C404.6 ~~Hot~~ Heated water system controls. Circulating hot water system pumps or heat trace water temperature maintenance systems shall be controlled in accordance with Sections C404.6.1 and C406.6.2. ~~arranged to be turned off either automatically or manually when there is limited hot water demand. Ready access shall be provided to the operating controls.~~ *A*utomatic controls, temperature sensors, and pumps shall be *accessible*. Manual controls shall be *readily accessible*. Heated water circulation systems without controls such as gravity and thermo-syphon circulation systems, shall be prohibited. Continuous operation of pumps in heated water circulation systems shall be prohibited.

C404.6.1 Circulation pumps. Controls for circulating hot water system pumps shall start the pump based on the identification of a demand for heated water within the occupancy. The controls shall automatically turn off the pump when the water in the circulation loop is at the desired temperature and when there is no demand for hot water.

C404.6.2 Heat trace. Heat trace controls shall automatically adjust the energy input to the piping to maintain the desired water temperature in the piping system. The controls shall adjust the energy input to the heat tracing when the controls identify demand for heated water.

Reason: The current code text allows for the use of continuously operating circulation pumps in a hot water system. With no limitation of prohibiting pumps that operate continuously, this control methodology is not energy efficient, even when there is no need for hot water or there is ample hot water available in the system.

Energy can be saved with circulating hot water systems by operating the pump only when there is a demand for hot water. In addition, the pump does not need to operate when the hot water system is capable of providing the hot water at the desired temperature.

Cost Impact: The code change proposal will not increase the cost of construction.

C404.6-EC-TOWSLEY.DOC

Committee Action Hearing Results

Parts I and II of this code changes were heard by the Commercial Energy Conservation Code Development Committee and Part III was heard by the Residential Energy Conservation Code Development Committee.

PART I – IECC - Commercial
Committee Action: Disapproved

Committee Reason: The committee liked the intent of the proposal but there could be some unintended consequences with regard to prohibiting continuous operation of pumps.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Greg Towsley, Grundfos, representing self, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

C404.6 Heated water system controls. Circulating hot water system pumps or heat trace water temperature maintenance systems shall be controlled in accordance with Sections C404.6.1~~ and C406.6.2~~. *A*utomatic controls, temperature sensors, and pumps shall be *accessible*. Manual controls shall be *readily accessible*. Heated water circulation systems without controls such as gravity and thermo-syphon circulation systems, shall be prohibited. Continuous operation of pumps in heated water circulation systems shall be prohibited.

C404.6.1 Circulation pumps. Controls for circulating hot water system pumps shall start the pump based on the identification of a demand for heated water within the occupancy. The controls shall automatically turn off the pump when the water in the circulation loop is at the desired temperature and when there is no demand for hot water.

~~**C404.6.2 Heat trace.** Heat trace controls shall automatically adjust the energy input to the piping to maintain the desired water temperature in the piping system. The controls shall adjust the energy input to the heat tracing when the controls identify demand for heated water.~~

Commenter's Reason: The Committee liked the intent of the original proposal because of the opportunity to reduce pumping energy in domestic hot water system AND allow for new automated and intuitive technologies to controls pumps. The Committee rejected this proposal because of concerns with "unintended consequences with regard to prohibiting continuous operation of pumps." In trying to research a response for the Committee's concern, I was unable to find any potential "unintended consequences" I was actually able to determine that California, Europe and the IGCC actually allow stopping or prohibiting continuous operation of the circulation pumps. As this proposal is for the IECC, it should be included in the code. The modifications shown above focuses the code change only on the circulating pump controls and eliminates any newly proposed reference to "heat trace" systems that are covered under other proposals.

Proponent: Greg Towsley, LEED AP BD+C Grundfos representing Grundfos (gtowsley@grundfos.com)

PART III – IECC-RESIDENTIAL PROVISIONS

Add new definition as follows:

SECTION R202 (N1101.9)
GENERAL DEFINITIONS

<u>**CIRCULATING HOT WATER SYSTEM.** A specifically designed water distribution system where one or more pumps are operated in the service hot water piping to circulate heated water from the water-heating equipment to fixtures and back to the water-heating equipment.</u>

Reason: A definition of a "circulating hot water system" does not exist in the code, yet it is referenced in the IRC and other ICC codes. This definition brings clarity to how a "circulating hot water system" should be designed and operated. In the codes and sections where "circulating hot water system" is used, this definition would also reduce the probability of confusion between hot water systems used for space heating or tempered water. Currently, the only place that the term CIRCULATING HOT WATER SYSTEM shows up in the code is IECC Section C404.6, IPC [E] 607.2.1 and IECC Section R403.4.1 (IRC N1103.4.1). Other proposals by other proponents will most likely be adding language that uses this term so it is important to have the term defined.

As referenced in CHAPTER 50 - SERVICE WATER HEATING of *ASHRAE Handbook-HVAC Applications* (2011, American Society of Heating, Refrigerating and Air-Conditioning Engineers, Inc.), "Some recirculation-loop systems...are equipped with circulating pumps to force water through the piping and back to the water heater, thus keeping water in the piping hot." Adding this definition in the code will be consistent with industry's understanding.

Cost Impact: The code change proposal will not increase the cost of construction.

C202-CIRCULATING HOT WATER SYSTEM (NEW)-EC-TOWLSEY.doc

<u>Committee Action Hearing Results</u>

Parts I and II of this code changes were heard by the Commercial Energy Conservation Code Development Committee and Part III was heard by the Residential Energy Conservation Code Development Committee.

PART III – IECC – Residential
Committee Action: Disapproved

Committee Reason: There needs to be a definition for heat trace because it is not understood what that is.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Greg Towsley, Grundfos, representing self, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R403.4.1 (N1103.4.1) Circulating hot water systems (Mandatory). Circulating hot water systems ~~and heat trace water temperature maintenance systems~~ shall be controlled in accordance with Sections R403.4.1.1~~ and R403.4.1.2~~. Automatic controls, temperature sensors, and pumps shall be *accessible*. Manual controls shall be *readily accessible*. Hot water circulation systems without controls such as gravity and thermo-syphon circulation systems, shall be prohibited. Continuous operation of pumps in hot water circulation systems shall be prohibited.

R403.4.1.1 (N1103.4.1.1) Circulation pumps. Controls for circulating hot water system pumps shall start the pump based on the identification of a demand for hot water within the occupancy. The controls shall automatically turn off the pump when the water in the circulation loop is at the desired temperature and when there is no demand for hot water.

~~**R403.4.1.2 (N1103.4.1.2) Heat trace.** Heat trace controls shall automatically adjust the energy input to the piping to maintain the desired water temperature in the piping system. The controls shall adjust the energy input to the heat tracing when the controls identify demand for heated water.~~

Commenter's Reason: The Committee generally thought the proposal was good because of the energy saving opportunity, especially the prohibition of gravity and thermo-syphon circulation systems and "openness" of the circulation pump control wording to allow for new, innovative technologies to be developed. The Committee rejected this proposal because of lack of a definition for heat trace. There was a lack of clarity as it related to "heat trace" systems in this section. To eliminate the confusion or understanding, especially as it relates to the focus of circulating systems with pumps, the proposal is being revised to delete the modification to add "heat trace".

CE280-13, Part III

Final Action: AS AM AMPC____ D

CE282-13, Part I

C404.7 (New), IPC Chapter 2, IPC [E]607.2.1.1 (New)

Proposed Change as Submitted

THIS IS A 2 PART CODE CHANGE PROPOSAL. PARTS I AND TWO WILL BE HEARD BY THE COMMERCIAL ENERGY CONSERVATION CODE DEVELOPMENT COMMITTEE.

Proponent: Gary Klein, Affiliated International Management, LLC, representing self, (gary@aim4sustainability.com)

PART I – IECC-COMMERCIAL PROVISIONS

Add new text as follows:

C404.7 Demand recirculation controls. A water distribution system having one or more recirculation pumps that pump water from a heated water supply pipe back to the heated water source through a cold water supply pipe shall be a *demand recirculation water system.* Pumps shall have controls that comply with both of the following:

1. The control shall start the pump upon receiving a signal from the action of a user of a fixture or appliance, sensing the presence of a user of a fixture or sensing the flow of hot or tempered water to a fixture fitting or appliance.
2. The control shall limit the water temperature increase in the cold water piping to not more than 10ºF (5.6 ºC) greater than the initial temperature of the water in the piping and limits the temperature entering the cold water piping to 102ºF (38.9 ºC).

Reason: The purpose of this code change proposal is to clarify the requirements for installing circulation pumps in applications that use a cold water supply pipe to circulate the water back to the water heater. Demand recirculation water systems are significantly more energy efficient than other recirculation systems and are inherently safer when the cold water supply is used as the return.

Figure 1 shows that demand activated circulation is significantly more energy efficient than any other type of heated water circulation system. The annual energy needed to keep the loop hot with water heated electrically or with natural gas are shown separately from the energy needed for the pump. The majority of the energy is lost in keeping the water in the loop at the desired temperature (all of it if there is a gravity loop). A small loop, 100 feet including the supply and the return was analyzed. The savings ranges from 87.5 percent when compared to a recirculation system that runs only 2-hours per day to 99 percent when compared to a recirculation system that runs only 24-hours per day. The operating costs and savings remain proportional as the length of the circulation loop and the flow rate of the pump increase.

Figure 1 Annual Energy Requirements for Demand Activated Circulation and Standard Recirculation

	Standard Recirculation						Demand Activated Circulation
	Daily Hours of Operation						
	24	12	8	6	4	2	0.25
Loop Heat Losses							
Natural Gas (therms)	292	146	97	73	49	24	3
Electric (kWh)	6,388	3,194	2,129	1,597	1,065	532	67
Pump Energy (kWh)	438	219	146	110	73	37	8

The inherently better safety comes from the fact that the controls specified for demand recirculation water systems limit the flow of water from the hot water supply into the cold water supply to only minutes a day and because they limit the temperature of the water that is allowed to go into the cold water supply. There are five other control strategies for heated water recirculation systems (thermosyphon (gravity), continuous pumping, timer controlled, bandwidth temperature sensor (aquastat) controlled and a combination of timer and bandwidth temperature sensor (aquastat) controlled and none of them has the ability to meet these stringent requirements.

The requirements of this section should be identical in both the IECC and the IPC, since the language for the controls does not depend on occupancy

For more information and background on issues related to hot water distribution and for a more detailed analysis in support of this proposal please go to http://www.aim4sustainability.com Follow the link on the home page to Codes.

Cost impact: This proposal will not increase the cost of construction, as it does not require the use of demand recirculation water systems. In addition, the ability to use cold-water supply piping as a return pipe may reduce the cost of installing a circulation loop.

C404.7-EC-KLEIN

Committee Action Hearing Results

Both parts of this code changes were heard by the Commercial Energy Conservation Code Development Committee.

PART I – IECC - Commercial
Committee Action: Approved as Submitted

Committee Reason: The proposal was approved to be consistent with a similar proposal that was approved for the IECC-Residential Provisions.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Gary Klein, Affiliated International Management, LLC, representing self, requests Approval as Submitted.

Commenter's Reason: I agree with the Committee's reason and urge your support of this proposal.

Public Comment 2:

Greg Towsley, Grundfos representing self, requests Approval as Modified by this Public Comment

Modify the proposal as follows:

[E] 607.2.1.1 Demand recirculation controls. A water distribution system having one or more recirculation pumps that pump water from a heated water supply pipe back to the heated water source through a cold water supply pipe shall be a demand recirculation water system. Pumps shall have controls that comply with both of the following:

1. The control shall start the pump upon receiving a signal from the action of a user of a fixture or appliance, sensing the presence of a user of a fixture, or sensing the flow of hot or tempered water to a fixture fitting or appliance.
2. The control shall limit the ~~water temperature increase in the cold water piping to not more than 10ºF (5.6 ºC) greater than the initial temperature of the water in the piping and limits the~~ temperature of the water entering the cold water piping to ~~102ºF (38.9 ºC)~~ 104°F (40°C).

Commenter's Reason: The addition of the comma after fixture clarifies that there are three (3) options on how the pump will start. Eliminating the requirement of a temperature rise allows for innovation and reduces restriction of technology from only one design. Most thermostats available in the market are designed for 104°F, not 102°F.

CE282-13, Part I
Final Action: AS AM AMPC____ D

CE282-13, Part II
C404.7 (New), IPC Chapter 2, IPC [E]607.2.1.1 (New)

Proposed Change as Submitted

THIS IS A 2 PART CODE CHANGE PROPOSAL. PARTS I AND TWO WILL BE HEARD BY THE COMMERCIAL ENERGY CONSERVATION CODE DEVELOPMENT COMMITTEE.

Proponent: Gary Klein, Affiliated International Management, LLC, representing self, (gary@aim4sustainability.com)

PART II-IPC

Add new text as follows:

[E] 607.2.1.1 Demand recirculation controls. A water distribution system having one or more recirculation pumps that pump water from a heated water supply pipe back to the heated water source through a cold water supply pipe shall be a *demand recirculation water system.* Pumps shall have controls that comply with both of the following:

1. The control shall start the pump upon receiving a signal from the action of a user of a fixture or appliance, sensing the presence of a user of a fixture or sensing the flow of hot or tempered water to a fixture fitting or appliance.
2. The control shall limit the water temperature increase in the cold water piping to not more than 10ºF (5.6 ºC) greater than the initial temperature of the water in the piping and limits the temperature entering the cold water piping to 102ºF (38.9 ºC).

Add definition as follows:

DEMAND RECIRCULATION WATER SYSTEM. A water distribution system where one more pumps prime the service hot water piping with heated water upon demand for hot water.

Reason: The purpose of this code change proposal is to clarify the requirements for installing circulation pumps in applications that use a cold water supply pipe to circulate the water back to the water heater. Demand recirculation water systems are significantly more energy efficient than other recirculation systems and are inherently safer when the cold water supply is used as the return.

Figure 1 shows that demand activated circulation is significantly more energy efficient than any other type of heated water circulation system. The annual energy needed to keep the loop hot with water heated electrically or with natural gas are shown separately from the energy needed for the pump. The majority of the energy is lost in keeping the water in the loop at the desired temperature (all of it if there is a gravity loop). A small loop, 100 feet including the supply and the return was analyzed. The savings ranges from 87.5 percent when compared to a recirculation system that runs only 2-hours per day to 99 percent when compared to a recirculation system that runs only 24-hours per day. The operating costs and savings remain proportional as the length of the circulation loop and the flow rate of the pump increase.

Figure 1 Annual Energy Requirements for Demand Activated Circulation and Standard Recirculation

	Standard Recirculation						Demand Activated Circulation
	Daily Hours of Operation						
	24	12	8	6	4	2	0.25
Loop Heat Losses							
Natural Gas (therms)	292	146	97	73	49	24	3
Electric (kWh)	6,388	3,194	2,129	1,597	1,065	532	67
Pump Energy (kWh)	438	219	146	110	73	37	8

The inherently better safety comes from the fact that the controls specified for demand recirculation water systems limit the flow of water from the hot water supply into the cold water supply to only minutes a day and because they limit the temperature of the water that is allowed to go into the cold water supply. There are five other control strategies for heated water recirculation systems (thermosyphon (gravity), continuous pumping, timer controlled, bandwidth temperature sensor (aquastat) controlled and a combination of timer and bandwidth temperature sensor (aquastat) controlled and none of them has the ability to meet these stringent requirements.

The requirements of this section should be identical in both the IECC and the IPC, since the language for the controls does not depend on occupancy

For more information and background on issues related to hot water distribution and for a more detailed analysis in support of this proposal please go to http://www.aim4sustainability.com Follow the link on the home page to Codes.

Cost impact: This proposal will not increase the cost of construction, as it does not require the use of demand recirculation water systems. In addition, the ability to use cold-water supply piping as a return pipe may reduce the cost of installing a circulation loop.

C404.7-EC-KLEIN

Committee Action Hearing Results

Parts I and II of this code changes were heard by the Commercial Energy Conservation Code Development Committee and Part III was heard by the Residential Energy Conservation Code Development Committee.

PART II – IPC
Committee Action: Approved as Submitted

Committee Reason: The proposal properly aligns the *International Plumbing Code* with the IECC-CE and adds a necessary definition to the IPC.

Assembly Action: None

PART I IECC-COMMERCIAL PROVISIONS

Revise as follows:

C404.7 Drain water heat recovery units. Drain water heat recovery units shall comply with CSA 55.2. Potable water-side pressure loss shall be less than 10 psi at maximum design flow. For Group R occupancies, the efficiency of drain water heat recovery unit efficiency shall be in accordance with CSA 55.1.

TABLE C407.5.1(1)
SPECIFICATIONS FOR THE STANDARD REFERENCE AND PROPOSED DESIGNS

BUILDING COMPONENT	STANDARD REFERENCE DESIGN	PROPOSED DESIGN
Service water weating[f,g,h,j]	Fuel type: same as proposed	As proposed
	Efficiency: in accordance with Table C404.2	For Group R, as proposed multiplied by SWHF For other than Group R, as proposed multiplied by efficiency as provided by the manufacturer of the DWHR unit.
	Capacity: same as proposed	As proposed
	Where a service water hot water system does not exist or is not specified in the proposed design, a service hot water heating shall not be modeled.	

(Portions of Table not shown remain unchanged)

j. SWHF means service water heat recovery factor. DWHR means drain water heat recovery. The SWHF shall be applied as follows:

= (1 – (DWHR unit efficiency x 0.36))

where potable water from the DWHR unit supplies not less than 1 shower and not greater than 2 showers, of which the drain water from the same showers flows through the DWHR unit.
= (1 – (DWHR unit efficiency x 0.33))
where potable water from the DWHR unit supplies not less than 3 showers and not greater than 4 showers, of which the drain water from the same showers flows through the DWHR unit.
= (1 – (DWHR unit efficiency x 0.26))
where potable water from the DWHR unit supplies not less than 5 showers and not greater than 6 showers, of which the drain water from the same showers flows through the DWHR unit,
= 1.0
where the other conditions are not met.

Add new standards to Chapter 5 as follows:

CSA

CSA 55.1-2012 Test method for measuring efficiency and pressure loss of drain water heat recovery units

CSA 55.2-2012 Drain water heat recovery units

Reason: There are two reasons for this proposal.1) To enable developers to take credit for efficiency improvements due to the use of drain water heat recovery devices in the performance calculations in the energy code; and 2) to make comparisons of the efficiency of different units based on an existing standard.

Drain water heat recovery (DWHR) works particularly well where heated water flows down the drain at the same time as water flows in that needs to be heated; this "coincident flow" occurs in occupancies with showering and lavatory use. Performance of a DWHR unit is characterized by both efficiency and pressure loss. It is important to ensure that DWHR devices do not impose large pressure losses in the piping in order to minimize the impact on water flow in the building. Given the available DWHR efficiencies, savings are typically 10% to 35% of the energy used for heating water. Over 25,000 drain water heat recovery units have been installed in homes in Canada and the United States.

This change adds two standards for drain water heat recovery units (DWHR units). Drain water heat recovery is often a cost effective way to add to energy efficiency by recapturing hot water energy that is literally "going down the drain". The proposed standards have already been in use by designers for 10 years and the resulting ratings are in use by a variety of energy efficiency programs. Commercial (i.e. non multi-unit residential) applications are engineered systems while multi-unit residential applications are non-engineered and straightforward.

CSA B55.2 standard is for fabrication and material quality of DWHR units. The CSA B55.1 standard is for testing and labeling of DWHR units efficiency and pressure loss at 2.5gpm (9.5lpm). These existing standards were developed through a consensus process by the Canadian Standards Association and are referenced by the Ontario Building Code.

A typical drain water heat recovery unit is shown below:

POWER-PIPE®

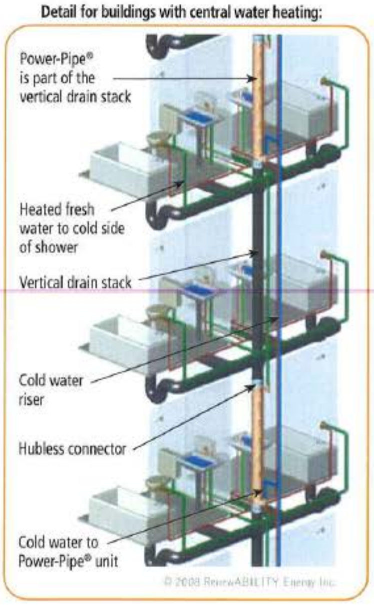
Drain Water Heat Recovery Systems

Reduce Operating Costs for Multi-Unit Residential Buildings

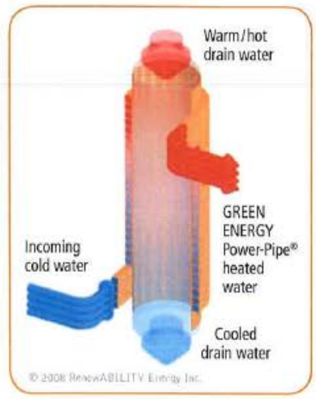
Cost-Effective Green Energy Technology

- The Power-Pipe® is **proven, practical, affordable** and in use today saving energy for thousands of residential suites.
- **Water heating is typically the second highest energy cost** in multi-unit residential buildings; in fact it can even be the highest energy cost.

Detail for buildings with central water heating:



- As building envelopes have become more efficient in recent years water heating has become an even larger portion of the remaining energy costs.
- Much of the drain water leaving a residential building carries with it valuable and recoverable heat energy.
- The all copper Power-Pipe is a double-wall heat exchanger that can **reduce water heating costs by 20-40%** by recovering heat energy from drain (waste) water in multi-residential building drain (waste) stacks.
- The patented and patent pending Power-Pipe design is the only heat exchanger that efficiently allows for up to 4 apartment suites to be plumbed without noticeable loss in water pressure... in fact this results in a **2 to 4 times faster payback** than other heat exchangers.
- The Power-Pipe is very **simple to specify and install** and its savings typically translate to a **3 to 4 year simple payback**; even faster with government or utility incentives.



How It Works

1. As drain water falls down any vertical drain stack it clings to the inner wall, rather than going down the middle of the pipe. This results in a quickly falling thin film.
2. The energy (heat) from this falling film of drain water is easily and efficiently transferred through the copper to the fresh cold water which is flowing around the drain pipe in the outer coils.
3. Cold fresh water is plumbed into the bottom of the Power-Pipe from the main cold water riser.
4. Power-Pipe heated water is then plumbed to either:
   - the cold side of up to 4 showers, for buildings with central water heating, thereby reducing hot water demand
   - the cold side of the shower and water heater, for buildings with in-suite water heaters

877-606-5559
www.renewability.com

Advantages of the Power-Pipe®

- The Power-Pipe® is **very simple to install** during new construction and it integrates with any plumbing system
- The Power-Pipe **can be retrofit** in buildings where there is access to the drain stacks and fresh water lines
- Maintenance-free, 50+ year life
- The Power-Pipe will increase effective hot water capacity, thereby reducing the risk of running out of hot water
- **Quality** is never compromised; the coils of every Power-Pipe unit consist of 100% Type L or heavier copper tube
- The Power-Pipe also provides significant cost-effective **reductions in green house gases** as a result of reduced primary energy demand
- The performance of the Power-Pipe has been **verified by the Canadian Government** *(Ministry of Natural Resources Canada and the University of Waterloo)* in independent third-party testing
- The Power-Pipe will **assist in obtaining LEED Certification** (and similar programs) for your building
- Many Governments and Utilities also offer **financial incentives** resulting in a quicker payback
- The Power-Pipe is the most proven, most used drain water heat recovery technology; many building designers have been specifying the Power-Pipe as a standard in their buildings for many years now, there are now thousands of suites in which Power-Pipes are saving money and energy daily.

SAVINGS VERIFIED BY Natural Resources Canada

877-606-5559
www.renewability.com

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: A review of the standards proposed for inclusion in the code, CSA B55.1 and B55.2 with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 1, 2013.

R405.5.2(1)T-EC-VANDECKER.DOC

Committee Action Hearing Results

Part I of this code changes was heard by the Commercial Energy Conservation Code Development Committee, Part II was heard by the Residential Energy Conservation Code Development Committee and Part III was heard by the Residential Plumbing Code Development Committee.

For staff analysis of the content of CSA 55.1-2012 and CSA 55.2-2012 relative to CP#28, Section 3.6, please visit: http://www.iccsafe.org:8888/cs/codes/Documents/2012-13cycle/Proposed-A/00a_updates.pdf

PART I – IECC - Commercial
Committee Action: **Disapproved**

Committee Reason: Drain waste heat recovery seems to be a valuable energy saving idea but there is some confusion about whether the proposal has the correct computational method to adjust (increase) the efficiency of the service water heating system when these products are installed.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Gary Klein, Affiliated International Management, LLC, representing self; Gerald Van Decker, RenewABILITY Energy Inc, representing self, request Approval as Submitted

Commenter's Reason: I agree with the Committee's reason that it is important for code officials, contractors and building owners to have recognized standards regarding safety and performance for building components. This code change provides these standards for drain water heat recovery units, and I urge your support of this code change.

PART III IRC-P

Add new text as follows:

<u>**P2903.11 Drain water heat recovery units.** Drain water heat recovery units shall be in accordance with Section N1103.4.3</u>

Reason: There are two reasons for this proposal.1) To enable developers to take credit for efficiency improvements due to the use of drain water heat recovery devices in the performance calculations in the energy code; and 2) to make comparisons of the efficiency of different units based on an existing standard.

Drain water heat recovery (DWHR) works particularly well where heated water flows down the drain at the same time as water flows in that needs to be heated; this “coincident flow” occurs in occupancies with showering and lavatory use. Performance of a DWHR unit is characterized by both efficiency and pressure loss. It is important to ensure that DWHR devices do not impose large pressure losses in the piping in order to minimize the impact on water flow in the building. Given the available DWHR efficiencies, savings are typically 10% to 35% of the energy used for heating water. Over 25,000 drain water heat recovery units have been installed in homes in Canada and the United States.

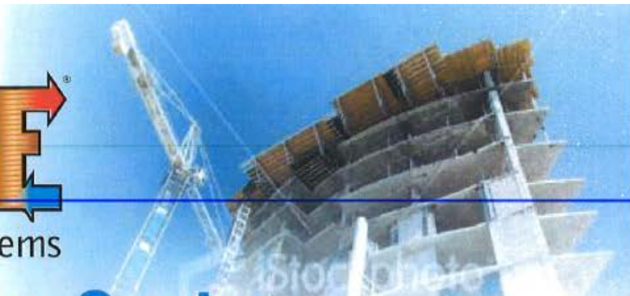
This change adds two standards for drain water heat recovery units (DWHR units). Drain water heat recovery is often a cost effective way to add to energy efficiency by recapturing hot water energy that is literally “going down the drain”. The proposed standards have already been in use by designers for 10 years and the resulting ratings are in use by a variety of energy efficiency programs. Commercial (i.e. non multi-unit residential) applications are engineered systems while multi-unit residential applications are non-engineered and straightforward.

