts to submit code changes to the ICC IRC Committee to give relief for stairs to attics and crawl spaces have been met with resistance from the Committee with the statement that they are already exempt. One can come to that conclusion only if you interpret the stair rules to apply to the means of egress and only one means of egress is required and that is only required from the dwelling, not attics, crawl spaces, and garages.

But if you take the position that the section only regulates those stairs that are part of the means of egress, stairways serving attics and crawl space and landscaping stairs would not be regulated but also stairs serving decks and the stairs commonly found serving as a path of travel from a dwelling to a garage would not be. In fact, R311.1 specifically prohibits a means of egress from traveling through a garage.

So there is confusion as to whether or not the code does regulate or intends to regulate certain stairs. This proposal makes it clear that all stairs are required to comply with the code unless specifically exempted. If this proposal is supported, stairs that are part of landscaping would be exempt unless they serve as a means of travel from a dwelling or accessory structure to grade. Stairs from a deck or from one level of a deck to another would be regulated. Stairs between a dwelling and garage would be regulated. Stairs serving an attic or crawl space would not be regulated. The current text already exempts stairs to crawl spaces by Section R311.4 but not directly. It exempts them because it does not list crawl spaces as a location where compliant stairs are required. But this also supports the possibility that the code does not regulate stairs serving a deck.

It is necessary to eliminate the confusion and inconsistency that exists in the enforcement of stair requirements that this language be approved. The proposal is reasonable because it puts into written format what is commonly accepted to be code language even if it cannot be supported by that text.

The following is for informational purposes only.

SECTION R311 MEANS OF EGRESS

R311.1 Means of egress. All *dwelling*s shall be provided with a means of egress as provided in this section. The means of egress shall provide a continuous and unobstructed path of vertical and horizontal egress travel from all portions of the *dwelling* to the exterior of the *dwelling* at the required egress door without requiring travel through a garage.

And,

R311.4 Vertical egress. Egress from habitable levels including habitable attics and *basements* not provided with an egress door in accordance with Section R311.2 shall be by a ramp in accordance with Section R311.8 or a stairway in accordance with Section R311.7.

Cost Impact: None

RB129-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R311.7-RB-DAVIDSON

RB130 – 13

R311.7.1

Proponent: David W. Cooper, Stair Manufacturing and Design Consultants, representing the Stairway Manufacturers' Association (sma@stairways.org)

Revise as follows:

R311.7.1 Width. *Stairways* shall not be less than 36 inches (914 mm) in clear width at all points above the permitted *handrail* height and below the required headroom height. *Handrails* shall not project more than ~~4.5~~ 6.5 inches (~~114~~165 mm) on either side of the *stairway* and the minimum clear width of the *stairway* at and below the *handrail* height, including treads and landings, shall not be less than 31½ inches (787 mm) where a *handrail* is installed on one side and 27 inches (698 mm) where *handrails* are provided on both sides.

Exception: The width of spiral *stairways* shall be in accordance with Section R311.7.10.1.

Reason: The required continuous handrail often needs to project an additional 2 inches from the side of the stairway to maintain the required finger clearance when passing nosing projections at a floor, landing, or return flight. This would not diminish the required width and would provide needed finger clearance to avoid nosing projections into the stairway.

Cost Impact: This code change will not increase the cost of construction

RB130-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R311,7.1-RB-COOPER

RB131 – 13

R311.7.2, R311.7.5.1, R311.7.5.2.1.

Proponent: David W. Cooper, Stair Manufacturing and Design Consultants, representing the Stairway Manufacturers' Association (sma@stairways.org)

Revise as follows:

R311.7.2 Headroom. The minimum headroom in all parts of the stairway shall not be less than 6 feet 8 inches (2032 mm) measured vertically from the sloped line adjoining the tread nosing or from the floor surface of the landing or platform on that portion of the stairway.

Exception- Exceptions:

1. Where the nosings of treads at the side of a flight extend under the edge of a floor opening through which the stair passes, the floor opening shall be allowed to project horizontally into the required headroom a maximum of 4¾ inches (121 mm).
2. The headroom for spiral stairways shall be in accordance with Section R311.7.10.1

R311.7.5.1 Risers. The maximum riser height shall be 7¾ inches (196 mm). The riser shall be measured vertically between leading edges of the adjacent treads. The greatest riser height within any flight of stairs shall not exceed the smallest by more than ¾ inch (9.5 mm). Risers shall be vertical or sloped from the underside of the nosing of the tread above at an angle not more than 30 degrees (0.51 rad) from the vertical. Open risers are permitted provided that the opening between treads does not permit the passage of a 4-inch-diameter (102 mm) sphere.

Exception- Exceptions:

1. The opening between adjacent treads is not limited on stairs with a total rise of 30 inches (762 mm) or less.
2. The opening between adjacent treads is not limited on spiral stairways.
3. The riser height of spiral stairways shall be in accordance with Section R311.7.10.1

R311.7.5.2.1 Winder treads. Winder treads shall have a minimum tread depth of 10 inches (254 mm) measured between the vertical planes of the foremost projection of adjacent treads at the intersections with the walkline. Winder treads shall have a minimum tread depth of 6 inches (152 mm) at any point within the clear width of the stair. Within any flight of stairs, the largest winder tread depth at the walkline shall not exceed the smallest winder tread by more than ¾ inch (9.5 mm). Consistently shaped winders at the walkline shall be allowed within the same flight of stairs as rectangular treads and do not have to be within ¾ inch (9.5 mm) of the rectangular tread depth.

Exception: The tread depth of spiral stair stairways shall be in accordance with Section R311.7.10.1

Reason: Exception 2 **Headroom** - The user of the code is currently only directed to R311.7.10.1 Spiral Stairways under R311.7.1 Width. Specific cross reference is needed under Headroom.

Exception 1 **Risers** – No change except numbering

Exception 2 **Risers** - Conformance with the IBC allowing open risers on spiral stairways.

Exception 3 **Risers** and new exception to **Winder treads** - The user of the code is currently only directed to R311.7.10.1 Spiral Stairways under R311.7.1 Width. Specific cross reference is needed under risers and winder treads.

Cost Impact: This code change will not increase the cost of construction

RB131-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R311.7.2-RB-COOPER

RB132– 13

R311.7.3

Proponent: David W. Cooper, Stair Manufacturing and Design Consultants, representing the Stairway Manufacturers' Association (sma@stairways.org)

Revise as follows:

R311.7.3 Vertical rise. A *flight of stairs* shall not have a vertical rise greater than ~~12 feet (3658 mm)~~ 147 inches (3734 mm) between floor levels or landings.

Reason: The elevation of 147 inches is a multiple of the maximum riser height of 7-3/4 inches (197 mm). (See Table 1) This minor change of just 3 inches (76 mm) in the total rise of the flight would in many cases eliminate the cost of incorporating a landing and the space required, reducing construction costs. As can be seen in the table below this change would require no additional steps in the stair than the current code requires and a change in riser height of just 5/32 inch (4 mm) or less when the minimum number of risers is desired. This represents no discernable difference consequential to the user.

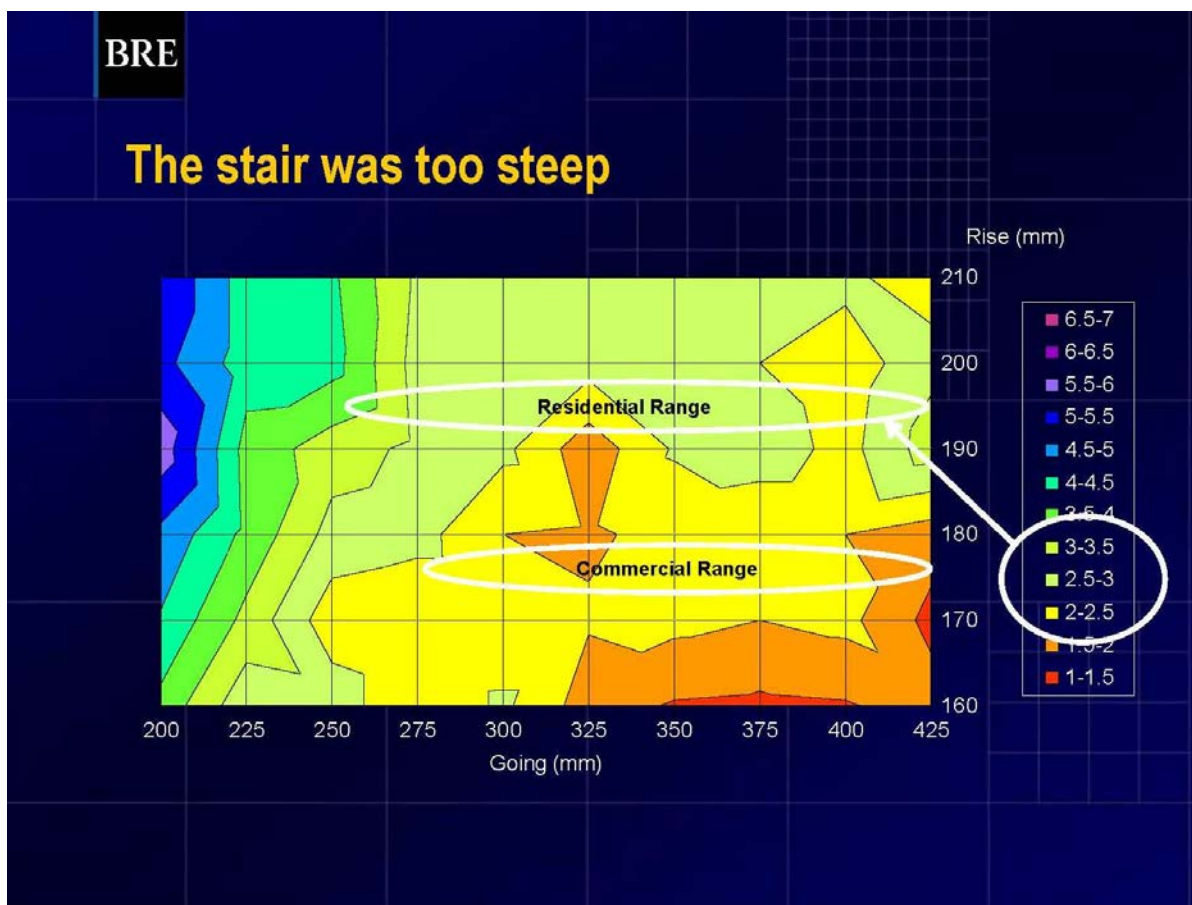

Figure 1 Residential Range = 7.58" (193mm) – 7.74" (197mm), Commercial Range = 6.84" (174mm) – 7" (178mm) see Table 1
Please note that the described circled ranges have been added to figures 1&2 by the proponent for the purpose of explanation.

I had to pull myself up the stair using the handrail

Figure 2 Residential Range = 7.58" (193mm) – 7.74" (197mm), Commercial Range = 6.84" (174mm) – 7" (178mm) see Table 1
Please note that the described circled ranges have been added to figures 1&2 by the proponent for the purpose of explanation.

	Vertical Rise	# Risers	Riser Height Inches	Change in Riser Height inches	Riser Height mm	Change in Riser Height mm
Most Occupancies	144	21	6.86		174	
	147	21	7.00	0.14	178	4
Dwelling Units	144	19	7.58		193	
	147	19	7.74	0.16	197	4

Table 1

Testing in support of this proposal, as shown in the data presentations (Figure 1 and 2) from; "The Influence of Rise and Going Combinations on Stair Safety" by M S Roys, June 2004, 7th World Conference on Injury Prevention and Safety Promotion, Vienna¹, the minor variation in rise does not produce any consequential effect that can be noticed by users when comparing riser heights within the range in question. *Please note that the circled ranges have been added to figure 1 & 2 by the proponent for the purpose of explanation.* Figures one and two can be related to the perceived energy required in ascent as described by the subjective rating of the steepness of the stair and the need to pull oneself up the stair using the handrail. In these figures the user's ratings are on a scale of 1-7 and color coded. The visual display of the data shows little difference in the users ratings over the range in question.

Additional testing data from this same study further illustrates little difference in the user's perception of riser height. When asked to rate descent of the stairway in response to the statement "I felt safe when walking down the stair" the risers heights of 6.69 inches, 7.09 inches, 7.48 inches (170 mm, 180 mm, 190 mm) all were rated the same with a tread depth of 10.83 inches (275 mm). Compared with the same tread depth the riser heights of 7.87 inches, 6.30 inches (200 mm, 160 mm) were within

approximately 0.5 points on a scale of 7 points further indicating little difference being perceived by the users. This provides further validation that the change proposed is reasonable and will not affect stair safety.

Construction cost reduction – It is common for the total rise to exceed 144 inches (3658 mm) with oversight of the requirement or minor changes in floor systems and finish flooring options. In particular new floor truss systems and engineered joist materials increase floor thickness and story height especially when added to older designs. This requires the addition of an intermediate landing. Adding a landing increases the footprint of the stairway and the cost if the space is available.

Understanding and Compliance – This change will not increase the number of risers needed in the stairway or make the stairway less safe, or add any significant or perceived increase in energy to climb the stairway. This needed change provides a direct relationship between the vertical rise requirement and the requirements for riser height that would assure better understanding and compliance.

Bibliography:

1. "The influence of rise and going combinations on stair safety"; M.S. Roys, 7th World Conference on Injury Prevention and Safety Promotion, Vienna, June 2004

Cost Impact: This will reduce the cost of construction.

	Assembly:	ASF	AMF	DF

R311.7.3-RB-COOPER

RB133 – 13

R311.7.5.1

Proponent: David W. Cooper, Stair Manufacturing and Design Consultants, representing the Stairway Manufacturers' Association (sma@stairways.org)

Revise as follows:

R311.7.5.1 Risers. The maximum riser height shall be 7¾ inches (196 mm). The riser shall be measured vertically between leading edges of the adjacent treads. The greatest riser height within any *flight of stairs* shall not exceed the smallest by more than ¾ inch (9.5 mm). Risers shall be vertical or sloped from the underside of the nosing of the tread above at an angle not more than 30 degrees (0.51 rad) from the vertical. Open risers are permitted provided that ~~the opening between treads does not permit the passage of a 4-inch diameter (102 mm) sphere.~~ riser openings between treads located more than 30 inches (762 mm) measured vertically to the floor or grade below at any point within 36 inches (914 mm) horizontally to the lower edge of the riser do not permit the passage of a 4 inch diameter (102 mm) sphere.

Exception: ~~The opening between adjacent treads is not limited on stairs with total rise of 30 inches (762 mm) or less.~~

Reason: The exception allows unrestricted openings in risers if the stair has a 30" total rise. This is a flawed requirement. Flights stacked in a well could have a total rise of 30 inches and an exposure to a much greater fall distance to the next level or flight below. This change correctly identifies the hazard and the needed requirement applies the language found in section R312, Guard and window fall protection.

Cost Impact: This code change would not increase the cost of construction.

RB133-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R311.7.5.1-RB-COOPER

RB134 – 13

R311.7.5.1, R312.1.3

Proponent: Rick Davidson, City of Maple Grove, Association of Minnesota Building Officials
(rdavidson@maplegrovern.gov)

Revise as follows:

R311.7.5.1 Risers. The maximum riser height shall be $7\frac{3}{4}$ inches (196 mm). The riser shall be measured vertically between leading edges of the adjacent treads. The greatest riser height within any flight of stairs shall not exceed the smallest by more than $\frac{3}{8}$ inch (9.5 mm). Risers shall be vertical or sloped from the underside of the nosing of the tread above at an angle not more than 30 degrees (0.51 rad) from the vertical. Open risers are permitted provided that the opening between treads does not permit the passage of a ~~4-inch diameter (102 mm) sphere~~ 6 inch diameter (153 mm) sphere.

Exception: The opening between adjacent treads is not limited on stairs with a total rise of 30 inches (762 mm) or less.

R312.1.3 Opening limitations. Required *guards* shall not have openings from the walking surface to the required *guard* height which allow passage of a sphere ~~4 inches (102 mm)~~ $4\frac{3}{8}$ (111 mm) in diameter.

Exceptions Exception:

4. The triangular openings at the open side of stair, formed by the riser, tread and bottom rail of a guard, shall not allow passage of a sphere 6 inches (153 mm) in diameter.
2. ~~Guards on the open side of stairs shall not have openings which allow passage of a sphere $4\frac{3}{8}$ inches (111 mm) in diameter.~~

Reason: Currently the code has three different limitations on openings in guards that could occur within inches of each other. Clearly something is amiss. It is impossible to offer a rational explanation to the public why there are three different opening limitations that are all intended to prevent children from falling through them. Let's put **some** meaningful uniformity in the code by allowing spacing on all guards to be $4\frac{3}{8}$ inches and six inches when it comes to riser openings. The proposal increases the spacing on all guards to the $4\frac{3}{8}$ inch standard allowed on guards on stairs and increases the openings on risers to 6 inches which is the standard permitted for the triangular space formed by the riser and the tread.

Cost Impact: None

RB134-13

	Assembly:	ASF	AMF	D

R311.7.5.1-RB-DAVIDSON

RB135 – 13

R311.7.5.3

Proponent: David W. Cooper, Stair Manufacturing and Design Consultants, representing the Stairway Manufacturers' Association (sma@stairways.org)

Revise as follows:

R311.7.5.3 Nosings. The radius of curvature at the nosing shall be no greater than 9/16 inch (14 mm). A nosing projection not less than $\frac{3}{4}$ inch (19 mm) but not more than 1 $\frac{1}{4}$ inches (32 mm) shall be provided on stairways with solid risers. The greatest nosing projection shall not exceed the smallest nosing projection by more than $\frac{3}{8}$ inch (9.5 mm) between two stories, including the nosing at the level of floors and landings. Beveling of nosings shall not exceed $\frac{1}{2}$ inch (12.7 mm).

Exceptions: A nosing projection is not required where the tread depth is a minimum of 11 inches (279 mm).

Reason: The addition of the word "projection" corrects and clarifies the intent of the requirement and exception.

Cost Impact: This code change does not increase the cost of construction.

RB135-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R311.7.5.3-RB-COOPER

RB136 – 13

R311.7.8.2

Proponent: Rick Davidson, City of Maple Grove, Association of Minnesota Building Officials
(rdavidson@maplegrovern.gov)

Revise as follows:

R311.7.8.2 Continuity. Handrails for stairways shall be continuous for the full length of the flight, from a point directly above the top riser of the flight to a point directly above the lowest riser of the flight. Handrail ends shall be returned or shall terminate in newel posts or safety terminals. Handrails adjacent to a wall shall have a space of not less than 1½ inch (38 mm) between the wall and the handrails.

Exceptions:

1. Handrails shall be permitted to be interrupted ~~by a newel posts at the turn.~~
2. The use of a volute, turnout, starting easing or starting newel shall be allowed over the lowest tread.
3. Handrails shall be permitted to be interrupted at the transition from a wall to a guard.
4. Handrails shall be permitted to be interrupted where a flight changes direction.

Reason: Handrails are required by the IRC to be continuous with two exceptions. The first allows the rail to be interrupted by a newel post “at a turn”. The term “at a turn” can be interpreted in different ways. Does this mean a ninety degree turn, a 180 degree turn, or perhaps a 45 degree turn? Does it apply only when flights are interrupted by a landing or does it also apply to winder stairs? But let’s face it. These rails are in dwellings, not public settings. These rails are often installed by homeowners who lack even simple joinery skills. The users of the stairs are familiar with their surroundings. The rails are not required for accessibility purposes. Yet they are required to meet the same standard that applies to high occupant load commercial applications. That is overkill.

If it is safe to remove one’s hand when maneuvering around a newel post “at a turn”, why is it not safe to do the same on a straight run of a stair, or when negotiating a turn on a winder stair, or when transitioning from a stair enclosed on both sides to open on both sides? Following are some attempts at compliance with current code

Does anyone really believe that the user of any of these stairs would maintain contact between their hand and the railing during the complete traverse of the stair? Likely not, because it requires twisting the wrist and hand in ways that are uncomfortable if not impossible.

Let's be realistic. For dwelling applications, it is reasonable to allow greater leeway in handrail designs. Following are some examples of railings designs that are no more hazardous than the ones deemed 100% compliant. The last example is commonly found by field inspectors on owner (and sometimes contractor) constructed deck stairs. Intermediate posts are necessary to stabilize the guard. But the post interrupts the handrail and results in a correction notice to install a continuous rail. This is usually met by complaints by the homeowner that no unsafe condition exists and many people would agree. Installing an additional railing on this type of stair "just to meet the code" smacks of over-regulation, generates complaints about the unsightly finished product, and adds unnecessary cost to the construction of the stair not to mention the ill will created between building departments and taxpaying homeowners.

It is time to add some reasonableness to the handrail requirements for dwellings. This proposal adds a number of changes. First, it allows the rail to be discontinued whenever a newel post occurs. It deletes the ambiguous term "at the turn" and allows the newel post be placed at any change of direction or at mid flight if desired. Either the interruption of a rail by a newel post is a hazard all of the time or none of the time. This proposal takes the position that a newel post poses no hazard. The second change allows the handrail to be discontinued where the stair makes a change from having walls on the side of the stair to having guards as is illustrated below. The basis for the argument is that creating a turn in the handrail that may cause the wrist to make a full ninety degree turn at this transition is not reasonable and that the average individual will take their hand off the rail anyway to make this transition. Furthermore, this situation, oft encountered when basements are finished, is difficult for most homeowners to overcome. The last change adds an exception allowing the handrail to be discontinued when the stair makes a change in direction as may occur with a winder stair. The following pictures illustrate some of those applications.

This proposal will not lessen the safety of stairs. In some cases it may enhance the safety by creating handrails that are more ergonomically useable. It will enable homeowners to comply with the rules and stay within their skill levels thus keeping costs reasonable.

Cost Impact: None

R311.7.8.2-RB-DAVIDSON

RB137 – 13

R311.7.9

Proponent: Wesley Walters, Clark County Nevada Development Services, representing self

Revise as follows:

R311.7.9 Illumination. All ~~stairs~~ stairways shall be provided with illumination in accordance with Section R303.6 7.

Reason: Section R303.7 heading is Stairways not stairs. Stairs are a component of a stairway.

Cost Impact: The code change proposal will not increase the cost of construction.

RB137-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R311.7.9-RB-WALTERS

RB138 – 13

R311.7.10.1

Proponent: David W. Cooper, Stair Manufacturing and Design Consultants, representing the Stairway Manufacturers' Association (sma@stairways.org)

Revise as follows:

R311.7.10.1 Spiral stairways. Spiral *stairways* are permitted, provided the minimum clear width at and below the *handrail* shall be 26 inches (660 mm) ~~with and the walkline radius is not greater than 24½ inches (622 mm). Each tread having shall have a minimum tread depth not less than 7½ inch (190 mm) minimum tread depth at 12 inches (914 mm) from the narrower edge the walkline.~~ All treads shall be identical, and the rise riser height shall be no more than 9½ inches (241 mm). ~~A minimum headroom shall be not less than 6 feet 6 inches (1982 mm) shall be provided.~~

Reason: The difference between Spiral Stairways and Curved Stairways is subject to interpretation. Spiral stairways provide a space saving alternative and by their nature are safely used with taller risers and treads that are narrower at the walkline. Currently spiral stairways may be of unrestricted size. This change defines a reasonable limit for the design of spiral stairways with the allowed "exceptions" for headroom, riser height and tread depth.

Stairs beyond the limit stated would be considered a curved stair. A 24½ inches maximum walkline radius dimension effectively provides a minimum radius no greater than 12½ inches at the inside of the turn. It represents that point at which the 6 inches minimum tread width of winder treads can be achieved with 13 treads in one revolution a typical and common manufacturing standard. Beyond this point curved stairways complying with **R311.7.5 Stair treads and risers** and **R311.7.2 Headroom** would be required. This change is meant to correlate with the newly proposed IRC definition of spiral stairway and eliminating the reference to a supporting column as found in the IBC.

We have also made editorial changes and substituted the code section title terms "walkline" and "riser height" to clarify and provide for more consistent interpretation.

Cost Impact: This code change will not increase the cost of construction.

RB138-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R311.7.10.1 #1-RB-COOPER

RB139 – 13

R311.7.10.1

Proponent: David W. Cooper, Stair Manufacturing and Design Consultants, representing the Stairway Manufacturers' Association (sma@stairways.org)

Revise as follows:

R311.7.10.1 Spiral stairways. Spiral stairways are permitted, provided the minimum clear width at and below the *handrail* shall be 26 inches (660 mm) with each tread having a ~~7½~~ 6¾ inch (490 171 mm) minimum tread depth at 12 inches (914 mm) from the narrower edge. All treads shall be identical, and the rise shall be no more than 9½ inches (241 mm). A minimum headroom of 6 feet 6 inches (1982 mm) shall be provided.

Reason: This change is largely editorial. Treads within Spiral Stairways meet the definition of winder treads and are sometimes interpreted to be measured for tread depth in the same fashion. This change simply adjusts the spiral stair tread depth in conformance with the 2009 change in the method of measuring for winder tread depth at the intersections of the walkline with the nosings instead of the prior method which was square to the leading edge. The effective tread depth remains unchanged as can be seen in figure one.

The intent of the 2009 change in measuring methods was to provide for consistent tread depth measurements conforming with stair design methodology not to change or increase tread depth.

The long accepted 7½ inches tread depth was based on the typical spiral layout with 13 treads per revolution or 27.692 degrees per tread. Figure one illustrates the 7½ inches measurement made square to the leading edge of the tread, and also shows the tread depth when measured at the intersections of the walkline and nosings. For the ease of enforcement we have rounded the required tread depth to 6¾ inches.

This change is necessary to allow long accepted manufacturing, material and design standards to continue to meet the requirement and does not change the effective depth of the tread.

FIGURE ONE illustrates a winder tread from a typical spiral stairway with 13 treads per revolution. The dimensions shown allow comparison of the tread depth when measured square to the leading edge and when measured at the intersection of the walkline with the nosings. This simply shows that the old requirement of 7½ inches needs to change to accommodate the new measuring method cited in **R311.7.5.2.1 Winder Treads.**

Cost Impact: This change will eliminate unintended increases in the cost of construction.

RB140 – 13

R202, R311.7.11 (New)

Proponent: David W. Cooper, Stair Manufacturing and Design Consultants, representing the Stairway Manufacturers' Association (sma@stairways.org)

Add new definition as follows:

SECTION R202 DEFINITIONS

ALTERNATING TREAD DEVICE. A device that has a series of steps between 50 and 70 degrees (0.87 and 1.22 rad) from horizontal, usually attached to a center support rail in an alternating manner so that the user does not have both feet on the same level at the same time.

Add new text as follows:

R311.7.11 Alternating tread devices. *Alternating tread devices* shall not be used as an element of a means of egress. *Alternating tread devices* shall be permitted provided the required means of egress stairway or ramp serves the same space at each adjoining level or where a means of egress is not required. The clear width at and below the handrails shall be not less than 20 inches (508 mm).

R311.7.11.1 Treads of alternating tread devices. *Alternating tread devices* shall have a tread depth of not less than 5 inches (127 mm), a projected tread depth of not less than 8 1/2 inches (216 mm), a tread width of not less than 7 inches (178 mm) and a riser height of not more than 9 1/2 inches (241 mm). The tread depth shall be measured horizontally between the vertical planes of the foremost projections of adjacent treads. The riser height shall be measured vertically between the leading edges of adjacent treads. The riser height and tread depth provided shall result in an angle of ascent from the horizontal of between 50 and 70 degrees (0.87 and 1.22 rad). The initial tread of the device shall begin at the same elevation as the platform, landing or floor surface.

R311.7.11.2 Handrails of alternating tread devices. *Handrails* shall be provided on both sides of *alternating tread devices* and shall comply with R311.7.8.2 thru R311.7.8.4. Handrail height shall be uniform, not less than 30 inches (762 mm) and not more than 34 inches (864 mm).

R311.7.12 Ship ladders. Ship ladders shall not be used as an element of a means of egress. Ship ladders shall be permitted provided a required means of egress stairway or ramp serves the same space at each adjoining level or where a means of egress is not required. The clear width at and below the handrails shall be not less than 20 inches.

R311.7.12.1 Treads of ship ladders. Treads shall have a tread depth of not less than 5 inches (127 mm). The tread shall be projected such that the total of the tread depth plus the *nosing* projection is not less than 8 1/2 inches (216 mm). The riser height shall be not more than 9 1/2 inches (241 mm).

R311.7.12.2 Handrails of ship ladders. *Handrails* shall be provided on both sides of ship ladders and shall comply with R311.7.8.2 thru R311.7.8.4. Handrail height shall be uniform, not less than 30 inches (762 mm) and not more than 34 inches (864 mm).

Reason: Alternating tread devices and ship ladders are used in residential applications but are not regulated. This language adopts the specifications from the IBC providing the needed guidance when they are used. This further clarifies that an Alternating Tread Device and or Ship Ladder cannot be used as an element of a means of egress, and can only be used when a means of egress is not required or when the required means of egress stairway or ramp is provided to serve the same spaces at each level.

Cost Impact: This code change will not increase the cost of construction.

RB140-13

Public Hearing:	Committee:	AS	AM	D

R311.7.11 (NEW)-RB-COOPER

RB141 – 13

R311.8.1

Proponent: Rick Davidson, City of Maple Grove Association of Minnesota Building Officials
(rdavidson@maplegrovern.gov)

Revise as follows:

R311.8.1 Maximum slope. Ramps serving the egress door required by section R311.2 shall have a maximum slope of 1 unit vertical in 12 units horizontal (8.3-percent slope). All other ramps shall have a maximum slope of 1 unit vertical to 8 units horizontal (12.5-percent slope).

Exception: Where it is technically infeasible to comply because of site constraints, ramps may have a maximum slope of one unit vertical in eight horizontal (12.5-percent slope).

Reason: When ramp slope requirements were changed a few years back, the reason stated was to enable persons with disabilities to stay in their homes. However, the scope of the proposal included all ramps, even those that could not be used by persons with disabilities. For example, dwelling additions to older homes sometimes have new basements at a deeper level and the owner wishes to make the transition by ramp. A 1:12 slope can sometimes be difficult to achieve and absorbs much more space than need be. Media rooms are often designed to have sloping floors with ramps serving the seating and again the 1:12 slope is problematic. This proposal gives some relief for those situations where accessibility may not be an issue. This also is consistent with section 1010.3 of the IBC which allows a 1:8 slope for pedestrian ramps not used as a means of egress.

IBC SECTION 1010 RAMPS

1010.3 Slope. Ramps used as part of a *means of egress* shall have a running slope not steeper than one unit vertical in 12 units horizontal (8-percent slope). The slope of other pedestrian ramps shall not be steeper than one unit vertical in eight units horizontal (12.5-percent slope).

Cost Impact: None

RB141-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R311.8.1-RB-DAVIDSON

RB142 – 13

R311.8.1, R311.8.2

Proponent: Glenn Mathewson, MCP., representing self (GlennMathewson@nadra.org)

Revise as follows:

R311.8.1 Maximum slope. Ramps shall have a maximum slope of 1 unit vertical in 12 units horizontal (8.3-percent slope).

Exception: Where it is technically infeasible to comply because of site constraints, ramps shall ~~may~~ have a maximum slope of ~~one~~ 1 unit vertical in ~~eight~~ 8 units horizontal (12.5-percent slope).

R311.8.2 Landings required. There shall be a floor or landing at the top and bottom of each ramp, where doors open onto ramps, and where ramps change directions. The width of the landing perpendicular to the ramp slope shall be not less than the width of the ramp. The depth of the landing in the direction of the ramp slope shall be not less than 36-inches. A minimum 3 foot by 3 foot (914 mm by 914 mm) landing shall be provided:

- ~~1. At the top and bottoms of ramps.~~
- ~~2. Where doors open onto ramps.~~
- ~~3. Where ramps change directions.~~

Reason: -It is inconsistent to present slope in one section using numerical symbols, and then in the exception use textual language. It appears to be more common in the IRC to use numerical symbols, thus the choice to modify the exception.

-Use of the word "may" is in appropriate when referring to a maximum value. "Shall" is clearer that the maximum value is the undisputable limit.

All other landings in the IRC (doors/stairs) reference the width of the feature they serve, as this is sensible. Currently ramp provisions refer to a specific geometric width, and would not properly and safely accommodate a ramp that was wider than the minimum 36 inches. Likely...landings are already built to the width of the ramps they serve.

-The use of a list of landing locations is not consistent with other similar IRC sections. The proposed language is more similar to that used to describe landings on stairs...a very similar feature.

Cost Impact: The code change proposal will not increase the cost of construction.

RB142-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R311.8.1-RB-MATHEWSON

RB143 – 13

R312.1.1

Proponent: Rick Davidson, City of Maple Grove, Association of Minnesota Building Officials
(rdavidson@maplegrovern.gov)

Revise as follows:

R312.1.1 Where required. *Guards shall be located along open-sided walking surfaces, including the open sides of floors, stairs, ramps and landings that are located more than 30 inches (762 mm) measured vertically to the floor or grade below at any point within 36 inches (914 mm) horizontally to the edge of the open side.* Insect screening shall not be considered as a *guard*.

Reason: The first portion of the proposal deletes the requirement that guards be located along open sided walking surfaces and replaces it with the same language found in the previous IRC. This is necessary because the term “open sided walking surfaces” is so broad in scope that it could be and is being applied to almost any surface on or in a building or a lot. It could be interpreted to require guards being installed around window wells, on the top of retaining walls, along driveways and sidewalks, on landings near window wells, at the edge of swimming pools, and even at the edge of flat roofs. The definitions for floors, stairs, ramps, and landings are well established. Everyone understands the application with these terms. It is reasonable to use terms that are understandable to all.

The second part of the proposal deletes the reference to measuring the height of the walking surface three feet from the edge of the walking surface and returns it to the language that existed in the IRC since its inception and in the previous model codes for decades.

It seems to be a widely held belief that the Uniform Building Code required that a measurement from floor to grade be taken at a point five feet from the floor to determine if a guard was required.

But, the Uniform Building Code never said that is how the distance should be measured nor did the BOCA National Building Code or the Southern Building Code. They all stated that the 30 inch height (15 ½ inches in the National Building Code and 30 inches in the Southern Building Code) be measured to the floor or grade below or very similar language.

Then where did the five foot measuring requirement come from? It came from the definition of “grade”. For years, ICBO staff taught that the use of the term “grade” in the phrase “30 inches above floor or grade below” was defined and that the definition in the UBC required that grade be measured five feet from the building or if the property line was less than five feet from the building then it would be measured from a point between the building and the property line.

This creates at least two inconsistencies if the argument was that the five foot distance was safety oriented. First, you only measured five feet over if what was below the walking surface was “grade”. If it were a floor, you just measured straight down. Second, if the building was near a property line, you only measured to the property line even if there were a severe drop at the property line. Theoretically under the UBC, one could have a walking surface that was adjacent to a property line with a 30 foot drop at the property line and no guard.

The idea that one should measure the 30 inch distance at some point other than the base of the walking surface was strictly an ICBO opinion and not binding on any building official. Based on the inconsistencies cited, there is certainly room for other opinions. Because a portion of the language in the UBC definition that stated that grade was between the building and the property line did not make it into the IRC, the IRC version requires that the measurement extend to adjoining lots in some cases.

But there is more.

The BOCA National Building Code required guards be provided when the walking surface was more than 15 ½ inches above the floor or grade below. But the BOCA code did not define “grade”, only “grade plane”. And the definition of “grade plane” was used exclusively to determine the reference point for the height and number of stories of a building for purposes of determining compliance with height and number of stories limitations based on use and type of construction. It is not known how BOCA staff taught how to measure for guards but the language in the BOCA code is the same as it has been in the IRC since its inception.

The Southern Building Code provided a definition for “grade” but the method of measuring the height of a floor surface was stated to be “30 inches above *finished ground level* or a floor below”. While grade required measuring a distance of six feet away, that term was not used in defining when a guard was required. It is not known how SBCCI staff taught how to measure guards but it doesn't appear the Southern Building Code provided any means to take the measurement at any location but straight down from the edge of the walking surface.

More about the UBC. Was it really intended that the measurement requiring guards be taken five feet from the walking surface or was that just happenstance and poor choices of terms in the code sections?

I would argue that it was never intended that the method used to determine whether or not a guard was required be five feet from the walking surface. Besides the inconsistencies above, the UBC definition of “grade” states that it is the distance “between the *building* and the property line”. The term “building” does not appear to mean a floor or walking surface that could be used to determine guard requirements.

And then there is more. The UBC contained references to measuring grade at a distance away from the building dating back at least into the 1930's. Apparently the game of piling dirt next to a building to reduce the height or number of stories is not new. Grade was always about height and number of stories of the building, not as a means to require a guard.

An explanation of the term "grade" from the "*Design Guide – 1988 UBC*" by Alfred Goldberg is provided below. Mr. Goldberg states that the "determination of the grade level is important to the designer for several reasons, including the qualification of a level as a basement and the measurement of the allowable overall height of the building." Mr. Goldberg goes on to explain the nuances of application of the term "grade" and cautions on the "repercussions" of errors in applying the rules. Not once in Mr. Goldberg's book does he reference that "grade" has anything to do with guards.

In the "*Handbook to the Uniform Building Code, An Illustrative Commentary*" published by ICBO, the statement is made in regards to "grade" that "This definition is important in determining the number of stories within a building as well as its height in feet." There is also a discussion on the issue of guards but never once is there a reference to how one determines whether a guard is required. One would think it is important to create the link because the section regarding guards only states measuring to the floor or grade below.

That brings us to today. Given that the Southern Building Code, the National Building Code, the CABO One and Two Family Dwelling Code, and possibly the Uniform Building Code (depending on how it was interpreted) all directed that the measurement used to determine whether or not a guard was required be taken by measuring to the area below the edge of the walking surface, did an unsafe condition exist? No evidence has been submitted with any prior code change to suggest that it did.

Then there are the practical aspects. What distance should a "landing area" be if one were to create one? Should that landing area extend onto another property? The code has always regulated building construction based on situations on the lot in question and given no credence to what occurs on an adjoining lot.

And there are other practicality issues. Permits are not required for a host of "walking surfaces". How does one enforce a guard requirement for things like concrete sidewalks? Do we really see sharp drops or cliffs adjoining low decks or are we more likely to see a gently sloping hill and are they a hazard? And suppose I create a floor or walking surface adjacent my property line and the land on the other side slopes sufficiently that a guard would be required but my neighbor has a fence at the top of the slope on his side of the property line. Do I still need to put up a guard right next to his fence? And if I can use the fence for the guard, does it need to meet the load requirement of 200 pounds at the top? And if I have a walking surface that doesn't require a guard but at a later date the neighboring property owner installs a retaining wall that places my walking surface in violation, is he required to install the guard? He was the one who created the hazard! Will the timing of events result in one situation requiring a guard and another not? How does one explain this to a homeowner and make sense of it?

And last is the issue of permitting of decks, porches, balconies, landings and other low floor surfaces. Low decks were exempted from permits in large part because guards were not required, and they might still not be required. One can only guess that proposals are being drafted to require permits for decks requiring guards. But the inquiry that comes into the building department regarding the need for a guard will go something like this. Q. "Do I need a permit for a deck that will be 28 inches above the ground?" A. "You will need a permit if the ground within X feet of the deck will be more than 30 inches below the floor of the deck at any point around the deck." Q. "I'm a homeowner. I know it will be less than 30 inches above grade around the perimeter of the deck but I don't know about X feet out. So do I need a permit or not? And if I take out a permit and it turns out I didn't need one, I will get my money back, right?"

Homeowners don't have access to sophisticated equipment. They will be dependent on string levels and garden hoses. Accuracy may not be a strong suit. Where will this place the building department?

It is necessary that there be clarity in where a guard is required so that there is uniformity of application and that intended safeguards are in place. It is also necessary that those requirements achieve in all cases what they set out to do. Because most, if not all, of the national model codes did not require that the determining factor of when a guard was required was anything but a direct measurement from the edge of the floor to the ground or floor directly below.

tion) to circulate the heated air to and from the unit. In the context of the code, the primary use of the term "furnace" refers to heating appliance units that combine a combustion chamber with related components, one or more heat exchangers and an air-handling system.

GLAZING AREA. The interior surface area of all glazed fenestration, including the area of sash, curbing or other framing elements, that enclose conditioned space. Includes the area of glazed fenestration assemblies in walls bounding conditioned basements.

❖ The glazing area includes not only the surface area of the exposed glazing but also the framing elements, including the sash and curbing. The amount of glazing area is regulated for natural light by Section R303; however, this definition applies to the energy efficiency provisions of Chapter 11.

GRADE. The finished ground level adjoining the building at all exterior walls.

❖ This is the point at which the finished exterior ground level intersects the exterior wall of the building. The grade around a building may remain relatively constant, such as on a flat site, or may change dramatically from one point to the next if the site is steeply sloping.

GRADE FLOOR OPENING. A window or other opening located such that the sill height of the opening is not more than 44 inches (1118 mm) above or below the finished ground level adjacent to the opening.

❖ In the requirements for emergency escape and rescue openings found in Section R310, the size of the openings may be reduced if they are grade floor openings. These are windows or other openings that are located within close proximity to the finished ground level. The sill of a grade floor opening may be located either above or below the adjacent ground level, provided it is located no more than 44 inches (1118 mm) vertically from the level of the ground.

GRADE, PIPING. See "Slope."

GRADE PLANE. A reference plane representing the average of the finished ground level adjoining the building at all exterior walls. Where the finished ground level slopes away from the exterior walls, the reference plane shall be established by the lowest points within the area between the building and the lot line or, where the lot line is more than 6 ft (1829 mm) from the building between the structure and a point 6 ft (1829 mm) from the building.

❖ This definition can be important in determining the number of stories within a building as well as its height in feet. In some cases, the finished surface of the ground may be artificially raised with imported fill to create a higher grade plane around a building to decrease the number of stories or height. The definition requires that the lowest elevation within 6 feet (1829 mm) of the exterior wall be used to determine the grade plane.

GRIDDED WATER DISTRIBUTION SYSTEM. A water distribution system where every water distribution pipe is

interconnected so as to provide two or more paths to each fixture supply pipe.

❖ These systems offer the advantage of a simplistic design, typically smaller sized distribution lines and aid water conservation. In a traditional water distribution system, the water contained in the larger diameter piping is wasted when the line is opened and the user has to wait until the water reaches the desired temperature.

Parallel or gridded water distribution systems differ from branch systems which have individual supply pipes that extend to each fixture or outlet from a central supply point [see Commentary Figure R202(1)]. The central supply point is a multiple-outlet manifold to which the distribution lines connect [see Commentary Figure R202(2)].

GROSS AREA OF EXTERIOR WALLS. The normal projection of all exterior walls, including the area of all windows and doors installed therein.

❖ The calculation for determining the gross area of exterior walls for energy efficiency purposes is based on the total area of the entire exterior surface, including openings such as windows and doors.

GROUND-SOURCE HEAT PUMP LOOP SYSTEM. Piping buried in horizontal or vertical excavations or placed in a body of water for the purpose of transporting heat transfer liquid to and from a heat pump. Included in this definition are closed loop systems in which the liquid is recirculated and open loop systems in which the liquid is drawn from a well or other source.

❖ This definition assists the user with a ready means of distinguishing ground-source heat pump loop systems from other hydronic systems.

GUARD. A building component or a system of building components located near the open sides of elevated walking surfaces that minimizes the possibility of a fall from the walking surface to the lower level.

❖ A guard is a component or system of components whose function is the prevention of falls from an elevated area. Placed adjacent to an elevation change, a guard must be of adequate height, strength and configuration to help prevent people, especially small children, from falling over or through the guard to the area below.

HABITABLE SPACE. A space in a building for living, sleeping, eating or cooking. Bathrooms, toilet rooms, closets, halls, storage or utility spaces and similar areas are not considered habitable spaces.

❖ An area within a building used for living, sleeping, dining or cooking is a habitable space. Those areas not meeting this definition include bathrooms, closets, hallways and utility rooms. Habitable spaces are typically occupied, and as such they are more highly regulated than accessory use areas.

HANDRAIL. A horizontal or sloping rail intended for grasping by the hand for guidance or support.

to assist ramp users. This provision differs from that of the IBC, where a slope of one unit vertical in 20 units horizontal (5-percent slope) and a ramp rise of 6 inches (152 mm) establishes the limits.

R311.6.3.1 Height. Handrail height, measured above the finished surface of the ramp slope, shall be not less than 34 inches (864 mm) and not more than 38 inches (965 mm).

❖ Where handrails are required, they must be installed at a height of at least 34 inches (864 mm) and not more than 38 inches (965 mm), measured vertically from the finished surface of the ramp slope. This height should be measured to the top of the handrail.

R311.6.3.2 Handrail grip size. Handrails on ramps shall comply with Section R311.5.6.3.

❖ See the commentary for Section R311.5.6.3.

R311.6.3.3 Continuity. Handrails where required on ramps shall be continuous for the full length of the ramp. Handrail ends shall be returned or shall terminate in newel posts or safety terminals. Handrails adjacent to a wall shall have a space of not less than 1.5 inches (38 mm) between the wall and the handrails.

❖ The continuity requirement for the ramp handrail is similar to the continuity requirement for the stair handrail. See the commentary for Section R311.5.6.2

guards not less than 34 inches (864 mm) in height measured vertically from the nosing of the treads.

Porches and decks which are enclosed with insect screening shall be equipped with guards where the walking surface is located more than 30 inches (762 mm) above the floor or grade below.

❖ The guard provisions of the IRC address the issue of protecting occupants from falling from any type of elevated walking surface. The provisions in Section R312 provide the scoping requirements as well as the general construction requirements for the guards. Besides this section, code users should be aware that Section R301.5 contains the design load criteria for guards.

Section R312.1 of the code establishes the requirement for and the minimum height requirements for guards. The code provides for guard protection at open sides along raised floor or walking surfaces such as those at balconies, mezzanines, stairways, ramps, porches and landings that are more than 30 inches (762 mm) above the grade or floor surface below.

The requirements for guards on stairs are different from other guard requirements in two ways. The first is the scoping requirements that establish the need for the guard, and the second is the required height of the guard. The scoping requirement for guards along open sides of stairs not only applies to the portion of a stairway that is more than 30 inches (762 mm) above the floor, but it will also apply to the entire open side of the stair, including the parts that are less than 30 inches (762 mm) above the floor. This requirement applies to the entire "open side" of the stairway, if any point of the open side is more than 30 inches (762 mm) high. See Commentary Figures R312.1(1) and (2) for examples of how this provision is applied.

SECTION R312 GUARDS

R312.1 Guards. Porches, balconies, ramps or raised floor surfaces located more than 30 inches (762 mm) above the floor or grade below shall have guards not less than 36 inches (914 mm) in height. Open sides of stairs with a total rise of more than 30 inches (762 mm) above the floor or grade below shall have

FIRE RESISTANCE or FIRE-RESISTIVE CONSTRUCTION is construction to resist the spread of fire, details of which are specified in this code.

FIRE-RETARDANT-TREATED WOOD is any wood product impregnated with chemicals by a pressure process or other means during manufacture, and which, when tested in accordance with UBC Standard 8-1 for a period of 30 minutes, shall have a flame spread of not over 25 and show no evidence of progressive combustion. In addition, the flame front shall not progress more than 10 1/2 feet (3200 mm) beyond the center line of the burner at any time during the test. Materials that may be exposed to the weather shall pass the accelerated weathering test and be identified as Exterior type, in accordance with UBC Standard 23-4. Where material is not directly exposed to rainfall but exposed to high humidity conditions, it shall be subjected to the hygroscopic test and identified as Interior Type A in accordance with UBC Standard 23-4.

All materials shall bear identification showing the fire performance rating thereof. Such identifications shall be issued by an approved agency having a service for inspection of materials at the factory.

FLAMMABLE LIQUID. See the Fire Code.

FLOOR AREA is the area included that the surrounding exterior walls of a building or portion thereof, exclusive of vent shafts and courts. The floor area of a building, or portion thereof, not provided with surrounding exterior walls shall be the usable area under the horizontal projection of the roof or floor above.

FM is Factory Mutual Engineering and Research, 1151 Boston-Providence Turnpike, Norwood, Massachusetts 02062.

FOAM PLASTIC INSULATION is a plastic that is intentionally expanded by the use of a foaming agent to produce a reduced-density plastic containing voids consisting of hollow spheres or interconnected cells distributed throughout the plastic for thermal insulating or acoustical purposes and that has a density less than 20 pounds per cubic foot (320 kg/m³).

FOOTING is that portion of the foundation of a structure that spreads and transmits loads directly to the soil or the piles.

FRONT OF LOT is the front boundary line of a lot bordering on the street and, in the case of a corner lot, may be either frontage.

SECTION 208 — G

GARAGE is a building or portion thereof in which a motor vehicle containing flammable or combustible liquids or gas in its tank is stored, repaired or kept.

GARAGE, PRIVATE, is a building or a portion of a building, not more than 1,000 square feet (93 m²) in area, in which only motor vehicles used by the tenants of the building or buildings on the premises are stored or kept. (See Section 312.)

GARAGE, PUBLIC, is any garage other than a private garage.

GAS ROOM is a separately ventilated, fully enclosed room in which only toxic and highly toxic compressed gases and associated equipment and supplies are stored or used.

GRADE (Adjacent Ground Elevation) is the lowest point of elevation of the finished surface of the ground, paving or sidewalk within the area between the building and the property line or, when the property line is more than 5 feet (1524 mm) from the building, between the building and a line 5 feet (1524 mm) from the building.

GRADE (Lumber) is the classification of lumber in regard to strength and utility.

GUARDRAIL is a system of building components located near the open sides of elevated walking surfaces for the purpose of minimizing the possibility of an accidental fall from the walking surface to the lower level.

GUEST is any person hiring or occupying a room for living or sleeping purposes.

GUEST ROOM is any room or rooms used or intended to be used by a guest for sleeping purposes. Every 100 square feet (9.3 m²) of superficial floor area in a dormitory shall be considered to be a guest room.

SECTION 209 — H

HABITABLE SPACE (ROOM) is space in a structure for living, sleeping, eating or cooking. Bathrooms, toilet compartments, closets, halls, storage or utility space, and similar areas, are not considered habitable space.

HANDLING is the deliberate movement of material by any means to a point of storage or use.

HANDRAIL is a railing provided for grasping with the hand for support. See also "guardrail."

HAZARDOUS PRODUCTION MATERIAL (HPM) is a solid, liquid or gas that has a degree of hazard rating in health, flammability or reactivity of 3 or 4 and that is used directly in research, laboratory or production processes that have, as their end product, materials that are not hazardous.

HEALTH HAZARD is a classification of a chemical for which there is statistically significant evidence based on at least one study conducted in accordance with established scientific principles that acute or chronic health effects may occur in exposed persons. The term "health hazard" includes chemicals that are carcinogens, toxic or highly toxic agents, reproductive toxins, irritants, corrosives, sensitizers, hepatotoxins, nephrotoxins, neurotoxins, agents that act on the hematopoietic system, and agents that damage the lungs, skin, eyes or mucous membranes.

HEIGHT OF BUILDING is the vertical distance above a reference datum measured to the highest point of the coping of a flat roof or to the deck line of a mansard roof or to the average height of the highest gable of a pitched or hipped roof. The reference datum shall be selected by either of the following, whichever yields a greater height of building:

1. The elevation of the highest adjoining sidewalk or ground surface within a 5-foot (1524 mm) horizontal distance of the exterior wall of the building when such sidewalk or ground surface is not more than 10 feet (3048 mm) above lowest grade.

2. An elevation 10 feet (3048 mm) higher than the lowest grade when the sidewalk or ground surface described in Item 1 is more than 10 feet (3048 mm) above lowest grade.

The height of a stepped or terraced building is the maximum height of any segment of the building.

HELIPORT is an area of land or water or a structural surface that is used, or intended for use, for the landing and take-off of helicopters, and any appurtenant areas that are used, or intended for use, for heliport buildings and other heliport facilities.

HELISTOP is the same as a heliport, except that no refueling, maintenance, repairs or storage of helicopters is permitted.

HIGHLY TOXIC MATERIAL is a material that produces a lethal dose or a lethal concentration that falls within any of the following categories:

hour for unenclosed mezzanines. The clear height above and below the mezzanine floor construction shall not be less than 7 feet (2134 mm).

2. There shall not be more than two levels of mezzanines in a room. However, there is no limitation on the number of mezzanines within a room.

3. The aggregate area of mezzanines within a room shall not exceed one third of the area of the room in which they are located.

4. All portions of a mezzanine shall be open and unobstructed to the room in which they are located, except for columns and posts and protective walls or railings not more than 44 inches (1118 mm) in height.

EXCEPTIONS: 1. Partitions may be installed if either of the following conditions exist:

- 1.1 The aggregate floor area of the enclosed space does not exceed 10 percent of the mezzanine area, or
- 1.2 The occupant load of the enclosed area of the mezzanine does not exceed 10.

2. A mezzanine having two or more means of egress need not be open into the room in which it is located, provided at least one of the means of egress gives direct access to a protected corridor, exit court or exit.

3. In industry facilities, mezzanines used for control equipment may be glazed on all sides.

5. Two means of egress shall be provided from a mezzanine when two are required by Table 10-A.

6. If any required means of egress enters the room below, the occupant load of the mezzanine shall be added to the occupant load of the room in which it is located.

SECTION 508 — FIRE-RESISTIVE SUBSTITUTION

When an approved automatic sprinkler system is not required throughout a building by other sections of this code, it may be used in a building of Type II One-hour, Type III One-hour and Type V One-hour construction to substitute for the one-hour fire-resistive construction. Such substitution shall not waive or reduce the required fire-resistive construction for:

1. Occupancy separations (Section 302.3).
2. Exterior wall protection due to proximity of property lines (Section 503.2).
3. Area separations (Section 504.6).
4. Dwelling unit separations (Section 310.2.2).
5. Shaft enclosures (Section 711).
6. Corridors (Sections 1004.3.4.3.1 and 1004.3.4.3.2).
7. Stair enclosures (Section 1005.3.3).
8. Exit passageways (Section 1005.3.4).
9. Type of construction separation (Section 601.1).
10. Boiler, central heating plant or hot-water supply boiler room enclosures (Section 302.5).

SECTION 509 — GUARDRAILS

509.1 Where Required. Unenclosed floor and roof openings, open and glazed sides of stairways, aisles, landings and ramps, balconies or porches, which are more than 30 inches (762 mm) above grade or floor below, and roofs used for other than service of the building shall be protected by a guardrail. Guardrails shall be provided at the ends of aisles where they terminate at a fascia of boxes, balconies and galleries.

EXCEPTION: Guardrails need not be provided at the following locations:

1. On the loading side of loading docks.
2. On the auditorium side of a stage, raised platforms and other raised floor areas such as runways, ramps and side stages used for entertainment or presentation. Along the side of an elevated walking surface when used for the normal functioning of special lighting or for access and use of other special equipment. At vertical openings in the performance area of stages.
3. Along vehicle service pits not accessible to the public.

509.2 Height. The top of guardrails shall not be less than 42 inches (1067 mm) in height.

EXCEPTIONS: 1. The top of guardrails for Group R, Division 3 and Group U, Division 1 Occupancies and interior guardrails within individual dwelling units, Group R, Division 3 congregate residences and guest rooms of Group R, Division 1 Occupancies may be 36 inches (914 mm) in height.

2. The top of guardrails on a balcony immediately in front of the first row of fixed seats and that are not at the end of an aisle may be 26 inches (660 mm) in height.

3. The top of guardrails for stairways, exclusive of their landings, may have a height as specified in Section 1003.3.3.6 for handrails.

Where an elevation change of 30 inches (762 mm) or less occurs between an aisle parallel to the seats (cross aisle) and the adjacent floor or grade below, guardrails not less than 26 inches (660 mm) above the aisle floor shall be provided.

EXCEPTION: Where the backs of seats on the front of the cross aisle project 24 inches (610 mm) or more above the adjacent floor of the aisle, a guardrail need not be provided.

The top of guardrails at the ends of aisles terminating at the fascia of boxes, balconies and galleries shall extend for the width of the aisle and be no closer than 42 inches (1067 mm) to the closest surface of the aisle where there are steps and 36 inches (914 mm) otherwise.

509.3 Openings. Open guardrails shall have intermediate rails or an ornamental pattern such that a sphere 4 inches (102 mm) in diameter cannot pass through.

EXCEPTIONS: 1. The open space between the intermediate rails or ornamental pattern of guardrails in areas of commercial and industrial-type occupancies which are not accessible to the public may be such that a sphere 12 inches (305 mm) in diameter cannot pass through.

2. The triangular openings formed by the riser, tread and bottom element of a guardrail at the open side of a stairway may be of such size that a sphere 6 inches (152 mm) in diameter cannot pass through.

For guardrail requirements at grandstands, bleachers or other elevated seating facilities, see Section 1008.3.7.

The floor area calculation is of such importance that the designer should establish this figure early in the preliminary discussions with the local enforcement agency.

Sec. 408. GARAGE is a building or portion thereof in which a motor vehicle containing flammable or combustible liquids or gas in its tank, is stored, repaired or kept.

GARAGE, PRIVATE, is a building or a portion of a building, not more than 1000 square feet in area, in which only motor vehicles used by the tenants of the building or buildings on the premises are stored or kept. (See Section 1101.)

GARAGE, PUBLIC, is any garage other than a private garage.

There are several definitions, and three different classifications, of garages. The least restrictive definition refers to a garage in conjunction with a dwelling or a small office building: a "private garage." It is classified as a Group M Occupancy.

When the garage is larger, or if it is in a larger building or serves occupants other than those in the building, it is called a "public garage." This garage is classified as a Group B, Division 1 Occupancy.

The third class of garage is a "repair garage" classed as a Group H, Division 4 Occupancy.

The reason for the three different garage classes is illustrated in Table No. 5-C. In a Type III-N building, a Group B, Division 1 Occupancy allows a floor area of 12,000 square feet. In a similar building, a Group H, Division 4 Occupancy limits the floor area to 7,500 square feet. The smaller allowable area is due to the presence of repair equipment, including torches and flammable liquids (oil and gasoline) which may permeate the area when repairs are made.