CSA B55.2 standard is for fabrication and material quality of DWHR units. The CSA B55.1 standard is for testing and labeling of DWHR units efficiency and pressure loss at 2.5gpm (9.5lpm). These existing standards were developed through a consensus process by the Canadian Standards Association and are referenced by the Ontario Building Code.

A typical drain water heat recovery unit is shown below:

POWER-PIPE®

Drain Water Heat Recovery Systems

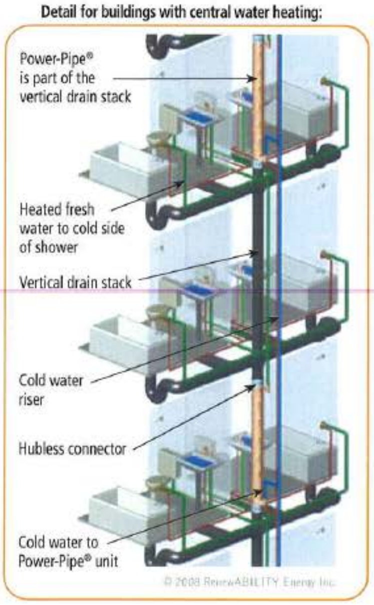


Reduce Operating Costs
for Multi-Unit Residential Buildings

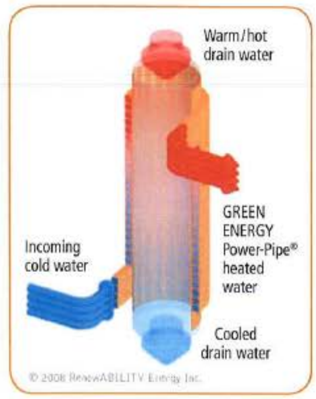
Cost-Effective Green Energy Technology

- The Power-Pipe® is **proven, practical, affordable** and in use today saving energy for thousands of residential suites.
- **Water heating is typically the second highest energy cost** in multi-unit residential buildings; in fact it can even be the highest energy cost.

Detail for buildings with central water heating:



- As building envelopes have become more efficient in recent years water heating has become an even larger portion of the remaining energy costs.
- Much of the drain water leaving a residential building carries with it valuable and recoverable heat energy.
- The all copper Power-Pipe is a double-wall heat exchanger that can **reduce water heating costs by 20-40%** by recovering heat energy from drain (waste) water in multi-residential building drain (waste) stacks.
- The patented and patent pending Power-Pipe design is the only heat exchanger that efficiently allows for up to 4 apartment suites to be plumbed without noticeable loss in water pressure... in fact this results in a **2 to 4 times faster payback** than other heat exchangers.
- The Power-Pipe is very **simple to specify and install** and its savings typically translate to a **3 to 4 year simple payback**; even faster with government or utility incentives.



How It Works

1. As drain water falls down any vertical drain stack it clings to the inner wall, rather than going down the middle of the pipe. This results in a quickly falling thin film.
2. The energy (heat) from this falling film of drain water is easily and efficiently transferred through the copper to the fresh cold water which is flowing around the drain pipe in the outer coils.
3. Cold fresh water is plumbed into the bottom of the Power-Pipe from the main cold water riser.
4. Power-Pipe heated water is then plumbed to either:
   - the cold side of up to 4 showers, for buildings with central water heating, thereby reducing hot water demand
   - the cold side of the shower and water heater, for buildings with in-suite water heaters

PART III – IRC – Plumbing
Committee Action: Disapproved

Committee Reason: There is no need to have this pointer in the plumbing chapter as the information is contained in the IRC and not some other publication.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Gary Klein, Affiliated International Management, LLC, representing self; Gerald Van Decker, RenewABILITY Energy Inc, representing self, request Approval as Modified by this Public Comment.

Modify proposal as follows:

P2903.11 Drain water heat recovery units. Drain water heat recovery units <u>that are installed for heat recovery</u> shall ~~be in accordance with~~ <u>meet the requirements of</u> Section N1103.4.3.

Commenter's Reason: Drain water heat recovery systems are relatively uncommon in residential construction at this time. Their installation affects the design and layout of the overall domestic piping supply and may affect other building subsystems. Having a reference in the plumbing chapter will help to avoid lapses in coordination with other trades and will improve the ease of compliance.

CE283-13, Part III
Final Action: AS AM AMPC____ D

NOTE: PART II REPRODUCED FOR INFORMATION PURPOSES ONLY – SEE ABOVE

PART II IECC-RESIDENTIAL PROVISIONS

Add new text as follows:

<u>**R403.4.3 (N1103.4.3) Drain water heat recovery units.** Drain water heat recovery units shall comply with CSA 55.2. Drain water heat recovery units shall be in accordance with CSA 55.1. Potable water-side pressure loss of drain water heat recovery units shall be less than 3 psi (20.7 kPa) for individual units connected to one or two showers. Potable water-side pressure loss of drain water heat recovery units shall be less than 2 psi (13.8 kPa) for individual units connected to three or more showers.</u>

Add new standards to Chapter 5 as follows:

CSA

CSA 55.1-2012 Test method for measuring efficiency and pressure loss of drain water heat recovery units

CSA 55.2-2012 Drain water heat recovery units

PART III IRC-P

Add new text as follows:

P2903.11 Drain water heat recovery units. Drain water heat recovery units shall be in accordance with Section N1103.4.3

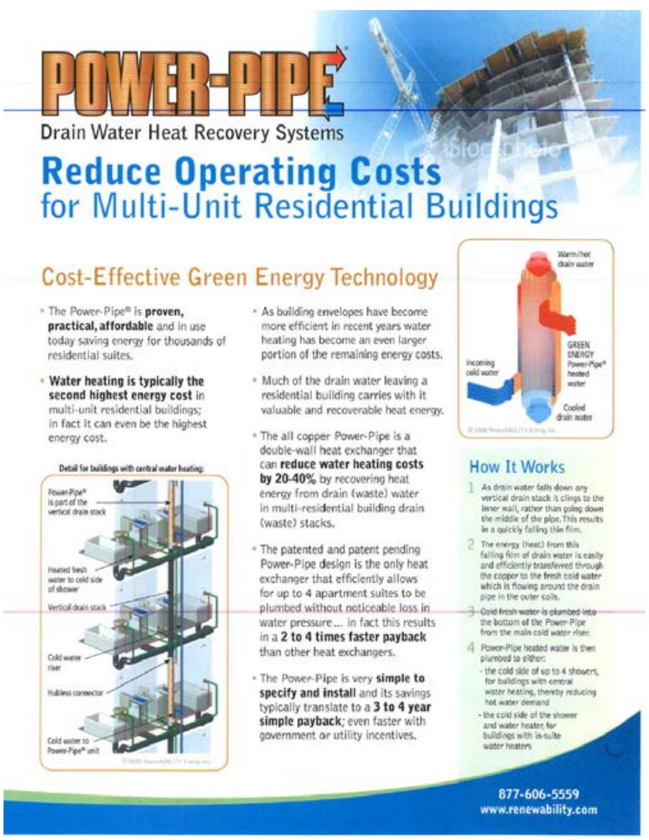
Reason: There are two reasons for this proposal.1) To enable developers to take credit for efficiency improvements due to the use of drain water heat recovery devices in the performance calculations in the energy code; and 2) to make comparisons of the efficiency of different units based on an existing standard.

Drain water heat recovery (DWHR) works particularly well where heated water flows down the drain at the same time as water flows in that needs to be heated; this "coincident flow" occurs in occupancies with showering and lavatory use. Performance of a DWHR unit is characterized by both efficiency and pressure loss. It is important to ensure that DWHR devices do not impose large pressure losses in the piping in order to minimize the impact on water flow in the building. Given the available DWHR efficiencies, savings are typically 10% to 35% of the energy used for heating water. Over 25,000 drain water heat recovery units have been installed in homes in Canada and the United States.

This change adds two standards for drain water heat recovery units (DWHR units). Drain water heat recovery is often a cost effective way to add to energy efficiency by recapturing hot water energy that is literally "going down the drain". The proposed standards have already been in use by designers for 10 years and the resulting ratings are in use by a variety of energy efficiency programs. Commercial (i.e. non multi-unit residential) applications are engineered systems while multi-unit residential applications are non-engineered and straightforward.

CSA B55.2 standard is for fabrication and material quality of DWHR units. The CSA B55.1 standard is for testing and labeling of DWHR units efficiency and pressure loss at 2.5gpm (9.5lpm). These existing standards were developed through a consensus process by the Canadian Standards Association and are referenced by the Ontario Building Code.

A typical drain water heat recovery unit is shown below:



Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: A review of the standards proposed for inclusion in the code, CSA B55.1 and B55.2 with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 1, 2013.

Part I of this code changes was heard by the Commercial Energy Conservation Code Development Committee, Part II was heard by the Residential Energy Conservation Code Development Committee and Part III was heard by the Residential Plumbing Code Development Committee.

For staff analysis of the content of CSA 55.1-2012 and CSA 55.2-2012 relative to CP#28, Section 3.6, please visit: http://www.iccsafe.org:8888/cs/codes/Documents/2012-13cycle/Proposed-A/00a_updates.pdf

PART II – IECC – Residential
Committee Action: **Approved as Submitted**

Committee Reason: Massachusetts recognizes drain waste heat recovery units in their "stretch" code. If these units are going to be installed, then there needs to be requirements to make sure the units operate properly and provide the intended performance.

Assembly Action: **None**

CE285-13, Part I
C202, C405.1, R202 (IRC N1109.1) R404.1 (IRC N1104.1)

NOTE: PART II DID NOT RECEIVE A PUBLIC COMMENT AND IS ON THE CONSENT AGENDA, PART II IS REPRODUCED ONLY FOR INFORMATION PUSPOSES FOLLOWING ALL OF PART I.

Proposed Change as Submitted

Proponent: Deborah Frankhouser, Four Point Lighting Design, representing the International Association of Lighting Designers (deborah@fourpointlighting.com)

THIS IS A 2 PART CODE CHANGE PROPOSAL. PART I WILL BE HEARD BY THE COMMERCIAL ENERGY CONSERVATION CODE DEVELOPMENT COMMITTEE AND PART II WILL BE HEARD BY THE RESIDENTIAL ENERGY CONSERVATION CODE DEVELOPMENT COMMITTEE.

PART I – IECC-COMMERCIAL PROVISIONS

Revise as follows:

C405.1 General (Mandatory). This section covers lighting system controls, the connection of ballasts, the maximum lighting power for interior applications, electrical energy consumption, and minimum acceptable lighting equipment for exterior applications.

> **Exception:** Dwelling units within commercial buildings shall not be required to comply with Sections C405.2 through C405.5 provided that they comply with Section R404.1. ~~not less than 75 percent of the permanently installed light fixtures, other than low voltage lighting, shall be fitted for, and contain only, high efficacy lamps.~~

Delete definition without substitution as follows:

SECTION C202
GENERAL DEFINITIONS

~~**HIGH-EFFICACYLAMPS.** Compact fluorescent lamps, T-8 or smaller diameter fluorescent lamps, or lamps with a minimum efficacy of:~~

1. ~~60 lumens per watt for lamps over 40 watts,~~
2. ~~50 lumens per watt for lamps over 15 watts to 40 watts,~~
3. ~~40 lumens per watt for lamps 15 watts or less.~~

Reason: (Part I) The exception to C405.1 establishes a different standard for lighting efficiency in dwellings from Section R404.1. Section C405.1 is a luminaire-based standard, whereas Section R404.1 is a lamp-based standard. There is no reason for the code to set an efficiency standard for lighting within dwelling units in multi-family buildings that is different from the standard for lighting in detached houses. Residential lighting is the same regardless of the building it is located in.
(Part II):
1. Increases the overall requirement for high-efficiency luminaires from 75% to 100% with certain exceptions designed to save energy and provide maximum flexibility to designers, owners and code officials.
2. Changes the Chapter 2 definitions from *high efficacy lamps* to *high efficiency luminaires* as determined by lamp efficacy. This means owners, designers, and building code officials would count luminaires (light fixtures) vs. counting light bulbs to determine the amount of high or low efficient lighting on a project. Luminaires often have multiple lamps, making counting more cumbersome for both the owner/designer as well as the code official. By counting luminaires, the code official simply has to identify lamp type, but doesn't have to count individual lamps within each luminaire.
3. Allows for an optional and more flexible energy savings approach for owners and designers by allowing up to 50% low efficiency luminaires as long as lighting controls are used to reduce or turn off the low efficiency luminaires.

   The current code requires 75% of lighting to be *high-efficacy.* However, there is a high amount of dissatisfaction with compact fluorescents because of their poor color, noise, incompatibility with dimming, and mercury content. (Reference, Dept. of Energy's "Compact Fluorescent Lighting in America: Lessons Learned on the Way to Market," prepared by Pacific Northwest National Laboratory, June 2006) LED technology is still emerging and many of the inexpensive LED's continue to have poor color and incompatibility with dimming.

The most efficient light is the one that is off. The current code does not use lighting controls as a means of energy savings. Regardless of efficacy, light sources achieve maximum energy savings when they are off or reduced to the minimum required by the task. For 120 volt incandescent/halogen sources, dimming reduces energy use, increases lamp life, and dimmers are inexpensive. Automatic controls turn lighting off when not being used. (See reference documentation listed below.)

Cost implications: In most cases, the required high efficiency Fluorescent and LED light fixtures are more expensive than their low efficiency 120 volt incandescent equivalents simply because fluorescent and LED have additional required components such as ballasts and drivers. Dimmers vary significantly in cost, but a 120v incandescent dimmer can be purchased for as little as $15. When installed with the less expensive 120v incandescent lighting, this combination can be less expensive than purchasing many fluorescent or LED versions controlled by a switch. There are many options for owners and adding dimmers does not necessarily equal adding dollars when comparing low efficiency and high efficiency luminaires. Also, in residential, dimming is important for reasons other than energy savings and dimming fluorescent and LED sources can significantly increase dimming costs.

Residential is not commercial. In residences, it is very common for decorative lighting to be the main lighting source in a room. Decorative chandeliers are often only available in120v incandescent medium or candelabra based sockets. Often times these chandeliers exceed the current allowance (25%) even when using high efficacy light sources for other types of architectural lighting such as down lights, task lighting, etc. These fixtures do not qualify for the Low Voltage Exception currently in the code. The proposed Exception 2 gives a greater allowance for 120v incandescent/halogen luminaires than the current code allows to accommodate these decorative products, but encourages energy savings through the use of controls.

4. Clarifies the low voltage lighting exception currently in the code and adds stringency by requiring lighting controls as an energy savings approach for these light fixture types. The current code allows for the use of low voltage with no limits. They are lower in VOLTAGE not WATTAGE. Adding controls will increase the overall energy efficiency of these products.

References

Several reports document savings from using controls residentially, such as:

- http://www.lrc.rpi.edu/programs/lightingTransformatio/economics/table2.asp [shows 20% to 40% savings depending on space type for using occupancy sensors]
- http://www.energy.ca.gov/title24/2013standards/prerulemaking/documents/current/Reports/Residential/Lighting/ open Residential Lighting PDF and see page 32 [shows 10% savings from dimmers, 30% savings from occupancy sensors]
- Heschong Mahone Group Lighting Efficiency Technology Report Vol. 1, see page 83. www.energy.ca.gov/efficiency/lighting/VOLUME01.PDF [shows 20% savings from dimmers and 54% savings from occupancy sensors]

Cost Impact: The code change proposal will not increase the cost of construction.

C405.1-EC-FRANKHOUSER.doc

Committee Action Hearing Results

Part I of this code changes was heard by the Commercial Energy Conservation Code Development Committee and Part II was heard by the Residential Energy Conservation Code Development Committee.

PART I – IECC - Commercial

Committee Action: **Approved as Submitted**

Committee Reason: Lighting within residential units should comply with consistent standards. Those are provided best in the Residential portion of the IECC.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Donald J. Vigneau, AIA, representing Northeast Energy Efficiency Partnerships Inc, requests Disapproval.

Commenter's Reason: The proposal may be well-intentioned but essentially flawed. It eliminates a general definition for all high-efficiency bulbs that is needed for compliance with other Section C405 lighting requirements; the Residential Committee AS decision referenced would allow for lighting inconsistent with the requirements of Table C405.5.2(1). The proposal also eliminates other lighting solutions that are not encompassed by the minimal number of lamp types listed. Disapproval is needed for consistency with the RE Committee recommendation for Disapproval.

CE285-13, Part I

Final Action: AS AM AMPC____ D

NOTE: PART II REPRODUCED FOR INFORMATION PURPOSES ONLY – SEE ABOVE

CE285-13, PART II – IECC-RESIDENTIAL PROVISIONS

Revise as follows:

R404.1 (N1104.1) Lighting equipment (Mandatory). ~~A minimum of 75 percent of the lamps in permanently installed lighting fixtures shall be high-efficacy lamps or a minimum of 75 percent of the permanently installed lighting fixtures shall contain only high efficacy lamps.~~ All permanently installed lighting shall be *high efficiency luminaires*.

Exception: ~~Low-voltage lighting shall not be required to use high-efficiency lamps.~~

1. Luminaires that utilize lamps that operate at less than 25 volts if separately controlled by a dimmer or an *automatic* control device and controlled separately from *high-efficiency luminaires.*
2. Up to 50 percent of the luminaires not qualifying for Exception 1 shall be permitted to be other than *high-efficiency luminaires* if they are controlled by a dimmer or *automatic* control device. *High- efficiency luminaires* shall be controlled separately from non *high-efficiency luminaires*.

Revise definition as follows:

SECTION R202 (N1101.9)
GENERAL DEFINITIONS

HIGH-EFFICIENCY ~~EFFICACY~~ ~~LAMPS~~ LUMINAIRES. Luminaires containing only compact fluorescent lamps, T-8 or smaller diameter fluorescent lamps with electronic ballasts, or lamps or light emitting diodes (LED's) with a minimum efficacy of:

1. 60 lumens per watt for lamps over 40 watts,
2. 50 lumens per watt for lamps over 15 watts to 40 watts,
3. 40 lumens per watt for lamps 15 watts or less.

Reason:
(Part I) The exception to C405.1 establishes a different standard for lighting efficiency in dwellings from Section R404.1. Section C405.1 is a luminaire-based standard, whereas Section R404.1 is a lamp-based standard. There is no reason for the code to set an efficiency standard for lighting within dwelling units in multi-family buildings that is different from the standard for lighting in detached houses. Residential lighting is the same regardless of the building it is located in.
(Part II):

5. Increases the overall requirement for high-efficiency luminaires from 75% to 100% with certain exceptions designed to save energy and provide maximum flexibility to designers, owners and code officials.
6. Changes the Chapter 2 definitions from *high efficacy lamps* to *high efficiency luminaires* as determined by lamp efficacy. This means owners, designers, and building code officials would count luminaires (light fixtures) vs. counting light bulbs to determine the amount of high or low efficient lighting on a project. Luminaires often have multiple lamps, making counting more cumbersome for both the owner/designer as well as the code official. By counting luminaires, the code official simply has to identify lamp type, but doesn't have to count individual lamps within each luminaire.
7. Allows for an optional and more flexible energy savings approach for owners and designers by allowing up to 50% low efficiency luminaires as long as lighting controls are used to reduce or turn off the low efficiency luminaires.
   The current code requires 75% of lighting to be *high-efficacy.* However, there is a high amount of dissatisfaction with compact fluorescents because of their poor color, noise, incompatibility with dimming, and mercury content. (Reference,

Dept. of Energy's "Compact Fluorescent Lighting in America: Lessons Learned on the Way to Market," prepared by Pacific Northwest National Laboratory, June 2006) LED technology is still emerging and many of the inexpensive LED's continue to have poor color and incompatibility with dimming.

The most efficient light is the one that is off. The current code does not use lighting controls as a means of energy savings. Regardless of efficacy, light sources achieve maximum energy savings when they are off or reduced to the minimum required by the task. For 120 volt incandescent/halogen sources, dimming reduces energy use, increases lamp life, and dimmers are inexpensive. Automatic controls turn lighting off when not being used. (See reference documentation listed below.)

Cost implications: In most cases, the required high efficiency Fluorescent and LED light fixtures are more expensive than their low efficiency 120 volt incandescent equivalents simply because fluorescent and LED have additional required components such as ballasts and drivers. Dimmers vary significantly in cost, but a 120v incandescent dimmer can be purchased for as little as $15. When installed with the less expensive 120v incandescent lighting, this combination can be less expensive than purchasing many fluorescent or LED versions controlled by a switch. There are many options for owners and adding dimmers does not necessarily equal adding dollars when comparing low efficiency and high efficiency luminaires. Also, in residential, dimming is important for reasons other than energy savings and dimming fluorescent and LED sources can significantly increase dimming costs.

Residential is not commercial. In residences, it is very common for decorative lighting to be the main lighting source in a room. Decorative chandeliers are often only available in120v incandescent medium or candelabra based sockets. Often times these chandeliers exceed the current allowance (25%) even when using high efficacy light sources for other types of architectural lighting such as down lights, task lighting, etc. These fixtures do not qualify for the Low Voltage Exception currently in the code. The proposed Exception 2 gives a greater allowance for 120v incandescent/halogen luminaires than the current code allows to accommodate these decorative products, but encourages energy savings through the use of controls.

8. Clarifies the low voltage lighting exception currently in the code and adds stringency by requiring lighting controls as an energy savings approach for these light fixture types. The current code allows for the use of low voltage with no limits. They are lower in VOLTAGE not WATTAGE. Adding controls will increase the overall energy efficiency of these products.

Several reports document savings from using controls residentially, such as:

- http://www.lrc.rpi.edu/programs/lightingTransformatio/economics/table2.asp [shows 20% to 40% savings depending on space type for using occupancy sensors]
- http://www.energy.ca.gov/title24/2013standards/prerulemaking/documents/current/Reports/Residential/Lighting/ open Residential Lighting PDF and see page 32 [shows 10% savings from dimmers, 30% savings from occupancy sensors]
- Heschong Mahone Group Lighting Efficiency Technology Report Vol. 1, see page 83. www.energy.ca.gov/efficiency/lighting/VOLUME01.PDF [shows 20% savings from dimmers and 54% savings from occupancy sensors]

Cost Impact: The code change proposal will not increase the cost of construction.

Part I of this code changes was heard by the Commercial Energy Conservation Code Development Committee and Part II was heard by the Residential Energy Conservation Code Development Committee.

PART II – IECC – Residential
Committee Action: **Disapproved**

Committee Reason: This code change proposal was disapproved in favor of RE150-13.

Assembly Action: **None**

CE286-13
C405.1, C405.8 (New)

Proposed Change as Submitted

Proponent: Steve Ferguson, American Society of Heating, Refrigerating, and Air-Conditioning Engineers (ASHRAE) (sferguson@ashrae.org)

Revise as follows:

C405.1 General (Mandatory). This section covers lighting system controls, the connection of ballasts, the maximum lighting power for interior applications, electrical energy consumption, controls for electric receptacles, and minimum acceptable lighting equipment for exterior applications.

> **Exception:** Dwelling units within commercial buildings shall not be required to comply with Sections C405.2 through C405.5 provided that not less than 75 percent of the permanently installed light fixtures, other than low voltage lighting, shall be fitted for, and contain only, high efficacy lamps.

C405.8 Automatic receptacle control. Automatic controls shall be provided for at least 50 percent of the 125 volt 15- and 20-Ampere receptacles in private offices, computer classrooms and individual workstations and receptacles associated with branch circuit feeds that are installed to supply electrical power to modular furniture in such spaces. These receptacles shall be labeled "Automatic Control Receptacle". The automatic controls shall:

1. Be capable of operating on a scheduled basis using a time-of-day operated control device that will turn receptacles off at specific programmed times and provide for an independent program schedule for areas not larger than 25,000 square feet but not larger than one floor, or
2. Be an occupant sensor that is capable of turning receptacles off within 30 minutes of all occupants leaving a *space*, or
3. Be capable of providing a signal to another control or alarm system that indicates the area is unoccupied.

> **Exceptions:** Automatic receptacle controls need not be provided for:
>
> 1. Receptacles specifically designated for equipment requiring 24 hour operation.
> 2. Spaces where an automatic shutoff would endanger the safety or security of the room or building occupants.

Reason: Energy is used in supplying power to receptacles in offices, computer classrooms, individual work stations and modular furniture in such spaces. As with occupancy sensors that can reduce energy use associated with lighting and mechanical ventilation, the equipment supported by electrical receptacles is also subject to use and non-use based on occupancy. ASHRAE/IES Standard 90.1, which is adopted by reference in the IECC Commercial Provisions, contains provisions to provide for at least half of the electrical receptacles in certain spaces to have automatic controls as enhanced by addendum v to the standard. This change ensures consistency between the IECC Commercial Provisions and the latest criteria in standard 90.1.

Cost Impact: The code change proposal will increase the cost of construction.

C405.1-EC-FERGUSON.doc

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: The technology to reduce power usage should be within the equipment and not rely on the building circuitry. Modular furniture is too easily broken down and reused to allow this to be enforceable by the code official.

Assembly Action: **Approved as Modified**

Modify the proposal as follows:

C405.8 Automatic receptacle control. Automatic controls shall be provided for at least 50 percent of the 125 volt 15- and 20-ampere receptacles in private offices, computer classrooms, individual workstations and receptacles associated with branch circuit feeds that are installed to supply electrical power to modular furniture in such spaces. ~~These receptacles shall be labeled "Automatic Control Receptacle."~~

Individual Consideration Agenda

This code change proposal is on the agenda for individual consideration because the proposal received a successful assembly action of Approved as Modified and because public comments were submitted.

Public Comment 1:

Steve Ferguson, ASHRAE, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

C405.8 Automatic receptacle control. Automatic controls shall be provided for at least 50 percent of the 125 volt 15- and 20-ampere receptacles in private offices, computer classrooms, individual workstations and receptacles associated with branch circuit feeds that are installed to supply electrical power to modular furniture in such spaces. ~~These receptacles shall be labeled "Automatic Control Receptacle."~~ All controlled receptacles shall be permanently marked to visually differentiate them from uncontrolled receptacles.

Commenter's Reason: The previous language was too precise in handling how receptacles that are controlled are labeled. The intent was not to specify exact language that must appear on controlled receptacles. There must be some sort of way to visually differentiate controlled receptacles from non-controlled receptacles.
This comment adds language to clarify that.