On the other hand, the Group M private garage is limited to 1,000 square feet with a maximum of 3,000 square feet in any one building. The provisions in Chapter 11 enable the private garage to reach the maximum of 3,000 square feet in the building provided each 1,000 square foot area is separated from another by a one-hour area separation wall.

GRADE (Adjacent Ground Elevation) is the lowest point of elevation of the finished surface of the ground, paving or sidewalk within the area between the building and the property line or, when the property line is more than 5 feet from the building, between the building and a line 5 feet from the building.

This definition requires that the elevation of the ground surface to be used be either:

- the level between the building and the property line, or
- where the property line is more than five feet from the building, the lowest point within a distance of five feet from the building.

The code intent is to establish what would be a "natural" ground line and to prevent someone from piling soil up against the foundation of the building and claiming that it represents the grade. By requiring the measurement to be the lowest elevation within five feet of the building, the code establishes a five-foot width to represent grade and not simply a mound of earth against the foundation. A retaining wall can be used to establish this five-foot level width.

The determination of the grade level is important to the designer for several reasons, including the qualification of a level as a basement and the measurement of the allowable overall height of the building. (See Figure 4-2.)

HEIGHT OF BUILDING is the vertical distance above a reference datum measured to the highest point of the coping of a flat roof or to the deck line of a mansard roof or to the average height of the highest gable of a pitched or hipped roof. The reference datum shall be selected by either of the following, whichever yields a greater height of building:

1. The elevation of the highest adjoining sidewalk or ground surface within a five-foot horizontal distance of the exterior wall of the building when such sidewalk or ground surface is not more than 10 feet above lowest grade.
2. An elevation 10 feet higher than the lowest grade when the sidewalk or ground surface described in Item 1 above is more than 10 feet above lowest grade.

The height of a stepped or terraced building is the maximum height of any segment of the building.

Height of building discussed in this definition relates to the provisions in Chapter 5 for considering the maximum height for a given type of construction and number of stories in a building.

Height and stories are interdependent in Table No. 5-D wherein the limitations for the height in feet and the number of stories are established. The provisions for measuring the height require reference to the ground surface. The five-foot horizontal width in Item 1 is comparable to the five-foot width measurement for determining "grade."

The concern with the method of height measurement is based on the fire and panic hazards presented by taller structures or those with more levels of occupancy. Many times the misinterpretation or misapplication of the height and story measurement has been the result of a desire to

avoid the added exit and fire protection requirements that apply when a building is three or more stories in height.

The designer is cautioned that any error in this part of the design can produce considerable repercussions; hence, the designer should use a conservative approach to the height measurement.

HOTEL is any building containing six or more guest rooms intended or designed to be used, or which are used, rented or hired out to be occupied, or which are occupied for sleeping purposes by guests.

The hotel is another sub-group of the R-1 Occupancy, multi-family usage. The controlling criterion is the number of guest rooms rather than dwelling units (as is used in the apartment house definition).

MECHANICAL CODE is the Uniform Mechanical Code promulgated jointly by the International Conference of Building Officials and the International Association of Plumbing and Mechanical Officials, as adopted by this jurisdiction.

One of the codes referenced in the UBC provisions is the Mechanical Code, in particular the Uniform Mechanical Code (UMC). It is adopted by a jurisdiction in a similar manner as is the UBC.

MEZZANINE OR MEZZANINE FLOOR is an intermediate floor placed within a room.

The construction provisions for mezzanines are contained in Section 1716. The key determinant in whether a level qualifies as a mezzanine is stated in Item 3 of that section, which reads:

3. The aggregate area of mezzanines within a room shall not exceed one third the area of the room in which it is located. Intermediate floor levels that are 6 or more feet above grade shall be considered a story when the area of such level exceeds one third the area of the room in which it is located.

Sec. 415. **NONCOMBUSTIBLE** as applied to building construction material means a material which, in the form in which it is used, is either one of the following:

1. Material of which no part will ignite and burn when subjected to fire. Any material conforming to U.B.C. Standard No. 4-1 shall be considered noncombustible within the meaning of this section.
2. Material having a structural base of noncombustible material as defined in Item No. 1 above, with a surfacing material not over 1/8 inch thick which has a flame-spread rating of 50 or less.

"Noncombustible" does not apply to surface finish materials. Material required to be noncombustible for reduced clearances to flues, heating appliances or other sources of high temperature shall refer to material conforming to Item No. 1. No material shall be classed as noncombustible which is subject to increase in combustibility or flame-spread rating, beyond the limits herein established,

HANDBOOK

TO THE

UNIFORM BUILDING CODE

An illustrative commentary

International Conference of Building Officials

SECTION 208 — G

GRADE (Adjacent Ground Elevation). The code indicates that grade is the lowest point of elevation of the finished surface of the ground within an area between the building and property line or where the property line is more than 5 feet (1524 mm) from the building between the building and a line 5 feet (1524 mm) from the building.

This definition is important in determining the number of stories within a building as well as its height in feet. In some cases the finished surface of the ground may be artificially raised with imported fill to create a higher grade around a building so as to decrease the number of stories or height in feet. The code does not prohibit this practice, and as long as a building meets the code definition and restrictions for height or number of stories, the intent of the code is met. See Figure 208-1.

For SI: 1 foot = 304.8 mm.

USE OF BUILT-UP SOIL TO RAISE FINISH GRADE

Figure 208-1

For SI: 1 foot = 304.8 mm.

DETERMINATION OF BUILDING HEIGHT IN FEET (mm)

Figure 209-1

Application Example 508-1

GIVEN: One-story building of Type V-N construction with an automatic fire-sprinkler system installed throughout. The building has no yards.

DETERMINE: Maximum allowable floor area for the building housing either a Group B Occupancy or a Group A, Division 2.1 Occupancy.

SOLUTION: Case I—Group B Occupancy:

The building can be evaluated with the automatic fire sprinklers used either to increase area according to Section 505.3 or to substitute for one-hour construction according to Section 508, thus upgrading the construction from Type V-N to Type V One-hour.

A. Section 505.3. Basic allowable area according to Table 5-B is 8,000 square feet for Type V-N construction.

Allowable Area = $8,000 \times 3 = 24,000$ square feet.

B. Section 508. Basic allowable area according to Table 5-B is 14,000 square feet for Type V One-hour. Obviously, it is more advantageous to use the provisions of Section 505.3.

Case II—Group A, Division 2.1 Occupancy:

Referring to Table 5-B, it is seen that a Group A, Division 2.1 Occupancy is not permitted to be of Type V-N construction. Thus, the automatic fire-sprinkler system must be used as a substitute for one-hour construction in order that the building will qualify as Type V One-hour construction. The allowable area for this type of construction is 10,500 square feet housing a Group A, Division 2.1 Occupancy.

GUARDRAILS

Figure 509-1

SECTION 509 — GUARDRAILS

In this section, the code provides for guardrail protection for unenclosed floor and roof openings, open and glazed sides of stairways, landings and ramps, and porches, which are more than 30 inches (762 mm) above grade or a floor or other surface below. Also, the protection is required for roofs which are used other than for service of the building and thus are subject to use by individuals walking on the roof. The need for guardrails in these circumstances is evident, although the arbitrary limit of 30 inches (762 mm) above grade or floor below is subject to conjecture. Nonetheless, in the case of the U.B.C., it is assumed that the height of 30 inches (762 mm) does not create a significant safety hazard.⁵

The guardrail must be of adequate height to prevent someone from falling over the edge of the protected areas and be designed to prevent someone, including small children, from falling through under the top rail. Therefore, the code establishes 42 inches (1067 mm) as the minimum height which is recognized nationally as the proper height for guardrail protection. The code also requires that for open-type rails, intermediate members be provided so that a sphere 4 inches (102 mm) in diameter cannot pass through between the intermediate members, a requirement which prevents small children from falling through the guardrail assembly. See Figure 509-1. The code also lessens the height for open sides of stairs; they may be protected with a guardrail hav-

ing a height the same as for stair railings as provided for in Section 1006.9. There are several more exceptions to the requirements for guardrails, as follows:

- Guardrails are not required on the loading side of docks or along vehicle service pits not accessible to the public for obvious reasons.
- Guardrails are required to be only 36 inches (914 mm) high in dwellings, Group U Occupancies, and within individual apartments or guest rooms in Group R, Division 1 Occupancies. This lower height is based on the good experience that has been exhibited in these uses; for several decades, the guardrail height in them has been no higher than 36 inches (914 mm).
- In commercial and industrial uses where the public is not invited (therefore, the guardrail is not subject to small children falling through), guardrails may have intermediate members spaced so that a 12-inch (305 mm) diameter sphere cannot pass through.
- In order to provide for proper viewing in theaters, a guardrail in front of the first row of fixed seats, and which is not at the end of an aisle, may be 26 inches (660 mm) in height.
- Again for obvious reasons, guardrails are not required on the auditorium side of a stage or enclosed platform.

1020.2 Vestibule: Where an *exit* discharges into an interior vestibule, the vestibule shall be used for ingress and means of egress only, and the vestibule shall comply with Sections 1020.2.1 and 1020.2.2.

1020.2.1 Depth and width: The vestibule depth from the exterior of the building shall not be greater than 10 feet (3048 mm) and the width shall not be greater than 20 feet (6096 mm).

1020.2.2 Separation: The vestibule shall be separated from the remainder of the level of *exit discharge* by self-closing doors and the equivalent of ¼-inch-thick wired glass in steel frames.

1020.3 Lobby: Where an *exit* discharges into an interior lobby located at the level of *exit discharge*, the lobby containing the lobby shall be equipped throughout with an automatic sprinkler system installed in accordance with Section 906.2.1 or 906.2.2. Opening protectives shall be required in accordance with Table 717.1 at the point in which an enclosed *exit stairway* discharges into a lobby.

Exception: An automatic sprinkler system is not required in areas that are separated from the lobby by fire separation assemblies (see Section 709.0) having a fire-resistance rating of not less than that required for *exit* enclosures.

1020.4 Width and height: The clear width of the passageway shall not be less than the width required for the capacity of the *exit stairways* leading thereto and all required *exit* doorways opening into the passageway. Such passageway shall have a minimum width of 44 inches (1118 mm) and a minimum clear ceiling height of 8 feet (2343 mm).

1020.5 Maximum stairway limitations: Not more than 50 percent of the required *stairways* shall discharge through the same passageway. Multiple lobbies constructed in accordance with Section 1020.3 located adjacent to one another shall be separated from each other in accordance with the requirements for enclosure of *exits*.

SECTION 1021.0 GUARDS

1021.1 Design and construction: Where required by the provisions of Sections 406.5, 408.3.2, 1005.5, 1014.7, 1016.5 and 825.5, guards shall be designed and constructed in accordance with the requirements of this section and Section 1606.4.

1021.2 Height: The guards shall be at least 42 inches (1067 mm) in height measured vertically above the leading edge of the tread or adjacent walking surface.

Exceptions

1. In other than occupancies in Use Group E, guards shall not be less than 36 inches (914 mm) in height above the leading edge of the tread along stairs which are not more than 20 feet (6096 mm) in height or which reverse direction at an intermediate landing with 12 inches (305 mm) or less measured horizontally between successive flights.
2. Guards along open-sided floor areas, *mezzanines* and landings within a single dwelling unit in Use Group R-2 and serving a single dwelling unit in Use Group R-3 shall not be less than 36 inches (914 mm) in height.

3. Guards along open-sided floor areas located less than 30 inches (762 mm) above the floor or grade below shall not be less than 36 inches (914 mm) in height.

1021.3 Opening limitations: In occupancies in Use Groups A, B, E, H-4, I-1, I-2, M and R, and in *public garages* and open parking structures, open guards shall have balusters or be of solid material such that a sphere with a diameter of 4 inches (102 mm) cannot pass through any opening. Guards shall not have an ornamental pattern that would provide a ladder effect.

Exceptions

1. The triangular openings formed by the riser, tread and bottom rail at the open side of a *stairway* shall be of a maximum size such that a sphere 6 inches (152 mm) in diameter cannot pass through the opening.
2. At elevated walking surfaces for access to and utilization of electrical, mechanical, or plumbing systems or equipment, guards shall have balusters or be of solid materials such that a sphere with a diameter of 21 inches (533 mm) cannot pass through any opening.

In occupancies in Use Groups I-3, F, H-1, H-2, H-3, S, (other than *public garages* and open parking structures), and along open-sided floor areas located less than 30 inches (762 mm) above the floor or grade below, balusters, horizontal intermediate rails or other construction shall not permit a sphere with a diameter of 21 inches (533 mm) to pass through any opening.

1021.4 Railings: Metal or other approved noncombustible railings shall be provided on balconies and galleries as prescribed in Sections 1021.4.1 through 1021.4.3.

1021.4.1 At fascia: Railings shall be provided at the fascia of boxes, balconies and galleries and shall not be less than 26 inches (660 mm) in height; at the end of aisles extending to the fascia for the full width of the aisle and shall not be less than 36 inches (914 mm) in height; and at the foot of steps for the full width of the steps and shall not be less than 42 inches (1067 mm) in height.

1021.4.2 At cross aisles: Railings shall be provided along cross aisles, and shall not be less than 26 inches (660 mm) in height except that railings are not required where the backs of the seats along the front of the aisles project 24 inches (610 mm) or more above the floor of the aisle.

1021.4.3 Successive tiers: Where seatings are arranged in successive tiers, and where the height of rise between platforms exceeds 18 inches (457 mm), railings not less than 26 inches (660 mm) in height shall be provided along the entire row of seats at the edge of the platform.

SECTION 1022.0 HANDRAILS

1022.1 General: Where required by the provisions of Sections 1012.5, 1013.0, 1014.6.6.1, 1014.7 and 1016.5, handrails shall be designed and constructed in accordance with this section and Section 1606.4.

1022.2 Handrail details: Handrails shall be continuous, without interruption by newel posts, other structure elements or obstructions. A handrail and any wall or other surface adjacent to the handrail shall be free of any sharp or abrasive elements. The clear space between the handrail and the adjacent wall or surface shall

SECTION 502.0 DEFINITIONS

502.1 General: The following words and terms shall, for the purposes of this chapter and as used elsewhere in this code, have the meanings shown herein.

Area, building: The area included within surrounding exterior walls (or exterior walls and fire walls) exclusive of vent shafts and courts. Areas of the building not provided with surrounding walls shall be included in the building area if such areas are included within the horizontal projection of the roof or floor above.

Basement: That portion of a building which is partly or completely below grade (see "Story above grade").

Grade plane: A reference plane representing the average of finished ground level adjoining the building at all exterior walls. Where the finished ground level slopes away from the exterior walls, the reference plane shall be established by the lowest points within the area between the building and the lot line or, where the lot line is more than 6 feet (1829 mm) from the building, between the building and a point 6 feet (1829 mm) from the building.

Height

Building: The vertical distance from grade plane to the average height of the highest roof surface.

1005.5 Open-sided walking areas: Guards shall be located along open-sided walking surfaces, mezzanines, stairways, ramps and landings which are located more than 15½ inches (394 mm) above the floor or grade below. The guards shall be constructed in accordance with Section 1021.0.

Exception: Guards are not required for the following locations:

1. On the loading side of loading docks.
2. On the auditorium side of stages and raised platforms.
3. On raised stage and platform floor areas such as runways, ramps and side stages utilized for entertainment or presentations.
4. At vertical openings in the performance area of stages and platforms.
5. At elevated walking surfaces appurtenant to stages and platforms for access to and utilization of special lighting or equipment.

GALLERY: That portion of the seating space of an assembly room having a seating capacity of more than ten located above a balcony.

GRADE: a reference plane representing the average of finished ground level adjoining the building at all exterior walls. When the finished ground level slopes away from the exterior walls, the reference plane shall be established by the lowest points within the area between the building and the lot line or between the building and a point 6 ft (1829 mm) from the building, whichever is closer to the building.

GRADE LUMBER: the division of sawn lumber into quality classes with respect to its physical

SOUTHERN BUILDING CODE

1015 GUARDRAILS

1015.1 General

All unenclosed floor and roof openings, open and glazed sides of landings and ramps, balconies or porches which are more than 30 inches (762 mm) above finished ground level or a floor below shall be protected by a guardrail. Guardrails shall form a vertical protective barrier not less than 42 inches (1067 mm) high. Open guardrails shall have intermediate rails or ornamental pattern such that a 6-inch (152 mm) diameter sphere cannot pass through any opening. A bottom rail or curb shall be provided that will reject the passage of a 2-inch (51 mm) diameter sphere. Construction of guardrails shall be adequate in strength, durability and attachment for their purpose as described in 1608.2.

EXCEPTIONS:

1. Guardrails are not required on the loading side of loading docks.
2. Guardrails shall be permitted in conformance with requirements for specific occupancies in 1018.

1015.3 Glass

Cost Impact: None

R312.1-RB-DAVIDSON

RB144 – 13

R312.1.1, Chapter 44

Proponent: Mitch Markham, representing Ascend Restoration Services

Revise as follows:

R312.1.1 Where Required. *Guards* shall be located along open-sided walking surfaces, including stairs, ramps and landings that are located more than 30 inches (762 mm) measured vertically to the floor or *grade* below at any point within 36 inches (914 mm) horizontally to the edge of the open side. Insect screening shall not be considered as a *guard*.

Exception: Permanent fall arrest and restraint anchorage connector devices meeting ANSI/ASSE Z359.1 affixed for use during the entire roof covering lifetime shall be permitted where mechanical equipment, systems, devices and various components that require service are located on roof surfaces. Fall arrest/restraint devices shall be reevaluated for possible replacement when the entire roof covering is replaced. The devices shall be placed no more than 10 feet (3048 mm) on center along hip and ridge lines and placed not less than 10 feet (3048 mm) from the roof edge or open side of the walking surface.

Add new standards to Chapter 44 as follows:

ANSI American National Standards Institute
25 West 43rd Street, Fourth Floor
New York, NY 10036

Z359.1-07 Safety Requirements for Personal Fall Arrest Systems, Subsystems and Components

ASSE American Society of Sanitary Engineering
901 Canterbury, Suite A
Westlake, OH 44145

Z359.1-2007 Safety Requirements for Personal Fall Arrest Systems, Subsystems and Components

Reason: This proposal is intended to correlate with E108-12 which was approved at the 2012 FAH as a consent agenda item during the code Group A process. This proposal is needed so there is consistency and correlation between the ICC codes. E108-12 added clarity to IBC sections 1013.6 and 1013.7, IFC sections 1013.6 and 1013.7, and IMC section 304.11. The existing code provisions requiring the construction of guards do not adequately address the expanding list of equipment, assemblies, systems, devices and items that are now commonly being placed on roof tops and elevated walking surfaces that require routine maintenance. The current requirement needs clarification and a cost effective alternative to constructing a guard on a roof since a guard is a method of fall protection required at the edge of elevated surfaces where people will walk and will provide service to roof-located equipment and other systems or devices. The code change proposal adds clarity to the current code language by identifying items within the exception that are now typical placements on roofs and elevated walking surfaces. This expands the fall protection, life-safety provisions to a growing number of trades and service workers that are working on elevated surfaces. The proposal also provides an alternate method of compliance with the inclusion of an exception which allows for the installation of fall arrest/restraint anchorage connector devices meeting ANSI Z359.1 which is the nationally recognized consensus general industry standard in use across the country. The proposed exception is a choice made by the designer and building owner that provides design flexibility and the opportunity to lower construction cost associated with building guards. The proposal will increase the uniform application of this section of the code. The Bureau of Labor Statistics, US Department of Labor reports the fatalities due to falls for the years from 1998 to 2010 are second to only highway incidents, with an average of 743 fatalities each year over this 12 year period. Of the 635 fatal falls in 2010, one third is from falls from ladders or roofs. In 2010 the construction industry had the highest number of fatal occupational injuries. In 2010 for nonfatal falls the median number of days away from work due to falls to a lower level was 14 days. Clearly the code needs to be improved to provide fall protection where mechanical equipment, appliances, equipment, fans, roof hatch openings, solar arrays, solar water heaters, photovoltaic panels, skylights, chimneys, attic vents, and ventilators, satellite dishes, antennas, television/radio/internet and other communication equipment and all other machinery and other components that require service are located on elevated surfaces more than 30 inches above a lower level.

Cost Impact: The code change proposal will not increase the cost of construction because the current code provisions can be interpreted to have the intent to require guards at all elevated working level more than 30 inches above a floor, roof or grade. The inclusion of an exception provides a choice to the builder and homeowner to lower the cost of construction.

Analysis: A review of the standards proposed for inclusion in the code, [ANSI/ASSE Z359.1-2007] with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 1, 2013.

RB144-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R312.1.1-RB-MARKHAM

RB145 – 13

R312.1.2

Proponent: Rick Davidson, City of Maple Grove, Association of Minnesota Building Officials (rdavidson@maplegrovern.gov); Steve Thomas, Colorado Code Consulting, LLC representing the Colorado Chapter ICC (sthomas@coloradocode.net)

Revise as follows:

R312.1.2 Height. Required *guards* at open-sided walking surfaces, including stairs, porches, balconies or landings, shall be not less than 36 inches (914 mm) high measured vertically above the adjacent walking surface, ~~adjacent fixed seating~~ or the line connecting the leading edges of the treads.

Exceptions:

1. *Guards* on the open sides of stairs shall have a height not less than 34 inches (864 mm) measured vertically from a line connecting the leading edges of the treads.
2. Where the top of the *guard* also serves as a handrail on the open sides of stairs, the top of the *guard* shall not be less than 34 inches (864 mm) and not more than 38 inches (965 mm) measured vertically from a line connecting the leading edges of the treads.

Reasons:

Davidson: This proposal deletes the term “adjacent fixed seating” from the rules on guards. The term “fixed seating” is not defined. This makes the intent ambiguous and unclear. This will result in a lack of uniformity. There is no evidence to suggest that this rule serves any purpose or that it corrects any problems. There was never any evidence submitted that there is a problem.

The intent of the current language could result in guards being five or six feet in height. Designing a guard to meet the load requirements at the top of such a guard will result in significant attachment concerns because the current load requirements were based on the assumption that the guard would only be 36 inches high and the code requires that the design load for guards be at the top. This code requirement is unreasonable because compliance with the rule will be extremely expensive yet provide little increase in safety over the previous rules.

Furthermore, it penalizes designs using fixed seating all the while ignoring chairs and other furniture than can be easily pushed next to a guard creating the same potential circumstances. If we really wanted to address a safety hazard, we would require self closing gates be installed across all stairways to prevent children from falling down stairs which is a much more frequent occurrence.

To avoid expensive and unintended design costs and to avoid confusion and a lack of uniformity of enforcement, this term must be deleted. It is reasonable to delete the term because the current language in the code has not been shown to cause unsafe conditions.

Thomas: This change is to delete the requirement to extend a guard 36 inches above the surface of fixed seating. The same requirement was deleted out of the 2012 IBC. Subsequent attempts to put it back in the 2015 IBC failed in Portland. This proposal will make the two codes consistent with each other in this area.

The original requirement was lumped in a larger change that was made to the guard provisions in the code. There was no technical justification to raise the height of the guard at the back of fixed seating. There was also no definition of what fixed seating is. This should never have been put in the IRC in the first place.

We feel that this requirement is over-restrictive. The responsibility of keeping children from climbing on the back of a deck bench or some type of landscape wall should not be placed on the code. At some point, parents need to be responsible for their children. Raising the height of the bench back rest to a height of 54 inches above the deck will not prevent children from climbing over and falling.

Cost Impacts :

Davidson: None

Thomas: This will reduce the cost of construction.

RB145-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R31.1.2-RB-DAVIDSON-THOMAS

RB146 – 13

R312.2.1

Proponent: Carl Baldassarra, P.E., FSFPE, Chair, ICC Code Technology Committee
(cbaldassarra@rjagroup.com)

Revise as follows:

R312.2 Window fall protection. Window fall protection shall be provided in accordance with Sections R312.2.1 and R312.2.2.

R312.2.1 Window sills. In dwelling units, where the opening of an operable window is located more than 72 inches (1829 mm) above the finished grade or surface below, the lowest part of the clear opening of the window shall be a minimum of 24 inches (610 mm) above the finished floor of the room in which the window is located. Operable sections of windows shall not permit openings that allow passage of a 4-inch-diameter (102 mm) sphere where such openings are located within 24 inches (610 mm) of the finished floor. the top of the sill of an operable window opening is located less than 24 inches above the finished floor and greater than 72 inches (1829 mm) above the finished grade or other surface below on the exterior of the building, the operable window shall comply with one of the following:

Exceptions:

1. Operable windows whose openings will not allow a 4-inch-diameter (102 mm) sphere to pass through the opening when the opening is in its largest opened position.
2. Operable windows Openings that are provided with window fall prevention devices that comply with ASTM F 2090.
3. Operable windows that are provided with window opening control devices that comply with Section R312.2.2.

Reason: This proposed change is a result of the CTC's investigation of the area of study entitled "Child Window Safety". The scope of the activity is noted as:

To evaluate the necessity of developing code proposals for the inclusion of requirements dealing with the conditions, circumstances and devices for window safety which could reduce the number of falls by children to surfaces below.

The purpose of this proposal is to coordinate the IRC with the changes approved to the IBC in the 2012 Group A cycle. Specifically, Code change E109-12 was approved as submitted to revise Section 1013.8 of the IBC (see below).

The CTC examined the IBC provisions during the preparation of the code changes for existing buildings and several questions came up regarding the original intent and the scope of what was being regulated. The IBC language was clarified to specify that the hazard exists with all windows in a dwelling unit and the height is to be measured to the top of the sill of an operable window. Additionally, the exceptions aren't actually exceptions, but conditions where various devices and their standards are allowed to be used. It should be noted that the minimum sill height in the IBC is 36 inches and this proposal retains the current 24 inch minimum sill height in the IRC.

For reference, the approved IBC text is as follows:

IBC 1013.8 Window openings. All windows in Groups R-2 and R-3 buildings including dwellings units, where the top of the sill of an operable window opening is located less than 36 inches above the finished floor and greater than 72 inches (1829 mm) above the finished grade or other surface below on the exterior of the building, shall comply with one of the following:

1. Operable windows where the top of the sill of the opening is located more than 75 feet (22 860 mm) above the finished grade or other surface below and that are provided with window fall prevention devices that comply with ASTM F 2006.
2. Operable windows whose openings will not allow a 4-inch-diameter (102 mm) sphere to pass through the opening when the window is in its largest opened position.
3. Operable windows whose openings that are provided with window fall prevention devices that comply with ASTM F 2090.
4. Operable windows that are provided with window opening control devices that comply with Section 1013.8.1.

1013.8.1 Window opening control devices. Window opening control devices shall comply with ASTM F 2090. The window opening control device, after operation to release the control device allowing the window to fully open, shall not reduce the minimum net clear opening area of the window unit to less than the area required by Section 1029.2.

This proposal is submitted by the ICC Code Technology Committee. The ICC Board established the ICC Code Technology Committee (CTC) as the venue to discuss contemporary code issues in a committee setting which provides the necessary time and flexibility to allow for full participation and input by any interested party. The code issues are assigned to the CTC by the ICC Board as "areas of study". Information on the CTC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CTC effort can be downloaded from the following website: <http://www.iccsafe.org/cs/CTC/Pages/default.aspx>. Since its inception in April/2005, the CTC has held twenty-five meetings - all open to the public. In 2012, three of the 25 face-to face meetings were held. In addition to the CTC meetings, the CTC established Study Groups (SG) of interested parties for each of the areas of study. These SG's are responsible for reviewing the available information and making recommendations to the CTC. All totaled, the SG's held over 70 conference calls in 2012.

Cost Impact: This code change proposal will not increase the cost of construction.

RB146-13

R312.2.1-RB-BALDASSARRA-CTC

RB147 – 13

R312.2.1

Proponent: Rick Davidson, City of Maple Grove, Association of Minnesota Building Officials
(rdavidson@maplegrovern.gov)

Revise as follows:

R312.2 Window fall protection. Window fall protection shall be provided in accordance with Sections R312.2.1 and R312.2.2.

R312.2.1 Window sills. In dwelling units, where the opening of an operable window is located more than 72 inches (1829 mm) above the finished grade or surface below, the lowest part of the clear opening of the window shall be a minimum of 24 36 inches (610 mm) above the finished floor of the room in which the window is located or above window seats or other adjacent fixed seating. Operable sections of windows shall not permit openings that allow passage of a 4-inch-diameter (102 mm) sphere where such openings are located within 24 36 inches (610 mm) of the finished floor or above window seats or other adjacent fixed seating.

Exceptions:

1. Windows whose openings will not allow a 4-inch-diameter (102 mm) sphere to pass through the opening when the opening is in its largest opened position.
2. Openings that are provided with window fall prevention devices that comply with ASTM F 2090.
3. Windows that are provided with window opening control devices that comply with Section R312.2.2.

Reason: It has been pointed out at recent hearings that the minimum sill height for child fall protection was set at 24 inches as a compromise. It is time to face reality and raise the sill height requirements to a justifiable level. This is a child safety issue and should be given a high priority. Children continue to fall out of windows resulting in serious injuries and deaths.