Public Comment 2:

Duane Jonlin, City of Seattle, Department of Planning and Development requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

C405.8 Automatic receptacle control. Automatic controls shall be provided for at least 50 percent of the 125 volt 15- and 20-Ampere receptacles in private offices, computer classrooms and individual workstations and receptacles associated with branch circuit feeds that are installed to supply electrical power to modular furniture in such spaces. ~~These receptacles shall be labeled "Automatic Control Receptacle."~~ These receptacles shall be visibly differentiated from non-controlled receptacles. The automatic controls shall:

1. Be capable of operating on a scheduled basis using a time-of-day operated control device that will turn receptacles off at specific programmed times and provide for an independent program schedule for areas not larger than 25,000 square feet but not larger than one floor. The device shall be capable of being overridden for periods of up to two hours by an override timer switch accessible to occupants. Each override switch shall control the controlled receptacles for a maximum area of 5,000 square feet (465 m2), and shall be permitted to control the lighting for the same area, or
2. Be an occupant sensor that is capable of turning receptacles off within 30 minutes of all occupants leaving a *space*, or
3. Be capable of providing a signal to another control or alarm system that indicates the area is unoccupied.

   Exceptions: Automatic receptacle controls need not be provided for:

   1. Receptacles specifically designated for equipment requiring 24 hour operation.
   2. Spaces where an automatic shutoff would endanger the safety or security of the room or building occupants.

Commenter's Reason: We support this code provision as an effective means of reducing building energy use.
We propose that the automatic time switch controls include an override switch to provide for convenient off-hours use of the receptacles controlled by the time switch. This parallels the override switch provisions for lighting controls, and in most cases can be provided with the same override switch.
In addition, we propose that the controlled receptacles be visually differentiated from the non-controlled receptacles.

Public Comment 3:

Andrei Moldoveanu, representing The National Electrical Manufacturers Association (NEMA), requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

C405.8 Automatic receptacle control. Automatic controls shall be provided for at least 50 percent of the 125 volt 15- and 20-ampere receptacles in private offices, computer classrooms, individual workstations and receptacles associated with branch circuit feeds that are installed to supply electrical power to modular furniture in such spaces.

Use the following guidelines for determining how to meet the requirement:

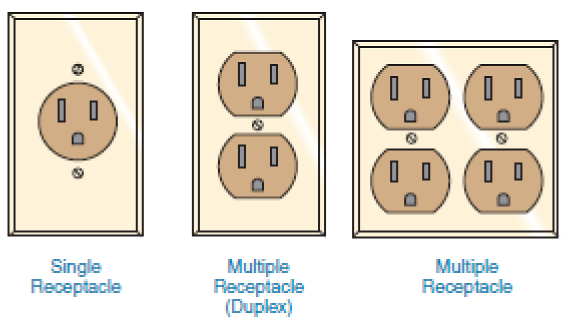
- If the receptacle outlets are single receptacles then 50 percent of them must be controlled. It may be necessary to add controlled receptacles.
- If the receptacle outlets are duplex receptacles then the devices may be split wired with one half being controlled. Alternatively additional controlled duplex receptacles could be added nearby.
- If the receptacle outlet consists of multiple receptacles then the devices may be split wired as above or half of the receptacles may be separately wired to achieve the 50 percent controlled requirement.
- In a defined workspace such as with modular partitions, 50 percent of the receptacles in each area accessible to the occupant must be controlled, i.e. one area would be above the desktop and another area might be below. See receptacle definitions below.

Receptacle Definitions according to 2011 NEC.

Receptacle: A receptacle is a contact device installed at the outlet for the connection of an attachment plug. A single receptacle is a single contact device with no other contact device on the same yoke. A multiple receptacle is two or more contact devices on the same yoke.

Receptacle Outlet: An outlet where one or more receptacles are installed.

Each of the three pictures below is a Receptacle Outlet as there are one or more receptacles installed at the location. 1 & 2 are also simple Receptacles as the contact devices are all on one yoke.



Commenter's Reason: The requirement language is difficult to interpret in the field: as written it's not clear if it calls for half of a duplex receptacle or half of the outlets in a room to be controlled.

Public Comment 3:

Hope Medina, City of Cherry Hills Village, CO, representing self, requests Disapproval.

Commenter's Reason: The committee's reasoning behind disapproving this code change has merit. We should be looking at the equipment to reduce power usage not the building's circuitry. This change no longer holds industry responsible for reducing it's energy usage.

This change not only over reaches the philosophy of this is a minimum/base code it potentially creates a life safety issue. When faced with receptacles providing power under these conditions an alternative means will be found, and it will involve power strips plugged into extension cords plugged into power strips plugged into extension cords.

CE286-13

Final Action: AS AM AMPC____ D

C202 (New), C405.2, C405.2.1, C405.2.1.1, C405.2.2, C405.2.2.1, C405.2.1.1, C405.2.1.2, C405.2.2, C405.2.2.1, C405.2.2.3, C405.2.2.3.1, C405.2.2.3.2, C405.2.2.3.3, C405.2.3, C405.2.4

Proposed Change as Submitted

Proponent: Brenda A. Thompson, Clark County Development Services, Clark County, Nevada, representing Sustainable/Energy/High Performance Code Action Committee (bat@clarkcounty.gov)

Revise as follows:

C405.2 Lighting Controls (Mandatory). Lighting systems shall be provided with controls as specified in Sections C405.2.1, C405.2.2, C405.2.3, ~~and~~ C405.2.4, and C405.2.5.

Exceptions: Lighting controls are not required for the following:

1. Areas designated as security or emergency areas that are required to be continuously lighted;
2. Stairways and corridors; and
3. Emergency egress lighting that is normally off.

~~**C405.2.1 Manual lighting controls.** All buildings shall include manual lighting controls that meet the requirements of Sections C405.2.1.1 and C405.2.1.2.~~

~~**C405.2.2.2**~~ **C405.2.1 Occupant ~~sensors~~ sensor controls.** *Occupant* ~~sensors~~ *sensor controls* shall be installed in all classrooms, conference/meeting rooms, employee lunch and break rooms, private offices, restrooms, storage rooms and janitorial closets, and other spaces 300 square feet (28 m^2) or less that are enclosed by floor-to-ceiling height partitions. ~~These automatic control devices shall be installed to~~

C405.2.1.1 Occupant sensor control function. Occupant sensor controls shall comply with the following:

1. Automatically turn off lights within 30 minutes of all occupants leaving the space; ~~and~~
2. Shall either be manual on or shall be controlled to automatically turn the lighting on to not more than 50 percent power; and
3. Shall incorporate a *manual control* to allow occupants to turn lights off.

Exception: Full automatic-on controls shall be permitted to control lighting in public corridors, stairways, restrooms, primary building entrance areas and lobbies, and areas where manual-on operation would endanger the safety or security of the room or building occupants

~~**C405.2.1.1 Interior lighting controls.** Each area enclosed by walls or floor-to-ceiling partitions shall have at least one manual control for the lighting serving that area. The required controls shall be located within the area served by the controls or be a remote switch that identifies the lights served and indicates their status.~~

~~**Exceptions:**~~

1. ~~Areas designated as security or emergency areas that need to be continuously lighted.~~
2. ~~Lighting in stairways or corridors that are elements of the means of egress.~~

C405.2.2 ~~Additional lighting~~ Time switch controls. ~~Each area that is required to have a manual control shall also have controls that meet the requirements of Sections C405.2.2.1, C405.2.2.2 and C405.2.2.3.~~

Each area of the building that is not provided with *occupant sensor controls* complying with Section C405.2.1.1 shall be provided with *time switch controls* complying with Section C405.2.2.1.

Exceptions: Where a *manual control* provides light reduction in accordance with Section C405.2.2.2, automatic controls ~~additional lighting controls~~ ~~need not be provided~~ shall not be required for the following:

1. *Sleeping units*.
2. Spaces where patient care is directly provided.
3. Spaces where an automatic shutoff would endanger occupant safety or security.
4. Lighting intended for continuous operation.

C405.2.2.1 ~~Automatic~~ Time switch control ~~devices~~ function. ~~Automatic time switch controls shall be installed to control lighting in all areas of the building.~~ Each space provided with *time switch controls* shall also be provided with a *manual control* for light reduction in accordance with Section C405.2.2.2. *Time switch controls* shall include an override switching device that complies with the following:

~~**Exceptions:**~~

~~1. Emergency egress lighting does not need to be controlled by an automatic time switch.~~
~~2. Lighting in spaces controlled by occupancy sensors does not need to be controlled by automatic time switch controls.~~

~~The automatic time switch control device shall include an override switching device that complies with the following:~~

1. The override switch shall be a *manual control* ~~in a readily accessible location;~~
~~2. The override switch shall be located where the lights controlled by the switch are visible; or the switch shall provide a mechanism which announces the area controlled by the switch;~~
~~3. The override switch shall permit manual operation;~~
2. ~~4.~~ The override switch, when initiated, shall permit the controlled lighting to remain on for a maximum duration of 2 hours; and
3. Any individual override switch shall control the lighting for a maximum area of 5,000 square feet (465 m^2).

Exceptions:

1. Within malls, arcades, auditoriums, single tenant retail spaces, industrial facilities and arenas:
   - ~~1.~~ 1.1. The time limit shall be permitted to exceed 2 hours provided the override switch is a captive key device; and
   - ~~2.~~ 1.2. The area controlled by the override switch is permitted to exceed 5,000 square feet (465 m^2), but shall not exceed 20,000 square feet (1860 m^2).
2. Where provided with *manual control*, the following areas are not required to have light reduction control:
   - 2.1. Spaces that have only one luminaire with a rated power of less than 100 watts;
   - 2.2. Spaces that use less than 0.6 watts per square foot (6.5 W/m^2); and
   - 2.3. Corridors, equipment rooms, public lobbies, electrical or mechanical rooms.

~~C405.2.1.2~~ C405.2.2.2 Light reduction controls. ~~Each area that is required to have a manual control shall also allow the occupant to~~ Spaces required to have light reduction controls shall have a *manual control* that allows the occupant to reduce the connected lighting load in a reasonably uniform pattern by at least 50 percent. Lighting reduction shall be achieved by one of the following or other *approved* methods:

1. Controlling all lamps or luminaires;
2. Dual switching of alternate rows of luminaires, alternate luminaires, or alternate lamps;

3. Switching the middle lamp luminaires independently of the outer lamps; or
4. Switching each luminaire or each lamp.

Exception: Light reduction controls ~~need not be provided in the following areas and spaces:~~ are not required in daylight zones with *daylight responsive controls* complying with C405.3.2.

1. ~~Areas that have only one luminaire, with rated power less than 100 watts.~~
2. ~~Areas that are controlled by an occupant-sensing device.~~
3. ~~Corridors, equipment rooms, storerooms, restrooms, public lobbies, electrical or mechanical rooms.~~
4. ~~Sleeping unit (see Section C405.2.3).~~
5. ~~Spaces that use less than 0.6 watts per square foot (6.5 W/m^2).~~
6. ~~Daylight spaces complying with Section C405.2.2.3.2.~~

C405.2.2.3 Manual controls. *Manual controls* for lights shall meet the following requirements:

1. Shall be readily accessible to occupants; and
2. Shall be located where the controlled lights are visible; or the control shall identify the area served by the lights and indicate their status.

~~C405.2.2.3~~ C405.3 Daylight zone control. *(Portions of text not shown remains unchanged)*

~~C405.2.2.3.1~~ C405.3.1 Manual daylight controls. *(Portions of text not shown remains unchanged)*

~~C405.2.2.3.2 Automatic daylight controls.~~ C405.3.2 Daylight responsive controls. *(Portions of text not shown remains unchanged)*

~~C405.2.2.3.3~~ C405.3.3 Multi-level lighting controls. *(Portions of text not shown remains unchanged)*

~~C405.2.3~~ C405.2.4 Specific application controls. *(Portions of text not shown remains unchanged)*

~~C405.2.4~~ C405.2.5 Exterior lighting controls. *(Portions of text not shown remains unchanged)*

Add new definitions as follows:

SECTION C202
GENERAL DEFINITIONS

TIME SWITCH CONTROL. An automatic control device or system that controls lighting or other loads, including switching off, based on time schedules.

OCCUPANT SENSOR CONTROL. An automatic control device or system that detects the presence or absence of people within an area and causes lighting, equipment, or appliances to be regulated accordingly.

DAYLIGHT RESPONSIVE CONTROL. A device or system that provides automatic control of electric light levels based on the amount of daylight in a space.

Reason: This public comment is submitted by the ICC Sustainability Energy and High Performance Code Action Committee (SEHPCAC). The SEHPCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portion thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the SEHPCAC has held 2 open meetings and over 15 workgroup calls which included members of the SEHPCAC as well as any interested party to discuss and debate proposed changes and public comments. Related documentation and reports are posted on the SEHPCAC website at: http://www.iccsafe.org/cs/SEHPCAC/Pages/default.aspx.

Reasons for this proposal are as follows:

Overview:

This proposal reorganizes, but does not delete requirements related to lighting controls in the 2012 IECC.
Section C405.2 of the 2012 IgCC is confusing. It puts information that is often irrelevant first, and surprises with essential and relevant information only after one has suffered through trying to decipher what the implications of the irrelevant information might be. Section C405.2 also contains redundant information and the relationship of various subsections of C405.2 to one another is often unclear and ambiguous. This proposal reorganizes Section C405.2 to provide the clarity that is necessary for its proper application and enforcement. This proposal is a reorganization only and does not contain technical changes or increases or decreases in stringency.

Section C405.2:

According to the IBC, all interior stairways and corridors are elements of the means of egress. The original intent of this language may have been to exempt corridors and stairways which are part of an exit as defined by the IBC, but the way the code is currently written it also exempts exit access and exit discharge components, i.e. the entire building. Exceptions 1 and 2 are moved here from deleted former Section C405.2.1.1.

Proposed Exception 3 to Section C405.2:

"Emergency egress lighting that is normally off" does not seem to be exempt from controls requirements in the current code, but it needs to be.

Section C405.2.1.1:

This proposal deletes existing Section C405.2.1.1 and replaces it with new text. The way the code is currently structured most users probably would not realize that a manual switch is always required, even with automatic-on occupant sensors. This clarifies the fact that a manual switch is always required.

Exception to Proposed Section C405.1.1:

Former Section C405.2.2 is proposed to be moved and split into two sections: Sections C405.2.1 and C405.2.1.1. The requirements under proposed new Section C405.2.1.1 have been itemized for clarity. Note that the requirement for occupant sensor controls in "other spaces 300 square feet or less" is extremely broad and will encompass all of the lighting on smaller projects. For example, this is applicable to sleeping units, dwelling units, etc. Whether or not this was the original intention, this is how the code currently reads, and this proposal is intended to provide clarity, it is not intended to make technical changes.

Exception 1 to Section C405.2.2:

Note that the current code does not offer an exception for dwelling units. Dwelling units that are not exempt from all of 405.2 are required to comply with the requirements for automatic controls and light reduction controls.

Exception 4 to Section C405.2.2:

The exception that is currently in the code is for "lighting" that is intended for continuous operation, not for "spaces". This is an important distinction, because it allows light fixtures that are intended for night lighting of unoccupied spaces to be left off the automatic control system (like retail stores for security reasons, where select lights might be left on all night long.

The current code does not offer a blanket exemption for continuously operational emergency egress "night" lighting. Under current code, all emergency egress lighting that is not located in a corridor or stairwell must have a manual control device for override, even though it does not need to be automatically controlled.

Exception 2 to Section C405.2.1 and Section C405.2.1.2:

This exception is derived from 2012 IECC Section C405.2.1.2, which this proposal deletes. Storerooms and restrooms should not be in this list because they are required to be provided with occupant sensor controls.

Sections C405.2.1.1, C405.2.2.1 and C405.2.2.3:

This new section is a combination of the requirements in existing Sections C405.2.1.1 and C405.2.2.1 that pertain to manual controls. Therefore, existing Section C405.2.1.1 is proposed to be deleted and Section C405.2.2.1 is proposed to be revised. Existing Section C405.2.2.3 is not replaced, it is renumbered, as are all affected subsequent sections.

Please note that the SEHPCAC has also submitted other proposals that are coordinated with this proposal and are intended to clarify and improve the usability of the code's prescriptive building thermal envelope provisions. This proposal, however, is intended to stand alone and is not contingent upon the success of other SEHPCAC proposals.

Cost Impact: The code change proposal will not increase the cost of construction. This proposal is a clarification and, as such, will not increase the cost of construction.

C405.2-EC-THOMPSON-SEHPCAC

Committee Action Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The lighting control section needed to be reorganized into a more logical format. The rearrangement will eliminate much confusion.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Jack Bailey, One Lux Studio, representing International Association of Lighting Designers, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

C405.2 Lighting controls (Mandatory). Lighting systems shall be provided with controls as specified in Sections C405.2.1, C405.2.2, C405.2.3, C405.2.4, and C405.2.5.

Exceptions: Lighting controls are not required for the following:

1. Areas designated as security or emergency areas that are required to be continuously lighted;
2. Emergency egress lighting that is normally off; and
~~2. Stairways and corridors; and~~
3. Interior exit stairways, interior exit ramps, and exit passageways.

(Portions of proposal not shown remain unchanged)

Commenter's Reason: The current exception in the code makes no sense. Why should lighting in a corridor, which is an exit access component, be exempt from the controls requirements in this code while lighting in an exit passageway is not?

This proposal would conform imprecise language in the IECC with the IBC, resulting in more consistent interpretation and enforcement of the code. It would also avoid potential conflicts between lighting controls requirements in this code and lighting requirements for luminous egress path markings in exits in Section 1024 of the IBC.

Public Comment 2:

Glenn Heinmiller, Lam Partners, representing International Association of Lighting Designers, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

C405.2.1 Occupant sensor controls. *Occupant sensor controls* shall be installed to control lights in the following space types:

1. Classroom~~s~~/lecture/training rooms,
2. Conference/meeting ~~rooms~~/multi-purpose rooms,
3. Copy/print rooms,
4. Lounges,
5. Employee lunch and break rooms,
6. Private offices,
7. Restrooms,
8. Storage rooms, ~~and~~
9. Janitorial closets,
10. Locker rooms,
11. Other spaces 300 square feet (28 m^2) or less that are enclosed by floor-to-ceiling height partitions.

(Portions of proposal not shown remain unchanged)

Commenter's Reason: The purpose of Proposal CE287 is to add clarity to the lighting controls requirements in the code. This comment further revises the paragraph that stipulates where occupant sensor controls must be used. The phrase "to control lights" is added to make it clear that the sensors not only have to be installed, but have to function. For clarity, the space types are presented as a list. Also for clarity, the space type names are revised to be consistent with the space type names used for determination of lighting power density. This comment also requires the use of occupancy sensors in certain additional space types where occupancy sensors can be used effectively.

CE287-13

Final Action: AS AM AMPC____ D

CE289-13
C405.2.1.1

Proposed Change as Submitted

Proponent: Jack Bailey, One Lux Studio, representing International Association of Lighting Designers (jbailey@oneluxstudio.com)

Revise as follows:

C405.2.1.1 Interior lighting controls. Each area enclosed by walls or floor-to-ceiling partitions shall have at least one manual control for the lighting serving that area. The required controls shall be located within the area served by the controls or be a remote switch that identifies the lights served and indicates their status.

Exceptions:

1. Areas designated as security or emergency areas that need to be continuously lighted.
2. Lighting in stairways or corridors that are exits or exit discharge elements~~ of the means of egress~~.

Reason: According to the IBC 2012, all interior stairways and corridors are elements of the means of egress (most are exit access components). This makes the current code language redundant and confusing.

Most users of the code interpret this exception to apply only to stairways and corridors that are part of exits, and this was probably the original intention of the language. Interior exit discharge elements are unusual, but are allowed by IBC 2012 Section 1027.1.

The proposed change will make this section of the code technically correct and consistent with other ICC family codes.

Cost Impact: This code change proposal will increase the cost of construction.

C405.2.1.1-EC-BAILEY.doc

Committee Action Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The revision clarifies the exception. It aligns with the terms as defined in the *International Building Code.*

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

J. William Degnan, President, National Association of State Fire Marshals, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

C405.2.1.1 Interior lighting controls. Each area enclosed by walls or floor-to-ceiling partitions shall have at least one manual control for the lighting serving that area. The required controls shall be located within the area served by the controls or be a remote switch that identifies the lights served and indicates their status.

Exceptions:

1. Areas designated as security or emergency areas that need to be continuously lighted.

2. Lighting in stairways or corridors that are ~~exits or exit discharge~~ elements of the means of egress meeting the requirements of the *International Building Code*.

Commenter's Reason: The change that the committee approved as submitted removed other components of a Means of Egress from the exception without proper technical justification. Both Corridors and stairways may be part of a MOE but not an exit or exit discharge. The original language actually is better. Adding conformance with the IBC would add the necessary clarification.

Public Comment 2:

Brenda Thompson, CBCO, Manager Building Inspections, Clark County Development Services, ICC Sustainability, Energy and High Performance Code Action Committee (SEHPCAC) Chair requests Disapproval.

Commenter's Reason: The text of the approved CE289 will set up a conflict between the IECC and the IBC. Means of egress is the term representing the whole egress system consisting of three parts: Exit access, exits and exit discharge. The 2012 code only addresses stairways and corridors in the means of egress system. And this section of the code only addresses interior lighting. While there are some exceptions that allow exit discharge within a building, most exit discharge is exterior and not regulated by this provision of the IECC. CE287 which was also approved eliminated the text of "means of egress' and would provide the exception for all stairways. CE287 is consistent with the current code. CE289 adds the qualify that it is only stairways and corridors in exits and exit discharge. Corridors are only located in exit access. If CE289 is allowed to remain approve it actually eliminates the application of this exception to all corridors and will eliminate its use for stairways also located in the exit access portion of the system. The current code is correct as will be the code if CE287 is allowed to stand. The IECC will be inconsistent with the IBC if CE289 remains approved.

This public comment is submitted by the ICC Sustainability Energy and High Performance Code Action Committee (SEHPCAC). The SEHPCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portion thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the SEHPCAC has held numerous open meetings and workgroup calls which included members of the SEHPCAC, as well as interested parties, to discuss and debate proposed changes and public comments.

CE289-13

Final Action: AS AM AMPC____ D

CE292-13
C405.2.2.2

Proposed Change as Submitted

Proponent: Tim Nogler, Washington State Building Code Council (tim.nogler@des.wa.gov)

Revise as follows:

C405.2.2.2 Occupancy sensors. Occupancy sensors shall be installed in all classrooms, conference/meeting rooms, employee lunch and break rooms, private offices, restrooms, <u>warehouse spaces</u>, storage rooms and janitorial closets, and other spaces 300 square feet (28 m^2) or less enclosed by floor-to-ceiling height partitions. These automatic control devices shall be installed to automatically turn off lights within 30 minutes of all occupants leaving the space, and shall either be manual on or shall be controlled to automatically turn the lighting on to not more than 50 percent power.

> **Exception:** Full automatic-on controls shall be permitted to control lighting in public corridors, stairways, restrooms, primary building entrance areas and lobbies, and areas where manual-on operation would endanger the safety or security of the room or building occupants

Reason: This provision adds warehouses to the list of areas requiring occupancy sensors for lighting control. Since most areas in a warehouse are unoccupied most of the time, while other spaces are in use, the savings on lighting energy are substantial. This has been an integral part of the Washington State Energy Code for many years.

Cost Impact: The code change proposal will increase the cost of construction.

C405.2.2.2-EC-NOGLER.doc

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee was concerned about the potential safety issues of having lights turn off automatically in a warehouse. The committee suggested working with proponent of CE293-13 to develop a coordinated public comment.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Tim Nogler, Washington State Building Code Council, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

C405.2.2.2 Occupancy sensors. Occupancy sensors shall be installed in all classrooms, conference/meeting rooms, employee lunch and break rooms, private offices, restrooms, ~~warehouse spaces~~, storage rooms and janitorial closets, and other spaces 300 square feet (28 m^2) or less enclosed by floor-to-ceiling height partitions.<u>.</u> ~~These~~ <u>The</u> automatic control devices <u>in these spaces</u> shall be installed to automatically turn off lights within 30 minutes of all occupants leaving the space, and shall either be manual on or shall be controlled to automatically turn the lighting on to not more than 50 percent power. <u>In aisle ways and open areas in warehouses, lighting shall be controlled with occupancy sensors that automatically reduce lighting power by at least 50 percent when the areas are unoccupied. The occupancy sensors in warehouses shall control lighting in each aisle way independently, and shall not control lighting beyond the aisle way being controlled by the sensor</u>.

Exception: Full automatic-on controls shall be permitted to control lighting in public corridors, stairways, restrooms, warehouses, primary building entrance areas and lobbies, and areas where manual-on operation would endanger the safety or security of the room or building occupants.

Commenter's Reason: The committee asked that the proponents of this proposal CE292 and the related proposal CE293 coordinate to provide a combined Public Comment to address lighting energy conservation in warehouses. This Comment addresses the safety concerns expressed at the Dallas hearing by requiring only a 50% lighting power reduction after 30 minutes of inactivity, rather than a full-off control, and by limiting the controlled areas to aisles and open spaces only. The proposed language is adapted from the California Title 24 code.

CE292-13

Final Action: AS AM AMPC____ D

CE293-13
C405.2.2.2, C405.2.2.2.1 (New), C405.2.2.2.2 (New)

Proposed Change as Submitted

Proponent: Glenn Heinmiller, Lam Partners, representing International Association of Lighting Designers, (glenn@lampartners.com). James Edelson, New Buildings Institute.

Revise as follows:

C405.2.2.2 Occupancy sensor~~s~~ controls. Occupancy sensors shall be installed to control lights in accordance with C405.2.2.2.1 and C405.2.2.2.2. These automatic control devices shall be installed to automatically turn off lights within 30 minutes of all occupants leaving the space, and shall either be manual-on or shall be controlled to automatically turn the lighting on to not more than 50 percent power.

Exception: Full automatic-on controls shall be permitted to control lighting in:

1. Public corridors,
2. Stairways,
3. Restrooms,
4. Primary building entrance areas and lobbies,
5. Parking garages,
6. Warehouses,
7. Areas where manual-on operation would endanger the safety or security of the room or building occupants.

C405.2.2.2.1. Occupancy sensors for 100 percent load control. Occupancy sensors shall be installed to control 100 percent of the connected lighting load in:

1. Classroom~~s~~/lecture/training rooms,
2. Conference/meeting ~~rooms~~/multi-purpose rooms,
3. Copy/print rooms,
4. Lounges,
5. Employee lunch and-break rooms,
6. Private offices,
7. Restrooms,
8. Storage rooms, ~~and~~
9. Janitorial closets,
10. Laboratory classrooms,
11. Locker rooms,
12. Other spaces 300 square feet (28 m^2) or less enclosed by floor-to-ceiling height partitions.