We require smoke alarms in bedrooms. The reason – adults smoke in bed and set themselves on fire.

We require Carbon Monoxide alarms in homes when the incidence of CO poisoning is rare. The reason – an adult might use their charcoal grill in their living room.

We require ramps to be flatter for single family dwellings than other buildings. The reason – adults need to be told what slope is best for them.

We require fire protection of floors in dwellings. The reason – fire fighters are entering buildings that have active fires below the floors of entry.

We require sprinklers in dwellings. The reason – smoking and cooking fires, the biggest cause of residential fires, occur because of inattention by adults.

We require large window wells for basement windows and then debate the need for guards to keep people from falling in them. We can't even agree on where guards should be placed or when they should be required to protect adults!

We have approved code changes to protect fire fighters, older people, younger people, smokers, and people who use charcoal grills in their living rooms. Yet children seem to be left out and when something is proposed to make things safer for children the events are said to be a parenting issue! Are the examples above also "parenting issues"? At least in my area of the country, it seems hardly a week goes by without the report of another child falling out of a window and being seriously injured or killed. And these events are occurring in single family homes. The fact of the matter is that children cannot be watched all of the time. Children falling out of windows is not a parenting issue, it is a poor design issue.

Guards are required to be not less than 36 inches in height and opening protection to prevent a 4 inch sphere from passing through the guard extends to the full height of the guard, not just the first 24 inches. The same should hold true for window openings because the risk is the same.

In the past you have heard a number of absurd arguments against proposals to increase sill heights and window fall protection in general. One argument is that a 24 inch sill height is safer than a 36 inch sill height because it is less likely that furniture will be placed in front of a window with a 24 inch sill. There have never been any scientific studies to support such a brainchild. And taken to an extreme, if 24 inches is safer than 36 inches, then 12 inches should be safer yet and if we really want to be safe we would mandate window openings start at the floor! Seriously, the studies that are out there contradict the claims that lower windows are safer. The vast majority of children fall out of windows with no furniture in front of them and that are located close to the floor. Toddlers are particularly susceptible and the lower sill heights act as a pivot for children of this age. Being top heavy, children simply leaning out a window can cause a fall. The average height of a two-year old is 31 inches. The average height of a four-year

old is 37 inches. It doesn't take a rocket scientist to see that children of these ages and these heights and lower window sill are a recipe for disaster and that is exactly what is happening.

There are numerous solutions available that would allow windows with to extend all the way to the floor if the designer wishes. And if the membership agrees to eliminate the need for emergency escape windows in sprinklered homes, that eliminates another concern.

Numerous requirements without substantiated need have been placed in the code in recent years that, at best, will provide limited benefit to a very small handful of individuals. Here we have an opportunity to provide increased levels of safety for children. This should be the proverbial "no-brainer".

Cost Impact: None

RB148 – 13

R313.1 (New), R313.1.1, R313.2, R313.2.1, R313.4 (New), R302.2

Proponent: Matt Archer, Douglas County, CO, representing self (marcher@douglas.co.us)

Revise as follows:

R313.1 General. The design, installation, inspection, maintenance, repair and replacement of residential automatic fire sprinkler systems and components shall comply with the manufacturer's instructions and Section P2904.

R313.4 ~~2~~ Townhouse automatic fire sprinkler systems. An automatic residential fire sprinkler system shall be installed in *townhouses*.

Exception: An automatic residential fire sprinkler system shall not be required when ~~additions or alterations are made to existing townhouses that do not have an automatic residential fire sprinkler system installed.~~ Townhouses separated by a fire rated wall assembly totaling 2 hours in accordance with Section R302.2 and fire protected floors complying with Section R501.3 shall not be required to have an automatic residential fire sprinkler system.

R313.1.1 ~~Design and installation.~~ Automatic residential fire sprinkler systems for ~~townhouses~~ shall be designed and installed in accordance with Section P2904.

R313.2 ~~R313.3~~ One- and two-family dwellings automatic fire systems. An automatic residential fire sprinkler system shall be installed in one- and two-family *dwellings*.

Exception: One- and two-family dwellings complying with the exterior wall construction of Table 302.1(1) and fire protected floors complying with Section R501.3 shall not be required to have an automatic residential fire sprinkler system.

Exception: R313.4 Additions and alterations. An automatic residential fire sprinkler system shall not be required for *additions* or *alterations* to existing buildings that are not already provided with an automatic residential sprinkler system.

R313.2.1 ~~Design and installation.~~ Automatic residential fire sprinkler systems shall be designed and installed in accordance with Section P2904 or NFPA 13D.

R302.2 Townhouses. Each *townhouse* shall be considered a separate building and shall be separated by fire-resistance-rated wall assemblies meeting the requirements of Section R302.1 for exterior walls.

Exception Exceptions:

1. Townhouses with an automatic residential fire sprinkler system are permitted to have a common 1-hour fire-resistance-rated wall assembly tested in accordance with ASTM E 119 or UL 263, ~~is permitted for townhouses if such walls do.~~ The common wall shall not contain plumbing or mechanical equipment, ducts or vents in the cavity of the common wall. The wall shall be rated for fire exposure from both sides and shall extend to and be tight against exterior walls and the underside of the roof sheathing. Electrical installations shall be installed in accordance with Chapters 34 through 43. Penetrations of electrical outlet boxes shall be in accordance with Section R302.4.
2. A common 2 hour fire-resistance-rated wall assembly tested in accordance with ASTM E 119 or UL 263 is permitted for townhouses where such walls do not contain plumbing or mechanical equipment, ducts or vents in the cavity of the common wall.

Reason: Creating a general section (R313.1 General) gives us a place to put all the design and installation charging language and alleviates the need for repetitive language in each section.

Creating an addition and alteration section (R313.4 Additions and alterations) puts all the information in one place and alleviates the need for repetitive exception language in each section.

Adding an exception (R302.2 Townhouses) for a common 2 hour fire-resistive-rated wall assembly give the builders the option to increase the separation requirements between dwelling units to avoid the installation of fire sprinklers.

Adding the fire-resistive language for townhouses and one- and two-family dwellings gives the builder an option to meet higher construction standards for compartmentalization or the option to sprinkler the structures to reduce the construction ratings.

Ultimately this brings the IRC back to being more of a performance code verses a prescriptive code. Fire sprinklers have proven to be an effective active system for life safety as much as compartmentalization has proven to be an effective passive system for life safety. Giving the designer or builder the option to choose which system works best for their product is what we want the code to do.

Fire sprinklers for several jurisdictions are an effective alternative to mitigate other conditions that may exist, such as: inadequate or no fire flow, steeply sloping access roads or driveways, long dead-end roads or driveways and areas that have volunteer fire departments or longer response times. Giving the building official the ability to use an alternative means to mitigate extenuating circumstances in rural or difficult areas with fire sprinklers is a great tool to have at our disposal.

Requiring fire sprinklers as a one size fits all approach is not right for the IRC to do, that's like requiring all windows in a home to have fall protection regardless of its height above grade or size. The requirement of fire sprinklers should be based on a risk assessment profile that balances the variables mentioned, plus staffing levels, response times, apparatus types etc. This is a decision that needs to be made at a local level where they have an understanding of their risk profile, not by a one size fits all national mandate.

The benefit of any code change needs to consider not only life safety but cost as well. The expense of sprinklers cannot be ignored. According to NFPA and an article by Marshall Klein and Julius Ballanco, the cost of a residential sprinkler system can range from \$0.05 – \$ 3.66 per square foot. Both documents indicate "the typical installation will be closer to the middle or higher end of the price range". This is a significant cost, a 2400 sqft, 1 story home with a full basement, pricing could range from \$8784.00 - \$17568.00. Since 2009 many jurisdictions have been reluctant to adopt this requirement as written because it drives up the cost of building new homes. The jurisdictions that choose to adopt the sprinkler mandate may put themselves at a competitive disadvantage as homebuilders may choose to develop in areas that do not require the sprinklers.

I do not believe a home with:

- fire roads designed to the IFC for access,
- hydrants spaced as required by code,
- the ability to provide a required fire flow,
- homes spaced with the required fire separation distance,
- code required egress through doors and windows,
- protected means of egress by rating basement stairs and all floor assemblies,
- compartmentalization of garages and Dwellings,
- active warning systems like smoke and CO detectors, are unsafe and the over regulation of requiring fire sprinklers, will now make a home safe to occupy.

NFPA article:

<http://www.firesprinklerinitiative.org/~media/Fire%20Sprinkler%20Initiative/Files/Reports/FireSprinklerCostAssessment.pdf>

P2904 article: <http://www.ircfiresprinkler.org/docs/Klein-Ballanco%20Residential%20Sprinkler%20Design%20Made%20Easy%20-%20Plumbing%20Systems%20and%20Design%20Mag.%20Sept%202008.pdf>

Cost Impact: None.

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R313.1 (NEW)-RB-ARCHER

RB149 – 13

R313.1.1

Proponent: Rita Neiderheiser, representing Road Sprinkler Fitters Local Union 669 (4ritan@gmail.com)

Revise as follows:

R313.1.1 Design and installation. Automatic residential fire sprinkler systems for townhouses shall be designed and installed in accordance with Section P2904 or NFPA 13D.

Reason: The current language is unclear as to whether National Fire Protection Association (NFPA) 13D designed and installed systems are allowed to be used in townhouses. Adding "NFPA 13D" to Section R313.1.1 will make it clear that either a NFPA 13D system or a system that complies with Section P2904 of the IRC may be installed in townhouses.

Cost Impact: The code change proposal will not increase the cost of construction.

RB149-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R313.1.1-RB-NEIDERHEISER

RB150 – 13

R313.1

Proponent: Kirk Nagle, City of Arvada, representing self (knagle@arvada.org)

Revise as follows:

R313.1 Townhouse automatic fire sprinkler systems. An automatic residential fire sprinkler system shall be installed in townhouses.

Exception: An automatic residential fire sprinkler shall not be required when a fire extinguisher has been installed in the kitchen and the separation for the townhouses is two 1-hour walls or a 2- hour common wall between units is provided or where additions or alterations are made to existing townhouse that do not have an automatic residential fire sprinkler system installed.

Reason: Residential fire sprinkler systems are not accepted by all the state legislatures in single family homes and have been written out of the adoption process by 30 of the 50 states in the US. This creates a code issue with the way states use the code adoption process and has elected officials writing or rewriting the codes we use. We do not want the state legislative system to make the code adoption process useless if the states then rewrite or prevent the use of codes that are decided through the consensus process that the ICC uses to validate and promote the codes. The process currently used by the ICC is, in my opinion the best in the world. Sometimes there a codes that are approved and they need to be cared for. I believe that showing the state legislatures that we hear them and understand what happened is very important, I strongly believe that sprinklers have a place but should not be mandated.

Fire sprinklers, as good as they are, do not provide a substantial saving of lives when you add that we already have smoke alarms in all buildings and that we require fire alarms be put into each home even with a very small remodel. Smoke alarms have a 99.45% life safety rating and where adding a fire sprinkler the, lifesaving rate only goes up to 99.87% as stated by the NFPA. The cost to have every new home put in fire sprinklers is very expensive and cost prohibitive in a fragile economy compared to the life safety that fire sprinklers will bring to building construction. Fire sprinklers should be voluntary for each home owner to choose, if they wish. Educating the public and state legislatures would be the first step to all-around acceptance. If we put fire sprinklers in the code they need to be understood so the legislative actions taken against fire sprinklers can be reversed so the codes can be enforced as they were meant to be and not changed by elected officials. The prohibition of fire sprinklers has made some situations where fire sprinklers are needed impossible because of the legislative actions against their use and this is a huge problem in rural areas where there is little or no fire protection at all.

Adopting codes where the controversy is to volatile is not a good thing, but I do believe that leaving the code adoption up to the local jurisdictions is important, plus it promotes stronger codes. I am not, I repeat not, against fire sprinklers in any way. The interested parties with political clout in the US have spoken and we need to address their concerns by showing that we listen. Our process should not become a point of contention where there are attacks of the process outside the code hearings. I feel very strongly that in order to gain acceptance we need to show we will work to get fire sprinklers accepted by the public and state legislatures before we require them in one- and two-family homes. We have an obligation to make the codes strong and acceptable to the populations they will serve. If we have a problem with acceptance, we need to make corrections to the written code. We want the people and the elected officials to see the codes as not only the standard of safety, but realize that adoption is for their safety and the safety of others and the most cost effective way to protect people's lives.

Cost Impact: This proposal will decrease the cost of townhouse construction.

RB150-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R313.1-RB-NAGLE

RB151 – 13

R313.2

Proponent: Ali M. Fattah, P.E., City of San Diego, representing the San Diego Area Chapter of ICC
(afattah@sandiego.gov)

Revise as follows:

R313.2 One- and two-family dwellings automatic fire systems. An automatic residential fire sprinkler system shall be installed in new dwelling units and new one- and two-family dwellings.

Exception: An automatic residential fire sprinkler system shall not be required for *additions or alterations* to existing ~~buildings-dwellings or dwelling units~~ that are not already provided with an automatic residential sprinkler system.

Reason: The 2009 IRC adopted fire sprinkler regulations that continue in the 2012 IRC. However upon implementation of the regulations it is apparent that an inconsistency appears in Section R313.2 when compared with Section R313.1. Section R313.1 in its exception exempts additions and alterations to townhouses that are not already protected with fire sprinklers. The exception does not exempt new townhouses added adjacent to existing townhouses from protection. Section R202 defines a townhouse as **"TOWNHOUSE.** A single-family *dwelling unit* constructed in a group..." and as a consequence R313.1 will require the new townhouse to be protected since it is a "single family dwelling unit".

Section R313.2 address a second configuration of dwelling that may be one dwelling or two attached dwelling units. It is not uncommon in more urban environments for a new dwelling unit to be added and attached to an existing dwelling and as a consequence the new dwelling unit should be protected as would a townhouse added adjacent to another townhouse dwelling unit.

The term building is not defined in the IRC and is not consistent with the heading of Section R313.2 and therefore the terms dwelling and dwelling unit are more appropriate.

Cost Impact: This code change will minimally increase the valuation of construction by less than 1 %.

RB151-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R313.2-RB-FATTAH

RB152 – 13

R313.2

Proponent: Kirk Nagle, City of Arvada, Co, representing self. (knagle@arvada.org)

Revise as follows:

R313.2 One and Two-family dwelling automatic fire systems. An automatic residential fire sprinkler system shall be installed in one-and two-family dwellings.

Exception: An automatic residential fire sprinkler system shall not be required where a fire extinguisher has been installed in the kitchen and the separation for a two-family dwelling is two 1-hour walls or a 2-hour common wall between units is provided or for additions or alterations in existing buildings that are not already provided with an automatic residential sprinkler system.

Reason: Residential fire sprinkler systems are not accepted by all the state legislatures in single family homes and have been written out of the adoption process by 30 of the 50 states in the US. This creates a code issue with the way states use the code adoption process and has elected officials writing or rewriting the codes we use. We do not want the state legislative system to make the code adoption process useless if the states then rewrite or prevent the use of codes that are decided through the consensus process that the ICC uses to validate and promote the codes. The code process currently used by the ICC is, in my opinion the best in the world. Sometimes there are codes that are approved and they need to be changed but rarely has the code process been challenged on such a scale. The code is not infallible but the process needs to be protected and cared for. I believe that showing the states legislatures that we hear them and understand what happened is very important. I strongly believe that sprinklers have a place but should not be mandated.

Fire sprinklers, as good as they are, do not provide a substantial saving of lives when you add that we already have fire alarms in all buildings and that we require fire alarms be put into each home even with a very small remodel. Fire alarms have a 99.46% life safety rating and adding a fire sprinklers the lifesaving rate only goes up to 99.86%. The cost to have every new home put in fire sprinklers is very expensive and cost prohibitive in a fragile economy compared to the life safety that fire sprinklers will bring to building construction. Fire sprinklers should be voluntary for each home owner to choose, if they wish. Educating the public and state legislatures would be the first step to all around acceptance. If we put fire sprinklers in the code they need to be understood so the legislative actions taken against fire sprinklers can be reversed so the codes can be enforced as they were meant to be and not changed by elected officials. The prohibition of fire sprinklers has made some situations where fire sprinklers are needed impossible because of the legislative actions against their use and this is a huge problem in rural areas where there is little or no fire protection at all.

Adopting codes where the controversy is too volatile is not a good thing but I do believe that leaving the code adoption up to the local jurisdictions is important plus it promotes stronger codes. I am not I repeat not against fire sprinklers in any way. The interested parties with political clout in the US have spoken and we need to address their concerns by showing that we listen. Our process should not become a point of contention where there are attacks of the process outside the code hearings. I feel very strongly that in order to gain acceptance we need to show we will work to get fire sprinklers accepted by the public and state legislatures before we require them in one- and two-single family homes. We have an obligation to make codes strong and acceptable to the populations they will serve, if we have a problem with acceptance, we need to make corrections to the written code. We want the people and the elected officials to see the codes as, not only the standard of safety but adoption is for their safety and the safety of others and the most cost effective way to protect peoples lives.

Cost Impact: This code change will reduce the cost of one- and two-family dwelling construction.

R313.2-RB-NAGEL

RB153 – 13

R313.2.1

Proponent: Tim Swanson, City of Greeley, representing Colorado Chapter of the International Code Council (tim.swanson@greeleygov.com)

Revise as follows:

R313.2.1 Design and installation. Automatic residential fire sprinkler systems shall be designed and installed in accordance with Section P2904, ~~or NFPA 13D.~~

Reason: The 2012 IRC specifies that the sprinkler system that is required by Section R313.1.1 for Townhouse applications comply with the requirements of P2904. In Section P2904.1, either the requirements of Section P2904, or the requirements of NFPA 13D are allowed for the installation of residential fire sprinklers. In Section R313.2.1, the code specifies that the NFPA 13D system may also be used. This is redundant, as it is already stated in P2904.1. It also does not mirror the language in 313.1.1, which could cause confusion, as both sections are addressing residential fire sprinkler applications required by the IRC. This change would now mirror IRC 313.1.1 and clear up any confusion and redundancy.

Cost Impact: None

R314

Proponent: Charles S. Bajnai, Chesterfield County, VA, ICC Building Code Action Committee (bajnaic@chesterfield.gov), and Adolf Zubia, Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee

Delete and substitute as follows:

SECTION R314 SMOKE ALARMS

~~R314.1 Smoke detection and notification.~~ All smoke alarms shall be listed and labeled in accordance with UL 217 and installed in accordance with the provisions of this code and the household fire warning equipment provisions of NFPA 72.

~~R314.2 Smoke detection systems.~~ Household fire alarm systems installed in accordance with NFPA 72 that include smoke alarms, or a combination of smoke detector and audible notification device installed as required by this section for smoke alarms, shall be permitted. The household fire alarm system shall provide the same level of smoke detection and alarm as required by this section for smoke alarms. Where a household fire warning system is installed using a combination of smoke detector and audible notification device(s), it shall become a permanent fixture of the occupancy and owned by the homeowner. The system shall be monitored by an *approved* supervising station and be maintained in accordance with NFPA 72.

Exception: Where smoke alarms are provided meeting the requirements of Section R314.4.

~~R314.3 Location.~~ Smoke alarms shall be installed in the following locations:

- ~~1. In each sleeping room.~~
- ~~2. Outside each separate sleeping area in the immediate vicinity of the bedrooms.~~
- ~~3. On each additional story of the dwelling, including basements and habitable attics but not including crawl spaces and uninhabitable attics. In dwellings or dwelling units with split levels and without an intervening door between the adjacent levels, a smoke alarm installed on the upper level shall suffice for the adjacent lower level provided that the lower level is less than one full story below the upper level.~~

~~R314.3.1 Alterations, repairs and additions.~~ When *alterations, repairs or additions* requiring a permit occur, or when one or more sleeping rooms are added or created in existing *dwellings*, the individual *dwelling unit* shall be equipped with smoke alarms located as required for new *dwellings*.

Exceptions:

- ~~1. Work involving the exterior surfaces of dwellings, such as the replacement of roofing or siding, or the addition or replacement of windows or doors, or the addition of a porch or deck, are exempt from the requirements of this section.~~
- ~~2. Installation, alteration or repairs of plumbing or mechanical systems are exempt from the requirements of this section.~~

~~R314.4 Power source.~~ Smoke alarms shall receive their primary power from the building wiring when such wiring is served from a commercial source, and when primary power is interrupted, shall receive power from a battery. Wiring shall be permanent and without a disconnecting switch other than those required for overcurrent protection.

Exceptions:

1. ~~Smoke alarms shall be permitted to be battery operated when installed in buildings without commercial power.~~
2. ~~Hard wiring of smoke alarms in existing areas shall not be required where the alterations or repairs do not result in the removal of interior wall or ceiling finishes exposing the structure, unless there is an attic, crawl space or basement available which could provide access for hard wiring without the removal of interior finishes.~~

~~**R314.5 Interconnection.** Where more than one smoke alarm is required to be installed within an individual dwelling unit in accordance with Section R314.3, the alarm devices shall be interconnected in such a manner that the actuation of one alarm will activate all of the alarms in the individual unit. Physical interconnection of smoke alarms shall not be required where listed wireless alarms are installed and all alarms sound upon activation of one alarm.~~

Exception: Interconnection of smoke alarms in existing areas shall not be required where alterations or repairs do not result in removal of interior wall or ceiling finishes exposing the structure, unless there is an attic, crawl space or basement available which could provide access for interconnection without the removal of interior finishes.

R314.1 General. Smoke alarms shall comply with NFPA 72 and Section R314.

R314.1.1 Listings. Smoke alarms shall be listed in accordance with UL 217. Combination smoke/carbon monoxide alarms shall be listed in accordance with UL 217 and UL 2034.

R314.2 Where required. Smoke alarms shall be provided in accordance with this section.

R314.2.1 New construction. Smoke alarms shall be provided in dwelling units.

R314.2.2 Alterations, repairs and additions. When alterations, repairs or additions requiring a permit occur, or when one or more sleeping rooms are added or created in existing dwellings, the individual dwelling unit shall be equipped with smoke alarms located as required for new dwellings.

Exceptions:

1. Work involving the exterior surfaces of dwellings, such as the replacement of roofing or siding, or the addition or replacement of windows or doors, or the addition of a porch or deck, are exempt from the requirements of this section.
2. Installation, alteration or repairs of plumbing or mechanical systems are exempt from the requirements of this section.

R314.3 Location. Smoke alarms shall be installed in the following locations:

1. In each sleeping room.
2. Outside each separate sleeping area in the immediate vicinity of the bedrooms.
3. On each additional story of the dwelling, including basements and habitable attics but not including crawl spaces and uninhabitable attics. In dwellings or dwelling units with split levels and without an intervening door between the adjacent levels, a smoke alarm installed on the upper level shall suffice for the adjacent lower level provided that the lower level is less than one full story below the upper level.

R314.4 Interconnection. Where more than one smoke alarm is required to be installed within an individual dwelling unit in accordance with Section R314.3, the alarm devices shall be interconnected in such a manner that the actuation of one alarm will activate all of the alarms in the individual dwelling unit. Physical interconnection of smoke alarms shall not be required where listed wireless alarms are installed and all alarms sound upon activation of one alarm.

Exception: Interconnection of smoke alarms in existing areas shall not be required where alterations or repairs do not result in removal of interior wall or ceiling finishes exposing the structure, unless there is an attic, crawl space or basement available which could provide access for interconnection without the removal of interior finishes.

R314.5 Combination alarms. Combination smoke/carbon monoxide alarms shall be permitted to be used in lieu of smoke alarms.

R314.6 Power source. Smoke alarms shall receive their primary power from the building wiring where such wiring is served from a commercial source, and when primary power is interrupted, shall receive power from a battery. Wiring shall be permanent and without a disconnecting switch other than those required for overcurrent protection.

Exceptions:

1. Smoke alarms shall be permitted to be battery operated when installed in buildings without commercial power.
2. Smoke alarms installed in accordance with Section R314.2.2 shall be permitted to be battery powered.

R314.7 Fire alarm systems. Fire alarm systems shall be permitted to be used in lieu of smoke alarms and shall comply with Sections R314.7.1 through R315.7.4.

R314.7.1 General. Fire alarm systems shall comply with the provisions of this code and the household fire warning equipment provisions of NFPA 72. Smoke detectors shall be listed in accordance with UL 268.

R314.7.2 Location. Smoke detectors shall be installed in the locations specified in Section R314.3.

R314.7.3 Permanent fixture. Where a household fire alarm system is installed, it shall become a permanent fixture of the occupancy, owned by the homeowner and shall be monitored by an approved supervising station.

R314.7.4 Combination detectors. Combination smoke/carbon monoxide detectors shall be permitted to be installed in fire alarm systems in lieu of smoke detectors, provided they are listed in accordance with UL 268 and UL 2075.

Reason: This proposal is submitted by the ICC Building Code Action Committee (BCAC) and the ICC Fire Code Action Committee (FCAC). These ICC committees were established by the ICC Board of Directors to pursue opportunities to improve and enhance an assigned International Codes or portion thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the these committees have held 6 open meetings and numerous workgroup meetings which included members of the committees as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the CAC website at: <http://www.iccsafe.org/cs/CAC/Pages/default.aspx>.

This proposal reformats the Section R314 smoke alarm requirements in a more logical order. It is not the intent of this proposal to increase or lessen the overall smoke alarm requirements. The format for this section is similar to one used on a companion proposal to the Section R315 carbon monoxide alarm requirements. Comments on the origin of specific requirements in this proposal are as follows:

1. R314.1 is a new simplified charging paragraph for the section. The UL 217 Listing requirement was moved to R314.1.1. The reference to NFPA 72 was moved to R314.7.1.
2. R314.1.1 includes new provisions to allow combination smoke/carbon monoxide alarms, if they are provided, to be listed in accordance with UL 217 and UL 2034.
3. R314.2 includes requirements for new construction and alterations and repairs. The section includes editorial revisions, but no substantive changes to existing requirements. R314.2.1 requirements are identical to existing R314.3.1 requirements.
4. The R314.3 location requirements are unchanged.
5. R314.4 requirements for interconnection are identical to the existing requirements in R314.5.
6. R314.5 allows listed combination smoke/carbon monoxide alarms to be used in lieu of smoke alarms. A companion change to allow these units to be used in lieu of carbon monoxide alarms is also being proposed for Section R315. If both

of these proposals are accepted, a single combination unit can be installed outside of each separate sleeping area in the immediate vicinity of the bedrooms and comply with R314 and R315 requirements.

7. R314.6 includes power supply requirements that are equivalent to the current power supply requirements in R314.4. There should be no changes for the applications under which permanently connected or battery operated smoke alarms are required.
8. R314.7 includes revised requirements for smoke detection systems. Sections R314.7.1 through R314.7.3 include requirements that are equivalent to existing R314.2 requirements.
9. R314.7.4 includes new requirements that allow the option to use combination smoke/carbon monoxide detectors.

Cost Impact: These revisions have the potential to reduce the cost of construction.

R314.2, R315.2

Proponent: Charles S. Bajnai, Chesterfield County, VA, ICC Building Code Action Committee and Virginia Building and Code Officials Association (bajnaic@chesterfield.gov), and Adolf Zubia, Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee

Revise as follows:

R314.2 Smoke detection systems. Household fire alarm systems installed in accordance with NFPA 72 that include smoke alarms, or a combination of smoke detector and audible notification device installed as required by this section for smoke alarms, shall be permitted. The household fire alarm system shall provide the same level of smoke detection and alarm as required by this section for smoke alarms. Where a household fire warning system is installed using a combination of smoke detector and audible notification device(s), it shall become a permanent fixture of the occupancy and owned by the homeowner. ~~The system shall be monitored by an approved supervising station and be maintained in accordance with NFPA 72.~~

Exception: Where smoke alarms are provided meeting the requirements of Section R314.4.

R315.2 Carbon monoxide detection systems. Carbon monoxide detection systems that include carbon monoxide detectors and audible notification appliances, installed and maintained in accordance with this section for carbon monoxide alarms and NFPA 720, shall be permitted. The carbon monoxide detectors shall be listed as complying with UL 2075. Where a household carbon monoxide detection system is installed, it shall become a permanent fixture of the occupancy, and owned by the homeowner. ~~and shall be monitored by an approved supervising station.~~

Exception: Where carbon monoxide alarms are installed meeting the requirements of Section R315.1, compliance with Section 315.2 is not required.

Reason: This proposal is submitted by the ICC Building Code Action Committee (BCAC) and the ICC Fire Code Action Committee (FCAC). These ICC committees were established by the ICC Board of Directors to pursue opportunities to improve and enhance an assigned International Codes or portion thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the these committees have held 6 open meetings and numerous workgroup meetings which included members of the committees as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the CAC website at: <http://www.iccsafe.org/cs/CAC/Pages/default.aspx>.

The code requires smoke alarms and carbon monoxide alarms to be installed in the dwelling, or allows smoke detection systems and carbon monoxide detection systems to be provided in lieu of individual alarms to provide the desired protection. These systems need to be a permanent fixture of the occupancy and owned by the homeowner. This is because the systems could be leased to the homeowner by an alarm company. If the homeowner discontinued service with the alarm company there is nothing to prevent them from removing the system from the premise. Then the home would be left with no protection.

It is difficult to justify requiring these systems to be monitored by an approved supervising station, as long as they provide local alarm notification. In addition Section 907.7.5 does not require monitoring of an automatic sprinkler system in one- and two-family dwellings. However there is nothing that prohibits these systems from being monitored.

In addition the reference in R314.2 to systems being maintained in accordance with NFPA 72 is being removed since the scope of the IRC does not cover maintenance of systems.

Cost Impact: The proposal has the potential to reduce costs.

R314.3.1 (New) and R314.3.2 (New)

Proponent: Charles S. Bajnai, Chesterfield County, VA, ICC Building Code Action Committee (bajnaic@chesterfield.gov), and Adolf Zubia, Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee

Add new text as follows:

R314.3.1 Installation near cooking appliances. Smoke alarms shall not be installed in the following locations unless this would prevent placement of a smoke alarm in a location required by Section R314.3.

1. Ionization smoke alarms shall not be installed less than 20 feet (6.1 m) horizontally from a permanently installed cooking appliance.
2. Ionization smoke alarms with an alarm-silencing switch shall not be installed less than 10 feet (3 m) horizontally from a permanently installed cooking appliance.
3. Photoelectric smoke alarms shall not be installed less than 6 feet (1.8 m) horizontally from a permanently installed cooking appliance.

R314.3.2 Installation near bathrooms. Smoke alarms shall be installed not less than 3 feet (0.91 m) horizontally from the door or opening of a bathroom that contains a bathtub or shower unless this would prevent placement of a smoke alarm required by Section R314.3.

Reason: This proposal is submitted by the ICC Building Code Action Committee (BCAC) and the ICC Fire Code Action Committee (FCAC). These ICC committees were established by the ICC Board of Directors to pursue opportunities to improve and enhance an assigned International Codes or portion thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the these committees have held 6 open meetings and numerous workgroup meetings which included members of the committees as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the CAC website at: <http://www.iccsafe.org/cs/CAC/Pages/default.aspx>

This proposal is intended to reduce nuisance alarms attributed to locating smoke alarms in close proximity to cooking appliances and bathrooms in which steam is produced. The proposed provisions are based on the findings in the Task Group Report - Minimum Performance Requirements for Smoke Alarm Detection Technology - February 22, 2008, and are consistent with similar requirements included in Section 29.8.3.4 of the 2010 and 2013 editions of NFPA 72.

Cost Impact: None.

RB156-13

Public Hearing:	Committee: AS	AM	D

R314.3.1 (NEW)-RB-BAJNAI-ZUBIA

RB157 – 13

R314.3.1

Proponent: Rick Davidson, City of Maple Grove, Association of Minnesota Building Officials
(rdavidson@maplegrovern.gov)

Revise as follows:

R314.3.1 Alterations, repairs and additions. When *alterations*, repairs or *additions* requiring a *permit* occur, or when one or more sleeping rooms are added or created in existing *dwellings*, the individual *dwelling unit* shall be equipped with smoke alarms located as required for new *dwellings*.

Exceptions:

- ~~1. Work involving the exterior surfaces of *dwellings*, such as the replacement of roofing or siding, or the *addition* or replacement of windows or doors, or the *addition* of a porch or deck, are exempt from the requirements of this section.~~
- ~~2. Installation, *alteration* or repairs of plumbing or mechanical systems are exempt from the requirements of this section.~~
 1. Addition, replacement or repair of windows or doors.
 2. Replacement or repair of roofing, siding, masonry, stucco, or other exterior surfaces.
 3. Additions of or repairs to porches, decks, or balconies.
 4. Work involving detached accessory structures.
 5. Installation of retaining walls or fences.
 6. Installation, repair, or alteration of plumbing, mechanical, or electrical systems that occurs on the exterior of the dwelling or in an accessory structure.
 7. Installation, alteration or repairs of plumbing or mechanical systems within a dwelling unit.

Reason: It is necessary to more definitively identify those circumstances when smoke alarms are not required when alterations, repairs and additions occur because of confusion within the code enforcement community over the current language. The same revision is proposed for the CO alarm section.

For example, if smoke alarms need not be installed when a home is reroofed, are they required when someone builds a storage shed in their back yard? Current language does not seem to exempt such work.

Cost Impact: None

RB157-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R314.3.1-RB-DAVIDSON

RB158 – 13

R314.3.1

Proponent: Tim Pate, City and County of Broomfield, CO representing the Colorado Chapter Code Change Committee

Revise as follows:

R314.3.1 Alterations, repairs and additions. When alterations, repairs or additions requiring a permit occur, or when one or more sleeping rooms are added or created in existing dwellings, the individual dwelling unit shall be equipped with smoke alarms located as required for new dwellings.

Exceptions:

1. Work involving the exterior surfaces of dwellings, such as the replacement of roofing or siding, ~~or the addition or replacement of windows or doors~~, or the addition of a porch or deck, are exempt from the requirements of this section.
2. Installation, *alteration* or repairs of plumbing or mechanical systems are exempt from the requirements of this section.

Reason: This code change will effectively require that smoke alarms be installed for all permits for window changeouts and for permits to add windows or doors. These two types of permits actually require part of the work to be done on both the exterior and the interior and therefore should be classified as an interior alteration. Adding smoke alarms to existing houses is a relatively inexpensive task considering that section R314 for the most part allows these smoke alarms to be battery operated. There is considerable evidence that houses with smoke alarms save lives in the cases of fire.

Cost Impact: This code change will increase the cost of construction.

R314.3.1-RB-PATE

RB159 – 13

R314.5 (New)

Proponent: Thomas P. Hammerberg, representing Automatic Fire Alarm Association
(TomHammerberg@afaa.org)

Add new text as follows:

R314.5. Residential Sprinkler Monitoring. Where a Residential Sprinkler System is installed, a sprinkler waterflow alarm-initiating device shall be permitted to be connected to the multiple-station alarm or household fire alarm system to activate an alarm signal.

Reason: This language is currently used in NFPA-72-2013, 29.7.7.7.3. The purpose is to provide notification to occupants of waterflow activation. If a sprinkler activates in another part of the dwelling unit, this provides earlier warning of the fire situation and will allow additional time to leave the premises. Since the time to escape has reduced significantly in recent years, this will improve fire safety for the occupants.

Cost Impact: Minimal

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R314.5 (NEW)-RB-HAMMERBERG

RB160 – 13

R315

Proponent: Charles S. Bajnai, Chesterfield County, VA, ICC Building Code Action Committee (bajnaic@chesterfield.gov), and Adolf Zubia, Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee

Delete and substitute as follows:

SECTION R315 CARBON MONOXIDE ALARMS

~~R315.1 Carbon monoxide alarms.~~ For new construction, an approved carbon monoxide alarm shall be installed outside of each separate sleeping area in the immediate vicinity of the bedrooms in *dwelling units* within which fuel-fired *appliances* are installed and in dwelling units that have attached garages.

~~R315.2 Carbon monoxide detection systems.~~ Carbon monoxide detection systems that include carbon monoxide detectors and audible notification appliances, installed and maintained in accordance with this section for carbon monoxide alarms and NFPA 720, shall be permitted. The carbon monoxide detectors shall be listed as complying with UL 2075. Where a household carbon monoxide detection system is installed, it shall become a permanent fixture of the occupancy, owned by the homeowner and shall be monitored by an approved supervising station.

~~Exception:~~ Where carbon monoxide alarms are installed meeting the requirements of Section R315.1, compliance with Section 315.2 is not required.

~~R315.3 Where required in existing dwellings.~~ Where work requiring a *permit* occurs in existing *dwellings* that have attached garages or in existing dwellings within which fuel-fired *appliances* exist, carbon monoxide alarms shall be provided in accordance with Section R315.1.

~~R315.4 Alarm requirements.~~ Single-station carbon monoxide alarms shall be listed as complying with UL 2034 and shall be installed in accordance with this code and the manufacturer's installation instructions.

R315.1 General. Carbon monoxide alarms shall comply with Section R315.

R315.1.1 Listings. Carbon monoxide alarms shall be listed in accordance with UL 2034. Combination carbon monoxide/smoke alarms shall be listed in accordance with UL 2034 and UL 217.

R315.2 Where required. Carbon monoxide alarms shall be provided in accordance with this section.

R315.2.1 New construction. Carbon monoxide alarms shall be provided in dwelling units when either or both of the following conditions exist.

1. The dwelling unit contains a fuel-fired appliance.
2. The dwelling unit has an attached garage with an opening that communicates with the dwelling unit.

R315.2.2 Alterations, repairs and additions. When alterations, repairs or additions requiring a permit occur, or when one or more sleeping rooms are added or created in existing dwellings, the individual dwelling unit shall be equipped with carbon monoxide alarms located as required for new dwellings.

Exceptions:

1. Work involving the exterior surfaces of dwellings, such as the replacement of roofing or siding, or the addition or replacement of windows or doors, or the addition of a porch or deck, are exempt from the requirements of this section.
2. Installation, alteration or repairs of plumbing or mechanical systems are exempt from the requirements of this section.

R315.3 Location. Carbon monoxide alarms in dwelling units shall be installed outside of each separate sleeping area in the immediate vicinity of the bedrooms. When a fuel-burning appliance is located within a bedroom or its attached bathroom, a carbon monoxide alarm shall be installed within the bedroom.

R315.4 Combination alarms. Combination carbon monoxide/smoke alarms shall be permitted to be used in lieu of carbon monoxide alarms.

R315.5 Power source. Carbon monoxide alarms shall receive their primary power from the building wiring when such wiring is served from a commercial source, and when primary power is interrupted, shall receive power from a battery. Wiring shall be permanent and without a disconnecting switch other than those required for overcurrent protection.

Exceptions:

1. Carbon monoxide alarms shall be permitted to be battery operated when installed in buildings without commercial power.
2. Carbon monoxide alarms installed in accordance with Section R315.2.2 shall be permitted to be battery powered.

R315.6 Carbon monoxide detection systems. Carbon monoxide detection systems shall be permitted to be used in lieu of carbon monoxide alarms and shall comply with Sections R315.6.1 to R315.6.4.

R315.6.1 General. Household carbon monoxide detection systems shall comply with NFPA 720. Carbon monoxide detectors shall be listed in accordance with UL 2075.

R315.6.2 Location. Carbon monoxide detectors shall be installed in the locations specified in Section R315.3. These locations supersede the locations specified in NFPA 720.

R315.6.3 Permanent fixture. Where a household carbon monoxide detection system is installed, it shall become a permanent fixture of the occupancy, owned by the homeowner and shall be monitored by an approved supervising station.

R315.6.4 Combination detectors. Combination carbon monoxide/smoke detectors shall be permitted to be installed in carbon monoxide detection systems in lieu of carbon monoxide detectors, provided they are listed in accordance with UL 2075 and UL 268.

Reason: This proposal is submitted by the ICC Building Code Action Committee (BCAC) and the ICC Fire Code Action Committee (FCAC). These ICC committees were established by the ICC Board of Directors to pursue opportunities to improve and enhance an assigned International Codes or portion thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the these committees have held 6 open meetings and numerous workgroup meetings which included members of the committees as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the CAC website at: <http://www.iccsafe.org/cs/CAC/Pages/default.aspx>.

This proposal clarifies requirements for the installation of CO alarm and CO detection systems as follows:

1. Section R315 was reorganized to provide requirements in a more logical location. Except as noted below no technical changes were made to the existing requirements.
2. Listed combination carbon monoxide/smoke alarms, and combination carbon monoxide /smoke detectors are readily available on the market. This proposal identifies the UL standards used to List these products, and allows them to be used in lieu of carbon monoxide alarms and detectors. A companion change to allow these units to be used in lieu of

smoke alarms and smoke detectors is being proposed for Section R314. If both of these proposals are accepted, a single combination unit can be installed outside of each separate sleeping area in the immediate vicinity of the bedrooms and comply with R314.3 (2) and R315.3 (above).

3. Current Section R315.1 requires carbon monoxide alarms to be provided in dwelling units with attached garages. Carbon monoxide is most likely to enter a dwelling from an attached garage if there is a communicating opening between the garage and dwelling. Some homes with attached garages do not have a communicating opening. Accordingly, proposed Section R315.2.1, item 2, only requires carbon monoxide alarms when the dwelling unit has an attached garage with an opening that communicates with the dwelling unit.
4. Current Section R315.3 requires CO alarms to be installed in existing dwellings whenever any kind of work that requires a permit is conducted, such as reroofing or adding a deck. Proposed section R315.2.2 reflects the more realistic requirements for providing carbon monoxide alarms in existing dwelling units to match the triggers used to require smoke alarms in existing dwelling units that are included in Section R314.3.1. In addition Section R315.5(2) only requires these alarms to be battery powered.
5. The IRC allows fuel burning appliances to be installed in bedrooms and bathrooms, but this is not a common practice. Section R315.3 requires carbon monoxide alarms to be installed in a bedroom when it or its attached bathroom contains a fuel burning appliance. This protects occupants who sleep with their bedroom door closed.
6. R315.5 clarifies the requirements for powering CO alarms that is consistent with R314.4 smoke alarm requirements.
7. The carbon monoxide detection system requirements have been moved from Section R315.2 to proposed Sections R315.6 through R315.6.2. The basic requirements for these systems are unchanged, but additional language was added to clarify that:
 - a. These systems can be used in lieu of carbon monoxide alarms.
 - b. All devices and equipment in the system must be listed for their intended purpose (see NFPA 720, section 9.3.1)
 - c. Combination carbon monoxide/smoke detectors can be used.
 - d. Detectors only need to be installed in locations specified in section R315.3, not in all locations specified in NFPA 720.

The code requires smoke alarms and carbon monoxide alarms to be installed in the dwelling, but allows smoke detection systems and carbon monoxide detection systems to be provided in lieu of individual alarms to provide the desired protection. These systems need to be a permanent fixture of the occupancy and owned by the homeowner. This is because the systems could be leased to the homeowner by an alarm company. If the homeowner discontinued service with the alarm company there is nothing to prevent them from removing the system from the premise. Then the home would be left with no protection.

It is difficult to justify requiring these systems to be monitored by an approved supervising station, provided they provide local alarm notification. In addition Section 907.7.5 does not require monitoring of an automatic sprinkler system in one- and two-family dwellings. However there is nothing that prohibits these systems from being monitored.

In addition the reference in R314.2 to systems being maintained in accordance with NFPA 72 is being removed since the scope of the IRC does not cover maintenance of systems.

Cost Impact: These revisions have the potential to reduce the cost of construction.

RB160-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R315.1-RB-BAJNAI-ZUBIA-BCAC

RB161 – 13

R315.3

Proponent: Jerry Anderson, City of Overland Park, Ks, representing self (jerry.anderson@opkansas.org)

Revise as follows:

R315.3 Where required in existing dwellings. Where work requiring a permit occurs in existing dwellings that have attached garages or in existing dwellings within which fuel fired appliances exist, carbon monoxide alarms shall be provided in accordance with Section R315.1.

Exceptions:

1. Work involving the exterior surfaces of dwellings, such as the replacement of roofing or siding, or the addition or replacement of windows or doors, or the addition of a porch or deck, are exempt from the requirements of this section.
2. Installation, alteration or repairs of plumbing or mechanical systems are exempt from the requirements of this section.

Reason: The purpose of the code change is to exempt some minor work from triggering carbon monoxide detectors. The exceptions to the base requirement for installing carbon monoxide detectors in existing dwellings are exactly the same as found in section R314.3.1 for smoke detectors. This change will make the code consistent in its approach in providing early warning detection devices in dwellings. It is unreasonable require the installation of carbon monoxide detectors for any work that is done on an existing dwelling.

Cost Impact: No cost associated with this change

RB161-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R315.3-RB-ANDERSON

RB162 – 13

R315.3

Proponent: Rick Davidson, City of Maple Grove, Association of Minnesota Building Officials
(rdavidson@maplegrovern.gov)

Revise as follows:

R315.3 Where required in existing dwellings. Where work requiring a *permit* occurs in an existing *dwellings* that ~~have~~ has an attached garages or in an existing dwellings within which fuel fired *appliances* exist, carbon monoxide alarms shall be provided in accordance with Section R315.1.

Exceptions:

1. Addition, replacement or repair of windows or doors.
2. Replacement or repair of roofing, siding, masonry, stucco, or other exterior surfaces.
3. Additions of or repairs to porches, decks, or balconies.
4. Work involving detached accessory structures.
5. Installation of retaining walls or fences.
6. Installation, repair, or alteration of plumbing, mechanical, or electrical systems that occurs on the exterior of the dwelling or in an accessory structure.
7. Installation, alteration, or repairs of plumbing, mechanical, or electrical systems not involving a fuel fired appliance.

Reason: Given the low number of deaths caused by CO poisoning compared to injuries and deaths caused by falls, fires, and other household accidents, the current rules regarding CO alarms are overly restrictive. Without exception, the code requires CO alarms be installed in a dwelling even when a permit is issued for a such mundane exterior work as retaining wall! This means homeowners must provide access to the interior of their homes to contractors and inspectors to install and inspect CO alarms (but not smoke alarms). Bluntly, this is ridiculous. The proposed revisions create a number of exceptions when CO alarms need not be installed. Unless some relief is given for exterior and other work that does not involve directly the ability to install CO alarms, permits will never get final inspections completed in a timely manner and building departments will be faced with a huge backlog of open permits.

Some folks will argue that the text says CO alarms are only required when work occurs "in" existing dwellings meaning exterior work is exempt. I might agree except the language used for CO alarms is the same used for smoke alarms and we seem to agree, based on exceptions in the code, that exterior work would trigger the smoke alarm requirements unless we have the exceptions. So if the text means one thing in one section, we conclude the same text means the same thing in another section.

R314.3.1 Alterations, repairs and additions. When *alterations, repairs or additions* requiring a *permit* occur, or when one or more sleeping rooms are added or created in existing *dwellings*, the individual *dwelling unit* shall be equipped with smoke alarms located as required for new *dwellings*.

Exceptions:

1. Work involving the exterior surfaces of *dwell-ings*, such as the replacement of roofing or siding, or the *addition* or replacement of windows or

Cost Impact: None

RB163 – 13

R316.3

Proponent: Vytenis Babrauskas, PhD, Fire Science & Technology Inc., representing The American Institute of Architects, Cascadia Green Building Council, Development Center for Appropriate Technology, Green Science Policy Institute, Hammond Fine Homes, International Living Future Institute, Perkins + Will, San Francisco Firefighters Cancer Prevention Foundation and the United States Green Building Council of California

Revise as follows:

R316.3 Surface burning characteristics. Unless otherwise allowed in R316.5 or 316.6, all foam plastic or foam plastic cores used as a component in manufactured assemblies used in building construction shall have a flame spread index of not more than 75 and shall have a smoke-developed index of not more than 450 when tested in the maximum thickness intended for use in accordance with ASTM E 84 or UL 723. Loose-fill-type foam plastic insulation shall be tested as board stock for the flame spread index and smoke-developed index.

Exception Exceptions:

1. Foam plastic insulation more than 4 inches (102 mm) thick shall have a maximum flame spread index of 75 and a smoke-developed index of 450 where tested at a minimum thickness of 4 inches (102 mm), provided the end use is *approved* in accordance with Sections R316.6 using the thickness and density intended for use.
2. Foam plastic insulation shall not be subject to this requirement where installed with a thermal barrier in accordance with Section R316.4.

Reason: This proposal addresses a material performance requirement currently in the code which is not supported by available evidence from fire science research. Removal of the performance requirement as proposed would provide choice for manufacturers and consumers by allowing foam plastic insulation materials without flame retardants to be used in compliance with the code in a fire safe way. This would result in a healthier product at a lower cost.

The proposed change considers fire safety, public health, fire fighter and emergency responder safety, and energy efficiency. It is not a tradeoff among them, and improves them in many ways relevant to the current code requirements as described below and in the Substantiation Section.

For applications in which foam plastics are required to meet flame spread and smoke developed requirements of R316.3 and to be separated from interior spaces by an approved thermal barrier per R316.4, research and testing conducted over many years demonstrate the following:

It is the approved thermal barrier and the fireblocking required by the code that provide the fire safety related to foam plastic insulation, not its meeting the required flame spread and smoke developed ratings of R316.3. Even when foam plastic insulation meets the requirements of R316.3, if it is not protected by a thermal barrier it still poses an unacceptable level of fire hazard (Babrauskas et al., 2012).

In order to meet the flame spread and smoke developed requirements of R316.3, flame retardant chemicals are added to foam plastic insulations.

The two most common flame retardants used, hexabromocyclododecane (HBCD or HBCDD) and Tris (1-chloro-2-propyl) phosphate (TCPP), add potential risks throughout the product life cycle. These include environmental pollution, fire toxicity and possible adverse health effects for building occupants, fire service professionals, and the general public (Babrauskas et al., 2012). These chemicals are added only to meet flame spread and smoke developed requirements; they do not prevent foam plastics from burning.

Thermal barriers prevent temperature rise and adequately protect foam plastic insulation from igniting during a fire. Fire statistics show very few fires, no fire deaths and very few injuries attributable to fire started or spread by insulation within structural areas (Ahrens, 2011).

A precedent for a similar approach exists in Sweden where foam plastic insulation without flame retardants is used with code mandated protection by fire safe materials and construction (Blomqvist, McNamee, & Thureson, 2011; Lassen, Maag, Høibye, Vesterlykke, & Lundegaard, 2011; POPRC, 2011; Posner, Roos, & Olsson, 2010). Since the transition to non-flame retardant foam, there has been no detrimental impact on fire safety statistics in Sweden (Harrami & McIntyre, 2006; Lundqvist, McIntyre, & Hedman, 2008; Remberger et al., 2004).

In light of the available evidence, changing the code as proposed could:

- reduce and prevent harm from flame retardants without resulting in a reduction in fire safety,
- better align with the intent of the codes to establish "minimum requirements to safeguard the public safety, health and general welfare" and to provide "safety to fire fighters and emergency responders during emergency operations (R101.3)," and
- increase use of foam plastic insulations which are important for building energy efficiency by decreasing cost and by allowing flame-retardant free materials to be used in a code-compliant way for those concerned about flame retardant chemicals.

Substantiation: A thermal barrier meets the criteria of NFPA 275 by preventing the energy of a fire from reaching the foam. Specifically, NFPA 275 states that after 15 minutes of a post-flashover fire, the temperature at the interface of the thermal barrier and foam cannot exceed 121°C average with 163°C at one peak value thermocouple. This is substantially below the auto-ignition temperature of plastic foams, which are in excess of 400°C for polystyrene and polyurethane (Babrauskas, 2003).

Due to protection by thermal barriers, fire statistics show that insulation very rarely starts or spreads home fires. Insulation within a structural area was the item first ignited in 2% of US home structure fires, resulting in 10 civilian deaths and 90 civilian injuries (0% and 1% of the death and injury totals for the whole US, respectively). Insulation within a structural area was the primary item contributing to flame spread in 2% of US home structure fires, resulting in 0 civilian deaths and 40 injuries (0% and 1% of the death and injury totals for the whole US, respectively) (Ahrens, 2011).

HBCD and TCPP are added to foam plastics to meet flame spread and smoke developed requirements. 90% percent of HBCD and 86% of TCPP produced is used for building insulation (EC, 2008; Env Can, 2012; US EPA, 2010). Both chemicals are now widespread global contaminants (Covaci et al., 2006; Marvin et al., 2011; Van der Veen & de Boer, 2012). The presence of flame retardant chemicals can significantly increase the toxicity of fires when materials burn (Stec & Hull, 2011). Materials with flame retardants can produce greater amounts of carbon monoxide, smoke, and soot, compared to non-flame retardant materials (Babrauskas, 1992; Purser, 2000; Schnipper, Smith-Hansen, & Thomsen, 1995; Wichman, 2003). When HBCD burns, it produces dioxins, which are potentially carcinogenic (Birnbaum, Staskal, & Diliberto, 2003; Desmet, Schelfaut, & Sandra, 2005; Ebert & Bahadir, 2003). Firefighters have higher rates of cancers associated with dioxin exposure (IARC, 2010; LeMasters et al., 2006).

Canada and the European Union have scheduled HBCD to be phased out in the next 3-4 years (EC, 2011; Env Can, 2012). The US Environmental Protection Agency states that the chemical is

“...persistent in the environment, bioaccumulative in living organisms, and highly toxic to aquatic organisms.”
and

“Human exposure is evidenced by the presence of HBCD in breast milk, adipose tissue, and blood, and it biomagnifies in the food chain. HBCD presents human health concerns based on animal test results indicating potential reproductive, developmental, and neurological effects. People may be exposed to HBCD from products and dust in the home and workplace, as well as its presence in the environment.”
(US EPA, 2012)

Less is known about TCPP but concerns include its persistence in the environment, human exposure, and the potential to cause cancer (Van der Veen & De Boer, 2012).

Sweden uses the Eurocode classification system to rate the combustibility of building components including foam plastic insulation. Foam plastics are classified as combustible, and thus building codes specify how these materials can be used in fire safe ways, such as behind thermal barriers, concrete or masonry, and with other construction techniques (Blomqvist et al., 2011; Lassen et al., 2011; POPRC, 2011; Posner et al., 2010). Since non-flame retardant foam plastics have been used in Sweden, building fires and deaths from building fires have not increased, indicating that fire safety is maintained by the code mandated measures (Harrami & McIntyre, 2006; Lundqvist et al., 2008; Remberger et al., 2004).

From IRC Section R101.3 Intent:

The purpose of this code is to establish minimum requirements to safeguard the public safety, health and general welfare through affordability, structural strength, means of egress facilities, stability, sanitation, light and ventilation, energy conservation and safety to life and property from fire and other hazards attributed to the built environment and to provide safety to fire fighters and emergency responders during emergency operations.

From IRC Section R316.4 Thermal Barrier:

Unless otherwise allowed in Section R316.5 or Section R316.6, foam plastic shall be separated from the interior of a building by an *approved* thermal barrier of minimum 1/2 inch (12.7 mm) gypsum wallboard or a material that is tested in accordance with and meets the acceptance criteria of both the Temperature Transmission Fire Test and the Integrity Fire Test of NFPA 275.

R316.3 #1-RB-BABRAUSKAS

RB164 – 13

R316.3

Proponent: Vytenis Babrauskas, PhD, Fire Science & Technology Inc., representing The American Institute of Architects, Cascadia Green Building Council, Development Center for Appropriate Technology, Green Science Policy Institute, Hammond Fine Homes, International Living Future Institute, Perkins + Will, San Francisco Firefighters Cancer Prevention Foundation, the United States Green Building Council of California

Revise as follows:

R316.3 Surface burning characteristics. Unless otherwise allowed in R316.5 or 316.6, all foam plastic or foam plastic cores used as a component in manufactured assemblies used in building construction shall have a flame spread index of not more than 75 and shall have a smoke-developed index of not more than 450 when tested in the maximum thickness intended for use in accordance with ASTM E 84 or UL 723. Loose-fill-type foam plastic insulation shall be tested as board stock for the flame spread index and smoke-developed index.

Exception Exceptions:

1. Foam plastic insulation more than 4 inches (102 mm) thick shall have a maximum flame spread index of 75 and a smoke-developed index of 450 where tested at a minimum thickness of 4 inches (102 mm), provided the end use is *approved* in accordance with Sections R316.6 using the thickness and density intended for use.
2. Foam plastic insulation shall not be subject to this requirement when used in a wall, floor, foundation or roof assembly where the foam plastic insulation is separated from the interior of the building by a minimum 1-inch (25 mm) thickness of masonry or concrete.

Reason: This proposal addresses a material performance requirement currently in the code which is not supported by available evidence from fire science research. Removal of the performance requirement as proposed would provide choice for manufacturers and consumers by allowing foam plastic insulation materials without flame retardants to be used in compliance with the code in a fire safe way. This would result in a healthier product at a lower cost.

The proposed change considers fire safety, public health, fire fighter and emergency responder safety, and energy efficiency. It is not a tradeoff among them, and improves them in many ways relevant to the current code requirements as described below and in the Substantiation Section.

For applications in which foam plastics are required to meet flame spread and smoke developed requirements of R316.3 and to be separated from interior spaces by an approved thermal barrier per R316.4, research and testing conducted over many years demonstrate the following:

It is the thermal barrier and the fireblocking required by the code that provide the fire safety related to foam plastic insulation, not its meeting the required flame spread and smoke developed ratings of R316.3. Even when foam plastic insulation meets the requirements of R316.3, if it is not protected by a thermal barrier it still poses an unacceptable level of fire hazard (Babrauskas et al., 2012).

In order to meet the flame spread and smoke developed requirements of R316.3, flame retardant chemicals are added to foam plastic insulations.

The two most common flame retardants used, hexabromocyclododecane (HBCD or HBCDD) and Tris (1-chloro-2-propyl) phosphate (TCPP), add potential risks throughout the product life cycle. These include environmental pollution, fire toxicity and possible adverse health effects for building occupants, fire service professionals, and the general public (Babrauskas et al., 2012). These chemicals are added only to meet flame spread and smoke developed requirements; they do not prevent foam plastics from burning.