C405.2.2.2.2. Occupancy sensors for 50 percent load control. Occupancy sensors shall be installed to control not less than 50 percent of the connected lighting load in:

1. Enclosed stairways,
2. Parking garages,
3. Warehouses.

Reason: Occupancy sensors are the automatic control type that leads to the most energy savings. This proposal requires the use of occupancy sensors in certain additional space types where occupancy sensors can be used effectively. The space type names are consistent with the space type names used for determination of lighting power density. The phrase “to control lights” is added to make it clear that the sensors not only have to be installed, but have to function. The section has been reformatted in list format for clarity.

Cost Impact: This code change proposal will increase the cost of construction if occupancy sensors would not already be specified for the space types not currently in the code.

C405.2.2.2-EC-HEINMILER.doc

Public Hearing Results

Committee Action: Disapproved

Committee Reason: The committee felt that previous proposals addressed these issues in a better way and perhaps this proponent could work some of these ideas through those items. There was also concern that a reduction of lighting to 50% within enclosed stairways could result in something below minimum illumination required by the *International Building Code.*

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Glenn Heinmiller, Lam Partners, representing International Association of Lighting Designers, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

C405.2.2.2 Occupancy sensor controls. Occupancy sensors shall be installed in the following areas and spaces ~~to control lights in accordance with C405.2.2.2.1 and C405.2.2.2.2. These automatic control devices shall be installed~~ to automatically turn off lights within 30 minutes of all occupants leaving the space, and shall either be manual-on or shall be controlled to automatically turn the lighting on to not more than 50 percent power~~.~~

~~**C405.2.2.2.1. Occupancy Sensors for 100% load control.** Occupancy sensors shall be installed to control 100 percent of the connected lighting load in:~~

1. Classroom~~s~~/lecture/training rooms,
2. Conference/meeting ~~rooms~~/multi-purpose rooms,
3. Copy/print rooms,
4. Lounges,
5. Employee lunch and break rooms,
6. Private offices,
7. Restrooms,
8. Storage rooms, and
9. Janitorial closets,

~~10. Laboratory classrooms,~~

10. Locker rooms,
11. Other spaces 300 square feet (28 m^2) or less that are enclosed by floor-to-ceiling height partitions.

Exception: Full automatic-on controls shall be permitted to control lighting in:

1. Public corridors,
2. Stairways,
3. Restrooms,
4. Primary building entrance areas and lobbies,

~~5. Parking garages,~~
~~6. Warehouses,~~

5 ~~7~~ Areas where manual-on operation would endanger the safety or security of the room or building occupants.

~~**C405.2.2.2.2. Occupancy Sensors for at least 50% load control.** Occupancy sensors shall be installed to control at least 50 percent of the connected lighting load in:~~

~~1 Enclosed stairways,~~
~~2. Parking garages,~~
~~3. Warehouses.~~

Commenter's Reason: CE293 was disapproved in Dallas for extending the mandatory use of occupancy sensors to some specific types. This Public Comment removes those space types (warehouses, parking garages, enclosed stairways, laboratory classrooms).

CE293-13

Final Action: AS AM AMPC____ D

CE294-13

C202, Figure C405.1 (NEW), Figure C405.2 (NEW), C405.2.2.3, C405.2.2.3.1 (NEW), C405.2.2.3.2 (NEW), C405.2.2.3.3 (NEW), Figure C405.3 (NEW), Figure C405.4 (NEW)

Proposed Change as Submitted

Proponent: Jack Bailey, One Lux Studio, representing International Association of Lighting Designers (jbailey@oneluxstudio.com), Jim Edelson, New Buildings Institute (jim@newbuildings.org)

Revise as follows:

~~**C405.2.2.3 Daylight zone control.** Daylight zones shall be designed such that lights in the daylight zone are controlled independently of general area lighting and are controlled in accordance with either Section C405.2.2.3.1 or Section C405.2.2.3.2. Each daylight control zone shall not exceed 2,500 square feet (232 m^2). Contiguous daylight zones adjacent to vertical fenestration are allowed to be controlled by a single controlling device provided that they do not include zones facing more than two adjacent cardinal orientations (i.e., north, east, south, west). Daylight zones under skylights more than 15 feet (4572 mm) from the perimeter shall be controlled separately from daylight zones adjacent to vertical fenestration.~~

> ~~**Exception:** Daylight zones enclosed by walls or ceiling height partitions and containing two or fewer light fixtures are not required to have a separate switch for general area lighting.~~

C405.2.2.3 Daylight responsive controls. *Daylight responsive controls* complying with Section C405.2.2.3.1 shall be provided to control the electric lights within *daylight zones* in the following spaces:

1. Spaces with a total of more than 150 watts of *general lighting* within sidelight *daylight zones* complying with Section C405.2.2.3.2. *General lighting* does not include lighting that is required to have specific application control in accordance with Section C405.2.3.
2. Spaces with a total of more than 150 watts of *general lighting* within toplight *daylight zones* complying with Section C405.2.2.3.3.

Exceptions: Daylight responsive controls are not required for the following:

1. Spaces in health care facilities where patient care is directly provided.
2. Dwelling units and sleeping units.
3. Lighting that is required to have specific application control in accordance with Section C405.2.3.

C405.2.2.3.1 Daylight responsive control function. Where required, *daylight responsive controls* shall be provided within each space for control of lights in that space and shall comply with all of the following:

1. Lights in toplight *daylight zones* in accordance with Section C405.2.2.3.3 shall be controlled independently of lights in sidelight *daylight zones* in accordance with Section C405.2.2.3.2;
2. *Daylight responsive controls* within each space shall be configured so that they can be calibrated from within that space by authorized personnel;
3. Calibration mechanisms shall be *readily accessible*;
4. When located in offices, classrooms, laboratories, and library reading rooms, *daylight responsive controls* shall dim lights continuously from full light output to 10 percent of full light output or lower;
5. *Daylight responsive controls* shall be capable of a complete shut off of all controlled lights; and
6. Lights in sidelight *daylight zones* in accordance with Section C405.2.2.3.2 facing different cardinal orientations (i.e. within 45 degrees of due north, east, south, west) shall be controlled independently of each other.

Exception: Up to 150 watts of lighting in each space is permitted to be controlled together with lighting in a daylight zone facing a different cardinal orientation.

C405.2.2.3.2 Sidelight daylight zone. The sidelight *daylight zone* is the floor area adjacent to vertical *fenestration* which complies with all of the following:

1. Where the *fenestration* is located in a wall, the *daylight zone* shall extend laterally to the nearest full height wall, or up to 1.0 times the height from the floor to the top of the *fenestration*, and longitudinally from the edge of the fenestration to the nearest full height wall, or up to 2 feet (610 mm), whichever is less, as indicated in Figure C405.1;
2. Where the *fenestration* is located in a rooftop monitor, the *daylight zone* shall extend laterally to the nearest obstruction that is taller than 0.7 times the ceiling height, or up to 1.0 times the height from the floor to the bottom of the *fenestration*, whichever is less, and longitudinally from the edge of the *fenestration* to the nearest obstruction that is taller than 0.7 times the ceiling height, or up to 0.25 times the height from the floor to the bottom of the *fenestration*, whichever is less, as indicated in Figures C405.2 and C405.3;
3. The area of the *fenestration* is at least 24 square feet;
4. The distance from the *fenestration* to any building or geological formation which would block access to daylight is greater than the height from the bottom of the *fenestration* to the top of the building or geologic formation; and
5. Where located in existing buildings, the *visible transmittance* of the *fenestration* is no less than 0.25.

C405.2.2.3.3 Toplight daylight zone. The toplight *daylight zone* is the floor area underneath a roof *fenestration* assembly which complies with all of the following:

1. The *daylight zone* shall extend laterally and longitudinally beyond the edge of the roof *fenestration* assembly to the nearest obstruction that is taller than 0.7 times the ceiling height, or up to 0.7 times the ceiling height, whichever is less, as indicated in Figure C405.4;
2. No building or geological formation blocks direct sunlight from hitting the roof *fenestration* assembly at the peak solar angle on the summer solstice; and
3. Where located in existing buildings, the product of the *visible transmittance* of the roof *fenestration* assembly and the area of the rough opening of the roof fenestration assembly, divided by the area of the daylight zone is no less than 0.008.

FIGURE C405.4
DAYLIGHT ZONE **UNDER A ROOF FENESTRATION ASSEMBLY**

Revise definitions as follows:

SECTION C202
GENERAL DEFINITIONS

DAYLIGHT RESPONSIVE CONTROL. A device or system that provides automatic control of electric light levels based on the amount of daylight in a space.

DAYLIGHT ZONE. That portion of a building's interior floor area that is illuminated by natural light.

1. ~~**Under skylights.** The area under skylights whose horizontal dimension, in each direction, is equal to the skylight dimension in that direction plus either the floor-to-ceiling height or the dimension to a ceiling height opaque partition, or one-half the distance to adjacent skylights or vertical fenestration, whichever is least.~~
2. ~~**Adjacent to vertical fenestration.** The area adjacent to vertical fenestration which receives daylight through the fenestration. For purposes of this definition and unless more detailed analysis is provided, the daylight *zone* depth is assumed to extend into the space a distance of 15 feet (4572 mm) or to the nearest ceiling height opaque partition, whichever is less. The daylight *zone* width is assumed to be the width of the window plus 2 feet (610 mm) on each side, or the window width plus the distance to an opaque partition, or the window width plus one-half the distance to adjacent skylight or vertical fenestration, whichever is least.~~

Reason: This proposal would replace the provisions in the code related to control of electric lights in daylight zones. It would not alter any of the envelope provisions in the code, nor would it set any minimum requirements for fenestration. The proposed changes are needed for two reasons:

1. The existing IECC code language is technically inadequate and confusing, and
2. There is a tremendous untapped potential for energy savings in buildings just by turning off electric lights in daylit spaces.

Inadequate and Confusing Language in 2012 IECC

1. The code describes all sidelight daylight zones as being 15 feet deep, regardless of whether the window is 5 feet high or 50 feet high. Lighting controls will not function properly if the daylight zone size is wrong, and the 15 foot depth requirement in the current code is actually an impediment to successful implementation of daylight responsive controls. New definitions that are based on the geometry of the building are proposed, and diagrams are provided to make the code easier to use. The proposed diagrams are modified slightly from the diagrams published in the 2012 IGCC, and if this proposal is approved these modifications should be proposed for the IGCC diagrams as well.
2. The code provides no clear guidance about the daylight zone associated with a rooftop monitor. This proposal clearly describes the daylight zone associated with rooftop monitors.
3. Small windows, windows with low-VT glass, and windows which are overshadowed by adjacent buildings are common in urban areas with older building stock. Daylight responsive controls should not be required in situations where they will be ineffective. The current code does not provide exceptions for these situations, but the proposed language does.
4. The code requires that separate control be provided for lights in each daylight zone. On facades where windows are spaced more than 4 feet apart, each window establishes a separate daylight zone, and hence a separate lighting control zone. This adds unnecessary cost and complexity to the lighting controls. The proposed daylight responsive control requirements in Section 405.2.2.3.1 resolve this issue and clarify which lights can be grouped together for control in a more sensible way.
5. The code allows step-switching in offices, laboratories, classrooms, and reading rooms, where we know this is objectionable to occupants. This proposal would require dimming in those areas, while still allowing less costly switching systems to be used in other areas.
6. The code is not specific enough about how daylight responsive controls should be required to function. An owner, developer, designer, or builder who looks for the lowest first-cost solution that meets the current code will likely end up with a lighting control system that doesn't work. The proposed Section 405.2.2.3.1 would establish minimum requirements for these systems to function properly. The code is not a design guideline, but it should prevent obvious shortcuts which subvert the intent of the code.

Additional Energy Savings from Daylight Responsive Controls

The IECC requires that daylight responsive controls only be provided in buildings following the prescriptive path which fail to meet certain fenestration requirements. This is obviously a very limited requirement, as most lighting installations are completed as part of alterations to existing buildings that do not include envelope alterations.

This proposal would require that daylight responsive controls be provided whenever more than 150 watts of lighting is installed in an area which receives effective daylight. Necessary exceptions are included for lighting in dwelling units, sleeping units, health care, etc. The 150 watt threshold was found to be cost effective by PNNL and HMG in research done to support the ASHRAE 90.1 Committee. If approved, this proposal would align the stringency of the lighting control requirements in the IECC with those of ASHRAE / ANSI / IESNA Standard 90.1 – 2013, but would still leave the IECC less stringent than California Title 24 – 2013.

Lighting in commercial buildings is responsible for 38% of electricity consumption in commercial buildings nationally. As a portion total energy use, lighting is the largest individual use of energy, accounting for one fifth (20%) of the combined energy total. This occurs despite the fact that many buildings have ample access to a free light source – daylight. A recent meta-analysis report on lighting controls in commercial buildings (Lighting Controls in Commercial Buildings, Williams, Atkins et al, 2012) estimated a 28% average lighting energy savings potential for buildings that incorporated daylighting strategies.

Guidelines published by NBI (http://patternguide.advancedbuildings.net) show that there are multiple ways to provide high quality daylight in most buildings. In addition to many energy code entities, almost every voluntary rating system has been increasing their reliance on daylighting to reduce energy consumption in commercial buildings. This proposal ensures that the IECC incorporates the energy saving priority that if sufficient daylight is available, then controls should be included to turn off the electric lights.

Cost Impact: The code change proposal will increase the cost of construction.

C405.2.2.3 (NEW)-EC-BAILEY-EDELSON

Committee Action Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: Daylight zones are already required and must be shown on the construction documents. This proposal clarifies the appropriate controls for each type of daylight space.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Jack Bailey, One Lux Studio, representing International Association of Lighting Designers; Jim Edelson, New Buildings Institute, Glenn Heinmiller, Lam Partners, representing self, request Approval as Modified by this Public Comment.

Modify the proposal as follows:

C405.2.2.3 Daylight Responsive Controls. *Daylight responsive controls* complying with Section C405.2.2.3.1 shall be provided to control the electric lights within *daylight zones* in the following spaces:

1. Spaces with a total of more than 150 watts of *general lighting* within sidelight *daylight zones* complying with C405.2.2.3.2. *General lighting* does not include lighting that is required to have specific application control in accordance with C405.2.3.
2. Spaces with a total of more than 150 watts of *general lighting* within toplight *daylight zones* complying with C405.2.2.3.3.

Exceptions:

1. Spaces in health care facilities where patient care is directly provided.
2. Dwelling units and sleeping units.
3. Lighting that is required to have specific application control in accordance with C405.2.3.
4. <u>Sidelight *daylight zones* on the first floor above grade in Group A-2 and Group M occupancies.</u>

C405.2.2.3.1 Daylight responsive control function. Where required, *daylight responsive controls* shall be provided within each space for control of lights in that space and shall comply with all of the following:

4. Where located in offices, classrooms, laboratories, and library reading rooms, *daylight responsive controls* shall dim lights continuously from full light output to ~~10~~ <u>15</u> percent of full light output or lower

C405.2.2.3.2 Sidelight Daylight Zone. The sidelight *daylight zone* is the floor area adjacent to vertical *fenestration* which satisfies the following criteria:

5. Where located in existing buildings, the *visible transmittance* of the *fenestration* is no less than ~~0.25~~ <u>0.20</u>.

(Portions of proposal not shown remain unchanged)

Commenter's Reason:
Bailey/Edelson: The sponsors of CE294 have worked with a group of interested parties to offer one consolidated public comment with several proposed revisions:

1. Add an exception for restaurants, bars, and retailers who often want to leave lights on during the day in their street level storefronts to draw attention to their establishment, and to convey to passersby that they are open for business. This seems like a reasonable exception, and Seattle already has a similar provision in place in their code.
2. Relax the requirement for lights in offices, classrooms, laboratories, and library reading rooms to dim to 10%. Changing this requirement to 15% will allow a much wider variety of lighting products to be used.
3. Reduce the VT exception for fenestration in existing buildings from 0.25 to 0.20. This will make daylight responsive controls more widely applicable in existing buildings, and will also discourage the use of lower transmittance fenestration in new construction. In many cases, permits for new construction do not include interior fitout, and interior fitout is subsequently filed as an alteration to the new building. When this happens, daylight controls will not be required if low VT fenestration is used. This creates a perverse incentive for the designers of the new building to select a lower transmittance fenestration assembly to avoid the requirement for daylight responsive controls inside the building. Lowering the threshold for this exception will make it less likely that this will happen, as most designers would not select fenestration with a VT lower than 0.20 for aesthetic reasons.

Heinmiller: This public comment incorporates three separate changes to the original proposal:

1. Add an exception for restaurants, bars, and retailers who often want to leave lights on during the day in their street level storefronts to draw attention to their establishment, and to convey to passersby that they are open for business. This seems like a reasonable exception, and Seattle already has a similar provision in place in their code.
2. Relax the requirement for lights in offices, classrooms, laboratories, and library reading rooms to dim to 10%. Changing this requirement to 15% will allow a much wider variety of lighting products to be used.
3. Reduce the VT exception for fenestration in existing buildings from 0.25 to 0.20. This will make daylight responsive controls more widely applicable in existing buildings, and will also discourage the use of lower transmittance fenestration in new construction. In many cases, permits for new construction do not include interior fitout, and interior fitout is subsequently filed as an alteration to the new building. When this happens, daylight controls will not be required if low VT fenestration is used. This creates a perverse incentive for the designers of the new building to select a lower transmittance fenestration assembly to avoid the requirement for daylight responsive controls inside the building. Lowering the threshold for this exception will make it less likely that this will happen, as most designers would not select fenestration with a VT lower than 0.20 for aesthetic reasons.

Public Comment 2:

Jack Bailey, One Lux Studio, representing International Association of Lighting Designers; Jim Edelson, New Buildings Institute, request Approval as Modified by this Public Comment.

Modify the proposal as follows:

~~**C405.2.2.3.1 Manual daylighting controls.** Manual controls shall be installed in daylight zones unless automatic controls are installed in accordance with Section C405.2.3.5.~~

~~**C405.2.2.3.2 Automatic daylighting controls.** Set-point and other controls for calibrating the lighting control device shall be readily accessible.~~

~~Daylighting controls device shall be capable of automatically reducing the lighting power in response to available daylight by either one of the following methods:~~

~~1. Continuous dimming using dimming ballasts and daylight-sensing automatic controls that are capable of reducing the power of general lighting in the daylit zone continuously to less than 35 percent of rated power at maximum light output.~~
~~2. Stepped dimming using multi-level switching and daylight-sensing controls that are capable of reducing lighting power automatically. The system shall provide a minimum of two control channels per zone and be installed in a manner such that at least one control step is between 50 percent and 70 percent of design lighting power and another control step is no greater than 35 percent of design power.~~

~~**C405.2.2.3.3 Multi-level lighting controls.** Where multi-level lighting controls are required by this code, the general lighting in the daylight zone shall be separately controlled by at least one multi-level lighting control that reduces the lighting power in response to daylight available in the space. Where the daylit illuminance in the space is greater than the rated illuminance of the general lighting of daylight zones, the general lighting shall be automatically controlled so that its power draw is no greater than 35 percent of its rated power. The multi-level lighting control shall be located so that calibration and set point adjustment controls are readily accessible and separate from the light sensor.~~

C402.3 Fenestration (Prescriptive). Fenestration shall comply with Table C402.3. Automatic daylighting controls specified by this section shall comply with Section ~~C405.2.2.3.2~~ C405.2.2.3.1

C402.3.2.1 Lighting controls in daylight zones under skylights. All lighting in the daylight zone shall be controlled by multilevel lighting controls that comply with Section ~~C405.2.2.3.3.~~ C405.2.2.3.1.

Exceptions (Remain unchanged.)

Commenter's Reason: This public comment eliminates superseded code subsections that are redundant and confusing.
CE294 was intended to completely replace existing provisions in the IECC related to daylight controls in Section C405.2.2.3 **and all of its subsections**. However, due to a misunderstanding of ICC procedures by the sponsors, CE294 as approved would only delete section C405.2.2.3, but subsections C405.2.2.3.1, C405.2.2.3.2, and C405.2.2.3.3 would remain in the code.
This public comment corrects that error. If the language remains in the IECC there will be two separate sets of requirements for daylight responsive controls – one for controls required by the envelope section C402, and a second for controls required by the lighting section C405.

Public Comment 3:

Duane Jonlin, City of Seattle, Department of Planning and Development, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

~~**C405.2.2.3.1 Manual daylighting controls.** Manual controls shall be installed in daylight zones unless automatic controls are installed in accordance with Section C405.2.3.5.~~

~~**C405.2.2.3.2 Automatic daylighting controls.** Set-point and other controls for calibrating the lighting control device shall be readily accessible.~~

~~Daylighting controls device shall be capable of automatically reducing the lighting power in response to available daylight by either one of the following methods:~~

1. ~~Continuous dimming using dimming ballasts and daylight-sensing automatic controls that are capable of reducing the power of general lighting in the daylit zone continuously to less than 35 percent of rated power at maximum light output.~~
2. ~~Stepped dimming using multi-level switching and daylight-sensing controls that are capable of reducing lighting power automatically. The system shall provide a minimum of two control channels per zone and be installed in a manner such that at least one control step is between 50 percent and 70 percent of design lighting power and another control step is no greater than 35 percent of design power.~~

~~**C405.2.2.3.3 Multi-level lighting controls.** Where multi-level lighting controls are required by this code, the general lighting in the daylight zone shall be separately controlled by at least one multi-level lighting control that reduces the lighting power in response to daylight available in the space. Where the daylit illuminance in the space is greater than the rated illuminance of the general lighting of daylight zones, the general lighting shall be automatically controlled so that its power draw is no greater than 35 percent of its rated power. The multi-level lighting control shall be located so that calibration and set point adjustment controls are readily accessible and separate from the light sensor.~~

C402.3 Fenestration (Prescriptive). Fenestration shall comply with Table C402.3. ~~Automatic daylighting~~ Daylight responsive controls specified by this section shall comply with Section ~~C405.2.2.3.3.~~ C405.2.2.3

C402.3.2.1 Lighting controls in daylight zones under skylights. All lighting in the daylight zone shall be controlled by ~~multilevel lighting~~ daylight responsive controls that comply with Section ~~C405.2.2.3.3.~~ C405.2.2.3

Exceptions (Remain unchanged.)

(The remainder of the proposal is not modified.)

Commenter's Reason: This public comment deletes unnecessary language from the code. If CE294 is approved, the sections proposed for deletion above would then remain in the code, but would not be referenced by any other sections. This would be confusing for users of the code.

CE294-13

Final Action:	AS	AM	AMPC____	D

CE299-13
C405.2.3

Proposed Change as Submitted

Proponent: Steve Ferguson, American Society of Heating, Refrigerating, and Air-Conditioning Engineers (ASHRAE) (sferguson@ashrae.org)

Revise as follows:

C405.2.3 Specific application controls. Specific application controls shall be provided for the following:

1. Display and accent light shall be controlled by a dedicated control which is independent of the controls for other lighting within the room or space
2. Lighting in cases used for display case purposes shall be controlled by a dedicated control which is independent of the controls for other lighting within the room or space.
3. Hotel and motel sleeping units and guest suites shall have a master control device ~~at the main room entry that controls all permanently installed luminaires and switched receptacles~~ that is capable of switching off all installed luminaires and switched receptacles within 20 minutes after all occupants leave the room.

   Exception: Lighting and switched receptacles controlled by captive key systems.

4. Supplemental task lighting, including permanently installed under-shelf or under-cabinet lighting, shall have a control device integral to the luminaires or be controlled by a wall-mounted control device provided the control device is readily accessible.
5. Lighting for nonvisual applications, such as plant growth and food warming, shall be controlled by a dedicated control which is independent of the controls for other lighting within the room or space.
6. Lighting equipment that is for sale or for demonstrations in lighting education shall be controlled by a dedicated control which is independent of the controls for other lighting within the room or space.

Reason: For consistency with ASHRAE/IES 90.1. These revisions introduce automatic lighting control to guestroom type spaces for additional energy savings and allow captive key systems that provide similar savings control to also comply.

Cost Impact: The code change proposal will increase the cost of construction when lighting controls are required in parking garages.

C405.2.3-EC-FERGUSON.doc

Committee Action Hearing Results

Committee Action: **Approved as Modified**

Modify the proposal as follows:

3. Hotel and motel sleeping units and guest suites shall have a master control device that is capable of automatically switching off all installed luminaires and switched receptacles within 20 minutes after all occupants leave the room.

(Balance of the proposal is unchanged.)

Committee Reason: The modification was approved to correct the readability of the sentence. The turning off of power when sleeping units are occupied will save significant energy.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jack Bailey, One Lux Studio, representing International Association of Lighting Designers, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

C405.2.3 Specific application controls. Specific application controls shall be provided for the following:

1. Display and accent light shall be controlled by a dedicated control which is independent of the controls for other lighting within the room or space
2. Lighting in cases used for display case purposes shall be controlled by a dedicated control which is independent of the controls for other lighting within the room or space.
3. Hotel and motel sleeping units and guest suites shall have a master control device that ~~is capable of~~ automatically ~~switching~~ <u>switches</u> off all installed luminaires and switched receptacles within 20 minutes after all occupants leave the room.

   Exception: Lighting and switched receptacles controlled by captive key systems.

4. Supplemental task lighting, including permanently installed under-shelf or under-cabinet lighting, shall have a control device integral to the luminaires or be controlled by a wall-mounted control device provided the control device is readily accessible.
5. Lighting for nonvisual applications, such as plant growth and food warming, shall be controlled by a dedicated control which is independent of the controls for other lighting within the room or space.
6. Lighting equipment that is for sale or for demonstrations in lighting education shall be controlled by a dedicated control which is independent of the controls for other lighting within the room or space.

Commenter's Reason: A manual switch is **capable** of switching lights off within 20 minutes of all occupants leaving the room if the occupants use the switch to turn the lights off when they walk out.

It is essential that the term "automatic" included in this proposal so that it achieves the intended result.

CE299-13

Final Action: AS AM AMPC____ D

CE302-13
C405.2.3

Proposed Change as Submitted

Proponent: Duane Jonlin, City of Seattle, representing City of Seattle Department of Planning and Development (duane.jonlin@seattle.gov)

Revise as follows:

C405.2.3 Specific application controls. Specific application controls shall be provided for the following:

1. Display and accent light shall be controlled by a dedicated control which is independent of the controls for other lighting within the room or space.
2. Lighting in cases used for display case purposes shall be controlled by a dedicated control which is independent of the controls for other lighting within the room or space.
3. Hotel and motel sleeping units and guest suites shall have a master control device at the main room entry that controls all permanently installed luminaires and switched receptacles.
4. Supplemental task lighting, including permanently installed under-shelf or under-cabinet lighting, shall have a control device integral to the luminaires or be controlled by a wall-mounted control device provided the control device is readily accessible.
5. Lighting for nonvisual applications, such as plant growth and food warming, shall be controlled by a dedicated control which is independent of the controls for other lighting within the room or space.
6. Lighting equipment that is for sale or for demonstrations in lighting education shall be controlled by a dedicated control which is independent of the controls for other lighting within the room or space.
7. Each stairway shall have one or more control devices to automatically reduce lighting power by not less than 50 percent when no occupants have been detected in the stairway for a period not exceeding 30 minutes, and restore lighting to full power when occupants enter the stairway. All portions of stairways shall remain illuminated to at least 1 footcandle (11 lux) at the walking surface when the lighting power is reduced.
8. Lighting in parking garages shall have one or more control devices to automatically reduce lighting power in any one controlled zone by not less than 50 percent when no occupants have been detected in that zone for a period not exceeding 30 minutes, and restore lighting to full power when occupants enter or approach the zone. Each lighting zone controlled by occupancy sensors shall be no larger than 7,200 square feet. Pedestrian occupancy sensors controlling any lighting zone are permitted to be configured to detect pedestrians no more than 30 feet outside of that zone. Vehicle occupancy sensors controlling any lighting zone are permitted to be configured to detect vehicles no more than 60 feet outside of that zone.

Reason: This provision allows stairs enclosures and parking garages lighting energy use to be reduced by half when unoccupied, then come back to full brightness when occupants enter those spaces. It provides a balance between safety, security and energy use. These measures are currently in force in Seattle.

Cost Impact: The code change proposal will increase the cost of construction.

C405.2.3-EC-JONLIN.doc

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee was concerned that there may be unintended consequences from the proposed language. Item 8 didn't have a minimum amount of light. The committee expressed concern about a scenario where one might happen to be sitting in a car in a parking garage while waiting for someone else to show up. The lights could go out leaving the occupant in the dark.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Duane Jonlin, City of Seattle, Department of Planning and Development, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

C405.2.3 Specific application controls. Specific application controls shall be provided for the following:

1. Display and accent light shall be controlled by a dedicated control which is independent of the controls for other lighting within the room or space.
2. Lighting in cases used for display case purposes shall be controlled by a dedicated control which is independent of the controls for other lighting within the room or space.
3. Hotel and motel sleeping units and guest suites shall have a master control device at the main room entry that controls all permanently installed luminaires and switched receptacles.
4. Supplemental task lighting, including permanently installed under-shelf or under-cabinet lighting, shall have a control device integral to the luminaires or be controlled by a wall-mounted control device provided the control device is readily accessible.
5. Lighting for nonvisual applications, such as plant growth and food warming, shall be controlled by a dedicated control which is independent of the controls for other lighting within the room or space.
6. Lighting equipment that is for sale or for demonstrations in lighting education shall be controlled by a dedicated control which is independent of the controls for other lighting within the room or space.
7. Each stairway shall have one or more control devices to automatically reduce lighting power by not less than 50 percent when no occupants have been detected in the stairway for a period not exceeding 30 minutes, and restore lighting to full power when occupants enter the stairway. All portions of stairways shall remain illuminated to the level required by Section 1006.2 of the *International Building Code* when the lighting power is reduced.
8. Lighting in parking garages shall have one or more control devices to automatically reduce lighting power in any one controlled zone by not less than 50 percent <u>and not more than 75 percent</u> when no occupants have been detected in that zone for a period not exceeding 30 minutes, and restore lighting to full power when occupants enter or approach the zone. Each lighting zone controlled by occupancy sensors shall be no larger than 7,200 square feet. Pedestrian occupancy sensors controlling any lighting zone are permitted to be configured to detect pedestrians no more than 30 feet outside of that zone. Vehicle occupancy sensors controlling any lighting zone are permitted to be configured to detect vehicles no more than 60 feet outside of that zone. <u>Lighting for covered vehicle entrances to and exits from the garage shall be separately controlled and comply with Section C405.2.4. Lighting is permitted to be turned off completely during hours when the garage not in operation.</u>

Commenter's Reason: The original code change proposal adds items #7 for stairways and #8 for parking garages. This Public Comment responds to the Committee's concern that no minimum garage lighting level had been specified. In addition, garage entrance and exit lighting is exempted from the requirement.

Public Comment 2:

Andrei Moldoveanu, representing The National Electrical Manufacturers Association (NEMA), requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

C405.2.3 Specific application controls. Specific application controls shall be provided for the following:

1. Display and accent light shall be controlled by a dedicated control which is independent of the controls for other lighting within the room or space.
2. Lighting in cases used for display case purposes shall be controlled by a dedicated control which is independent of the controls for other lighting within the room or space.
3. Hotel and motel sleeping units and guest suites shall have a master control device at the main room entry that controls all permanently installed luminaires and switched receptacles.
4. Supplemental task lighting, including permanently installed under-shelf or under-cabinet lighting, shall have a control device integral to the luminaires or be controlled by a wall-mounted control device provided the control device is readily accessible.
5. Lighting for nonvisual applications, such as plant growth and food warming, shall be controlled by a dedicated control which is independent of the controls for other lighting within the room or space.
6. Lighting equipment that is for sale or for demonstrations in lighting education shall be controlled by a dedicated control which is independent of the controls for other lighting within the room or space.
7. Each stairway shall have one or more control devices to automatically reduce lighting power by not less than 50 percent when no occupants have been detected in the stairway for a period not exceeding 30 minutes, and restore lighting to full power when occupants enter the stairway. All portions of stairways shall remain illuminated to at least 1 footcandle (11 lux) at the walking surface when the lighting power is reduced.
8. ~~Lighting in parking garages shall have one or more control devices to automatically reduce lighting power in any one controlled zone by not less than 50 percent when no occupants have been detected in that zone for a period not exceeding 30 minutes, and restore lighting to full power when occupants enter or approach the zone. Each lighting zone controlled by occupancy sensors shall be no larger than 7,200 square feet. Pedestrian occupancy sensors controlling any lighting zone are permitted to be configured to detect pedestrians no more than 30 feet outside of that zone. Vehicle occupancy sensors controlling any lighting zone are permitted to be configured to detect vehicles no more than 60 feet outside of that zone.~~

Commenter's Reason: The Committee rejected the original proposal because "item 8 didn't have a minimum amount of light". Also, "the lighting could go out [in parking garages] leaving occupants in the dark". The committee did not appear to have an issue with item 7. This modification eliminates item 8 thereby removing the committee's objections.

CE302-13

Final Action: AS AM AMPC____ D

CE303-13
C405.2.4

Proposed Change as Submitted

Proponent: Jeremiah Williams, U.S. Department of Energy (jeremiah.williams@ee.doe.gov)

Delete and substitute as follows:

~~**C405.2.4 Exterior lighting controls.** Lighting not designated for dusk-to-dawn operation shall be controlled by either a combination of a photosensor and a time switch, or an astronomical time switch. Lighting designated for dusk-to-dawn operation shall be controlled by an astronomical time switch or photosensor. All time switches shall be capable of retaining programming and the time setting during loss of power for a period of at least 10 hours.~~

C405.2.4 Exterior lighting controls. Exterior lighting shall be controlled by either an astronomical time switch or a photo sensor and a time switch. Time switches shall be capable of retaining programming and the time setting for at least 10 hours without power.

> **Exception:** Lighting designed for dusk to dawn operation shall be permitted to have a photo sensor without a time switch.

Reason: This proposal simplifies the provisions covering exterior lighting controls in the code, to foster the ability to implement and verify compliance with the code.

Cost Impact: The code change proposal will not increase the cost of construction.

C405.2.4 (NEW)-EC-WILLIAMS.doc

Committee Action Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: Clarifies the text of the section. There are no technical changes resulting from the revision.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jeremiah Williams, U.S. Department of Energy, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

C405.2.4 Exterior lighting controls. All exterior lighting shall be ~~controlled by either an astronomical time switch or a photo sensor and a time switch~~. provided with a control that automatically turns off the lighting when daylighting is available.

Where lighting the building façade or landscape, the lighting shall also be provided with controls that automatically shut off the lighting as a function of dawn/dusk and a set opening and closing time.

Exterior lighting other than building façade or landscape lighting shall be provided with controls configured to automatically reduce the connected lighting power by at least 30 percent from 12 midnight or within one hour of the end of business operations, whichever is later until 6 a.m. or business opening whichever is earlier or during any period when no activity has been detected for a time of no longer than 15 minutes.

All ~~time switches~~ controls that operate as a function of time shall be capable of retaining programming and the time setting during a loss of power of at least 10 hours.

Exceptions:

1. ~~Lighting designed for dusk to dawn operation shall be permitted to have a photo sensor without a time switch.~~
1. Emergency lighting that is intended to be automatically off during building operation.
2. Lighting specifically required to satisfy health and life safety requirements.
3. Decorative gas lighting systems
4. Lighting for covered vehicle entrances or exits from buildings or parking structures where required for safety, security, or eye adaptation.

Commenter's Reason: At the code development hearing, both CE303-13 and CE304-13 were approved as submitted. The intent of CE303-13 was to simplify the provisions in the code covering exterior lighting controls and in so doing foster the ability to implement the code and to verify compliance with the code. The language approved pursuant to CE304-13, which is intended to foster consistency between the IECC and ANSI/ASHRAE/IESNA Standard 90.1-13, is as follows:

C405.2.4 Exterior lighting controls. *Lighting for exterior applications other than emergency lighting that is intended to be automatically off during building operation, lighting specifically required to meet health and life safety requirements or decorative gas lighting systems shall:*

1. *Be provided with a control that automatically turns off the lighting as a function of available daylight.*
2. *Where lighting the building façade or landscape the lighting shall have controls that automatically shut off the lighting as a function of dawn/dusk and a set opening and closing time.*
3. *Where not covered in Item 2 the lighting shall have controls configured to automatically reduce the connected lighting power by at least 30 percent from no later than 12 midnight to 6 a.m. or from one hour after business closing to one hour before business opening or during any period when no activity has been detected for a time of no longer than 15 minutes.*

All time switches shall be able to retain programming and the time setting during loss of power for a period of at least ten hours.

Exception: *Lighting for covered vehicle entrances or exits from buildings or parking structures* where required for safety, security, or eye adaptation.

The approval of both CE303-13 and CE304-13 would provide a challenge in reconciling the text approved in both changes. In all likelihood the approved text in CE303-13 would be overshadowed and more or less eliminated by the text approved in CE304-13. As a result, the simplicity and clarification intended in CE303-13 would be lost. The intent of this public comment is to reconcile the provisions in CE303-13 and CE304-13 in a way that addresses both the simplicity and clarity intended in CE303-13, and the technical improvement and consistency with ANSI/ASHRAE/IESNA Standard 90.1-13 intended CE304-13. This public comment allows the voting members of ICC to review and vote on how these two approved changes would be reconciled and appear in the 2015 IECC.

Two comments were received on DOE's draft public comment; the first made suggestions to the code language in the public comment to reconcile CE303 and CE304, and the second recommended the deletion of the exception for decorative gas lighting.

Since CE304 excepted decorative gas lighting, which is consistent with Standard 90.1 (Section 9.1.1), and both CE303 and CE304 were recommended for approval at the first hearing, and the purpose of this public comment is to simply reconcile what was approved at the first hearing, it did not seem appropriate for DOE to remove that exception.

DOE did revise the public comment based on the suggestions made in the first comment. As such, DOE believes that this public comment reconciles both CE303 and CE304 in a manner acceptable to both proponents, and, since both were recommended for approval at the first hearing, this reconciliation of the text should be acceptable to the ICC membership in voting for approval of CE303 as modified by this public comment.

DOE posted its draft proposals and public comments for the IECC on its Building Energy Codes website prior to submitting to the ICC. Interested parties were provided a 30 day public review in June 2013, for which notice was published in the *Federal Register* (Docket No. EERE-2012-BT-BC-0030) and announced via the DOE Building Energy Codes news email list. In response to stakeholder input, DOE revised its proposals and public comments, as appropriate, and submitted to the ICC.

For more information on DOE proposals and public comments, including how DOE participates in the ICC code development process, please visit: http://www.energycodes.gov/development.

CE303-13

Final Action: AS AM AMPC____ D

CE304-13
C405.2.4

<u>Proposed Change as Submitted</u>

Proponent: Steve Ferguson, American Society of Heating, Refrigerating, and Air-Conditioning Engineers (ASHRAE) (sferguson@ashrae.org)

Delete and substitute as follows:

~~**C405.2.4 Exterior lighting controls.** Lighting not designated for dusk-to-dawn operation shall be controlled by either a combination of a photosensor and a time switch, or an astronomical time switch. Lighting designated for dusk-to-dawn operation shall be controlled by an astronomical time switch or photosensor. All time switches shall be capable of retaining programming and the time setting during loss of power for a period of at least 10 hours~~

C405.2.4 Exterior lighting controls. <u>Lighting for exterior applications other than emergency lighting that is intended to be automatically off during building operation, lighting specifically required to meet health and life safety requirements or decorative gas lighting systems shall:</u>

1. <u>Be provided with a control that automatically turns off the lighting as a function of available daylight.</u>
2. <u>Where lighting the building façade or landscape the lighting shall have controls that automatically shut off the lighting as a function of dawn/dusk and a set opening and closing time.</u>
3. <u>Where not covered in Item 2 the lighting shall have controls configured to automatically reduce the connected lighting power by at least 30 percent from no later than 12 midnight to 6 a.m. or from one hour after business closing to one hour before business opening or during any period when no activity has been detected for a time of no longer than 15 minutes.</u>

<u>All time switches shall be able to retain programming and the time setting during loss of power for a period of at least ten hours.</u>

> <u>**Exception:** Lighting for covered vehicle entrances or exits from buildings or parking structures where required for safety, security, or eye adaptation.</u>

Reason: For consistency with ASHRAE/IES 90.1-2010. Section 9.4.1.7 of that document contains provisions for exterior lighting controls that differ from those in Section C405.2.4 of the IECC Commercial Provisions. As that standard is an alternative path to compliance with the IECC and there is a desire to maintain equivalency of the IECC with 90.1 this change is needed.

Cost Impact: The code change proposal will not increase the cost of construction.

C405.2.4-EC-FERGUSON.doc

<u>Committee Action Hearing Results</u>

Committee Action: **Approved as Submitted**

Committee Reason: The proposal clarifies the requirements as well as providing 2 additional compliance options. This proposal does leave the lights on, versus completely shutting them off. Many exterior lights are provided for safety purposes and should remain on to a certain level.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Maureen Traxler, City of Seattle Department of Planning & Development, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

C405.2.4 Exterior lighting controls. Lighting for exterior applications ~~other than emergency lighting that is intended to be automatically off during building operation, lighting specifically required to meet health and life safety requirements or decorative gas lighting systems~~ shall:

1. Be provided with a control that automatically turns off the lighting as a function of available daylight.
2. Where lighting the building façade or landscape the lighting shall have controls that automatically shut off the lighting as a function of dawn/dusk and a set opening and closing time.
3. Where not covered in Item 2 the lighting shall have controls configured to automatically reduce the connected lighting power by at least 30 percent from no later than 12 midnight to 6 a.m. or from one hour after business closing to one hour before business opening or during any period when no activity has been detected for a time of no longer than 15 minutes.

   Exception: The following types of lighting are not required to comply with this section:

   1. Emergency lighting that is intended to be automatically off during building operation.
   2. Lighting specifically required to meet health and life safety requirements.
   3. Decorative gas lighting systems.
   4. Lighting for covered vehicle entrances or exits from buildings or parking structures where required for safety, security, or eye adaptation.

All time switches shall be able to retain programming and the time setting during loss of power for a period of at least ten hours.

~~**Exception:** Lighting for covered vehicle entrances or exits from buildings or parking structures where required for safety, security, or eye adaptation.~~

Commenter's Reason: These modifications are intended to be an editorial reorganization of the original proposal. The "other than" phrase in the first sentence contains exceptions which are combined with the exception at the end of the section.

Public Comment 2:

Martha VanGeem, representing self, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

C405.2.4 Exterior lighting controls. Lighting for exterior applications other than emergency lighting that is intended to be automatically off during building operation, lighting specifically required to meet health and life safety requirements or decorative gas lighting systems shall:

1. Be provided with a control that automatically turns off the lighting as a function of available daylight.
2. Where lighting the building façade or landscape the lighting shall have controls that automatically shut off the lighting as a function of dawn/dusk and a set opening and closing time.
3. Where not covered in Item 2 the lighting shall have controls configured to automatically reduce the connected lighting power by at least 30 percent from no later than 12 midnight to 6 a.m. or from one hour after business closing to one hour before business opening or during any period when no activity has been detected for a time of no longer than 15 minutes.

All time switches shall be able to retain programming and the time setting during loss of power for a period of at least ten hours.

Exceptions:

1. Lighting for covered vehicle entrances or exits from buildings or parking structures where required for safety, security, or eye adaptation.
2. Lighting that is integral to signage and installed in the signage by the manufacturer.

Commenter's Reason: In response to industry feedback, an additional exterior lighting control exception will be incorporated into 90.1-2013 in addendum DT. This modification adds an exception for lighting integral to signage. Addendum DT to 90.1-2010 will be incorporated into 90.1-2013, so this also will make the IECC consistent with 90.1-2013.

Public Comment 3:

Craig Conner, Building Quality, representing self; Shaunna Mozingo, City of Cherry Hills Village, CO, representing Colorado Chapter of ICC; request Disapproval.

Commenter's Reason: Eleven approved ASHRAE proposals, listed below, lack a reason and substantiation. In order to evaluate proposals the I-code development process requires a reason and substantiation. Disapproval is requested on the following proposals due to a lack of reason and substantiation. The proposals are CE227, CE239, CE240, CE251, CE254, CE255, CE259, CE304, CE329, CE331, and CE333. (The first two proposals have a longer reason covering all eleven proposals.)

According to ICC's CP# 28-05 on "Code Development"

3.3.5.2 Reasons: *The proponent shall justify changing the current Code provisions, stating why the proposal is superior to the current provisions of the Code. Proposals which add or delete requirements shall be supported by a logical explanation which clearly shows why the current Code provisions are inadequate or overly restrictive, specifies the shortcomings of the current Code provisions and explains how such proposals will improve the Code.*
3.3.5.3 Substantiation: *The proponent shall substantiate the proposed code change based on technical information and substantiation. …*

Public Comment 4:

Glenn Heinmiller, Lam Partners, representing International Association of Lighting Designers, requests Disapproval.

Commenter's Reason: The Committee approved this proposal because they believed that it "clarifies the requirements". In fact, the opposite is true. This proposal makes the provision confusing by introducing awkward and unclear language and undefined terms. The proposal adds unnecessary complexity.

The Committee approved this proposal because they believed that it is "providing 2 additional compliance options". The proposal does NOT appear to provide any options; it only seems to add new requirements to turn off lights at specific times and amounts depending on the type of lighting.

By requiring that lights be shut off according to "set opening and closing time" and "no later than 12 midnight to 6 a.m. or from one hour after business closing to one hour before business opening" the provision is regulating building operations. According to C101.3 of this code the IECC regulates the "design and construction" of buildings. The IECC should not regulate building operations.

Before hearing this proposal, the committee approved proposal CE303. The committee correctly approved proposal CE303 because it "clarifies the text" as desired by the committee. If CE304 is approved it would counteract that clarity, and as noted above, make the provision much more confusing.

Lighting designers who have reviewed this proposal do not understand it, or what they would have to do to comply with it. Code provisions that are vague and confusing can lead to lack of compliance and arguments about interpretation.

Code officials should read this proposal carefully and ask themselves if they understand the language, and if they would be able to verify compliance if necessary.

CE304-13
Final Action: AS AM AMPC____ D

CE306-13
C405.2.5 (NEW)

Proposed Change as Submitted

Proponent: Eric Makela, Britt/Makela Group, Inc., representing Northwest Energy Codes Group (eric@brittmakela.com)

Add new text as follows:

C405.2.5 Lighting in refrigerated display cases and walk-in coolers. Lighting in refrigerated display cases, and lights on glass doors installed on walk-in coolers and freezers shall be controlled by one of the following:

1. Automatic time switch controls to turn off lights during non-business hours.
2. Motion sensor controls on each case that reduce display case lighting power by not less than 50 percent within 30 minutes after the area near the case is vacated

Reason: The proposal reduces energy waste by reducing the power level of display lights in refrigerated display cases and glass doors in walk-in coolers during non-business hours and when the nearby area is not in use. Providing automatic controls ensures that lights not in use are automatically reduced in power by at least 50%. Reducing unnecessary lighting of refrigerated areas reduces energy used both for lighting and for the additional cooling load from added heat source. The language for the proposal is adapted from California Title 24-2013.

Cost Impact: The code change proposal will increase the cost of construction but will reduce the overall operating cost of the display case offsetting the first cost of the control.

C405.2.5 (NEW)-EC-MAKELA.doc

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: The text would appear to prohibit a single control on multiple cases. The phrase 'near the case' is undefined. People working in non-business hours may need the ability to override to automatic control.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Eric Makela, Britt/Makela Group, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

C405.2.5 Lighting in refrigerated display cases and walk-in coolers. Lighting in refrigerated display cases, and lights on glass doors installed on walk-in coolers and freezers shall be controlled by one of the following:

1. ~~Automatic time switch controls to turn off lights during non-business hours.~~ Automatic time switch controls to turn off lights during non-business hours. Timed overrides for display cases or walk-in coolers and freezers shall be used to turn the lights on for up to one hour and shall automatically time out to turn the lights off.

2. ~~Motion sensor controls on each case that reduce display case lighting power by not less than 50 percent within 30 minutes after the area near the case is vacated.~~ Motion sensor controls on each display case or walk-in door section that reduce lighting power by at least 50 percent within 3 minutes after the area within the sensor range is vacated.

Commenter's Reason: The IECC Code Development committee voted to disapprove this code change proposal based on three key points:

1. The text would appear to prohibit a single control on multiple cases.
2. The phrase 'near the case' is undefined.
3. People working in non-business hours may need the ability to override to automatic control.

The revised proposal addresses each point by modifying the language accordingly. The code allows either the installation of a motion sensor control on each case or an automatic time switch that could control several cases giving the designer the option to choose either. The language near the case has been deleted. Either the motion sensor is on the case or an automatic time switch can be used that can be located in a remote location. The revised language also requires a timed override for the display case lighting to allow for people working at non-business hours.

The proposal reduces energy waste by reducing the power level of display lights in refrigerated display cases and glass doors in walk-in coolers during non-business hours and when the nearby area is not in use. Providing automatic controls ensures that lights not in use are automatically reduced in power by at least 50%. Reducing unnecessary lighting of refrigerated areas reduces energy used both for lighting and for the additional cooling load from added heat source.

CE306-13

Final Action: AS AM AMPC____ D

CE307-13
C405.2.5 (New)

Proposed Change as Submitted

Proponent: Steve Ferguson, American Society of Heating, Refrigerating, and Air-Conditioning Engineers (ASHRAE) (sferguson@ashrae.org)

Add new text as follows:

C405.2.5 Lighting controls in parking garages. Parking garages shall comply with the provisions of Section C405.2.1 and C405.2.2. Lighting shall be provided with controls which are capable of automatically reducing the power supplied to each luminaire by not less than 30 percent after 30 minutes of inactivity in an area not greater than 36,000 square feet. Lighting for covered vehicle entrances to and exits from the garage shall be separately controlled and comply with of Section C405.2.4.

Luminaires within 20 feet of any perimeter wall that has a net opening to wall area ratio of at least 40 open and no exterior obstructions within 20 feet of the wall shall be provided with controls that will automatically adjust the lighting in response to available daylight.

Exceptions: Controls are not required for the following:

1. High-intensity discharge lamps not greater than 150 watts
2. Induction lamps
3. Luminaires that illuminate daylight transitions zones without parking
4. Luminaires that illuminate ramps without parking.
5. Luminaires proximate to exterior walls.

Reason: For consistency with ASHRAE/IES 90.1-2010. Section 9.4.1.3 of that document contains provisions for lighting controls in parking garages and no such provisions exist in the IECC Commercial Provisions. As that standard is an alternative path to compliance with the IECC and there is a desire to maintain equivalency of the IECC with 90.1 this change is needed.

Cost Impact: The code change proposal will increase the cost of construction when lighting controls are required in parking garages.

C405.2.5 (NEW)-EC-FERGUSON.doc

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee felt the proposed text was unclear and may actually conflict with itself.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Steve Ferguson, ASHRAE, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

C405.2.5 Lighting controls in parking garages. Parking garages shall comply with the provisions of Section C405.2.1 and C405.2.2 and the following:

1. Lighting shall be provided with controls which are capable of automatically reducing the power supplied to each luminaire y not less than 30 percent after 30 minutes of inactivity in an area not greater than ~~36000~~ 3600 square feet.
2. Lighting for covered vehicle entrances to and exits from the garage shall be separately controlled and comply with of Section C405.2.4.
3. Luminaires within 20 feet of any perimeter wall that has a net opening to wall area ratio of at least 40 percent open and no exterior obstructions within 20 feet of the wall shall be provided with controls that will automatically adjust the lighting in response to available daylight.

Exceptions: Controls are not required ~~for the following~~ as follows:

1. High-intensity discharge lamps not greater than 150 watts are exempt from Item 2 of Section C405.2.5.
2. Induction lamps are exempt from Item 2 of Section C405.2.5.
3. Luminaires that illuminate daylight transitions zones without parking are exempt from Items 2 and 4 of Section C405.2.5.
4. Luminaires that illuminate ramps without parking. are exempt from Items 2 and 4 of Section C405.2.5.
5. ~~Luminaires proximate to exterior walls.~~

Commenter's Reason: During the Committee Action hearings, this was disapproved because "The committee felt the proposed text was unclear and may actually conflict with itself. "The conflicting language has been removed in this comment which also fixes a couple of small typos.

The proposal is written to only reduce lighting power, not shut off the lighting, when there is no occupancy in the space and the control automatically returns light to full power and output as soon as an occupant enters the space.
The additional changes clarify the actual and realistic exemptions and make the provision more energy effective.