Thermal barriers prevent temperature rise and adequately protect foam plastic insulation from igniting during a fire. Fire statistics show very few fires, no fire deaths and very few injuries attributable to fire started or spread by insulation within structural areas (Ahrens, 2011).

The Commentary for the 2012 IRC for Section R316.5.1 Masonry or concrete construction states: "No thermal barrier is required when 1 inch (25 mm) or more of masonry or concrete is placed between the foam plastic and the interior of the building. The intent is to accept 1-inch (25 mm) of masonry or concrete as adequate protection against ignition, even though the concrete does not necessarily meet the performance criteria for thermal barriers."

This suggests that when foam plastic is separated from the interior of a building by minimum 1-inch (25mm) concrete or masonry, the flame spread and smoke developed requirements are not needed.

A precedent for a similar approach exists in Sweden where foam plastic insulation without flame retardants is used with code mandated protection by fire safe materials and construction (Blomqvist, McNamee, & Thureson, 2011; Lassen, Maag, Høiby, Vesterlykke, & Lundegaard, 2011; POPRC, 2011; Posner, Roos, & Olsson, 2010). Since the transition to non-flame retardant foam,

there has been no detrimental impact on fire safety statistics in Sweden (Harrami & McIntyre, 2006; Lundqvist, McIntyre, & Hedman, 2008; Remberger et al., 2004).

In light of the available evidence, changing the code as proposed could:

- reduce and prevent harm from flame retardants without resulting in a reduction in fire safety,
- better align with the intent of the codes to establish "minimum requirements to safeguard the public safety, health and general welfare" and to provide "safety to fire fighters and emergency responders during emergency operations (R101.3)," and
- increase use of foam plastic insulations which are important for building energy efficiency by decreasing cost and by allowing flame-retardant free materials to be used in a code-compliant way for those concerned about flame retardant chemicals.

Substantiation: 1 inch (25 mm) or greater of concrete or masonry protects foam plastic from ignition in the same way as a thermal barrier which meets the criteria of NFPA 275- by preventing the energy of a fire from reaching the foam. Specifically, NFPA 275 states that after 15 minutes of a post-flashover fire, the temperature at the interface of the thermal barrier and foam cannot exceed 121°C average with 163°C at one peak value thermocouple. This is substantially below the auto-ignition temperature of plastic foams, which are in excess of 400°C for polystyrene and polyurethane (Babrauskas, 2003). As stated in the Commentary, concrete or masonry also has these characteristics.

Due to protection by thermal barriers, fire statistics show that insulation very rarely starts or spreads home fires. Insulation within a structural area was the item first ignited in 2% of US home structure fires, resulting in 10 civilian deaths and 90 civilian injuries (0% and 1% of the death and injury totals for the whole US, respectively). Insulation within a structural area was the primary item contributing to flame spread in 2% of US home structure fires, resulting in 0 civilian deaths and 40 injuries (0% and 1% of the death and injury totals for the whole US, respectively) (Ahrens, 2011).

HBCD and TCPP are added to foam plastics to meet flame spread and smoke developed requirements. 90% percent of HBCD and 86% of TCPP produced is used for building insulation (EC, 2008; Env Can, 2012; US EPA, 2010). Both chemicals are now widespread global contaminants (Covaci et al., 2006; Marvin et al., 2011; Van der Veen & de Boer, 2012). The presence of flame retardant chemicals can significantly increase the toxicity of fires when materials burn (Stec & Hull, 2011). Materials with flame retardants can produce greater amounts of carbon monoxide, smoke, and soot, compared to non-flame retardant materials (Babrauskas, 1992; Purser, 2000; Schnipper, Smith-Hansen, & Thomsen, 1995; Wichman, 2003). When HBCD burns, it produces dioxins, which are potentially carcinogenic (Birnbaum, Staskal, & Diliberto, 2003; Desmet, Schelfaut, & Sandra, 2005; Ebert & Bahadir, 2003). Firefighters have higher rates of cancers associated with dioxin exposure (IARC, 2010; LeMasters et al., 2006).

Canada and the European Union have scheduled HBCD to be phased out in the next 3-4 years (EC, 2011; Env Can, 2012). The US Environmental Protection Agency states that the chemical is

"...persistent in the environment, bioaccumulative in living organisms, and highly toxic to aquatic organisms."

and

"Human exposure is evidenced by the presence of HBCD in breast milk, adipose tissue, and blood, and it biomagnifies in the food chain. HBCD presents human health concerns based on animal test results indicating potential reproductive, developmental, and neurological effects. People may be exposed to HBCD from products and dust in the home and workplace, as well as its presence in the environment."

(US EPA, 2012)

Less is known about TCPP but concerns include its persistence in the environment, human exposure, and the potential to cause cancer (Van der Veen & De Boer, 2012).

Sweden uses the Eurocode classification system to rate the combustibility of building components including foam plastic insulation. Foam plastics are classified as combustible, and thus building codes specify how these materials can be used in fire safe ways, such as behind thermal barriers, concrete or masonry, and with other construction techniques (Blomqvist et al., 2011; Lassen et al., 2011; POPRC, 2011; Posner et al., 2010). Since non-flame retardant foam plastics have been used in Sweden, building fires and deaths from building fires have not increased, indicating that fire safety is maintained by the code mandated measures (Harrami & McIntyre, 2006; Lundqvist et al., 2008; Remberger et al., 2004).

From IRC Section 316.5.1 Commentary:

No thermal barrier is required when 1 inch (25 mm) or more of masonry or concrete is placed between the foam plastic and the interior of the building. The intent is to accept 1-inch (25 mm) of masonry or concrete as adequate protection against ignition, even though the concrete does not necessarily meet the performance criteria for thermal barriers. This condition can arise when foam plastics are installed either within a wall or on one side of a wall. Some common examples are when foam plastics are installed:

- In the cavity of a hollow masonry wall,
- As the core of a concrete-faced panel,
- On the exterior face of a masonry wall and covered with an exterior finish, or
- Within the cores of hollow masonry units.
- Encapsulated within a minimum of 1 inch (25 mm) concrete or masonry wall, floor or roof system, as in insulated tilt-up or pour-in-place

Also, the flame spread rating of the foam plastic used must comply with the requirements of Section R316.3, but the smoke-developed rating of the foam plastic is not limited.

From IRC Section R101.3 Intent:

The purpose of this code is to establish minimum requirements to safeguard the public safety, health and general welfare through affordability, structural strength, means of egress facilities, stability, sanitation, light and ventilation, energy conservation and safety to life and property from fire and other hazards attributed to the built environment and to provide safety to fire fighters and emergency responders during emergency operations.

R316.3 #2-RB-BABRAUSKAS

RB165 – 13

R316.3

Proponent: Michael D. Fischer, Kellen Company, representing the Center for the Polyurethanes Industry (mfischer@kellencompany.com)

Revise as follows:

R316.3 Surface burning characteristics. Unless otherwise allowed in Section R316.5 or R316.6, all foam plastic or foam plastic cores used as a component in manufactured assemblies used in building construction shall have a flame spread index of not more than 75 and shall have a smoke developed index of not more than 450 when tested in the maximum thickness and density intended for use in accordance with ASTM E 84 or UL 723. Loose-fill-type foam plastic insulation shall be tested as board stock for the flame spread index and smoke-developed index.

Exception: Foam plastic insulation more than 4 inches (102 mm) thick shall have a maximum flame spread index of 75 and a smoke-developed index of 450 where tested at a minimum thickness of 4 inches (102 mm), provided the end use is *approved* in accordance with Section R316.6 using the thickness and density intended for use.

Reason: As applied to foam plastics, performance certifications (i.e. *approvals*) based on results for tests in accordance to ASTM E84 are limited to the maximum (nominal) thickness and density of the materials tested. Adding language with regard to density to R316.3 serves to more fully clarify and communicate the application of ASTM E84 test results to foam plastics.

Cost Impact: None.

Proponent: Sean DeCrane, Battalion Chief, representing Cleveland Division of Fire, International Association of Fire Fighters (rovloc93@aol.com)

Revise as follows:

R316.4 Thermal barrier. Unless otherwise allowed in Section R316.5 or Section R316.6, foam plastic shall be separated from the interior of a building and the exterior of the building when installed within ten feet of a property line by an *approved* thermal barrier of minimum 1/2 inch (12.7 mm) gypsum wallboard or a material that is tested in accordance with and meets the acceptance criteria of both the Temperature Transmission Fire Test and the Integrity Fire Test of NFPA 275.

R316.5 Specific requirements. The following requirements shall apply to these uses of foam plastic unless specifically *approved* in accordance with Section R316.6 or by other sections of the code or the requirements of Sections R316.2 through R316.4 have been met.

R316.5.1 Masonry or concrete construction. The thermal barrier specified in Section R316.4 is not required in a masonry or concrete wall, floor or roof when the foam plastic insulation is separated from the interior of the building and the exterior of the building where installed within ten feet of a property line by a minimum 1-inch (25 mm) thickness of masonry or concrete.

R316.5.2 Roofing. The thermal barrier specified in Section R316.4 is not required when the foam plastic in a roof assembly or under a roof covering is installed in accordance with the code and the manufacturer's installation instructions and is separated from the interior of the building by tongue-and-groove wood planks or wood structural panel sheathing in accordance with Section R803, not less than 15/32 inch (11.9 mm) thick bonded with exterior glue and identified as Exposure 1, with edges supported by blocking or tongue-and-groove joints or an equivalent material. The smoke-developed index for roof applications shall not be limited. A thermal barrier meeting the requirements of R316.4 is required where foam plastic in a roof assembly is installed within 10 feet of a property line.

R316.5.3 Attics. The thermal barrier specified in Section R316.4 is not required in attics where all of the following apply:

1. *Attic* access is required by Section R807.1.
2. The space is entered only for purposes of repairs or maintenance.
3. The foam plastic insulation is protected against ignition using one of the following ignition barrier materials:
 - 3.1. 1 1/2-inch-thick (38 mm) mineral fiber insulation;
 - 3.2. 1/4-inch-thick (6.4 mm) wood structural panels;
 - 3.3. 3/8-inch (9.5 mm) particleboard;
 - 3.4. 1/4-inch (6.4 mm) hardboard;
 - 3.5. 3/8-inch (9.5 mm) gypsum board; or
 - 3.6. Corrosion-resistant steel having a base metal thickness of 0.016 inch (0.406 mm);
 - 3.7. 1 1/2-inch-thick (38 mm) cellulose insulation.

The above ignition barrier is not required where the foam plastic insulation has been tested in accordance with Section R316.6.

R316.5.4 Crawl spaces. The thermal barrier specified in Section R316.4 is not required where all of the following apply:

1. Crawlspace access is required by Section R408.4

2. Entry is made only for purposes of repairs or maintenance.
3. The foam plastic insulation is protected against ignition using one of the following ignition barrier materials:
 - 3.1. 1 1/2-inch-thick (38 mm) mineral fiber insulation;
 - 3.2. 1/4-inch-thick (6.4 mm) wood structural panels
 - 3.3. 3/8-inch (9.5 mm) particleboard;
 - 3.4. 1/4-inch (6.4 mm) hardboard;
 - 3.5. 3/8-inch (9.5 mm) gypsum board; or
 - 3.6. Corrosion-resistant steel having a base metal thickness of 0.016 inch (0.406 mm). The above ignition barrier is not required where the foam plastic insulation has been tested in accordance with Section R316.6.

The above ignition barrier is not required where the foam plastic insulation has been tested in accordance with Section R316.6.

R316.5.5 Foam-filled exterior doors. Foam-filled exterior doors are exempt from the requirements of Sections R316.3 and R316.4.

R316.5.6 Foam-filled garage doors. Foam-filled garage doors in attached or detached garages are exempt from the requirements of Sections R316.3 and R316.4.

R316.5.7 Foam backer board. ~~The thermal barrier specified in Section R316.4 is not required where siding backer board foam plastic insulation has a maximum thickness of 0.5 inch (12.7 mm) and a potential heat of not more than 2000 Btu per square foot (22 720 kJ/m²) when tested in accordance with NFPA 259 provided that:~~

- ~~1. The foam plastic insulation is separated from the interior of the building by not less than 2 inches (51mm) of mineral fiber insulation;~~
- ~~2. The foam plastic insulation is installed over existing exterior wall finish in conjunction with re-siding; or~~
- ~~3. The foam plastic insulation has been tested in accordance with Section R316.6.~~

R316.5.8 Re-siding. ~~The thermal barrier specified in Section R316.4 is not required where the foam plastic insulation is installed over existing exterior wall finish in conjunction with re-siding provided the foam plastic has a maximum thickness of 0.5 inch (12.7 mm) and a potential heat of not more than 2000 Btu per square foot (22 720 kJ/m²) when tested in accordance with NFPA 259.~~

R316.5.9 Interior trim. The thermal barrier specified in Section R316.4 is not required for exposed foam plastic interior trim, provided all of the following are met:

1. The minimum density is 20 pounds per cubic foot (320 kg/m³).
2. The maximum thickness of the trim is 0.5 inch (12.7 mm) and the maximum width is 8 inches (204 mm).
3. The interior trim shall not constitute more than 10 percent of the aggregate wall and ceiling area of any room or space.
4. The flame spread index does not exceed 75 when tested per ASTM E 84 or UL 723. The smoke-developed index is not limited.

R316.5.10 Interior finish. Foam plastics shall be permitted as interior finish where *approved* in accordance with Section R316.6 Foam plastics that are used as interior finish shall also meet the flame spread index and smoke developed index requirements of Sections R302.9.1 and R302.9.2.

R316.5.11 Sill plates and headers. Foam plastic shall be permitted to be spray applied to a sill plate and header without the thermal barrier specified in Section R316.4 subject to all of the following:

1. The maximum thickness of the foam plastic shall be 3 1/4 inches (83 mm).

2. The density of the foam plastic shall be in the range of 0.5 to 2.0 pounds per cubic foot (8 to 32 kg/m3).
3. The foam plastic shall have a flame spread index of 25 or less and an accompanying smoke-developed index of 450 or less when tested in accordance with ASTM E 84 or UL 723.

R316.5.12 Sheathing. Foam plastic insulation used as sheathing shall comply with Section R316.3 and Section R316.4. Where the foam plastic sheathing is exposed to the *attic* space at a gable or kneewall, the provisions of Section R316.5.3 shall apply.

R316.5.13 Floors. The thermal barrier specified in Section R316.4 is not required to be installed on the walking surface of a structural floor system that contains foam plastic insulation when the foam plastic is covered by a minimum nominal 1/2-inch-thick (12.7 mm) wood structural panel or equivalent. The thermal barrier specified in Section R316.4 is required on the underside of the structural floor system that contains foam plastic insulation when the underside of the structural floor system is exposed to the interior of the building.

R316.6 Specific approval. Foam plastic not meeting the requirements of Sections R316.3 through R316.5 shall be specifically *approved* on the basis of one of the following *approved* tests: NFPA 286 with the acceptance criteria of Section R302.9.4, FM4880, UL 1040, or UL 1715, or fire tests related to actual end-use configurations. Approval shall be based on the actual end use configuration and shall be performed on the finished foam plastic assembly in the maximum thickness intended for use. Assemblies tested shall include seams, joints and other typical details used in the installation of the assembly and shall be tested in the manner intended for use.

R316.7 Termite damage. The use of foam plastics in areas of “very heavy” termite infestation probability shall be in accordance with Section R318.4.

Reason: One of the main challenges the fire service is encountering in today's environment is a pressing need of resources. Across the United States we are experiencing the loss of structures due to exterior exposures. These exposure fires can have devastating effects on an individual's home and also place responding fire fighters at risk for rapidly spreading fires.

As the Fire Service encounters the economic realities of smaller budgets and increased demand we are continuously being asked to do more with less. Responding units many times must address growing exposure fires due to the narrow property lines.

In today's environment there is a growing trend to promote energy conservation. While this is widely supported, and a worthy goal, we must also factor in a level of safety. As with most things in life there must be a balance between efficiency and safety.

A search of the Vinyl Siding Institute's website www.vinylsiding.org produces a great deal of information on the R-Values and potential cost benefits of increasing the use of foam backing on the vinyl siding. There is little information on the fire performance of these products. It is true many of the foam insulation products are given a Class A flame spread rating in an ASTM E 84 Test Standard. That is one of the problems, the E 84 is a horizontal test standard yet we install the foam insulation products vertically drastically impacting the true fire performance in the field. In fact to demonstrate the safety of vinyl siding it is compared to the performance of vinyl sheathed wiring: *“Additionally, vinyl meets the stringent National Fire Protection Association (NFPA) requirements. The NFPA Electrical Code recognizes the strong fire-safe characteristics of vinyl through its approved use as a residential wiring insulator. Millions of homes have been wired using safe vinyl-sheathed electrical systems for decades.”*¹

They further state; *Safe homes use fire-safe claddings, which include vinyl siding. Why does vinyl siding provide good fire performance? It is composed mainly of polyvinyl chloride, more commonly known as vinyl or PVC. Due to its chlorine base, vinyl siding does not ignite quickly and is inherently flame-retardant. Read on to discover more facts on vinyl siding's fire performance.....All organic materials (that is, anything containing carbon) will ignite. But the higher the temperature a material has to reach before it flames, the safer it is. PVC won't ignite, even from another flame, until it reaches about 730°F (387°C) and won't self-ignite until about 850°F (454°C).* ¹ Fire doesn't propagate until 750°F, what is the temperature of flame? Again, our issue isn't necessarily the siding it is the foam backing behind it as the siding when exposed to high temperatures will begin to melt and fall away exposing the increasing amounts of foam insulation.

Current tests are being conducted by UL and NIST and additional testimony and data will be presented during the code development process.

1. 2005 National Electrical Code, NFPA 70, Article 334.

Cost Impact: Will not increase the cost of construction

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R316.4-RB-DECRANE

RB167 – 13

R316.4

Proponent: Dennis Pitts, American Wood Council, representing American Wood Council
(dpitts@awc.org)

Revise as follows:

R316.4 Thermal barrier. Unless otherwise allowed in Section R316.5 or Section R316.6, foam plastic shall be separated from the interior of a building by an *approved* thermal barrier of minimum 1/2 inch (12.7 mm) gypsum wallboard, 23/32 inch (18.2 mm) wood structural panel or a material that is tested in accordance with and meets the acceptance criteria of both the Temperature Transmission Fire Test and the Integrity Fire Test of NFPA 275.

Reason: Wood structural panels are permitted prescriptively as a thermal barrier in various thicknesses in subsections of R316.5. R316.5.2 allows 15/32" WSP as a thermal barrier in roofs, R316.5.3 allows 1/4" WSP for attics, and R316.5.4 allows 1/4" WSP for crawlspaces. This proposal would prescriptively allow a thicker WSP to be used as a thermal barrier in other applications that might arise.

Prior to a recent change in NFPA 275 that essentially requires a Class A flame spread rating for materials used as thermal barriers, 23/32" WSP complied with NFPA 275. This proposal prescriptively recognizes a history of satisfactory service as a thermal barrier, even for thinner panels, although the material isn't a Class A material.

Cost Impact: No increase in cost of construction.

RB167-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R316.4-RB-PITTS

RB168 – 13

R316.5.3

Proponent: John Mulder, Intertek Testing Services NA, Inc., representing International Standards Organization Technical Committee 77, *Products in Fibre-reinforced Cement*, James Hardie Building Products, and Self

Revise as follows:

R316.5.3 Attics. The thermal barrier specified in Section R316.4 is not required where all of the following apply:

1. *Attic* access is required by Section R807.1.
2. The space is entered only for purposes of repairs or maintenance.
3. The foam plastic insulation is protected against ignition using one of the following ignition barrier materials:
 - 3.1. 1½-inch-thick (38 mm) mineral fiber insulation;
 - 3.2. 1/4-inch-thick (6.4 mm) wood structural panels;
 - 3.3. 3/8-inch (9.5 mm) particleboard;
 - 3.4. 1/4-inch (6.4 mm) hardboard;
 - 3.5. 3/8-inch (9.5 mm) gypsum board; **or**
 - 3.6. Corrosion-resistant steel having a base metal thickness of 0.016 inch (0.406 mm);
 - 3.7. 1½-inch-thick (38 mm) cellulose insulation; **or**
 - 3.8. 1/4-inch (6.4 mm) fiber-cement panel, soffit or backer board.

The above ignition barrier is not required where the foam plastic insulation has been tested in accordance with Section R316.6.

Reason: 1/4-inch fiber-cement panel complying with ASTM C1186, Type A, or ASTM C1288, or ISO 8336, Category C, has a flame spread of 0 and smoke developed index of 5 or less. The proposed fiber-cement is also classed as noncombustible in accordance with ASTM E 136 (see attached ICC-ES ESR-1381[reference Section 3.0], ESR-1572[reference Section 3.0], ESR-1844[reference Section 3.1], ESR-2290[reference Section 3.1], and ESR-2894[reference Section 3.2]) documenting these claims. The fiber-cement panel has also been tested in accordance with NFPA 268 (see attached test reports) for compliance with the provisions of IBC Section 2603.5.7 "Exceptions" for "Ignition".

IBC Section 2603.5.7 has, as a result of the Group A IBC Code Hearings, been revised to add fiber-cement when tested in accordance with both ASTM E84 and NFPA 268. This proposed revision brings the two building codes (IBC & IRC) and the applicable code sections and standards references into general alignment.

Performance requirements of ISO 8336, *Fibre-cement flat sheets – Product specification and test methods*, have been harmonized with the performance requirements of ASTM C1288, *Standard Specification for Discrete Non-Asbestos Fiber-Cement Interior Substrate Sheets*. Fiber-cement producers in Mexico, Central and South America, Europe, Asia, Australia and New Zealand currently manufacture and test their fiber-cement products for compliance with ISO 8336. The inclusion of this Standard reference in the IRC will permit manufacturers worldwide to demonstrate product compliance to IBC requirements. The addition of a reference to ISO 8336 in the Code removes a barrier to trade.

Cost Impact: The code change proposal will not increase the cost of construction because the proposed code change is editorial in nature to better clarify and present the backer board products currently recognized in the Code.

R316.5.3-RB-MULDER

RB169 – 13

R316.5.3, R316.5.4

Proponent: Rick Thornberry, P.E., representing Cellulose Insulation Manufacturers Association (CIMA)

Revise as follows:

R316.5.3 Attics. The thermal barrier specified in Section R316.4 is not required where all of the following apply:

1. *Attic* access is required by Section R807.1.
2. The space is entered only for purposes of repairs or maintenance.
3. The foam plastic insulation is protected against ignition using one of the following ignition barrier materials:
 - 3.1. 1 1/2-inch-thick (38 mm) mineral fiber insulation;
 - 3.2. 1/4-inch-thick (6.4 mm) wood structural panels;
 - 3.3. 3/8-inch-thick (9.5 mm) particleboard;
 - 3.4. 1/4-inch-thick (6.4 mm) hardboard;
 - 3.5. 3/8-inch-thick (9.5 mm) gypsum wallboard; ~~or~~
 - 3.6. Corrosion-resistant steel having a base metal thickness of 0.016 inch (0.406 mm);
 - 3.7. 1.5-inch thick (38 mm) cellulose insulation; ~~or~~
 - 3.8. Other approved material installed in such a manner that the foam plastic insulation is not exposed.

The above ignition barrier is not required where the foam plastic insulation has been tested in accordance with Section R316.6.

R316.5.4 Crawl spaces. The thermal barrier specified in Section R316.4 is not required where all of the following apply:

1. Crawlspace access is required by Section R408.4
2. ~~Entry is made~~ The space is entered only for purposes of repairs or maintenance.
3. The foam plastic insulation is protected against ignition using one of the following ignition barrier materials:
 - 3.1. 1 1/2-inch-thick (38 mm) mineral fiber insulation;
 - 3.2. 1/4-inch-thick (6.4 mm) wood structural panels;
 - 3.3. 3/8-inch-thick (9.5 mm) particleboard;
 - 3.4. 1/4-inch-thick (6.4 mm) hardboard;
 - 3.5. 3/8-inch-thick (9.5 mm) gypsum wallboard; ~~or~~
 - 3.6. Corrosion-resistant steel having a base metal thickness of 0.016 inch (0.406 mm); ~~or~~
 - 3.7. Other approved material installed in such a manner that the foam plastic insulation is not exposed

The above ignition barrier is not required where the foam plastic insulation has been tested in accordance with Section R316.6.

Reason: The purpose of this code change proposal is to make Sections R316.5.3 and R316.5.4 in the IRC more consistent with Section 2603.1.4.6 in the IBC. This should help to avoid possible misapplications of these sections and make the code more user friendly.

Cost Impact: This code change proposal will not increase the cost of construction.

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R316.5.3-RB-THORNBERRY.doc

RB170– 13

R316.5.3

Proponent: John Woestman, Kellen Company, representing Extruded
(jwoestman@kellencompany.com)

Revise as follows:

R316.5.3 Attics. The thermal barrier specified in Section R316.4 is not required where the foam plastic insulation has been tested in accordance with R316.6 or where all of the following apply:

1. *Attic* access is required by Section R807.1.
2. The space is entered only for purposes of repairs or maintenance.
3. The foam plastic insulation is protected against ignition using one of the following ignition barrier materials:
 - 3.1. 11/2-inch-thick (38 mm) mineral fiber insulation;
 - 3.2. 1/4-inch-thick (6.4 mm) wood structural panels;
 - 3.3. 3/8-inch (9.5 mm) particleboard;
 - 3.4. 1/4-inch (6.4 mm) hardboard;
 - 3.5. 3/8-inch (9.5 mm) gypsum board; or
 - 3.6. Corrosion-resistant steel having a base metal thickness of 0.016 inch (0.406 mm);
 - 3.7. 11/2-inch-thick (38 mm) cellulose insulation.

~~The above ignition barrier is not required where the foam plastic insulation has been tested in accordance with Section R316.6.~~

Reason: This proposal is an attempt to clarify requirements of the IRC in Section R316.5.3. Section R316.6 specifically allows foam plastic insulation meeting one of the tests specified in R316.6 to not be required to meet the prescriptive requirements of Sections R316.3 through R316.5. This proposal makes it explicitly clear Items 1 and 2 (and Item 3) of R316.5.3 are not a requirement for foam plastic insulation that complies with R316.6.

Cost Impact: None

RB170-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R316.5.3-RB-WOESTMAN

RB171 – 13

R316.5.4

Proponent: John Woestman, Kellen Company, Representing Extruded Polystyrene Foam Association (XPSA) (jwoestman@kellencompany.com)

Revise as follows:

R316.5.4 Crawl spaces. The thermal barrier specified in Section R316.4 is not required where the foam plastic insulation has been tested in accordance with Section R316.6 or where all of the following apply:

1. Crawlspace access is required by Section R408.4
2. Entry is made only for purposes of repairs or maintenance.
3. The foam plastic insulation is protected against ignition using one of the following ignition barrier materials:
 - 3.1. 1 1/2-inch-thick (38 mm) mineral fiber insulation;
 - 3.2. 1/4-inch-thick (6.4 mm) wood structural panels;
 - 3.3. 3/8-inch (9.5 mm) particleboard;
 - 3.4. 1/4-inch (6.4 mm) hardboard;
 - 3.5. 3/8-inch (9.5 mm) gypsum board; or
 - 3.6. Corrosion-resistant steel having a base metal thickness of 0.016 inch (0.406 mm).

~~The above ignition barrier is not required where the foam plastic insulation has been tested in accordance with Section R316.6.~~

Reason: This proposal is an attempt to clarify requirements of the IRC in Section R316.5.4. Section R316.6 specifically allows foam plastic insulation meeting one of the tests specified in R316.6 to not be required to meet the prescriptive requirements of Sections R316.3 through R316.5. This proposal makes it explicitly clear Items 1 and 2 (and Item 3) of R316.5.4 are not a requirement for foam plastic insulation that complies with R316.6.

Cost Impact: None

RB171-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R316.5.4-RB-WOESTMAN

RB172 – 13

R316.5.11

Proponent: Rick Davidson, City of Maple Grove, Association of Minnesota Building Officials
(rdavidson@maplegrovern.gov)

Revise as follows:

R316.5.11 Sill plates and headers. Foam plastic shall be permitted to be ~~spray~~ applied to a sill plates and headers ~~or installed in the perimeter joist space~~ without the thermal barrier specified in Section R316.4 subject to all of the following:

1. The maximum thickness of the foam plastic shall be 3 1/4 inches (83 mm).
2. The density of the foam plastic shall be in the range of 0.5 to 2.0 pounds per cubic foot (8 to 32 kg/m³).
3. The foam plastic shall have a flame spread index of 25 or less and an accompanying smoke-developed index of 450 or less when tested in accordance with ASTM E 84 or UL 723.

Reason: This proposal extends the same liberties to rigid foam that are currently enjoyed by spray foam products provided they meet the same criteria. Also, the language is tweaked to make clear that the application includes the rim joist area.