CE307-13

Final Action: AS AM AMPC____ D

CE308-13
C405.3

Proposed Change as Submitted

Proponent: Glenn Heinmiller, Lam Partners, representing International Association of Lighting Designers (glenn@lampartners.com)

Delete without substitution as follows:

~~**C405.3 Tandem wiring (Mandatory).** The following luminaires located within the same area shall be tandem wired:~~

1. ~~Fluorescent luminaires equipped with one, three or odd-numbered lamp configurations, that are recess- mounted within 10 feet (3048 mm) center-to-center of each other.~~
2. ~~Fluorescent luminaires equipped with one, three or any odd-numbered lamp configuration that are pendant- or surface-mounted within 1 foot (305 mm) edge-to-edge of each other.~~

~~**Exceptions:**~~

1. ~~Where electronic high-frequency ballasts are used.~~
2. ~~Luminaires on emergency circuits.~~
3. ~~Luminaires with no available pair in the same area.~~

Reason: Simplify the code by removing an obsolete provision. This provision refers to obsolete magnetic ballast technology and no longer serves any purpose. Electronic ballasts are now used for all fluorescent luminaires, and since luminaires with electronic ballasts are exempt, then this provision would never apply and is pointless. It was removed from the 2010 version of Standard 90.1 for these reasons.

Cost Impact: The code change proposal will not increase the cost of construction.

C405.3-EC-HEINMILLER.doc

Committee Action Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The provisions address obsolete technology.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Glenn Heinmiller, Lam Partners, representing International Association of Lighting Designers, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

C405.1 General (Mandatory). This section covers lighting system controls, ~~the connection of ballasts~~, the maximum lighting power for interior and exterior applications, electrical energy consumption, and minimum acceptable lighting equipment for exterior applications.

Commenter's Reason: This proposal CE308 removes the only requirement in the code covering the "connection of ballasts". The general description in C405.1 needs to be modified to reflect this

CE308-13

Final Action: AS AM AMPC____ D

CE309-13
C405.5.1

Proposed Change as Submitted

Proponent: Jeremiah Williams, U.S. Department of Energy (jeremiah.williams@ee.doe.gov)

Revise as follows:

C405.5.1 Total connected interior lighting power. The total connected interior lighting power ~~(watts)~~ shall be ~~the sum of the watts of all interior lighting equipment as determined in accordance with Sections C405.5.1.1 through C405.5.1.4~~ determined in accordance with Equation 4-6.

TCLP = [SL + LV + LTPB + Other] (**Equation 4-6)**

where:

TCLP = total connected lighting power (watts)
SL = labeled wattage of luminaires for screw in lamps
LV = wattage of the transformer supplying low-voltage lighting
LTPB = wattage of line-voltage lighting tracks and plug-in busways as the specified wattage of the luminaires but at least 30 W/lin. ft. (100 W/lin m), or the wattage limit of the system's circuit breaker, or the wattage limit of other permanent current limiting devices on the system
Other = the wattage of all other luminaires and lighting sources not covered above and associated with interior lighting verified by data supplied by the manufacturer or other *approved* sources.

Exceptions:

1. The connected power associated with the following lighting equipment is not included in calculating total connected lighting power.
   - 1.1. Professional sports arena playing field lighting.
   - 1.2. *Sleeping unit* lighting in hotels, motels, boarding houses or similar buildings.
   - 1.3. Emergency lighting automatically off during normal building operation.
   - 1.4. Lighting in spaces specifically designed for use by occupants with special lighting needs including the visually impaired visual impairment and other medical and age-related issues.
   - 1.5. Lighting in interior spaces that have been specifically designated as a registered interior historic landmark.
   - 1.6. Casino gaming areas.
2. Lighting equipment used for the following shall be exempt provided that it is in addition to general lighting and is controlled by an independent control device:
   - 2.1. Task lighting for medical and dental purposes.
   - 2.2. Display lighting for exhibits in galleries, museums and monuments.
3. Lighting for theatrical purposes, including performance, stage, film production and video production.
4. Lighting for photographic processes.
5. Lighting integral to equipment or instrumentation and is installed by the manufacturer.
6. Task lighting for plant growth or maintenance.
7. Advertising signage or directional signage.
8. In restaurant buildings and areas, lighting for food warming or integral to food preparation equipment.
9. Lighting equipment that is for sale.

10. Lighting demonstration equipment in lighting education facilities.
11. Lighting *approved* because of safety or emergency considerations, inclusive of exit lights.
12. Lighting integral to both open and glass-enclosed refrigerator and freezer cases.
13. Lighting in retail display windows, provided the display area is enclosed by ceiling-height partitions.
14. Furniture mounted supplemental task lighting that is controlled by automatic shutoff.

Reason: The provisions in Section C405.5.1 deal with the determination of a value for the actual connected interior lighting power in a building that is more appropriately addressed as an equation. This proposal simplifies the provisions associated with connected interior lighting power to present as an equation what is now text that guides how the connected lighting power is calculated. The objective of this proposal is to simplify the code to foster implementation and compliance verification.

Cost Impact: The code change proposal does not increase the cost of construction.

C405.5.1 #1-EC-WILLIAMS.doc

Committee Action Hearing Results

The following errata were not posted to the ICC website. The proposal also includes deleting the following sections.

~~**C405.5.1.1 Screw lamp holders.** The wattage shall be the maximum *labeled* wattage of the luminaire.~~

~~**C405.5.1.2 Low-voltage lighting.** The wattage shall be the specified wattage of the transformer supplying the system.~~

~~**C405.5.1.3 Other luminaires.** The wattage of all other lighting equipment shall be the wattage of the lighting equipment verified through data furnished by the manufacturer or other *approved* sources.~~

~~**C405.5.1.4 Line-voltage lighting track and plug-in busway.** The wattage shall be:~~

1. ~~The specified wattage of the luminaires included in the system with a minimum of 30 W/lin ft. (98 W/lin. m);~~
2. ~~The wattage limit of the system's circuit breaker; or~~
3. ~~The wattage limit of other permanent current limiting device(s) on the system.~~

(Portions of proposal not shown remain unchanged)

Committee Action: Approved as Submitted

Committee Reason: The proposal takes existing text in 4 subsections and replaces them with an equation that does the same thing. The committee felt the proposal simplified the code without any resulting technical change.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jeremiah Williams, U.S. Department of Energy, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

C405.5.1 Total connected interior lighting power. The total connected interior lighting power (watts) shall be the sum of the watts of all interior lighting equipment as determined in accordance with Equation 4-6.

~~TCLP~~ TCILP = [SL + LV + LTPB + Other] (**Equation 4-6)**

where:

~~TCLP~~ TCILP = total connected interior lighting power (watts)
SL = labeled wattage of luminaires for screw in lamps

LV = wattage of the transformer supplying low-voltage lighting

LTPB = wattage of line-voltage lighting tracks and plug-in busways as the specified wattage of the luminaires but at least 30 W/lin. ft. (100 W/lin m), or the wattage limit of the system's circuit breaker, or the wattage limit of other permanent current limiting devices on the system

Other = the wattage of all other luminaires and lighting sources not covered above and associated with interior lighting verified by data supplied by the manufacturer or other *approved* sources.

Exceptions:

1. The connected power associated with the following lighting equipment is not included in calculating total connected lighting power.
   1.1. Professional sports arena playing field lighting.
   1.2. *Sleeping unit* lighting in hotels, motels, boarding houses or similar buildings.
   1.3. Emergency lighting automatically off during normal building operation.
   1.4. Lighting in spaces specifically designed for use by occupants with special lighting needs including the visually impaired visual impairment and other medical and age-related issues.
   1.5. Lighting in interior spaces that have been specifically designated as a registered interior historic landmark.
   1.6. Casino gaming areas.
2. Lighting equipment used for the following shall be exempt provided that it is in addition to general lighting and is controlled by an independent control device:
   2.1. Task lighting for medical and dental purposes.
   2.2. Display lighting for exhibits in galleries, museums and monuments.
3. Lighting for theatrical purposes, including performance, stage, film production and video production.
4. Lighting for photographic processes.
5. Lighting integral to equipment or instrumentation and is installed by the manufacturer.
6. Task lighting for plant growth or maintenance.
7. Advertising signage or directional signage.
8. In restaurant buildings and areas, lighting for food warming or integral to food preparation equipment.
9. Lighting equipment that is for sale.
10. Lighting demonstration equipment in lighting education facilities.
11. Lighting *approved* because of safety or emergency considerations, inclusive of exit lights.
12. Lighting integral to both open and glass-enclosed refrigerator and freezer cases.
13. Lighting in retail display windows, provided the display area is enclosed by ceiling-height partitions.
14. Furniture mounted supplemental task lighting that is controlled by automatic shutoff

Commenter's Reason: At the code development hearing, there was a concern raised through opposing testimony about "double-counting." The proponent indicated that there was no double-counting in the proposal, and this was re-verified when looking at the change and considering if a public comment to address any double counting was needed.

DOE reviewed how the code change placed the current provisions in Sections C405.5.1.1 through C405.5.1.4 in equation form, and verified that there is no double-counting in the code change proposal. When doing that re-evaluation, DOE did note that the term TCLP would be more accurate if it referred to <u>interior</u> lighting power, so as not to confuse the user of the code with exterior lighting power. The only change suggested in this public comment is to reference 'total connected <u>interior</u> lighting power," or TC<u>I</u>LP.

One comment DOE received on their draft public comment suggesting the following additional revisions to the code text that was recommended for approval at the first hearing.

SL = labeled wattage of luminaires <u>for 120-277 Volt</u> screw in lamps

LV = <u>Labeled wattage of low voltage lamps plus the estimated</u> wattage <u>loss</u> of the transformer<u>s</u> supplying low-voltage lighting

As stated in the original code change, the intent was to take what is currently a series of criteria in C405.5.1.1 through C405.5.1.4 that guide how wattage is to be determined, and put the provisions in those subsections in a more understandable and usable equation format. DOE did not propose any technical changes to the provisions in those subsections in the original change that was recommended for approval.

DOE feels a further modification to this public comment, as suggested above, would change the requirement in the current code and the equation form of that requirement as approved at the first hearing. For that reason, DOE did not choose to implement the above recommendation by further revising this public comment. The purpose for using the transformer rating in the current requirements is similar to the purpose for using the circuit capacity or permanent circuit limiter capacity associated with line voltage track. Since these systems can have additional lamps easily installed after compliance is verified, the code must capture what that maximum could be for compliance. It currently does that in C405.5.1.2 and the LV component of the equation above. Similarly C405.5.1.1 does not specify a voltage range for screw in lamps so DOE did not include it in the original code change that was approved and does not feel it appropriate to include it in this public comment.

DOE posted its draft proposals and public comments for the IECC on its Building Energy Codes website prior to submitting to the ICC. Interested parties were provided a 30 day public review in June 2013, for which notice was published in the *Federal Register* (Docket No. <u>EERE-2012-BT-BC-0030</u>) and announced via the DOE Building Energy Codes news email list. In response to stakeholder input, DOE revised its proposals and public comments, as appropriate, and submitted to the ICC.

For more information on DOE proposals and public comments, including how DOE participates in the ICC code development process, please visit: http://www.energycodes.gov/development.

Proposed Change as Submitted

Proponent: Glenn Heinmiller, Lam Partners, representing International Association of Lighting Designers (glenn@lampartners.com)

Revise as follows:

C405.5.1 Total connected interior lighting power. The total connected interior lighting power (watts) shall be the sum of the watts of all interior lighting equipment as determined in accordance with Sections C405.5.1.1 through C405.5.1.4.

Exceptions:

1. The connected power associated with the following lighting equipment is not included in calculating total connected lighting power.
   1.1. Professional sports arena playing field lighting.
   1.2. *Sleeping unit* lighting in hotels, motels, boarding houses or similar buildings<u>, provided that the lighting complies with Section R404.1.</u>
   1.3. Emergency lighting automatically off during normal building operation.
   1.4. Lighting in spaces specifically designed for use by occupants with special lighting needs including the visually impaired visual impairment and other medical and age-related issues.
   1.5. Lighting in interior spaces that have been specifically designated as a registered interior historic landmark.
   1.6. Casino gaming areas.
   <u>1.7. Mirror lighting in dressing rooms.</u>

(Portions of text not shown remains unchanged)

<u>**C405.5.3 Additional interior lighting power.** Where using the Space-by-Space Method, an increase in the interior lighting power allowance is permitted for specific lighting functions. Additional power shall be permitted only where the specified lighting is installed and automatically controlled, separately from the general lighting, to be turned off during nonbusiness hours. This additional power shall be used only for the specified luminaires and shall not be used for any other purpose. An increase in the interior lighting power allowance is permitted in the following cases:</u>

1. <u>For spaces in which lighting is specified to be installed in addition to the general lighting for the purpose of decorative appearance or for highlighting art or exhibits, provided that the additional lighting power shall not exceed 1.0 W/ft^2 of such spaces.</u>

(Portions of Table not shown remain unchanged)

Reason: The purpose of this change is to adjust the lighting power density allowances to the best available values. “Best” means values and methodology for determining allowances that will lead to high energy-efficiency while still allowing high-quality lighting and sufficient light levels. We believe that the best source for these values are the models maintained by Pacific Northwest National Lab (PNNL) for the DOE in support of ASHRAE/IES Standard 90.1 development. Recently the models were updated to account for some changes in recommended light levels in the new Lighting Handbook, 10th Edition from the Illuminating Engineering Society

(IES). Additionally several new space types were added and some space types renamed or removed for clarity. Also, the Building Area Method values were based on a larger data set with 56% additional representative buildings.

Additional explanation of proposed changes by section:

Exception 1.2 to C405.5.1, (Sleeping Unit exception to lighting power limits)

Sleeping Units should be subject to the same requirements as Dwelling Units and residential buildings covered by Chapter 4 [RE].

Add exception for Mirror Lighting in Dressing Rooms.

Because this exception is in Standard 90.1, we assume that the LPD for Dressing/Fitting Room space types was developed with mirror lighting excluded. Without this exception the LPD limit for Dressing Rooms would be too low.

Add "Additional Interior Lighting Power" section.

This provision is an integral part of the space-by-space method. IECC-2012 already includes the additional power for retail as a footnote to the LPD table. The proposal adds the special allowance for decorative lighting and lighting for art and exhibits. IECC-2012 is missing this allowance, which is why some of the LPD values in IECC-2012 for some space types are higher than 90.1-2010. This allowance is a "use it or lose it" addition that can only be used for certain types of lighting. This provision gives the designer more flexibility but should not result in significant increase or decrease in stringency. The proposed new space-by-space LPD values were developed with the understanding that this additional allowance is available to the designer. The LPDs would not be valid for many space types without this additional allowance.

Revise Building Area Method LPDs (Table C405.5.2(1))

As mentioned above, these proposed values are from current PNNL models. These values were published in the public review draft of Addendum "co" to ASHRAE/IES Standard 90.1.

Revise Space-by-space Method LPDs (Table C405.5.2(2))

As mentioned above, these proposed values and space types are from current PNNL models. These values were published in the public review draft of Addendum "bh" to ASHRAE/IES Standard 90.1. The formatting and the ordering of space types that is in the IECC-2012 table were changed as little as possible. In order to accommodate the new space types, and the renaming or removal of a few space types, some rearrangement was necessary.

Cost Impact: The code change proposal will not increase the cost of construction.

C405.5.1 #1-EC-HEINMILLER.doc

Committee Action Hearing Results

Committee Action: Approved as Submitted

Committee Reason: The changes proposed increase the usability of the IECC. Designers are already using these revised provisions in their designs.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Steve Ferguson, ASHRAE, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

TABLE C405.5.2(2)

… at a Terminal Ticket Counter	0.8
Warehouse - Storage Area	
…for medium to bulky, palletized items	0.58
… for smaller, hand-carried items	0.95

a. In cases where both a common space type and a building area specific space type are listed, the building area specific space type shall apply

b. In corridors, the extra LPD allowance is not based on the RCR and shall be permitted when the width of the corridor is less than 8 feet

c. A ‘Facility for the Visually Impaired’ is a facility that is licensed or will be licensed by local or state authorities for either senior long-term care, adult daycare, senior support and/or people with special visual needs.

(Portions of the proposal not shown remain unchanged)

Commenter’s Reason: The intent of the original proposal is to have the space by space lighting power densities in the IECC match the lighting power densities in 90.1. Standard 90.1-2013 will also be published to include a reformatted space by space table which is intended to have consistent formatting, and hopefully more readable and usable. For example, the current Table in the IECC has separate rows for Atriums less than 40 feet in height, and Atriums greater than 40 feet in height, then in the next row for audience/seating areas, there are three rows in the group. This comment makes it so similar types of spaces are grouped together, then if there are separate requirements for different types of spaces in a similar grouping, the requirements are broken out in a consistently formatted manner.

This proposal will make the values in the table, and the formatting of the table consistent with how they will be published in 90.1-2013.

CE310-13

Final Action: AS AM AMPC____ D

CE312-13
C405.5.1

Proposed Change as Submitted

Proponent: Jeremiah Williams, U.S. Department of Energy (jeremiah.williams@ee.doe.gov)

Revise as follows:

C405.5.1 Total connected interior lighting power. The total connected interior lighting power (watts) shall be the sum of the watts of all interior lighting equipment as determined in accordance with Sections C405.5.1.1 through C405.5.1.4

Exceptions:

1. The connected power associated with the following lighting equipment is not included in calculating total connected lighting power.
   - 1.1. Professional sports arena playing field lighting.
   - 1.2. Lighting *units* ~~lighting in hotels, motels, boarding houses or similar buildings~~.
   - 1.3. Emergency lighting automatically off during normal building operation.
   - 1.4. Lighting in spaces specifically designed for use by occupants with special lighting needs including the visually impaired visual impairment and other medical and age-related issues.
   - 1.5. Lighting in interior spaces that have been specifically designated as a reg-istered interior historic landmark.
   - 1.6. Casino gaming areas.
2. Lighting equipment used for the following shall be exempt provided that it is in addition to general lighting and is controlled by an independent control device:
   - 2.1. Task lighting for medical and dental purposes.
   - 2.2. Display lighting for exhibits in galleries, museums and monuments.
3. Lighting for theatrical purposes, including performance, stage, film production and video production.
4. Lighting for photographic processes.
5. Lighting integral to equipment or instrumentation and is installed by the manufacturer.
6. Task lighting for plant growth or maintenance.
7. Advertising signage or directional signage.
8. In restaurant buildings and areas, lighting for food warming or integral to food preparation equipment.
9. Lighting equipment that is for sale.
10. Lighting demonstration equipment in lighting education facilities.
11. Lighting *approved* because of safety or emergency considerations, inclusive of exit lights.
12. Lighting integral to both open and glass-enclosed refrigerator and freezer cases.
13. Lighting in retail display windows, provided the display area is enclosed by ceiling-height partitions.
14. Furniture mounted supplemental task lighting that is controlled by automatic shutoff.

Reason: This proposal simplifies the exception to the interior lighting power in sleeping units. The definition of sleeping unit is such that there is no further need to delineate the building type in which the sleeping unit is located. In fact, the delineation suggests there are others that are not "similar" to hotels, motels, and boarding houses where the exception would not apply (e.g., dormitories).

Cost Impact: The code change proposal does not increase the cost of construction.

C405.5.1 #2-EC-WILLIAMS.doc

Committee Action Hearing Results

The following errata were not posted to the ICC website. The added text 'Lighting in ' should have been underlined.

Exceptions:

1. The connected power associated with the following lighting equipment is not included in calculating total connected lighting power.
   1.1. Professional sports arena playing field lighting.
   1.2. Lighting in *sleeping units.*

Committee Action: Disapproved

Committee Reason: The committee is concerned that reducing the text to sleeping units, that the application to guest rooms that are full dwelling units is unclear.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jeremiah Williams, U.S. Department of Energy, requests Approval as Submitted.

Commenter's Reason: At the code development hearing, there was no opposition to proposal CE312-13 from the floor. After it went to committee, there was a concern raised that the proposal language would open the door to exempting suites from the lighting provisions in the code. As it had gone to committee, there was no further opportunity to provide a response. The apparent confusion about sleeping units was enough to create doubt, and the code change proposal was disapproved with a vote of 5 to 4.

Proposal CE312-13 is simply a clarification to the code. The term "lighting in" is needed to provide a subject for the exception, and is consistent with other exceptions to Section C405.5.1 and general criteria in Section C405. The code currently uses a vague and undefined term "other similar buildings" that leads to interpretation issues when considering buildings other than hotels, motels, or boarding houses. Most important, regardless of the above two clarifications in the code, the end result is the current code exempts lighting in sleeping units from consideration in the LPD calculation, and the proposed code text does, as well.

The current code clearly intends that lighting in sleeping units not be included in the LPD calculations. *Sleeping unit* is defined in Chapter 2 of the code as:

> A room or space in which people sleep, which can also include permanent provisions for living, eating, and either sanitation or kitchen facilities but not both. Such rooms and spaces that are also part of a dwelling unit are not sleeping units.

As defined, there appears no need to indicate what types of buildings such a unit must be located in. For instance, if a suite meets the definition of a sleeping unit, then under the current code and proposed code it would be exempt. If it is not a sleeping unit, then, by definition, it is a dwelling unit and is **not** exempt – the distinction being a dwelling unit, unlike a sleeping unit, has **both** sanitation and kitchen facilities.

The reason given for disapproval was the unclear nature of the application of lighting requirements to guest rooms that are full dwelling units. Both terms are defined in the code, and the intent of proposal CE312-13 is not to change the definitions or requirements, but simply to clarify the exception. If a room, suite, area or other living space in any building is defined as a sleeping unit, then the code exempts the lighting in that space from the LPD criterion. If not a sleeping unit, then it is a dwelling unit and therefore not exempt. CE312-13 makes no change to those requirements. If there is a concern about the unclear application of the lighting criteria, it will remain in the existing code if this change is disapproved, because the terms used are defined in the current code without respect to the type of building in which the sleeping units or dwelling units are located.

DOE posted its draft proposals and public comments for the IECC on its Building Energy Codes website prior to submitting to the ICC. Interested parties were provided a 30 day public review in June 2013, for which notice was published in the *Federal Register* (Docket No. EERE-2012-BT-BC-0030) and announced via the DOE Building Energy Codes news email list. In response to stakeholder input, DOE revised its proposals and public comments, as appropriate, and submitted to the ICC.

For more information on DOE proposals and public comments, including how DOE participates in the ICC code development process, please visit: http://www.energycodes.gov/development.

CE312-13
Final Action: AS AM AMPC____ D

CE319-13
C405.6, C405.6.1, C405.6.2

Proposed Change as Submitted

Proponent: Glenn Heinmiller, Lam Partners, International Association of Lighting Designers (glenn@lampartners.com)

Revise as follows:

C405.6 Exterior lighting (Mandatory). Where the power for exterior lighting is supplied through the energy service to the building, all exterior lighting, ~~other than low-voltage landscape lighting~~, shall comply with Section~~s~~ ~~C405.6.1 and~~ C405.6.2.

> **Exception:** Where *approved* because of historical, safety, signage or emergency considerations.

~~**C405.6.1 Exterior building grounds lighting.** All exterior building grounds luminaires that operate at greater than 100 watts shall contain lamps having a minimum efficacy of 60 lumens per watt unless the luminaire is controlled by a motion sensor or qualifies for one of the exceptions under Section C405.6.2.~~

C405.6.2 Exterior building lighting power. The total exterior lighting power allowance for all exterior building applications is the sum of the base site allowance plus the individual allowances for areas that are to be illuminated and are permitted in Table C405.6.2(2) for the applicable lighting zone. Tradeoffs are allowed only among exterior lighting applications listed in Table C405.6.2(2), Tradable Surfaces section. The lighting zone for the building exterior is deter- mined from Table C405.6.2(1) unless otherwise specified by the local jurisdiction. ~~Exterior lighting for all applications (except those included in the exceptions to Section C405.6.2) shall comply with the requirements of Section C405.6.1.~~

> **Exception:** Lighting used for the following exterior applications is exempt where equipped with a control device independent of the control of the nonexempt lighting:
>
> 1. Specialized signal, directional and marker lighting associated with transportation;
> 2. Advertising signage or directional signage;
> 3. Integral to equipment or instrumentation and is installed by its manufacturer;
> 4. Theatrical purposes, including performance, stage, film production and video production;
> 5. Athletic playing areas;
> 6. Temporary lighting;
> 7. Industrial production, material handling, transportation sites and associated storage areas;
> 8. Theme elements in theme/amusement parks; and
> 9. Used to highlight features of public monuments and registered historic landmark structures or buildings.

Reason: Simplify the code without reducing stringency.
C405.6 -The exemption of “low-voltage landscape lighting” makes no sense and adds unnecessary complexity. This exemption is not in Standard 90.1.
C405.6.1 This is an obsolete and redundant provision that should have been removed from IECC when the lighting power density method was introduced for exterior lighting. The provision adds no value to the code and increases complexity.

Cost Impact: The code change proposal will not increase the cost of construction.

C405.6-EC-HEINMILLER.doc

Committee Action Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: Refines the requirement to focus on the system of lighting and not individual fixtures.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Glenn Heinmiller, Lam Partners, representing International Association of Lighting Designers, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

C405.1 General (Mandatory). This section covers lighting system controls, the connection of ballasts, the maximum lighting power for interior <u>and exterior</u> applications, electrical energy consumption, ~~and minimum acceptable lighting equipment for exterior applications~~.

Commenter's Reason: This proposal CE319 removes the only requirement in the code covering the "minimum acceptable lighting equipment for exterior applications". Exterior lighting is regulated by limiting lighting power. The general description in C405.1 needs to be modified to reflect this.

CE319-13

Final Action: AS AM AMPC____ D

CE323-13
C405.7, C405.7.1 (NEW), C405.7.2 (NEW)

Proposed Change as Submitted

Proponent: Steve Ferguson, American Society of Heating, Refrigerating, and Air-Conditioning Engineers (ASHRAE) (sferguson@ashrae.org)

Revise as follows:

C405.7 Electrical energy consumption (Mandatory). ~~In buildings having individual dwelling units, provisions shall be made to determine the electrical energy consumed by each tenant by separately metering individual dwelling units~~. Meters, metering devices or other provisions shall be installed capable of determining the electrical energy consumed by and within the building in accordance with this section.

C405.7.1 Multi-family residential buildings. In buildings having individual dwelling units, provisions shall be made to determine the electrical energy consumed within each dwelling unit by separately metering individual dwelling units.

C405.7.2 Buildings other than multi-family residential buildings. Metering devices capable of measuring electrical energy use shall be provided for the total electrical energy system, HVAC systems, interior lighting systems, exterior lighting systems and receptacle circuits in each building and, for other than shared systems, each separate tenancy within the building. The measurement devices shall have the capability to record electrical energy use at least every 15 minutes and report that use on at least an hourly, daily, monthly and annual basis and retain the recorded data at least 36 months.

Exceptions: Metering devices are not required for the following spaces and systems:

1. Buildings less than 10,000 square feet in net floor area.
2. Individual tenant spaces less than 5,000 square feet in net floor area.
3. Dwelling units
4. Residential buildings with less than 10,000 square feet of common area.
5. Critical and equipment branches covered in the Article 517 of NFPA 70

Reason: ASHRAE/IES Standard 90.1-2010, which is adopted by reference as an alternative to the IECC Commercial Provisions, has been revised with respect to energy metering. The change ensures continued consistency between the IECC and standard 90.1-2010. It retains the current provisions in the IECC for multi-family residential buildings and then includes electrical metering provisions for other building types and occupancies.

Cost Impact: The code change proposal will increase the cost of construction when monitoring devices are required.

C405.7-EC-FERGUSON.doc

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: Consistent with the action taken on CE325-13, this similar proposal was disapproved.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Steve Ferguson, ASHRAE, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

C405.7 ~~Electrical~~ Energy ~~consumption~~ monitoring (Mandatory). Meters, metering devices or other provisions shall be installed in new buildings capable of determining the ~~electrical~~ energy consumed by and within the building in accordance with this section.

C405.7.1 System electrical energy monitoring. Metering devices capable of measuring electrical energy use shall be provided for each of the following: total electrical energy system, HVAC systems, interior lighting systems, exterior lighting systems and receptacle circuits in each building.

Metering devices capable of measuring electrical energy use shall be provided in each building for each of the following: total electrical energy system, HVAC systems, interior lighting systems, exterior lighting systems and receptacle circuits.

> **Exception:** Up to 10 percent of the electrical load being metered or monitored for HVAC systems, interior lighting systems, exterior lighting systems, and receptacle circuits shall be permitted to be from other electrical loads.

C405.7.1,1 Multi-family residential buildings. In buildings having individual dwelling units, provisions shall be made to determine the electrical energy consumed within each dwelling unit by separately metering individual dwelling units.

C405.7.2 ~~Buildings other than multi-family residential buildings~~ Recording and reporting from monitoring. ~~Metering devices capable of measuring electrical energy use shall be provided for the total electrical energy system, HVAC systems, interior lighting systems, exterior lighting systems and receptacle circuits in each building.~~
The measurement devices shall have the capability to record electrical energy use at least every 15 minutes and report that use on at least an hourly, daily, monthly and annual basis and retain the recorded data for at least 36 months.

> **Exceptions:** Metering devices are not required for the following spaces and systems:
>
> 1. Buildings less than ~~10,000~~ 25,000 square feet in net floor area.
> 2. Individual tenant spaces less than ~~5,000~~ 10,000 square feet in net floor area.
> 3. Dwelling units and sleeping units
> 4. Group R-2 occupancy ~~Residential~~ buildings with less than 10,000 square feet of common area.
> 5. Critical and equipment branches covered in the Article 517 of NFPA 70
> 6. Group R-1 and A-2 occupancies.

C405.7.3 Whole building energy monitoring. Meters, metering devices or other provisions shall be installed at the building site to monitor the energy usage of each new building to monitor the building use of the following types of energy supplied by a utility, energy provider, or plant that is not within the building:

1. Natural gas
2. Fuel oil
3. Propane
4. Steam
5. Chilled water
6. Hot water

Exception: Whole building energy monitoring is not required for the following buildings, spaces, or equipment:

1. Buildings less than 25,000 square feet in net floor area.
2. Individual tenant spaces less than 10,000 square feet in net floor area.
3. Group R-2 occupancy buildings with less than 10,000 square feet of common area.
4. Equipment that uses fuel for on-site emergencies

C405.7.3.1 Recording and reporting or whole building energy use. When measurement devices are required in accordance with Section C405.7.3, the measurement devices shall have the capability to record energy use at least every 60 minutes and report that use on at least an hourly, daily, monthly and annual basis and retain the recorded data for at least 36 months.

Commenter's Reason: Submetering requirements were added to ASHRAE 90.1-2010. The proposed addendum expands the submetering requirements to cover all fuels that are used by a building. This will ensure that the building owners and operators receive information about all of the energy being used by building equipment.

This language will make the IECC consistent with the latest submetering requirements that will be published in ASHRAE 90.1-2013. This language is an improvement in that it requires that only new buildings meet the requirements, and also requires the metering of fossil fuels at buildings, which will lead to more energy savings. Several studies have shown that submetering, with the information provided to key personnel, leads to more energy savings during the operation of a building.

The requirements were changed to in addendum bn to 90.1-2013 which will be incorporated into 90.1-2013. There are cases where the submetering requirements would not be cost-justified, due to the number of submeters required, associated installation costs, and potentially low energy cost savings.

A new exception has been added so that for each of the systems being submetered, 10% of the loads can be different equipment (e.g., the meter for receptacles can also be monitoring some lighting). This is to account for electric panel and outlet connection reality (e.g., a desk lamp that is plugged into a receptacle is not really a "plug load", or if there are some receptacle loads being monitored by the "interior lighting" submeter).

These modifications focus the metering requirements on buildings and will ensure that the requirement is cost effective and will result in energy savings, especially in multi-building sites.

By requiring that all major forms of energy are metered, the proposed modifications will ensure that all opportunities for all types of energy and cost savings are addressed, rather than for just one form of energy.

By making these changes, we will prevent situations where hundreds of submeters are installed at a significant cost, especially for major renovations at existing buildings (e.g., hotels and motels with hundreds of fan coil units, PTACs, rooftop units, exhaust fans, etc), that are likely not to be cost-effective.

CE323-13

Final Action: AS AM AMPC____ D

CE326-13
C405.8 (New)

Proposed Change as Submitted

Proponent: Wayne Stoppelmoor, Schneider Electric (wayne.stoppelmoor@schneider-electric.com)

Add new text as follows:

C405.8 Energy monitoring (Mandatory). Buildings with a gross conditioned floor area over 25,000 square feet shall comply with Section C405.8.1 through C405.8.5. Buildings shall be equipped to measure, monitor, record and report energy consumption data for each end-use category required by Section C405.8.2.

> **Exception:** Individual tenant spaces are not required to comply with this section provided the space has its own utility services and meters and has less than 5,000 square feet of conditioned floor area.

C405.8.1 Electrical energy metering. For electrical energy, including all electrical energy supplied to the building and its associated site, including but limited to site lighting, parking, recreational facilities, and other areas that serve the building and its occupants, meters or other measurement devices shall be provided to collect energy consumption data for each end-use category required by Section C405.8.2.

C405.8.2 End-use metering categories. Meters or other measurement devices shall be provided to collect energy use data for each end-use category listed in Table 405.8.1. These meters shall have the capability to collect energy consumption data for the whole building or for each separately metered portion of the building. Where multiple meters are used to measure any end-use category, the data acquisition system shall total all of the energy used by that category. Not more than 5 percent of the measured load for each of the end-use categories listed in Table 405.8.1 is permitted to be from a load not within that category.

Exceptions:

1. HVAC and water heating equipment serving only an individual dwelling unit does not require end-use metering.
2. End-use metering is not required for fire pumps, stairwell pressurization fans or any system that operates only during testing or emergency.
3. End-use metering is not required for and individual tenant space having a floor area not greater than 2,500 square feet where a dedicated source meter complying with Section C405.8.3 is provided.

TABLE 405.8.1
ENERGY USE CATEGORIES

Load Category	**Description of energy use**
Total HVAC system	Heating, cooling and ventilation including, but not limited to fans, pumps, boilers, chillers and water heating. Energy used by 120 volt equipment, or by 208/120 volt equipment that is located in a building where the main service is 480/277 volt power, is permitted to be excluded from Total HVAC system energy use.
Interior lighting	Lighting systems located within the *building.*
Exterior lighting	Lighting systems located on the *building site* but not within the *building.*
Plug loads	Devices, appliances and equipment connected to convenience receptacle outlets
Process loads	Any single load that is not included in a HVAC, lighting, or plug load category and that exceeds 5 percent of the peak connected load of the whole building including, but not limited to data centers, manufacturing equipment and commercial kitchens.
Building operations and other miscellaneous loads	The remaining loads not included elsewhere in this table including, but not limited to, vertical transportation systems, automatic doors, motorized shading systems, ornamental fountains, ornamental fireplaces, swimming pools, in-ground spas, and snow-melt systems.

C405.8.3 Meters. Meters or other measurement devices required by this section shall be configured to automatically communicate energy consumption data to the data acquisition system required by Section C405.8.4. Source meters shall be allowed to be any digital-type meter. Lighting, HVAC, or other building systems that can monitor their energy consumption shall be permitted instead of meters. Current sensors shall be permitted, provided that they have a tested accuracy of +/-2 percent. Required metering systems and equipment shall have the capability to provide at least hourly data that is fully integrated into the data acquisition system and graphical energy report in accordance with Sections C405.8.4 and C405.8.5.

C405.8.4 Data acquisition system. A data acquisition system shall have the capability to store the data from the required meters and other sensing devices for a minimum of 36 months. The data acquisition system shall have the capability to store real-time energy consumption data and provide hourly, daily, monthly, and yearly logged data for each end-use category required by Section C405.8.2.

C405.8.5 Graphical energy report. A permanent and readily accessible reporting mechanism shall be provided in the building that is accessible by building operation and management personnel. The reporting mechanism shall have the capability to graphically provide the energy consumption for each end-use category required by Section C405.8.2 at least every hour, day, month and year for the previous 36 months.

Reason: This proposal saves energy by providing actionable and timely energy consumption data to building owners and operators. For large buildings, this data is further broken out by the major sub-systems (HVAC, lighting, process loads, and plug loads). Estimates in available literature of the energy savings to be expected from metering and monitoring systems vary from 2% to 15%. The effectiveness of each system depends on owners and facility managers observing and acting upon the data provided. Additionally, the 2013 version of ASHRAE Std. 90.1 and several state energy codes will be requiring energy monitoring.

Cost Impact: This requirement will cause a modest increase to the cost of construction. However, such increase in cost will be recovered in a short period of time due to the decreased energy consumed in the building.

. **C405.8 (NEW)-EC-STOPPELMOOR.doc**

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: The proposal was similar to CE325-13 and was disapproved for the same reasons.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Duane Jonlin, City of Seattle, Department of Planning and Development, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

C405.8 Energy monitoring (Mandatory). New ~~B~~ buildings with a gross conditioned floor area over 25,000 square feet shall comply with Section C405.8.1 through C405.8.5. Buildings shall be equipped to measure, monitor, record and report energy consumption data for each energy supply category required by Section C405.8.1 and each end-use category required by Section C405.8.2.

> **Exception:** Individual tenant spaces are not required to comply with this section provided the space has its own utility services and meters and has less than 5,000 square feet of conditioned floor area.

C405.8.1 Energy supply metering. Buildings shall have a meter at each supply for electrical energy, natural gas, district steam, district chilled water and district hot water.

C405.8.1.1 Electrical energy metering. For electrical energy, including all electrical energy supplied to the building and its associated site, including but limited to site lighting, parking, recreational facilities, and other areas that serve the building and its occupants, meters or other measurement devices shall be provided to collect energy consumption data for each end-use category required by Section C405.8.2.

C405.8.2 End-use metering categories. Meters or other measurement devices shall be provided to collect electrical energy use data for each end-use category listed in Table 405.8.1. These meters shall have the capability to collect energy consumption data for the whole building or for each separately metered portion of the building. Where multiple meters are used to measure any end-use category, the data acquisition system shall total all of the energy used by that category. Not more than 5 percent of the measured load for each of the end-use categories listed in Table 405.8.1 is permitted to be from a load not within that category.

Exceptions:

1. HVAC and water heating equipment serving only an individual dwelling unit does not require end-use metering.
2. End-use metering is not required for fire pumps, stairwell pressurization fans or any system that operates only during testing or emergency.
3. End-use metering is not required for and individual tenant space having a floor area not greater than 2,500 square feet where a dedicated source meter complying with Section C405.8.3 is provided.

TABLE 405.8.1
ENERGY USE CATEGORIES

Load Category	Description of energy use
Total HVAC system	Heating, cooling and ventilation including, but not limited to fans, pumps, boilers, chillers and water heating. Energy used by 120 volt equipment, or by 208/120 volt equipment that is located in a building where the main service is 480/277 volt power, is permitted to be excluded from Total HVAC system energy use.
Interior lighting	Lighting systems located within the *building.*
Exterior lighting	Lighting systems located on the *building site* but not within the *building.*
Plug loads	Devices, appliances and equipment connected to convenience receptacle outlets
Process loads	Any single load that is not included in a HVAC, lighting, or plug load category and that exceeds 5 percent of the peak connected load of the whole building including, but not limited to data centers, manufacturing equipment and commercial kitchens.
Building operations and other miscellaneous loads	The remaining loads not included elsewhere in this table including, but not limited to, vertical transportation systems, automatic doors, motorized shading systems, ornamental fountains, ornamental fireplaces, swimming pools, in-ground spas, and snow-melt systems.

C405.8.3 Meters. Meters or other measurement devices required by this section shall be configured to automatically communicate energy consumption data to the data acquisition system required by Section C405.8.4. Source meters shall be allowed to be any digital-type meter. Lighting, HVAC, or other building systems that can monitor their energy consumption shall be permitted instead of meters. Current sensors shall be permitted, provided that they have a tested accuracy of +/-2 percent. Required metering systems and equipment shall have the capability to provide at least hourly data that is fully integrated into the data acquisition system and graphical energy report in accordance with Sections C405.8.4 and C405.8.5.

C405.8.4 Data acquisition system. A data acquisition system shall have the capability to store the data from the required meters and other sensing devices for a minimum of 36 months. The data acquisition system shall have the capability to store real-time energy consumption data and provide hourly, daily, monthly, and yearly logged data for each energy supply category required by Section C405.8.1 and each end-use category required by Section C405.8.2.

C405.8.5 Graphical energy report. A permanent and readily accessible reporting mechanism shall be provided in the building that is accessible by building operation and management personnel. The reporting mechanism shall have the capability to graphically provide the energy consumption for each energy supply category required by Section C405.8.1 and each end-use category required by Section C405.8.2 at least every hour, day, month and year for the previous 36 months.

Commenter's Reason: The overall energy supply entering a building provides the most important data for energy management. Such metering is a relatively inexpensive addition when using pulse meters attached to the main utility meters that serve the building and delivering data to the same monitoring system used for the sub-metering data. Cost for installing pulse meters varies by the utility, generally $500 to $1500 each for gas and electric.

In addition, the word "new" was added to the beginning of the proposal to clarify that it applies only to new construction.

Public Comment 2:

Andrei Moldoveanu, representing The National Electrical Manufacturers Association (NEMA), requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

C405.8 Energy monitoring (Mandatory). ~~Buildings~~ New buildings with a gross conditioned floor area over ~~25,000~~ 50,000 square feet shall comply with Section C405.8.1 through C405.8.5. The gross conditioned floor area shall exclude the area of dwelling and sleeping units. Buildings shall be equipped to measure, monitor, record and report ~~energy~~ electric consumption data for each end-use category required by Section C405.8.2.

> **Exception:** Individual tenant spaces, including dwelling and sleeping units, are not required to comply with this section provided the space has its own ~~utility~~ electric meter ~~services and meters~~ and has less than ~~5,000~~ 20,000 square feet of conditioned floor area.

(*Balance of proposal remains unchanged)*

Commenter's Reason: The Committee rejected the proposal because 1) it was unclear if it applied to existing buildings; 2) the threshold of 25,000 square feet was too low; and 3) it was not clear if residential dwelling units were exempted. The modified proposal 1) makes it clear that this requirement only applies to new buildings; 2) increases the threshold to 50,000 square feet; and 3) exempts residential dwelling units. It is believed that this revised proposal overcomes the committee's objections. Additionally, there are numerous studies that show the installation of meters and sub-meters in buildings cause a reduction in energy usage.

The committee was not accurate when it said that this proposal (CE326) is similar to CE325. CE325 requires metering of many different fuel types; however, this proposal (CE326) only requires metering of electric energy, which has been demonstrated to reduce energy usage.

CE326-13

Final Action: AS AM AMPC____ D

CE328-13

C405.8 (NEW), C405.8.1 (NEW), C405.8.2 (NEW)

Proposed Change as Submitted

Proponent: Jim Edelson, New Buildings Institute (jedelson@comcast.net), Eric Makela, Britt/Makela Group, Inc., representing Northwest Energy Codes Group (eric@brittmakela.com)

Add new text as follows:

C405.8 Requirements for solar-ready energy systems (Mandatory). In climates zones 1 through 6, infrastructure shall be provided within the building and space shall be allocated on the roof for future installation of on-site renewable energy systems. The infrastructure and allocated roof space shall be capable of accommodating an energy system with a minimum rating of 3.7 W/ft^2 or 13 Btu/h·ft^2 (40 W/m^2) multiplied by the total roof area in square feet (m^2) and shall comply with Section C405.8.2. Compliance with this section shall be documented as specified in Section C405.8.1.

Exceptions:

1. The portion of the total roof area shaded during the peak sun angle on the summer solstice by natural objects, permanent features of the building or by permanent features of adjacent buildings can be excluded from the total roof area for the purposes of this section.
2. Buildings incorporating an on-site renewable energy systems with a minimum rating of 3.7 W/ft^2 or 13 Btu/h·ft^2 (40 W/m^2) multiplied by the total roof area in square feet (m^2) do not have to meet the requirements of this section.
3. Buildings with four or more stories do not have to meet the requirements of this section .
4. Additions, alterations and repairs to existing buildings do not have to meet the requirements of this section.

C405.8.1 Documentation. Construction documents shall show allocated space and pathways for installation of on-site solar energy systems and associated infrastructure. Documents shall indicate a pathway for one of the following:

1. A pathway for routing of conduit from the roof or alternate reserved space to the main electrical service panel.
2. A pathway for routing of plumbing from the roof or alternate reserved space to the water-heating system.

C405.8.2 Building service for renewable systems. For solar electric the main electrical service panel shall have a minimum busbar rating sufficient to accommodate the power supply from the system and shall have a reserved space to allow for the installation of a double pole circuit breaker for a future solar electric installation. The reserved space shall be positioned at the opposite (load) end from the input feeder location or main circuit location and shall be permanently labeled with “For Solar Electric”.

Reason: This proposal provides for the option of installing a future on-site renewable energy system. Design alternatives for renewable systems are generally most plentiful and at the lowest cost at the time of new construction. As the cost of solar energy systems continues to fall, a building’s value can be enhanced by providing for the future installation of on-site renewable systems if they are not installed at the time of new construction.

The technical requirements in the proposal are based on values from Title 24 and ASHRAE 189.1 - 2008. The 3-story limitation in this proposal matches the broadest height exclusion in Title 24. The climate zone limits generally follow the annual insolation level of 4 kwh per square meter (source: NREL Flat Plate PV Solar Radiation map). The minimum equipment size ratings are based on ASHRAE 189.1.

The 2011 CASE study for the Title 24 solar-ready measure states: “The proposed code change does not require equipment installation nor does it have any incremental maintenance costs. The only costs associated with the measure are design costs. Initially designers will need to familiarize themselves with the solar-ready requirement, but over time design will become streamlined and the costs will be minimal.

Cost savings from retrofits will result when photovoltaic or solar water heating equipment is easily interconnected with the building electrical or plumbing systems. Installing PV or SWH systems on solar-ready buildings (as defined in the recommended code language) could reduce the installed cost of the system by as much as 10 percent."

Cost Impact: The code change proposal will not increase the cost of construction.

C405.8 (NEW)-EC-EDELSON-MAKELA.doc

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: The proposal only addresses solar and not other renewable energy installations such as wind. While intended to reduce barriers, it actually requires installation of features that may never be used.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jim Edelson, New Buildings Institute; Eric Makela / Britt/Makela Group, Inc. representing Northwest Energy Codes Group, request Approval as Modified by this Public Comment.

Modify the proposal as follows:

APPENDIX A

RENEWABLE READY ENERGY SYSTEMS

The provisions contained in this appendix are not mandatory unless specifically referenced in the adopted ordinance.

SECTION AC101
GENERAL

AC101.1 General ~~**C405.8 Requirements for solar ready energy systems (Mandatory).**~~ Building projects ~~in climate zones 1-6~~ shall provide for the future installation of *on-site renewable energy* systems with a minimum rating of 3.7 W/ft2 or 13 Btu/h·ft2 (40 W/m2) multiplied by the ~~total roof area~~ horizontally-projected gross roof area less the area covered by rooftop equipment, skylights, occupied roof decks and planted areas. ~~in ft2 (m2). Building projects shall comply with sections C405.8.1 through C405.8.2.~~

Exceptions:

~~1. The proportion of the total roof area shaded during the peak sun angle on the summer solstice by natural objects, permanent features of the building or by permanent features of adjacent buildings.~~

~~2~~ 1. Buildings incorporating an *on-site renewable energy* system. ~~s with a minimum rating of 3.7 W/ft2 or 13 Btu/h·ft2 (40 W/m2) multiplied by the total roof area in ft2 (m2).~~

~~3~~ 2. Buildings with four or more stories.

~~4~~ 3. Additions, alterations and repairs to existing buildings

SECTION AC102
DOCUMENTATION

~~**C405.8.1**~~ **AC102.1 Documentation**. Construction documents shall show allocated space and pathways for installation of ~~*on-site renewable energy*~~ ~~solar energy~~ systems and associated infrastructure~~. Documents shall indicate a pathway for one of the following:~~

~~1. A pathway for routing of conduit from the roof or alternate reserved space to the main electrical service panel.~~

~~2. A pathway for routing of plumbing from the roof or alternate reserved space to the water-heating system.~~

~~**C405.8.2 Building service for renewable systems.** For solar electric the main electrical service panel shall have a minimum busbar rating sufficient to accommodate the power supply from the system and shall have a reserved space to allow for the installation of a double pole circuit breaker for a future solar electric installation. The reserved space shall be positioned at the opposite (load) end from the input feeder location or main circuit location and shall be permanently labeled with "For Solar Electric".~~

~~If accommodating future solar thermal systems, building projects shall document a pathway for routing of plumbing from the roof or alternate reserved space to the water heating system.~~

Commenter's Reason: The committee asked that this provision be placed in an Appendix and that it be made technology-neutral. The Comment simplifies and abbreviates the language, applies the existing definition of *on-site renewable energy* and renumbers the proposal to accomplish this. By placing the renewable-ready language in an Appendix, each jurisdiction will have the option for a technology-neutral measure that can help their state or community meet future planning goals with a low or no-cost requirement in current construction.

CE328-13

Final Action: AS AM AMPC____ D

CE329-13
C405.8 (NEW), Table C405.8 (NEW)

Proposed Change as Submitted

Proponent: Steve Ferguson, American Society of Heating, Refrigerating, and Air-Conditioning Engineers (ASHRAE) (sferguson@ashrae.org)

Revise as follows:

C405.8 Electrical transformers (Mandatory). Electric transformers shall meet the minimum efficiency requirements of Table C405.8 as tested and rated in accordance with the test procedure listed in DOE 10 CFR 431. The efficiency shall be verified through certification under an approved certification program or, where no certification program exists, the equipment efficiency ratings shall be supported by data furnished by the transformer manufacturer.

Exceptions: The following transformers are exempt:

1. Transformers that meet the Energy Policy Act of 2005 exclusions based on the DOE 10 CFR 431 definition of special purpose applications.
2. Transformers that meet the Energy Policy Act of 2005 exclusions that are not to be used in general purpose applications based on information provided in DOE 10 CFR 431
3. Transformers that meet the Energy Policy Act of 2005 exclusions with multiple voltage taps where the highest tap is at least 20 percent more than the lowest tap.
4. Drive transformers
5. Rectifier transformers
6. Auto-transformers
7. Uniterruptible power system transformers
8. Impendance transformers
9. Regulating transformers
10. Sealed and nonventilating transformers
11 Machine tool transformer
12. Welding transformer
13. Grounding transformer
15. Testing transformer

TABLE C405.8
Minimum Nominal Efficiency Levels for 10 CFR 431 Low Voltage Dry-Type Distribution Transformers

Single Phase Transformers		Three Phase Transformers	
kVA[a]	Efficiency (%)[b]	kVA[a]	Efficiency (%)[b]
15	97.7	15	97.0
25	98.0	30	97.5
37.5	98.2	45	97.7
50	98.3	75	98.0
75	98.5	112.5	98.2
100	98.6	150	98.3
167	98.7	225	98.5
250	98.8	300	98.6
333	98.9	500	98.7
		750	98.8
		1000	98.9

a. kiloVolt-Amp rating.

b. Nominal efficiencies shall be established in accordance with the DOE 10 CFR 431 test procedure for low voltage dry-type transformers.

Add new definitions as follows:

LOW VOLTAGE DRY-TYPE DISTRIBUTION TRANSFORMER: A transformer that is air-cooled, does not use oil as a coolant, has an input voltage less than or equal to 600 Volts, and is rated for operation at a frequency of 60 Hertz

Reason: ASHRAE/IES Standard 90.1-2010, which is adopted by reference as an alternative to the IECC Commercial Provisions, has been revised with respect to electric low-voltage dry-type transformer efficiency provisions, an issue that is not currently addressed in the IECC Commercial Provisions. The change ensures continued consistency between the IECC and standard 90.1-2010/2013 and addresses an important component associated with improving building energy efficiency.

Cost Impact: The code change proposal will increase the cost of construction.

C405.8 (NEW)-EC-FERGUSON.doc

Committee Action Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The proposal is consistent with federal regulations of transformers and its placement in the code will restrict the reuse of older transformers. Some on the committee felt that this wasn't appropriate for inclusion in an energy code.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Craig Conner, Building Quality; Shaunna Mozingo, City of Cherry Hills Village, CO, representing Colorado Chapter of ICC, request Disapproval.

Commenter's Reason: Eleven approved ASHRAE proposals, listed below, lack a reason and substantiation. In order to evaluate proposals the I-code development process requires a reason and substantiation. Disapproval is requested on the following proposals due to a lack of reason and substantiation. The proposals are CE227, CE239, CE240, CE251, CE254, CE255, CE259, CE304, CE329, CE331, and CE333. (The first two proposals have a longer reason covering all eleven proposals.)

According to ICC's CP# 28-05 on "Code Development"

3.3.5.2 Reasons: *The proponent shall justify changing the current Code provisions, stating why the proposal is superior to the current provisions of the Code. Proposals which add or delete requirements shall be supported by a logical explanation which clearly shows why the current Code provisions are inadequate or overly restrictive, specifies the shortcomings of the current Code provisions and explains how such proposals will improve the Code.*
3.3.5.3 Substantiation: *The proponent shall substantiate the proposed code change based on technical information and substantiation. …*

[a] Average full load efficiencies shall be established in accordance with 10 CFR 431.