Cost Impact: None

RB172-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R316.5.11-RB-DAVIDSON

RB173 – 13

R316.5.11

Proponent: Michael D. Fischer, Kellen Company, representing the Center for the Polyurethanes Industry (mfischer@kellencompany.com)

Revise as follows:

R316.5.11 Sill plates and headers. Foam plastic shall be permitted to be spray applied to a sill plate and header without the thermal barrier specified in Section R316.4 ~~subject to all of the following:~~ when

- ~~1. The maximum thickness of the foam plastic shall be 3-1/4 inches (83 mm).~~
- ~~2. The density of the foam plastic shall be in the range of 0.5 to 2.0 pounds per cubic foot (8 to 32 kg/m³).~~
3. The foam plastic shall have has a flame spread index of 25 or less and an accompanying smoke-developed index of 450 or less, at the maximum thickness and density intended for use, when tested in accordance with ASTM E 84 or UL723.

Reason: The two, main applications for spray-applied foam plastic in sill plate and joist header areas are insulation and air sealing. Sill plates and joist headers (a.k.a. rim joists or band joists), by virtue of their location and function, exist in attics, crawl spaces, concealed spaces between floors and / or basements. In addition to location limitations, the relative volume available in these locations (into which the spray-applied foam plastic will be installed) is small and highly compartmentalized due to the floor / ceiling joists (see Commentary Figure R316.5.11). The intent of this section is to waive the prescriptive thermal barrier requirement for very limited amounts of foam plastic insulation in very specific and compartmentalized locations.

Although originally based on industry testing, the current limitations of 3-1/4 inches thickness and a density range of 0.5 to 2.0 lbs/cu-ft appear somewhat arbitrary and unnecessarily restrictive to products that provide flame spread index \leq 25 and smoke developed index \leq 450; for example 4 inches thickness and 2.2 lbs/cu-ft or 6-inches thickness at 0.5 lbs/cu-ft.

The intent of this proposal is not to circumvent provisions for interior finishes or plastic trim.

Cost Impact: None.

RB173-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R316.5.11-RB-FISCHER

RB174 – 13

R316.6

Proponent: Tony Crimi, A.C. Consulting Solutions, Inc., representing North American Insulation Manufacturers Association (NAIMA) (tcrimi@sympatico.ca)

Revise as follows:

R316.6 Specific approval. Foam plastic not meeting the requirements of Sections R316.3 through R316.5 shall be specifically *approved* on the basis of one of the following *approved* tests: NFPA 286 with the acceptance criteria of Section R302.9.4, FM4880, UL 1040, or UL 1715, or fire tests related to actual end-use configurations. Approval shall be based on the actual end use configuration and shall be performed on the finished foam plastic assembly in the maximum thickness intended for use. Foam plastics that are used as an interior finish on the basis of special tests shall also conform to the smoke-developed requirements of Section R302.9.4 or Section R316.3. Assemblies tested shall include seams, joints and other typical details used in the installation of the assembly and shall be tested in the manner intended for use.

Reason: At a minimum, the provision for special approvals for foamed plastics, which waives other requirements of the IRC for foamed plastics needs to provide a comparable level of performance and safety to the existing provisions. The exception for foamed plastics in R316.6 does not adequately cover smoke developed performance of foamed plastics. Current requirements for glass fiber, mineral fiber, cellulose and reflective plastic core insulation all require both flame spread and smoke development requirements either based on ASTM E84 or UL 723 or R302.10. Alternative methods are acceptable for use, however, their performance level needs to address the same hazards as the base requirement, plus any additional hazards that might arise as a result of a specific material. This proposal makes the section more consistent with the parallel provision in the IBC.

Justification: For all other thermal and sound insulating materials within the IRC, including non-combustible insulation materials, the minimum performance level for materials permitted to be used includes at least some requirements for both flame spread (fire growth) and smoke production. These requirements are primarily based on either ASTM E84 testing or alternative methods such as NFPA 286 and CAN/ULC-S102.2. However, in the case of foamed plastics, of the four alternative test methods permitted by 2603.9, only NFPA 286 contains any limits on smoke developed for any foamed plastics by virtue of the inclusion of a reference to section R302.9.4.

Room corner tests such as FM 4880, UL 1040, NFPA 286 or UL 1715 do evaluate fire growth and flashover. However, with the exception of the criteria for NFPA 286 in R302.9.4, the pass/fail criteria proposed for the room corner tests in the proposed acceptance criteria do not include quantitative evaluation of smoke density. Criteria for fire and smoke performance of building materials are based as much on issues arising from smoke production from burning materials, and smoke migration within the occupied spaces. It is not reasonable to provide an exception to the basic ASTM E84 flame spread and smoke developed requirements which apply to all other types of insulations, even non-combustible insulations, for foamed plastics based on room corner tests unless the limits on smoke production are applied to all of the room corner tests.

There are numerous reported instances of the hazards associated with smoke production from building materials. One is the tragic fire at the Greenwood Health Center in Hartford, CT on Feb 26 2003. The New York Times quoted Chief Charles A. Teale of the Hartford Fire Department as stating that "Most of the 10 residents killed, ranging in ages from 27 to 76, died of smoke inhalation". The same article further goes on to quote officials as saying: "The nursing home itself suffered little damage, though, and the fire was put out in about 15 minutes. Most of the residents were then led back inside, and by midday, 84 of the 148 residents remained at the center".

It is reasonable to allow alternative methods of testing materials to determine their acceptability for use, however, their performance criteria needs to address the same hazards as the base requirement, plus any additional hazards that might arise as a result of a specific material.

Cost Impact: This code change proposal will not increase the cost of construction.

RB174-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R316.6-RB-CRIMI.doc

RB175 – 13

R316.5.12, R316.8 (New), Chapter 44

Proponent: Jay Crandell, P.E., ARES Consulting, representing Foam Sheathing Committee of the American Chemistry Council – Plastics Division (Jcrandell@aresconsulting.biz)

Revise as follows:

R316.5.12 Sheathing. Foam plastic insulation used as sheathing shall comply with Section R316.3 and Section R316.4. Where the foam plastic sheathing is exposed to the *attic* space at a gable or knee wall, the provisions of Section R316.5.3 shall apply. Where foam plastic insulation is used as exterior wall sheathing on framed wall assemblies, it shall comply with Section R316.8.

R316.8 Wind Resistance. Foam plastic insulation complying with ASTM C 578 and ASTM C 1289 and used as exterior wall sheathing on framed wall assemblies shall comply with SBCA FS 100 for wind pressure resistance unless installed directly over a sheathing material that is separately capable of resisting the wind load or otherwise exempted from the scope of SBCA FS 100.

Add new standards to Chapter 44 as follows:

SBCA

Standard Reference	Title	Referenced in code section number
FS 100-12	<u>Standard Requirements for Wind Pressure Resistance of Foam Plastic Insulating Sheathing Used in Exterior Wall Covering Assemblies</u> R316.8

Reason: This ANSI standard (FS 100-12) was approved for the 2015 IBC. It also is needed in the IRC to address the use of foam plastic insulating sheathing in exterior wall covering assemblies where resistance to wind pressure is required. This standard provides a methodology by which a manufacturer can qualify their product, through testing, to meet the requirements of the I-codes in establishing the wind pressure resistance of the product. It also provides for on-going quality control procedures to ensure that the product continues to meet its qualified wind pressure resistance. The ANSI standard supplements the applicable ASTM materials standards also referenced in the code change proposal. The current version of the standard is available at www.sbcindustry.com/fs100.php

Cost Impact: The code change proposal will increase the cost of construction.

Analysis: A review of the standards proposed for inclusion in the code, [SBCA FS 100-12] with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 1, 2013.

RB175-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R316.8 (NEW)-RB-CRANDELL

RB176 – 13

R317.3

Proponent: Randall Shackelford, P.E., representing Simpson Strong-Tie Co., Inc.
(rshackelford@strongtie.com)

Revise Sections as follows:

R317.3 Fasteners and connectors in contact with preservative-treated and fire-retardant-treated wood. Fasteners, including nuts and washers, and connectors in contact with preservative-treated wood and fire-retardant-treated wood shall be in accordance with this section. The coating weights for zinc-coated fasteners shall be in accordance with ASTM A 153. Stainless steel driven fasteners shall be in accordance with the material requirements of ASTM F 1667.

Reason: The reason for this proposal is to specify the permissible types of stainless steel that driven fasteners used with treated wood can be manufactured from.

ASTM F 1667 reads as follows:

6. Material Requirements

- 6.1 Steel wire used in the manufacture of driven fasteners shall be of low carbon, medium-low carbon, or medium-high carbon.
- 6.2 Stainless steel wire used in the manufacture of driven fasteners shall be of Types 302, 304, 305, or 316.
So the intent here is to require fasteners used with treated wood to be manufactured from Types 302, 304, 305, or 316 stainless steel.

There has been a lot of work done on fasteners and connectors in contact with treated wood in the last 8-10 years. All the testing and historical performance of stainless steel were based on the traditional use of 300 series stainless steel. Yet there are many types of stainless steel, and some are much less corrosion resistant than others. By limiting the types of stainless steel to these specific series, it ensures that the stainless steel fasteners will be corrosion resistant when exposed to treated wood.

There is precedent for this. Section 402.1.1 specifies that for wood foundations stainless steel fasteners must be "of Type 304 or 316 stainless steel". Section R905.10.4 states "Copper, brass, bronze, copper alloy and 300-series stainless steel fasteners shall be used for copper roofs." Further, ASTM F 1667 is already specified for several different types of fasteners in the IRC. The result of this proposal is not to require the exclusive use of 300-series stainless steel fasteners. This section permits hot-dipped, zinc-coated galvanized steel, stainless steel, silicon bronze, or copper fasteners. The existing sentence before the added one is meant to specify a minimum coating weight for the galvanized fasteners so they perform as expected. The new proposed sentence does the same thing for stainless steel fasteners.

Cost Impact: The vast majority of driven stainless steel fasteners are manufactured from 300 series stainless steel. However, if a manufacturer were supplying the lesser-performing (and lower cost) stainless steel types and a builder had to use the standard 300 series stainless steel instead, there could be a cost increase. But the increase in performance would justify the additional cost. However, the use of the stainless steel fastener is not required anyway, as stated in the reason statement.

RB176-13

	Assembly:	ASF	AMF	DF

R317.3-RB-SHACKELFORD

RB177 – 13

R320.1, R320.1.1 (New)

Proponent: Carl Baldassarra, P.E., FSFPE, Chair, ICC Code Technology Committee
(cbaldassarra@rjagroup.com)

Revise as follows:

R320.1 Scope. Where there are four or more *dwelling units* ~~or sleeping units~~ in a single structure, the provisions of Chapter 11 of the *International Building Code* for Group R-3 shall apply.

R320.1.1 Guest rooms. A dwelling with guestrooms shall comply with the provisions of Chapter 11 of the *International Building Code* for Group R-3. For the purpose of applying the requirements of IBC chapter 11, *guestrooms* shall be considered sleeping units.

Exception: Lodging houses.

Reason: Residential and institutional occupancies with 6 or more residents are within the scope of the IRC only and cannot be constructed under the IRC. This is based on both the scope of the IRC and IBC. Scoping provisions of the IRC and IBC, and code provisions within the IBC permit some residential and institutional occupancies with 5 or fewer occupants to be constructed in accordance with the IRC as an alternative to compliance with the IBC. The IBC occupancies that allow use of the IRC for five or fewer guests are: Group R-3 lodging houses (see G40-13), lodging houses are also in the scope of the IRC in section 101.2 #2; section 308.3.1 for Group I-1 and 308.4.1 for Group I-2.

Per the 2010 ADA Standard for Accessible Design and the IBC 1103.2.11 owner occupied lodging houses with 5 or fewer guests are not required to be accessible. So compliance with the IRC works for this condition without causing any conflicts with the IBC. If the lodging house is not owner occupied or accommodates more than 5 guests the building is outside of the scope of the IRC and accessibility is addressed since the building will be constructed per the IBC.

The issue addressed by this code change is how to handle 2012 IBC Sections 308.3.1 for I-1 and 308.4.1 for I-2. These sections classify the building as Group R-3 or allow use of the IRC for these institutional uses that have 5 or fewer care recipients. If it is classified as Group R-3 then IBC section 1107.6.3 provides requirements for accessibility of the building. Clearly the intent of Section 1107.6.3 is that if you have 4 or 5 care recipients the "sleeping units" must be Type B (subject to Section 1107.7 exceptions). The problem is that IRC structures by scope and definition do not have sleeping units:

R101.2 Scope. The provisions of the *International Residential Code for One- and Two-family Dwellings* shall apply to the construction, *alteration*, movement, enlargement, replacement, repair, equipment, use and occupancy, location, removal and demolition of detached one- and two-family dwellings and townhouses not more than three stories above *grade plane* in height with a separate means of egress and their *accessory structures*.

DWELLING. Any building that contains one or two *dwelling units* used, intended, or designed to be built, used, rented, leased, let or hired out to be occupied, or that are occupied for living purposes.

Adding the IBC definition of sleeping units to the IRC does not work because IBC sleeping units are not part of a dwelling unit. The current IBC definition of sleeping units states that "Such rooms and spaces that are also part of a dwelling unit are not sleeping units". Having a building constructed under the IRC that is not a dwelling unit, but a building with multiple sleeping units, is outside of the scope of the IRC.

Any of the Group I uses for 5 and under that are built to the IRC should have the same accessibility requirements as a Group R-3 constructed building. The IRC does not have sleeping units. Under the IRC such facilities are a dwelling unit with guest rooms. While the IRC contains a definition for guestroom, it is not clear on how the guestrooms should be counted for accessibility. Since the resident rooms are not sleeping units but guest rooms the current Section R320.1 does not require accessibility per Chapter 11 of the IBC for any IRC structures that have multiple guest rooms in one dwelling unit. The solution proposed here is to delete sleeping units from Section R320.1 to remove the confusion about the scope of sleeping units in the IRC and to add new Section R320.1.1 to address guestrooms. The statement that guestrooms shall be considered sleeping units for the purpose of applying IBC Chapter 11 is necessary because we cannot change the IBC language until the 2018 cycle. We plan to propose a more coordinated change for both the IBC and IRC to address this issue in the 2018 cycle. The exception for lodging houses is to maintain the exemption from accessibility requirements for lodging houses consistent with IBC Section 1103.2.11.

The ICC Board established the ICC Code Technology Committee (CTC) as the venue to discuss contemporary code issues in a committee setting which provides the necessary time and flexibility to allow for full participation and input by any interested party. The code issues are assigned to the CTC by the ICC Board as "areas of study". Information on the CTC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CTC effort can be downloaded from the following website: <http://www.iccsafe.org/cs/CTC/Pages/default.aspx>. Since its inception in April/2005, the CTC has held twenty five meetings - all open to the public.

Cost Impact: None

RB177-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R320.1-RB-BALDASSARRA

RB178 – 13

R320.1

Proponent: Steve Orlowski, representing National Association of Home Builders (NAHB)
(sorlowski@nahb.org)

Add new text as follows:

R320.1 Scope. Where there are four or more *dwelling* units or sleeping units in a single structure, the provisions of Chapter 11 of the *International Building Code* for Group R-3 shall apply.

Exception: Owner-occupied lodging houses with five or fewer guestrooms or sleeping units constructed in accordance with the *International Residential Code* are not required to be accessible.

Reason: Based on the action taken during the Group A Hearings, Lodging houses are now referenced in the IBC. It was noted during the hearings, that lodging houses with five or fewer guest rooms or sleeping units are not required to be accessible under the 2010 ADA Guidelines. This proposal simply clarifies that lodging houses are not subject to the provisions of Chapter 11 of the IBC if they contain five or fewer guest rooms or sleeping units.

Cost Impact: The code change proposal will not increase the cost of construction.

RB178-13

Public Hearing:	Committee: AS	AM	D
	Assembly: ASF	AMF	DF

R320.1-RB-ORLOWSKI

RB179– 13

R320.2 (New)

Proponent: Dominic Marinelli, representing United Spinal Association (dmarinelli@accessibility-services.com)

Revise as follows:

R320.2 Type C units. Dwelling units and townhouses shall be provided with the accessible features for Type C units in accordance with the applicable portions of Chapter 10 of ICC A117.1. Type C units are permitted to be designed and constructed as accessible units, Type A units or Type B units.

Exception: An exterior circulation path is not required where site constraints beyond the control of the owner prevent its installation.

Reason: As the Type C dwelling unit technical criteria are now included in the 2009 ANSI A117.1 Standard (Section 1005) we would like to insert A117.1 as a reference standard in the IRC to make it clear for jurisdictions that wish to adopt Section 1005 of ANSI A117.1 through legislative scoping amendments to the IRC, that A117.1 is indeed a reference standard applicable for the IRC. The scoping in R320.2 will trigger compliance with Type C unit criteria, while the exception permits a reduction in Type C criteria based on site impracticality or other restrictions outside the owner's control.

Type C units are representative of the term also known as "Visitability" . Visitability is a growing trend nationwide that refers to single-family or owner-occupied housing designed in such a way that it can be lived in or visited by people who have trouble with steps or who use wheelchairs or walkers. The visitability criteria are intended to ensure that in new construction, certain basic accessible features are included at the time of construction, including a unit entrance located on a circulation path complying with Type C criteria, an accessible circulation path that connects the entrance of the unit with one toilet or bathroom, one habitable space with an area 70 square feet minimum, and if a food preparation area is provided on the entrance level, the circulation path shall connect to the food preparation area. There are also features for the bathroom that include reinforcements for grab bars and clearances similar to those required by the Fair Housing Act at the toilet room or bathroom on the entrance level of the unit. Doors along the unit interior circulation path shall have a clear width of 31 ¾ inches – the same as required by FHA.

As stated on Concrete Change's website by Eleanor Smith, a leading advocate for visitability, "First, the spirit of Visitability is as important as the list of features. That spirit says it's not just unwise, but unacceptable that new homes continue to be built with gross barriers — given the how easy it is to build basic access in the great majority of new homes, and given the harsh effects major barriers have on so many people's lives. These easily-avoided barriers cause daily drudgery; unsafe living conditions; social isolation; and forced institutionalization. Visitability is a movement to change home construction practices so that virtually all new homes — not merely those custom-built for occupants who currently have disabilities — offer a few specific features making the home easier for mobility-impaired people to live in and visit. Several people have asked for a more detailed definition, noting that the list of required features has not been identical in all Visitability-type legislation, handouts and other materials."

The inclusion of the Type C criteria in the A117.1 standard was the culmination of a task group that worked to take the various visitability ordinances in place throughout the country and incorporate visitability criteria into A117.1, which designers and builders were familiar with, so that when Visitability was presented to them, they could look to a familiar "standard" to understand what "Visitability" means in terms of design and construction.

Cost Impact: Indicate whether or not this proposal will impact construction costs.

RB179-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R320.2-RB-MARINELLI

RB180 – 13

R322.1, R322.1.6, R322.1.8, R322.1.9, R322.2, R322.2.1, R322.3, R322.3.2, R322.3.3, R322.3.4, and R106.1.3

Proponent: Gregory Wilson, representing Department of Homeland Security, Federal Emergency Management Agency (Gregory.wilson2@fema.dhs.gov; Rebecca Quinn, RCQuinn Consulting, Inc., representing Federal Emergency Management Agency (rcquinn@earthlink.net).

Revise as follows:

R322.1 General. Buildings and structures constructed in whole or in part in flood hazard areas (including A or V Zones and Coastal A Zones) as established in Table R301.2(1) shall be designed and constructed in accordance with the provisions contained in this section. Buildings and structures located in whole or in part in identified floodways shall be designed and constructed in accordance with ASCE 24.

R322.1.6 Protection of mechanical and electrical systems. Electrical systems, equipment and components; heating, ventilating, air conditioning; plumbing appliances and plumbing fixtures; duct systems; and other service equipment shall be located at or above the elevation required in Section R322.2 (flood hazard areas including A Zones) or R322.3 (coastal high-hazard areas including V Zones and Coastal A Zones). If replaced as part of a substantial improvement, electrical systems, equipment and components; heating, ventilation, air conditioning and plumbing appliances and plumbing fixtures; duct systems; and other service equipment shall meet the requirements of this section. Systems, fixtures, and equipment and components shall not be mounted on or penetrate through walls intended to break away under flood loads.

Exception: Locating electrical systems, equipment and components; heating, ventilating, air conditioning; plumbing appliances and plumbing fixtures; duct systems; and other service equipment is permitted below the elevation required in Section R322.2 (flood hazard areas including A Zones) or R322.3 (coastal high-hazard areas including V Zones and Coastal A Zones) provided that they are designed and installed to prevent water from entering or accumulating within the components and to resist hydrostatic and hydrodynamic loads and stresses, including the effects of buoyancy, during the occurrence of flooding to the design flood elevation in accordance with ASCE 24. Electrical wiring systems are permitted to be located below the required elevation provided they conform to the provisions of the electrical part of this code for wet locations.

R322.1.8 Flood-resistant materials. Building materials used below the elevation required in Section R322.2 (flood hazard areas including A Zones) or R322.3 (coastal high-hazard areas including V Zones and Coastal A Zones) shall comply with the following:

1. All wood, including floor sheathing, shall be pressure-preservative-treated in accordance with AWP A U1 for the species, product, preservative and end use or be the decay-resistant heartwood of redwood, black locust or cedars. Preservatives shall be listed in Section 4 of AWP A U1.
2. Materials and installation methods used for flooring and interior and exterior walls and wall coverings shall conform to the provisions of FEMA-TB-2.

R322.1.9 Manufactured homes. New or replacement manufactured homes shall be elevated in accordance with Section R322.2 (flood hazard areas including A Zones) or Section R322.3 in coastal high-hazard areas (V Zones and Coastal A Zones). The anchor and tie-down requirements of Sections AE604 and AE605 of Appendix E shall apply. The foundation and anchorage of manufactured homes to be located in identified floodways shall be designed and constructed in accordance with ASCE 24.

R322.2 Flood hazard areas (including A Zones). All areas that have been determined to be prone to flooding but not subject to high-velocity wave action shall be designated as flood hazard areas. Flood hazard areas that have been delineated as subject to wave heights between 1.5 feet and 3 feet or otherwise designated by the jurisdiction shall be designated as Coastal A Zones and are subject to the requirements in Section R322.3. All buildings and structures constructed in whole or in part in flood hazard areas shall be designed and constructed in accordance with Sections R322.2.1 through R322.2.3.

R322.2.1 Elevation requirements.

1. Buildings and structures in flood hazard areas not designated as Coastal A Zones shall have the lowest floors elevated to or above the design flood elevation.
- ~~2. Buildings and structures in flood hazard areas designated as Coastal A Zones shall have the lowest floors elevated to or above the base flood elevation plus 1 foot (305 mm), or to the design flood elevation, whichever is higher.~~
- ~~2.3~~ In areas of shallow flooding (AO Zones), buildings and structures shall have the lowest floor (including basement) elevated at least as high above the highest adjacent grade as the depth number specified in feet (mm) on the FIRM, or at least 2 feet (610 mm) if a depth number is not specified.
- ~~3.4~~ Basement floors that are below grade on all sides shall be elevated to or above the design flood elevation.

Exception: Enclosed areas below the design flood elevation, including basements whose floors are not below grade on all sides, shall meet the requirements of Section R322.2.2.

R322.3 Coastal high-hazard areas (including V Zones and Coastal A Zones, where designated).

Areas that have been determined to be subject to wave heights in excess of 3 feet (914 mm) or subject to high-velocity wave action or wave-induced erosion shall be designated as coastal high-hazard areas. Flood hazard areas that have been delineated as subject to wave heights between 1.5 feet and 3 feet or otherwise designated by the jurisdiction shall be designated as Coastal A Zones. All buildings and structures constructed in whole or in part in coastal high-hazard areas and in Coastal A Zones, where designated, shall be designed and constructed in accordance with Sections R322.3.1 through R322.3.6.

R322.3.2 Elevation requirements.

1. All buildings and structures erected within coastal high-hazard areas and Coastal A Zones, shall be elevated so that the lowest portion of all structural members supporting the lowest floor, with the exception of mat or raft foundations, piling, pile caps, columns, grade beams and bracing, is:
 - 1.1 Located at or above the design flood elevation, if the lowest horizontal structural member is oriented parallel to the direction of wave approach, where parallel shall mean less than or equal to 20 degrees from the direction of approach, or
 - 1.2 Located at the base flood elevation plus one foot (305 mm), or the design flood elevation, whichever is higher, if the lowest horizontal structural member is oriented perpendicular to the direction of wave approach, where perpendicular shall mean greater than 20 degrees from the direction of approach.
2. Basement floors that are below grade on all sides are prohibited.
3. The use of fill for structural support is prohibited.
4. Minor grading, and the placement of minor quantities of fill, shall be permitted for landscaping and for drainage purposes under and around buildings, and for support of parking slabs, pool decks, patios, and walkways.

Exception: Walls and partitions enclosing areas below the design flood elevation shall meet the requirements of Sections R322.3.4 and R322.3.5.

R322.3.3 Foundations. All buildings and structures erected in coastal high-hazard areas and Coastal A Zones, shall be supported on pilings or columns and shall be adequately anchored to such pilings or columns. The space below the elevated building shall be either free of obstruction or, if enclosed with

walls, the walls shall meet the requirements of Section R322.3.4. Piling shall have adequate soil penetrations to resist the combined wave and wind loads (lateral and uplift). Water loading values used shall be those associated with the design flood. Wind loading values shall be those required by this code. Pile embedment shall include consideration of decreased resistance capacity caused by scour of soil strata surrounding the piling. Pile systems design and installation shall be certified in accordance with Section R322.3.6. Spread footing, mat, raft or other foundations that support columns shall not be permitted where soil investigations that are required in accordance with Section R401.4 indicate that soil material under the spread footing, mat, raft or other foundation is subject to scour or erosion from wave-velocity flow conditions. If permitted, spread footing, mat, raft or other foundations that support columns shall be designed in accordance with ASCE 24. Slabs, pools, pool decks and walkways shall be located and constructed to be structurally independent of buildings and structures and their foundations to prevent transfer of flood loads to the buildings and structures during conditions of flooding, scour or erosion from wave-velocity flow conditions, unless the buildings and structures and their foundation are designed to resist the additional flood load.

Exception: In Coastal A Zones, stem wall foundations supporting a floor system above and backfilled with soil or gravel to the underside of the floor system shall be permitted provided the foundations are designed to account for wave action, debris impact, erosion, and local scour. Where soils are susceptible to erosion and local scour, stem wall foundations shall have deep footings to account for the loss of soil.

R322.3.4 Walls below design flood elevation. Walls and partitions are permitted below the elevated floor, provided that such walls and partitions are not part of the structural support of the building or structure and:

1. Electrical, mechanical, and plumbing system components are not to be mounted on or penetrate through walls that are designed to break away under flood loads; and
2. Are constructed with insect screening or open lattice; or
3. Are designed to break away or collapse without causing collapse, displacement or other structural damage to the elevated portion of the building or supporting foundation system. Such walls, framing and connections shall have a design safe loading resistance of not less than 10 (479 Pa) and no more than 20 pounds per square foot (958 Pa); or
4. Where wind loading values of this code exceed 20 pounds per square foot (958 Pa), the construction documents shall include documentation prepared and sealed by a registered design professional that:
 - 4.1. The walls and partitions below the design flood elevation have been designed to collapse from a water load less than that which would occur during the design flood.
 - 4.2. The elevated portion of the building and supporting foundation system have been designed to withstand the effects of wind and flood loads acting simultaneously on all building components (structural and nonstructural). Water loading values used shall be those associated with the design flood. Wind loading values used shall be those required by this code.
5. In Coastal A Zones walls shall be provided with flood openings that meet the criteria of Section 322.2.2.

Add new text as follows:

R106.1.3 Information for construction in flood hazard areas. For buildings and structures located in whole or in part in flood hazard areas as established by Table R301.2(1), construction documents shall include:

1. Delineation of flood hazard areas, floodway boundaries and flood zones and the design flood elevation, as appropriate;
2. The elevation of the proposed lowest floor, including basement; in areas of shallow flooding (AO zones), the height of the proposed lowest floor, including basement, above the highest adjacent finished grade; and

3. The elevation of the bottom of the lowest horizontal structural member in coastal high hazard areas (V Zone) and in Coastal A Zones where such zones are delineated on flood hazard maps identified in Table R301.2(1) or otherwise designated by the jurisdiction; and
4. If design flood elevations are not included on the community's Flood Insurance Rate Map (FIRM), the building official and the applicant shall obtain and reasonably utilize any design flood elevation and floodway data available from other sources.

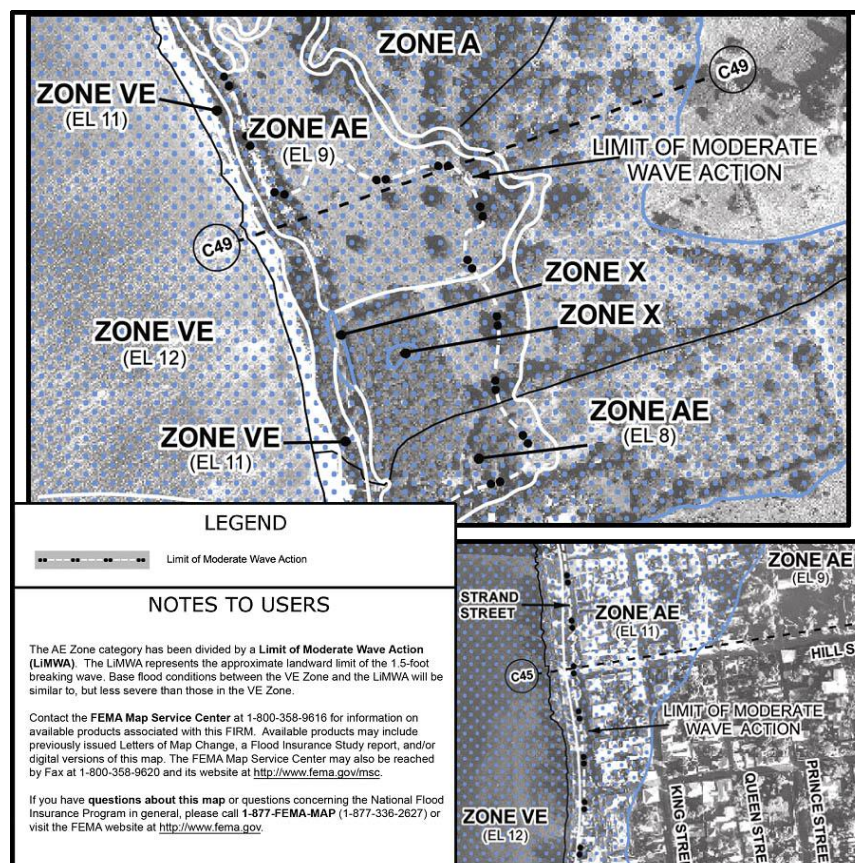

Reason: This proposal would require that dwellings in areas designated as "Coastal A Zones" meet the requirements of Section 322.3 for dwellings in coastal high hazard areas (Zone V), including open foundations (pilings or columns) with an exception that permits filled stemwalls.

The Coastal A Zone (CAZ) has been in ASCE 7 since the late '90s and in ASCE 24 since its initial publication in 1998. Recognition of CAZ was added to the 2009 edition of IRC Section R322.2, with the only requirement that if the area subject to waves between 1.5 ft and 3 ft is delineated, then the area is designated a Coastal A Zone and lowest floors shall be at least one-foot above the design flood elevation (i.e., in all other respects, the 2009 and 2012 IRC requires dwellings in Coastal A Zones to comply with the requirements for Zone A).

The inland boundary of the coastal high hazard area (Zone V) is drawn by FEMA where breaking wave heights are expected to drop below 3.0 ft during base flood conditions. The requirements for foundations of dwellings that are located just landward of the Zone V boundary are predicated on the assumption that hydrodynamic loads associated with waves – even waves that are 2.9-ft – are not significant and that conventional foundations such as perimeter walls can resist those loads and associated erosion and local scour.

FEMA's many post-disaster investigations after severe coastal storms have long recommended application of coastal high hazard area (Zone V) requirements to areas inland of the Zone V/Zone A boundary – in the area subject to waves between 1.5 ft and 3 ft – the area now referred to as "Coastal A Zone". Starting in fiscal year 2009, all coastal flood studies by FEMA will include analyses of moderate wave action and FIRMs will show the Limit of Moderate Wave Action (LiMWA).

The total land area that is likely to be designated as CAZ is small. FEMA has estimated that less than 3 percent of all mapped flood hazard areas are Zone V and the LiMWA generally is determined to be a relatively short distance inland from the Zone V boundary. The graphic below is from the December 2008 Procedure Memorandum No. 50 which established FEMA's policy to delineate the LiMWA on FIRMs

Every FEMA publication on coastal construction since mid-2000 has recommended the use of Zone V construction requirements in Coastal A Zones. As early as 1979 some communities were augmenting the minimum NFIP requirements because of observed wave damage to conventional, closed foundations (Santa Rosa Island Authority, Florida, 1979). FEMA's first Coastal Construction Manual, published in 1981, recognized that "high velocity water may be experienced due to the forward momentum of

breaking waves, especially in the vicinity of the V zone/A zone interface.” The defined term “Coastal A Zone” is used in the 1986 revision of the Coastal Construction Manual, and numerous papers and investigations have followed. Research performed in 1992 for the U.S. Army Corps of Engineers demonstrated that buildings on typical Zone A foundations (masonry walls, masonry piers, shallow piles, and slabs) “would be subject to failure for shallow erosion and /or wave heights less than 2-3 feet.”

Observations after Superstorm Sandy continue to reinforce the damage potential in areas just inland of the Zone V boundary. FEMA’s report based on field investigations will be completed mid-2013. Given that open foundations (piles and columns) perform well under velocity and wave conditions, FEMA believes it is time for the IRC to acknowledge that dwellings in Coastal A Zones should meet the same requirements as dwellings in coastal high hazard areas – with the exception of filled stemwalls that account for the potential for scour and erosion. Surveys and press reports after major coastal events such as Superstorm Sandy regularly report that citizens support stricter requirements (see www.reuters.com/article/2012/11/27/us-storm-sandy-newjersey-idUSBRE8AQ0V620121127, http://blog.nj.com/njv_editorial_page/2012/11/editorial_rebuild_carefully.html).

Cost Impact: This proposal will increase the cost of construction in areas shown on Flood Insurance Rate Maps as seaward of the Limit of Moderate Wave Action (or if a community elects to designate areas as “Coastal A Zones”). However, the risk of wave-induced damage or damage due to erosion and local scour is significantly reduced.

RB180-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R322.1-RB-QUINN-WILSON

RB181 – 13

R322.1.4.2

Proponent: Gregory Wilson, representing Department of Homeland Security, Federal Emergency Management Agency (Gregory.wilson2@fema.dhs.gov); Rebecca Quinn, RCQuinn Consulting, Inc., representing Federal Emergency Management Agency (rcquinn@earthlink.net).

Revise as follows:

R322.1.4.2 Determination of impacts. In riverine flood hazard areas where design flood elevations are specified but floodways have not been designated, the applicant shall demonstrate with hydrologic and hydraulic analyses that the effect of the proposed buildings and structures on design flood elevations, including fill, when combined with all other existing and anticipated flood hazard area encroachments, will not increase the design flood elevation more than one foot (305 mm) at any point within the jurisdiction.

Reason: The existing language simply requires applicants to demonstrate the effect of proposed buildings and structures on DFEs, without saying how it should be accomplished. This places an undue burden on the building official. The added phrase clarifies that analyses are required, specifically hydrologic and hydraulic analyses that are common terms in civil and water resources engineering. FEMA uses those terms to broadly refer to the study methods used to delineate flood hazard areas and to model the floodway.

Cost Impact: None

RB181-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R322.1.4.2-RB-QUINN-WILSON

RB182 – 13

R322.1.5

Proponent: Gregory Wilson, representing Department of Homeland Security, Federal Emergency Management Agency (Gregory.wilson2@fema.dhs.gov); Rebecca Quinn, RCQuinn Consulting, Inc., representing Federal Emergency Management Agency (rcquinn@earthlink.net).

Revise as follows:

R322.1.5 Lowest floor. The lowest floor shall be the lowest floor of the lowest enclosed area, including basement, but excluding any unfinished flood-resistant enclosure that is useable solely for vehicle parking, building access or limited storage provided that such enclosure is not built so as to render the building or structure in violation of this section.

Reason: The addition makes this provision match the definition in the NFIP regulations at 44 CFR 59.1 which is shown below (bold emphasis added to show where in the federal definition the word appears):

"Lowest Floor means the **lowest** floor of the lowest enclosed area (including basement). An unfinished or flood resistant enclosure, usable solely for parking of vehicles, building access or storage in an area other than a basement area is not considered a building's lowest floor; provided, that such enclosure is not built so as to render the structure in violation of the applicable non-elevation design requirements of Sec. 60.3."

Cost Impact: None

RB182-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R322.1.5-RB-QUINN-WILSON

RB183 – 13

R322.1.8

Proponent: Dennis Pitts, American Wood Council, representing American Wood Council
(dpitts@awc.org)

Revise as follows:

R322.1.8 Flood damage-resistant materials. Building materials and installation methods used below the elevation required in Section R322.2 (flood hazard areas including A Zones) or R322.3 (coastal high-hazard areas including V Zones) shall be flood damage-resistant materials that conform to the provisions of FEMA TB-2. ~~comply with the following:~~

- ~~1. All wood, including floor sheathing, shall be pressure-preservative-treated in accordance with AWWA U1 for the species, product, preservative and end use or be the decay-resistant heartwood of redwood, black locust or cedars. Preservatives shall be listed in Section 4 of AWWA U1.~~
- ~~2. Materials and installation methods used for flooring and interior and exterior walls and wall coverings shall conform to the provisions of FEMA TB-2.~~

Reason: This proposal reflects changes approved to the IBC in FS150-12. Adoption of this change will make the IBC and IRC consistent. The specific requirement for preservative-treated wood or naturally decay-resistant wood below the elevation required in Section R322.2 is deleted because wood products such as plywood sheathing, plywood panel siding, and stud walls have been shown to be resistant to the effects of flood exposure without the aid of preservatives or the use of naturally durable wood.

Primary considerations for material performance and use in flood hazard areas are outlined in FEMA TB2, *Flood Resistant Materials Requirements for Buildings Located in Special Flood Hazard Areas*, which is already referenced in the IRC. A flood damage resistant material is one that is "... capable of withstanding direct and prolonged contact with floodwaters without sustaining significant damage." Evaluation consists of consideration of material performance following 72 hour immersion and presence of only limited damage requiring no more than cosmetic repair (i.e. cleaning, sanitizing and resurfacing such as sanding, repair of joints, repainting). Research conducted by Oak Ridge National Laboratory and Tuskegee University (ORNL/TM-2005/34 *Field Testing of Energy-Efficient Flood-Damage-Resistant Residential Envelope Systems Summary Report*, June 2004) and field observations of material performance from actual floods were considerations in the update of FEMA TB2-2008. Within TB2 examples of wood that are not required to be preservative treated for flood damage resistance that may form a part of exterior walls and floors include studs and Exterior and Marine plywood used as wall sheathing. While preservative treated studs and preservative treated exterior plywood sheathing were not tested in the ORNL/Tuskegee study, it is not expected that presence of preservative treatment would improve the already acceptable performance of these materials.

General requirements for preservative treated or naturally durable wood for protection from decay and termites are addressed elsewhere in the IRC, and those applications will continue to be in effect, including in flood hazard areas.

Cost Impact: No increase in the cost of construction.

RB183-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R322.1.8-RB-PITTS

RB184 – 13

R322.1.8, R322.2.2, R322.3.2, R322.3.4, and R322.3.5

Proponent: Gregory Wilson, representing Department of Homeland Security, Federal Emergency Management Agency (Gregory.wilson2@fema.dhs.gov); Rebecca Quinn, RCQuinn Consulting, Inc., representing Federal Emergency Management Agency (rcquinn@earthlink.net).

Revise as follows:

R322.1.8 Flood-resistant materials. Building materials used below the elevation of the lowest floor required in Section R322.2 (flood hazard areas including A Zones) or R322.3 (coastal high-hazard areas including V Zones) shall comply with the following:

1. All wood, including floor sheathing, shall be pressure-preservative-treated in accordance with AWPA U1 for the species, product, preservative and end use or be the decay-resistant heartwood of redwood, black locust or cedars. Preservatives shall be listed in Section 4 of AWPA U1.
2. Materials and installation methods used for flooring and interior and exterior walls and wall coverings shall conform to the provisions of FEMA-TB-2.

R322.2.2 Enclosed area below lowest floor design flood elevation. Enclosed areas, including crawl spaces, that are below the lowest floor design flood elevation shall:

1. Be used solely for parking of vehicles, building access or storage.
2. Be provided with flood openings that meet the following criteria:
 - 2.1. There shall be a minimum of two openings on different sides of each enclosed area; if a building has more than one enclosed area below the design flood elevation, each area shall have openings on exterior walls.
 - 2.2. The total net area of all openings shall be at least 1 square inch (645 mm²) for each square foot (0.093 m²) of enclosed area, or the openings shall be designed and the construction documents shall include a statement by a registered design professional that the design of the openings will provide for equalization of hydrostatic flood forces on exterior walls by allowing for the automatic entry and exit of floodwaters as specified in Section 2.6.2.2 of ASCE 24.
 - 2.3. The bottom of each opening shall be 1 foot (305 mm) or less above the adjacent ground level.
 - 2.4. Openings shall be not less than 3 inches (76 mm) in any direction in the plane of the wall.
 - 2.5. Any louvers, screens or other opening covers shall allow the automatic flow of floodwaters into and out of the enclosed area.
 - 2.6. Openings installed in doors and windows, that meet requirements 2.1 through 2.5, are acceptable; however, doors and windows without installed openings do not meet the requirements of this section.

R322.3.2 Elevation requirements.

1. All buildings and structures erected within coastal high-hazard areas shall be elevated so that the lowest portion of all structural members supporting the lowest floor, with the exception of piling, pile caps, columns, grade beams and bracing, is:
 - 1.1 Located at or above the design flood elevation, if the lowest horizontal structural member is oriented parallel to the direction of wave approach, where parallel shall mean less than or equal to 20 degrees (0.35 rad) from the direction of approach, or
 - 1.2 Located at the base flood elevation plus 1 foot (305 mm), or the design flood elevation, whichever is higher, if the lowest horizontal structural member is oriented perpendicular to the direction of wave approach, where perpendicular shall mean greater than 20 degrees (0.35

- rad) from the direction of approach.
2. Basement floors that are below grade on all sides are prohibited.
3. The use of fill for structural support is prohibited.
4. Minor grading, and the placement of minor quantities of fill, shall be permitted for landscaping and for drainage purposes under and around buildings and for support of parking slabs, pool decks, patios and walkways.

Exception: Walls and partitions enclosing areas below the lowest floor design flood elevation shall meet the requirements of Sections R322.3.4 and R322.3.5.

R322.3.4 Walls below lowest floor design flood elevation. Walls and partitions are permitted below the lowest elevated floor, provided that such walls and partitions are not part of the structural support of the building or structure and:

1. Electrical, mechanical, and plumbing system components are not to be mounted on or penetrate through walls that are designed to break away under flood loads; and
2. Are constructed with insect screening or open lattice; or
3. Are designed to break away or collapse without causing collapse, displacement or other structural damage to the elevated portion of the building or supporting foundation system. Such walls, framing and connections shall have a design safe loading resistance of not less than 10 (479 Pa) and no more than 20 pounds per square foot (958 Pa); or
4. Where wind loading values of this code exceed 20 pounds per square foot (958 Pa), the construction documents shall include documentation prepared and sealed by a registered design professional that:
 - 4.1. The walls and partitions below the lowest floor design flood elevation have been designed to collapse from a water load less than that which would occur during the design flood.
 - 4.2. The elevated portion of the building and supporting foundation system have been designed to withstand the effects of wind and flood loads acting simultaneously on all building components (structural and nonstructural). Water-loading values used shall be those associated with the design flood. Wind-loading values shall be those required by this code.

R322.3.5 Enclosed areas below lowest floor design flood elevation. Enclosed areas below the lowest floor design flood elevation shall be used solely for parking of vehicles, building access or storage.

Reason: The lowest floor, as defined in R322.1.5, may be required to be above the design flood elevation (e.g., if a Coastal A Zone is designated or in a coastal high hazard area depending on orientation of the lowest horizontal structural member). Also, owners and builders may elect to elevate the lowest floor higher than the minimum required elevation. Whether lowest floors are higher by choice or by the code, the walls that enclose areas below the lowest floors should meet the requirements. Floodwaters can and do rise higher than the elevations specified on flood maps, which show the elevation of the base flood (the 1 percent-annual chance (100-year) flood).

FEMA has observed enclosures where breakaway walls have a horizontal failure joint precisely at the base flood elevation, and enclosures where flood damage-resistant materials are used only below the base flood elevation. When floodwaters rise even a slightly higher, damage results. This does not meet the overall intent nor the letter of the NFIP regulations.

Cost Impact: There is no cost increase for the majority of dwellings; there may be a small increase for those where walls would be built to have different characteristics above and below the design flood elevation (e.g., a failure joint or different materials above and below the required elevation).

RB184-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R322.1.8 #1-RB-QUINN-WILSON

RB185 – 13

R322.1.9

Proponent: Gregory Wilson, representing Department of Homeland Security, Federal Emergency Management Agency (Gregory.wilson2@fema.dhs.gov); Rebecca Quinn, RCQuinn Consulting, Inc., representing Federal Emergency Management Agency (rcquinn@earthlink.net).

Revise as follows:

R322.1.9 Manufactured homes. New or replacement *manufactured homes* shall be elevated in accordance with Section R322.2 (flood hazard areas including A Zones) or Section R322.3 in coastal high-hazard areas (V Zones). The anchor and tie-down requirements of the applicable state or federal requirements ~~Sections AE604 and AE605 of Appendix E~~ shall apply. The foundation and anchorage of *manufactured homes* to be located in identified floodways shall be designed and constructed in accordance with ASCE 24.

Reason: Many states and local jurisdictions do not adopt IRC Appendix E. Rather than point to an appendix that is rarely adopted, this proposal replaces the requirement for anchor and tie-downs with a general reference to state or federal requirements. This permits compliance with state manufactured home installation standards or HUD's installation standards, whichever is required. HUD's regulations at CFR § 3285.302 specifies that "foundations, anchoring, and support systems must be capable of resisting loads associated with design flood and wind events or combined wind and flood events, and homes must be installed on foundation supports that are designed and anchored to prevent floatation, collapse, or lateral movement of the structure."

Cost Impact: None; no change in requirements for anchoring and tie-down, just change to citation to the requirements.

RB185-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R322.1.9 #1-RB-QUINN-WILSON

RB186 – 13

R322.1.9

Proponent: Gregory Wilson, representing Department of Homeland Security, Federal Emergency Management Agency (Gregory.wilson2@fema.dhs.gov); Rebecca Quinn, RCQuinn Consulting, Inc., representing Federal Emergency Management Agency (rcquinn@earthlink.net).

Revise as follows:

R322.1.9 Manufactured homes. The bottom of the frame of new and ~~New or~~ replacement manufactured homes ~~on foundations that conform to the requirements of Section R322.2 or Section R322.3, as applicable,~~ shall be elevated ~~to or above the elevations specified in accordance with~~ Section R322.2 (flood hazard areas including A Zones) or Section R322.3 in coastal high-hazard areas (V Zones). The anchor and tie-down requirements of Sections AE604 and AE605 of Appendix E shall apply. The foundation and anchorage of manufactured homes to be located in identified floodways shall be designed and constructed in accordance with ASCE 24

Reason: This proposal is based on the fact that manufactured homes are the most vulnerable type of structures in terms of risk of flood damage. The figures below illustrate how damage increases dramatically for just one foot of water above the lowest floor (walking surface). Requiring the bottom of the frame to be the reference point means the homes will be approximately one foot above the base flood elevation. Not only will the homes be less vulnerable to damage, owners will have lower flood insurance premiums.

The figure below is based on the data found in Table B-10 (Coastal A Zones and V Zones) and Table B-17 (all other SFHAs) *FEMA Benefit-Cost Analysis Re-engineering (BCAR), Flood Module Revision: Updates to Residential Depth Damage Functions (DDFs) and Guidance for Coastal Flooding* (January 2011; version 4.5.5). The riverine depth damage function curves for manufactured homes were originally developed by the NFIP many years ago and been used in FEMA's Benefit-Cost Analysis (BCA) software for years. FEMA convened an expert panel in 2010 to develop updated DDFs coastal high hazard areas and Coastal A Zones for various residential structures including manufactured homes.

The depth-damage functions show that a manufactured home in a Zone A will sustain more about 8% structure damage if floodwaters rise just to the elevation of the lowest floor (the walking surface), and more than 40% if water rises one foot higher. By requiring elevation based on the bottom of the frame, virtually no damage would be expected during base flood conditions.

If located in a Zone V or Coastal A Zone, the curve shows that a manufactured home will sustain nearly 100% damage if floodwaters rise to the elevation of the lowest floor. IRC R322.3.2 already references the bottom of the lowest horizontal structural member, which is the bottom of the frame.

Cost Impact: The cost of a foundation in Zone A will be marginally higher because of the approximately one additional foot that will have to be added to the foundation. The requirement to conform to the foundation requirements based on flood zone has always

been implicit in the NFIP requirement that manufactured homes be “elevated on a permanent foundation . . . and be securely anchored to an adequately anchored foundation system to resist floatation collapse and lateral movement” (see 44 CFR 60.3(c)(6)).

R322.1.9 #2-RB-QUINN-WILSON

RB187 – 13

R322.1.9 (New)

Proponent: Gregory Wilson, representing Department of Homeland Security, Federal Emergency Management Agency (Gregory.wilson2@fema.dhs.gov); Rebecca Quinn, RCQuinn Consulting, Inc., representing Federal Emergency Management Agency (rcquinn@earthlink.net).

Add new text as follows

R322.1.9 Stairways and ramps. Stairways and ramps that are located below the lowest floor elevations specified in Sections R322.2.1 or R322.3.2, as applicable to the flood hazard area, shall either:

1. Be designed and constructed to resist flood-related loads and to minimize transfer of flood-related loads to the building or structure; or
2. Break away during design flood conditions without causing damage to the building or structure; or
3. Be retractable, or be able to be raised, to or above the lowest floor elevations, provided the ability to be retracted or raised prior to onset of conditions of flooding is not contrary to means of egress requirements of the code.

(Renumber subsequent sections)

Reason: This proposal lays out options for satisfying the general requirement in R322.1.3 which requires “All buildings and structures erected in flood hazard areas shall be constructed by methods and practices that minimize flood damage.” That means stairways and ramps should resist flood loads along with the dwellings they serve. These same requirements are included in ASCE 24-13.

In coastal high hazard areas (Zone V), stairs that are not properly constructed to meet the free-of-obstructions requirement below elevated buildings can damage the building when they fail. This damage has been observed during FEMA’s post-flood investigations after numerous flood events (also see Figure 1 from NFIP Technical Bulletin 2 Free-of-Obstruction Requirements).

Figure 1. Stairs did not break away cleanly, resulting in damage to the elevated building.

Cost Impact: There should be no additional costs because of the existing requirement in R322.1.3.

R322.1.9-(NEW)-RB-QUINN-WILSON

RB188 – 13

R322.2.1, R322.3.2

Proponent: Gregory Wilson, representing Department of Homeland Security, Federal Emergency Management Agency (gregory.p.wilson@dhs.gov); Rebecca Quinn, RCQuinn Consulting, Inc., representing Federal Emergency Management Agency (rcquinn@earthlink.net).

Revise as follows:

R322.2.1 Elevation requirements.

1. Buildings and structures in flood hazard areas, including flood hazard areas not designated as Coastal A Zones, shall have the lowest floors elevated to or above the base flood elevation plus 1 foot (305 mm), or the design flood elevation, whichever is higher.
- ~~2. Buildings and structures in flood hazard areas designated as Coastal A Zones shall have the lowest floors elevated to or above the base flood elevation plus 1 foot (305 mm), or to the design flood elevation, whichever is higher.~~
- ~~2.3~~ In areas of shallow flooding (AO Zones), buildings and structures shall have the lowest floor (including basement) elevated at least as high above the highest adjacent grade as the depth number specified in feet (mm) on the FIRM plus 1 foot (305 mm), or at least 3 feet (15 mm) 2 feet (610 mm) if a depth number is not specified.
- ~~3.4~~ Basement floors that are below grade on all sides shall be elevated to or above base flood elevation plus 1 foot (305 mm), or the design flood elevation, whichever is higher.

Exception: Enclosed areas below the design flood elevation, including basements whose floors are not below grade on all sides, shall meet the requirements of Section R322.2.2.

R322.3.2 Elevation requirements.

1. All buildings and structures erected within coastal high-hazard areas shall be elevated so that the bottom of the lowest portion of all horizontal structural members supporting the lowest floor, with the exception of piling, pile caps, columns, grade beams and bracing, is elevated to or above the base flood elevation plus 1 foot (305 mm) or the design flood elevation, whichever is higher.
 - ~~1.1 Located at or above the design flood elevation, if the lowest horizontal structural member is oriented parallel to the direction of wave approach, where parallel shall mean less than or equal to 20 degrees (0.35 rad) from the direction of approach, or~~
 - ~~1.2 Located at the base flood elevation plus 1 foot (305 mm), or the design flood elevation, whichever is higher, if the lowest horizontal structural member is oriented perpendicular to the direction of wave approach, where perpendicular shall mean greater than 20 degrees (0.35 rad) from the direction of approach.~~
2. Basement floors that are below grade on all sides are prohibited.
3. The use of fill for structural support is prohibited.
4. Minor grading, and the placement of minor quantities of fill, shall be permitted for landscaping and for drainage purposes under and around buildings and for support of parking slabs, pool decks, patios and walkways.

Exception: Walls and partitions enclosing areas below the design flood elevation shall meet the requirements of Sections R322.3.4 and R322.3.5.

Reason: The purpose of this code change is to reduce flood risks on homes by adding a factor of safety of one-foot of additional height (called freeboard) to the elevation requirements. This proposal will align the IRC with the elevation requirements for Category II buildings (includes Group R), by reference to ASCE 24 which requires elevation to BFE + 1 or DFE, whichever is higher.

This statement identifies several reasons to add just one foot to the elevation requirements to the IRC.

More than 20 states adopt the I-Codes at the state level and mandate local enforcement. Many of those states do not permit communities to modify the code. Some states do not explicitly recognize that communities may have a “stand alone” floodplain management ordinance that includes requirements for buildings, including elevation, and some provide that only the building code governs buildings (which may have the effect of nullifying building requirements in local ordinances). It is no longer valid to argue that the IRC should not provide reasonable protection of just one additional foot of elevation for dwellings based on the assumption that communities can separately adopt higher standards.

In New Jersey and New York, about 43 percent of the areas flooded by Superstorm Sandy had water that rose above the BFE (according to preliminary analyses). Of the land area where flooding exceeded BFE, about half was between BFE and BFE +1, and about a quarter was between BFE + 1 and BFE + 2. Although there isn't a count of the total number of flooded homes in those areas, it's easy to see that if lowest floors had been elevated just one foot higher, the majority would have had considerably less damage. According to a Quinnipiac University Polling poll taken shortly after Superstorm Sandy and cited by Reuters, “Seven in 10 New Jersey voters favored rebuilding the Jersey Shore under stricter building codes, including three-quarters of shore residents.”

An independent report prepared for FEMA, *Evaluation of the National Flood Insurance Program's Building Standards* (October 2006), provides clear evidence of the benefits associated with adding freeboard. It documents the added costs (as a percent of the cost of building to the base flood elevation) and the benefits of adding freeboard. Approximately 1,500 combinations of house size, foundation type, flood zone, flood elevation, freeboard added, and discount rate were evaluated. The benefits considered are two-fold: flood damages avoided and flood insurance premium savings.

The report concluded that – based on flood damages avoided only -- it is worth spending an additional percentage of the at-BFE building cost to incorporate freeboard, where the percentage generally ranges from less than 1% to 5% for one-foot of freeboard, depending on the flood hazard zone. The cost of adding one-foot of freeboard, on the other hand, ranged from 0.25% to 3% of the at-BFE building cost (see cost statement below) depending on the type of foundation and the flood hazard zone. The flood damage reduction benefits of BFE + 1 ft outweighed the costs of constructing that freeboard in all but a few cases (e.g., where large quantities of fill are already needed to raise a Zone A building to the BFE).

The savings in insurance premium reduction (see graphic), which are realized by every homeowner for the life of the building, are on top of savings associated with avoiding future damage. Flood insurance premium savings alone can recover the added cost of freeboard in just a few years. Importantly, the report acknowledges that the computed benefits “are conservative, and will understate the true benefits” because some avoided costs are not accounted for, including clean-up and demolition costs, debris disposal costs, uninsured losses, displacement and relocation costs, loss of jobs and tax base, etc.

Additional substantiation for the additional elevation requirement is found in the insurance rating structure of the NFIP which bases rates for new buildings as a function of risk. Freeboard reduces risk because the lowest floors of buildings are elevated above the predicted flood levels associated with the base (100-year) flood. This risk reduction is reflected in reduced insurance rates, with reductions of 20% or more for the first foot of freeboard above the base flood elevation. The graphic below shows examples of how the cost of insurance varies as a function of elevation (based on insurance rates in effect in 2009). Note: the graphic illustrates insurance costs for four scenario dwellings with different foundation types and different values of the structure and contents; it should not be used for any purpose other than to illustrate the general variation in costs as a function of elevation. In Zone V, the annual cost of flood insurance is approximately 25% less if a number is one foot higher than the minimum (House A). In Zone A, the annual cost is approximately 40% less.

Further substantiation for this code change is found in Mitigation Assessment Team reports prepared by teams of experts assembled by FEMA after significant disasters. Reports prepared after hurricanes and flood disasters include recommendations to reduce future damage, including adding at least one-foot of freeboard (see bibliography). Specific recommendations are to adopt freeboard requirements that are consistent with those specified in ASCE 24.