Add new definitions as follows:

GENERAL PURPOSE ELECTRIC MOTOR (SUBTYPE I): A motor which is designed in standard ratings with either:

1. Standard operating characteristics and standard mechanical construction for use under usual service conditions, such as those specified in NEMA MG1, paragraph 14.02, “Usual Service Conditions,” and without restriction to a particular application or type of application; or
2. Standard operating characteristics or standard mechanical construction for use under unusual service conditions, such as those specified in NEMA MG1, paragraph 14.03, “Unusual Service

Conditions," or for a particular type of application, and which can be used in most general purpose applications.

General purpose electric motors (subtype I) are constructed in NEMA T-frame sizes, or IEC metric equivalent, starting at 143T.

GENERAL PURPOSE ELECTRIC MOTOR (SUBTYPE II). A motor incorporating the design elements of a general purpose electric motor (subtype I) that is configured as one of the following:

1. A U-frame motor
2. A Design C motor
3. A close-coupled pump motor
4. A footless motor
5. A vertical, solid-shaft, normal-thrust motor (as tested in a horizontal configuration)
6. An 8-pole motor (900 rpm)
7. A polyphase motor with voltage of not more than 600 volts (other than 230 or 460 volts)

SMALL ELECTRIC MOTOR. A general purpose, alternating current, single speed induction motor.

Add new standard to Chapter 5 as follows:

DOE

10 CFR 431 Subpart B, App B, Uniform Test Method for Measuring Nominal Full Load Efficiency of Electric Motors.

NEMA National Electrical Manufacturers Association
1300 North 17th Street, Suite 1752
Rosslyn, VA 22209

MG1-2011 Motors and Generators.

Reason: ASHRAE/IES Standard 90.1-2010, which is adopted by reference as an alternative to the IECC Commercial Provisions, has been revised with respect to electric motor efficiency provisions, an issue not currently addressed in the IECC Commercial Provisions. The change ensures continued consistency between the IECC and standard 90.1-2010 and addresses an important component associated with improving building energy efficiency.

Cost Impact: The code change proposal will increase the cost of construction.

C405.8-EC-FERGUSON.doc

Committee Action Hearing Results

For staff analysis of the content o*f* DOE 10CFR 431 Subpart B, App. B, and NEMA MG1-2011 relative to CP#28, Section 3.6, please visit: http://www.iccsafe.org:8888/cs/codes/Documents/2012-13cycle/Proposed-A/00a_updates.pdf

Committee Action: **Approved as Submitted**

Committee Reason: While the proposal integrates federal standard which need to be complied with in the manufacturer of new equipment, placing this in the code will act to limit aftermarket use of existing equipment in new buildings.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Craig Conner, Building Quality; Shaunna Mozingo, City of Cherry Hills Village, CO, representing Colorado Chapter of ICC, request Disapproval.

Commenter's Reason: Eleven approved ASHRAE proposals, listed below, lack a reason and substantiation. In order to evaluate proposals the I-code development process requires a reason and substantiation. Disapproval is requested on the following proposals due to a lack of reason and substantiation. The proposals are CE227, CE239, CE240, CE251, CE254, CE255, CE259, CE304, CE329, CE331, and CE333. (The first two proposals have a longer reason covering all eleven proposals.)

According to ICC's CP# 28-05 on "Code Development"

3.3.5.2 Reasons: *The proponent shall justify changing the current Code provisions, stating why the proposal is superior to the current provisions of the Code. Proposals which add or delete requirements shall be supported by a logical explanation which clearly shows why the current Code provisions are inadequate or overly restrictive, specifies the shortcomings of the current Code provisions and explains how such proposals will improve the Code.*
3.3.5.3 Substantiation: *The proponent shall substantiate the proposed code change based on technical information and substantiation. …*

CE331-13
Final Action: AS AM AMPC____ D

CE332-13
C405.8 (NEW), C405.8.1 (NEW)

Proposed Change as Submitted

Proponent: Lee Kranz, City of Bellevue, WA, representing Washington Association of Building Officials Technical Code Development (WABO TCD)

Add new text as follows:

C405.8 Variable speed escalators and moving walks. Escalators and moving walks shall be capable of reducing their operating speed to no more than 15 feet per minute when no passengers have been detected for a period of time not exceeding three times the amount of time required to transfer a passenger between landings.

> **Exception:** A power factor controller that reduces operating voltage in response to light loading conditions is permitted to be provided in place of the variable speed function.

C405.8.1 Regenerative drive. An escalator designed either for one-way down operation only or for reversible operation shall have a variable frequency regenerative drive that supplies electrical energy to the building electrical system when the escalator is loaded with passengers whose combined weight exceeds 750 pounds.

Reason: This proposal will result in reduced energy use and longer equipment life due to reduced wear and tear during the hours on standby mode or light loading conditions. These escalator controls have been standard in Canada, Europe and most of Asia for many years. The 2010 ANSI/ASME A17.1 safety standard for elevators and escalators now allows use of escalators and moving walks with "sleep mode" for reducing speed during unoccupied periods and provides for their safe operation. Sensors detect approaching passengers and bring the escalator or walk up to full speed before the passenger steps on. The 750-pound threshold for activation of the regenerative drive is derived from the 5-passenger threshold mentioned in manufacturers' literature (5 passengers x 150# = 750).

Energy savings:

The energy consumed by a typical pair of escalators is approximately 24,000 – 36,000 kWh per year, and the predicted energy savings ranges between 25% and 60%. The higher figure applies to escalators that have bursts of usage at wide intervals, as occurs with performing arts or transportation facilities. The lower figure would apply where usage is scattered throughout the day, as in shopping malls or office buildings. Annual savings per pair of escalators would equate to an energy cost savings of $600 - $2,140. The installed cost of escalators would typically increase by 1% - 4%, although one major manufacturer now includes these capabilities as standard for all escalators.

Cost Impact: The code change proposal will increase the cost of construction.

C405.8-EC-KRANZ.doc

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee felt this proposal was inferior to later items. The standard for this equipment needs to be referenced as shown in CE333-13.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Lee Kranz, City of Bellevue, WA, representing Washington Association of Building Officials Technical Code Development Committee, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

~~**C405.8 Variable speed escalators and moving walks.** Escalators and moving walks shall be capable of reducing their operating speed to no more than 15 feet per minute when no passengers have been detected for a period of time not exceeding three times the amount of time required to transfer a passenger between landings.~~

> ~~**Exception:** A power factor controller that reduces operating voltage in response to light loading conditions is permitted to be provided in place of the variable speed function.~~

~~**C405.8.1**~~ **C405.8** **Regenerative drive.** An escalator designed either for one-way down operation only or for reversible operation shall have a variable frequency regenerative drive that supplies electrical energy to the building electrical system when the escalator is loaded with passengers whose combined weight exceeds 750 pounds.

Commenter's Reason: A regenerative drive system for the "down" escalator supplies electricity back into the building's electrical system. If it becomes an IECC requirement, a regenerative drive system will be provided as a standard feature rather than a "special order" and costs will decrease. Regenerative drives are permitted by ASME A17.1 standard. As we explained in our original proposal, these systems can save as much as 60% of the energy used by an escalator.

Section C405.8 is proposed to be deleted because similar text was included in CE333-13 and was approved in Dallas. This public comment is proposed to be appended to CE333-13 if it is approved for the 2015 IECC.

CE332-13

Final Action: AS AM AMPC____ D

CE333-13
C405 (NEW), C405.1 (NEW), C405.2 (NEW), Chapter 5

Proposed Change as Submitted

Proponent: Steve Ferguson, American Society of Heating, Refrigerating, and Air-Conditioning Engineers (ASHRAE) (sferguson@ashrae.org)

Add new text as follows:

C405 Vertical and horizontal transportation systems and equipment. Vertical and horizontal transportation systems and equipment shall comply with this section.

C405.1 Elevator cabs. For the luminaires in each elevator cab, not including signals and displays, the sum of the lumens divided by the sum of the watts shall be no less than 35 lumens per watt. Ventilation fans in elevators that do not have their own air conditioning system shall not consume more than 0.33 watts/cfm at the maximum rated speed of the fan. Controls shall be provided that will de-energize ventilation fans and lighting systems when the elevator is stopped, unoccupied and with its doors closed for over 15 minutes.

C405.2 Escalators and moving walks. Escalators and moving walks shall comply with ASME A17.1/CSA B44 and shall have automatic controls configured to reduce speed to the minimum permitted speed in accordance with ASME A17.1/CSA B44 or applicable local code when not conveying passengers.

Add new standard to Chapter 5 as follows:

ASME

ASME/A17.1/CSA B44-2010 Safety Code for Elevators and Escalators

Reason: Energy is used in lighting and ventilating elevators when in operation and when not in operation. ASHRAE/IES Standard 90.1-2010, which is adopted by reference in the IECC Commercial Provisions, contains provisions to reduce the amount of energy used by elevators. This change ensures consistency between the IECC Commercial Provisions and standard 90.1 and owners/developers who choose to comply with standard 90.1 via the IECC are afforded this opportunity to save energy and reduce their operating costs.

Cost Impact: The code change proposal will increase the cost of construction if controls for ventilation on fans and systems are required.

C405 (NEW) #1-EC-FERGUSON.doc

Committee Action Hearing Results

For staff analysis of the content of ASME A17.1/CSA B44-2010 relative to CP#28, Section 3.6, please visit: http://www.iccsafe.org:8888/cs/codes/Documents/2012-13cycle/Proposed-A/00a_updates.pdf

Committee Action: **Approved as Submitted**

Committee Reason: The proposal will lead to energy savings. The industry has developed the acceptable methodologies and included them in the referenced standards. There was some concern that the threshold for application of this new provision was unclear.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Lee Kranz, City of Bellevue, WA, representing Washington Association of Building Officials Technical Code Development Committee, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

C405.2 Escalators and moving walks. Escalators and moving walks shall comply with ASME A17.1/CSA B44 and shall provide one of the following systems:

1. Automatic controls configured to reduce speed to the minimum permitted speed in accordance with ASME A17.1/CSA B44 or applicable local code when not conveying passengers. or
2. A power factor controller that reduces electrical consumption in response to light loading conditions.

(*Balance of proposal is unchanged)*

Commenter's Reason: A power factor controller system is less expensive to install than a variable-speed escalator, and saves more energy where escalators are frequently in use by only a few people at a time. This is a common condition in office buildings and shopping malls. The variable speed escalator system, by contrast, is most energy-efficient for escalators that are heavily loaded in short bursts, followed by periods of complete inactivity. This is a common usage pattern in transportation and entertainment venues.

This public comment allows owners and designers to select the most appropriate power-saving system for each condition, rather than requiring one system type for all conditions. It reduces construction costs, saves more energy, and provides options for owners.

Public Comment 2:

Craig Conner, Building Quality; Shaunna Mozingo, City of Cherry Hills Village, CO, representing Colorado Chapter of ICC, request Disapproval.

Commenter's Reason: Eleven approved ASHRAE proposals, listed below, lack a reason and substantiation. In order to evaluate proposals the I-code development process requires a reason and substantiation. Disapproval is requested on the following proposals due to a lack of reason and substantiation. The proposals are CE227, CE239, CE240, CE251, CE254, CE255, CE259, CE304, CE329, CE331, and CE333. (The first two proposals have a longer reason covering all eleven proposals.)

According to ICC's CP# 28-05 on "Code Development"

3.3.5.2 Reasons: *The proponent shall justify changing the current Code provisions, stating why the proposal is superior to the current provisions of the Code. Proposals which add or delete requirements shall be supported by a logical explanation which clearly shows why the current Code provisions are inadequate or overly restrictive, specifies the shortcomings of the current Code provisions and explains how such proposals will improve the Code.*
3.3.5.3 Substantiation: *The proponent shall substantiate the proposed code change based on technical information and substantiation. …*

Proposed Change as Submitted

Proponent: Eric Makela, Britt/Makela Group, Inc., representing Northwest Energy Codes Group (eric@brittmakela.com), Jim Edelson, New Buildings Institute

Revise as follows:

C406.1 Requirements. Buildings shall comply with at least one of the following:

1. More efficient HVAC equipment ~~performance~~ in accordance with Section C406.2.
2. Reduced ~~efficient~~ lighting power density system in accordance with Section C406.3.
3. Enhanced lighting controls in accordance with Section C406.4
4. On-site supply of renewable energy in accordance with Section C406.5.
5. Provision of a dedicated outdoor air system for certain HVAC equipment in accordance with Section C406.6.
6. High efficiency service water heating in accordance with Section C406.8.

C406.2. More efficient HVAC equipment performance. Equipment shall exceed the minimum efficiency requirements listed in Tables C403.2.3(1) through 403.2.3(7) by 10 percent in addition to the requirements of Section C403. Where multiple performance requirements are provided, the equipment shall exceed all requirements by 10 percent. *Variable refrigerant flow systems* shall exceed the energy efficiency provisions of ANSI/ASHRAE/IES 90.1 by 10 percent. Equipment not listed in Tables C403.2.3(1) through 403.2.3(7) shall be limited to 10 percent of the total building system capacity.

~~For SI: 1 Ton = 3516 W.~~

~~NA = Not applicable and cannot be used for compliance. NR = No minimum requirements.~~

~~a. Compliance with this standard can be obtained by meeting the minimum requirements of Path A or Path B. However both the full load and IPLV shall be met to fulfill the requirements of Path A and Path B.~~

~~b. Chapter 6 of the referenced standard contains a complete specification of the referenced test procedure, including the referenced year version of the test procedure.~~

~~c. Path B is intended for applications with significant operating time at part load. All Path B machines shall be equipped with demand limiting capable controls.~~

~~d. The chiller equipment requirements do not apply for chillers used in low-temperature applications where the design leaving fluid temperature is greater than 40°F.~~

~~e. Only allowed to be used in heat recovery applications.~~

~~f. Packages that are not designed for operation at ARI Standard 550/590 test conditions (and, thus, cannot be tested to meet the requirements of Table C-3) of 44°F leaving chilled-water temperature and 85°F entering condenser-water temperature with 3 gpm/ton condenser-water flow shall have maximum full-load kW/ton and *NPLV* ratings adjusted using the following equation:~~

~~Adjusted maximum full load kW/ton rating = (full load kW/ton from Table C-3)/~~K_{adj}

~~Adjusted maximum NPLV rating = (IPLV from Table C-3)/~~K_{adj}

~~where:~~

K_{adj} = 6.174722 – 0.303668(X) + 0.00629466(X)^2 – 0.000045780(X)^3

X = DT_{std} + LIFT (°F)

DT_{std} = [(24 + (full load kW/ton from Table C-3) × 6.83)]/flow (°F)

~~Flow = condenser-water flow (gpm) / cooling full load capacity (tons)~~

~~LIFT = CEWT – CLWT (°F)~~

~~CEWT = full load entering condenser-water temperature (°F)~~

~~CLWT = full load leaving chilled-water temperature (°F)~~

~~The adjusted full load and *NPLV* values are only applicable over the following full-load design ranges:~~

~~Minimum leaving chilled-water temperature: 38°F~~

~~Maximum condenser entering water temperature: 102°F~~

~~Condenser-water flow: 1 to 6 gpm/ton~~

X ≥ 39°F and ≤60°F

~~TABLE C406.2(7)~~
~~ABSORPTION CHILLERS—EFFICIENCY REQUIREMENTS~~

~~EQUIPMENT TYPE~~	~~MINIMUM EFFICIENCY FULL LOAD COP (IPLV)~~
~~Air cooled, single effect~~	~~0.60, allowed only in heat recovery applications~~
~~Water cooled, single effect~~	~~0.70, allowed only in heat recovery applications~~
~~Double effect – direct fired~~	~~1.0 (1.05)~~
~~Double effect – indirect fired~~	~~1.20~~

C406.3 Reduced lighting power density The total interior lighting power (watts) of the building shall be determined by using 90 percent of the lighting power values in Table C405.5.2(1)~~the reduced whole building interior lighting power in Table C406.3~~ times the floor area of the building types~~.~~ or by using 90 percent of the interior lighting power allowance calculated by the Space by Space method in section C405.5.2.

C406.4 Enhanced digital lighting controls. Interior lighting in the building shall have the following enhanced lighting controls which shall be located, scheduled, and operated in accordance with Section C405.2.2.

1. Luminaires shall be capable of continuous dimming.
2. Luminaires shall be capable of being addressed individually. Where individual addressability is not available for the luminaire class type, a controlled group of no more than 4 luminaries shall be allowed.
3. No more than 8 luminaires shall be controlled together in a *daylight zone*
4. Fixtures shall be controlled through a digital control system that includes the following function:
   - 1.1. Control reconfiguration based on digital addressability
   - 1.2. Load shedding
   - 1.3. Individual user control of overhead general illumination in open offices
   - 1.4. Occupancy sensors shall be capable of being reconfigured through the digital control system.
5. Construction documents shall include submittal of a Sequence of Operations, including a specification outlining each of the functions in Item 4 of Section C406.4.
6. Functional testing of lighting controls shall comply with Section 408.

~~C406.4~~ C406.5 On-site renewable energy Total minimum ratings of on-site renewable energy systems shall comply with one of the following:

1. Provide not less than 1.75 btu's, or not less than 0.50 watts, per square foot of conditioned floor area.
2. Provide not less than 3 percent of the energy used within the building for building mechanical and service water heating equipment and lighting regulated in Chapter 4;

C406.6 Dedicated outdoor air system. Buildings covered by Section C403.4 shall be equipped with an independent ventilation system designed to provide no less than the minimum 100 percent outdoor air to each individual occupied space as specified by the *International Mechanical Code*, to each individual occupied space. The ventilation system shall be capable of total energy recovery. The HVAC system shall include supply-air temperature controls that automatically reset the supply-air temperature in response to representative building loads, or to outdoor air temperatures. The controls shall reset the supply air temperature at least 25 percent of the difference between the design supply-air temperature and the design room air temperature.

C406.7 Reduced energy use in service water heating. Buildings shall be of the following types to use this compliance method:

1. Group R-1, Boarding houses, Hotels or motels;
2. Group I-2, Hospitals, mental hospitals, and nursing homes;
3. Group A-2, Restaurants and Banquet halls or buildings containing food preparation areas;
4. Group F, Laundries;
5. Group R-2 Buildings with residential occupancies;
6. Group A-3 Health clubs and spas; or
7. Buildings showing a service hot water load of 10 percent or more of total building energy loads as shown with an energy analysis as described in Section C407.

C406.7.1 Load fraction. The building service water heating system shall have one or more of the following that are sized to provide at least 60 percent of hot water requirements, or sized to provide 100 percent of hot water requirements if the building must otherwise comply with Section C403.4.6:

1. Waste heat recovery from service hot water, heat recovery chillers, building equipment, process equipment, or a combined heat and power system.
2. Solar water heating systems.

Add new definition as follows:

SECTION C202
GENERAL DEFINITIONS

VARIABLE REFRIGERANT FLOW SYSTEM. An engineered direct expansion (DX) refrigerant system that incorporates a common condensing unit, at least one variable capacity compressor, a distributed refrigerant piping network to multiple indoor fan heating and cooling units each capable of individual zone temperature control, through integral zone temperature control devices and common communications network. Variable refrigerant flow utilizes three or more steps of control on common inter-connecting piping.

Reason: This proposal increases the number of optional packages in the IECC from three to six for compliance with Section C406, in addition to the modeling options available both in Section 507 of the IECC and the Energy Cost Budget method of ASHRAE 90.1. The purpose of this section is to provide flexibility for compliance, and to recognize that all buildings may not be able to meet higher levels of efficiency in today's prescriptive model codes without providing options. The specifications included in the six approximately equal energy packages were based on preliminary modeling done by New Buildings Institute.

HVAC

The equipment tables have been removed and replaced with a requirement for a 10% increase in efficiency over the base requirements. This will ensure that the HVAC equipment efficiency levels contained in this section provide the necessary energy savings over equipment efficiencies contained in Section C403. This will allow the base efficiencies to be increased in future code cycles without needing to make corresponding changes to Section C406. The proposed option limits the use of heating and cooling equipment not listed in the C403 tables to no more than 10% of the total building capacity. This would allow some systems, e.g. electric resistance heat, to be used in a limited capacity for the proposed project and still allow the code user to use this option. Under the 2012 IECC all systems must comply with the equipment efficiency requirements.

LPD

The LPD tables have been removed and replaced with a requirement for a 10% increase in efficiency over the base requirements for whole building or space-by-space. This will ensure that the LPD levels contained in this section provide the necessary energy savings over the LPDs contained in Section C405. This will allow the base efficiencies to be increased in future code cycles without needing to make corresponding changes to Section C406. The 2012 IECC Additional Package Options only allowed whole building LPDs to be used. This proposal allows the use of space-by-space LPDs to provide more flexibility to the code user thereby increasing the viability of this option. The values proposed in this section are similar to those included as part of ASHRAE Standard 189.1.

The renewable option has not been modified from the 2012 IECC and provides three straightforward compliance approaches: electricity generation, thermal collection, and a calculation method for any type or combination of energy production. A path to include purchase of renewable power or credits was carefully considered, but not included based on concerns regarding verification and permanence of the transaction after the certificate of occupancy has been issued.

The Dedicated Outdoor Air System package is based on technical specifications from the 50% Technical Support Documents of the Pacific Northwest National Lab. The measure requires that adequate quantity of outside air is delivered separately to spaces in the buildings while employing 100% energy recovery. This reduces the need for excess outdoor air or supply air, and uses less energy for terminal reheating.

The Enhanced Lighting Controls Package provides a non-LPD lighting alternative package requires a digital control system to allow continuous dimming and a significant level of controllability on individual luminaires, or groups of no more than eight luminaires.

The Service Water Heating Package language is modified from similar language in the IgCC and the 2012 North Carolina commercial code. The requirements for use of waste energy to heat service hot water are in excess of what is otherwise required in Section C403 of the IECC, when applicable. Solar thermal water heating systems may also be used. This package is independent of the package offered in Section C406.5 since only one package is required for compliance with Section 406 in total.

Cost Impact: The code change proposal will not increase the cost of construction.

C406.1-EC-EDELSON-MAKELA.doc

Committee Action Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The proposal both simplifies the provisions for additional efficiency packages and increases the options open to designers of each building. The existing tables have known flaws and replacing the HVAC proposal with a simple percentage increase in savings increases flexibility.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Eric Makela, Britt/Makela Group, representing Northwest Energy Codes Group; Jim Edelson, New Buildings Institute, request Approval as Modified by this Public Comment.

Modify the proposal as follows:

C401.2 Application. Commercial buildings shall comply with one of the following:

1. The requirements of ANSI/ASHRAE/IESNA 90.1.
2. The requirements of Sections C402, C403, C404 and C405. In addition, commercial buildings shall comply with ~~either~~ Section ~~C406.2, C406.3 or C406.4~~ Section C406, and tenant spaces shall comply with Section C406.1.1.
3. The requirements of Section C407, C402.4, C403.2, C404, C405.2, C405.3, C405.4, C405.6 and C405.7. The building energy cost shall be equal to or less than 85 percent of the standard reference design building.

~~Individual tenant spaces shall comply with either Section C406.2 or Section C406.3 unless documentation can be provided that demonstrates compliance with Section C406.4 for the entire building.~~

C406.1.1 Tenant Spaces. Tenant spaces shall comply with Section C406.2, C406.3, C406.4, C406.6 or C406.7. Alternatively tenant spaces shall comply with Section C406.5 when the entire building is in compliance.

~~**C406.3 Efficient Lighting System** Whole building lighting power density shall comply with the requirements of Section C406.3.1.~~

~~**C 406.3.1**~~ **C406.3 Reduced lighting power density** The total interior lighting power (watts) of the building shall be determined by using 90 percent of the lighting power values in Table C405.5.2(1) times the floor area of the building types or by using 90 percent of the interior lighting power allowance calculated by the Space by Space method in section C405.5.2.

~~**TABLE C406.3**~~
~~**REDUCED INTERIOR LIGHTING POWER**~~

Commenter's Reason: CE 337 was Approved as Submitted because it was recognized to simplify the provisions, increase flexibility by providing more options for compliance, and eliminating tables with errors.

A few technical and editorial issues were brought to the attention of the Proponents. This Comment accomplishes three objectives in addressing those issues:

1. Corrects the pointer language in C401.2
2. Clarifies and updates the Tenant Space application language in C406.1.1
3. Deletes orphaned language in 406.3 and renumbers accordingly.

Public Comment 2:

Steve Rosenstock, Edison Electric Institute, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

C406.1 Requirements. Buildings shall comply with at least one of the following:

1. More efficient HVAC equipment ~~performance~~ in accordance with Section C406.2.

2. Reduced lighting power density system in accordance with Section C406.3.
3. Enhanced lighting controls in accordance with Section C406.4
4. On-site supply of renewable energy in accordance with Section C406.5.
5. Provision of a dedicated outdoor air system for certain HVAC equipment in accordance with Section C406.6.
6. High efficiency service water heating in accordance with Section C406.8.

C406.1.1. Tenant spaces. Except where an entire building is in compliance with Section C406.5, individual tenant spaces shall comply with either Section C406.2 or Section C406.3.

C406.2 More efficient HVAC equipment performance. Equipment shall exceed the minimum efficiency requirements listed in Tables C403.2.3(1) through C403.2.3(7) by ~~10~~ 3 percent in addition to the requirements of Section C403. Where multiple performance requirements are provided, the equipment shall exceed all requirements by ~~10~~ 3 percent. *Variable refrigerant flow systems* shall exceed the energy efficiency provisions of ANSI/ASHRAE/IES 90.1 by ~~10~~ 3 percent. Equipment not listed in Tables C403.2.3(1) through C403.2.3(7) shall be allowed ~~limited~~ to meet ~~10~~ 100 percent of the total building system capacity.

C406.3 Efficient lighting system. Whole building lighting power density (Watts/sf) shall comply with the requirements of Section C406.3.1.

C406.3.1 Reduced lighting power density. The total interior lighting power (watts) of the building shall be determined by using ~~90~~ 97 percent of the lighting power values in Table C405.4.2(1) times the floor area for the building types or by using ~~90~~ 97 percent of the interior lighting power allowance calculated by the Space by Space method in Section C405.4.2.

C406.5 On-site renewable energy. Total minimum ratings of on-site renewable energy systems shall comply with one of the following:

1. Provide not less than 1.7~~5~~1 Btu ~~(1850 W)~~, or not less than 0.50 watts per square foot (5.4 W/m^2) of conditioned floor area.

2. Provide not less than 3 percent of the energy used within the building for building mechanical and service water heating equipment and lighting regulated in Chapter 4.

C406.7 Reduced energy use in service water heating. Buildings shall be designed to reduce service hot water usage by at least 3 percent. ~~of the following types to use this compliance method:~~

~~1. Group R-1, Boarding houses, hotels or motels.~~

~~2. Group I-2, Hospitals, mental hospitals, and nursing homes.~~

~~3. Group A-2, Restaurants and banquet halls or buildings containing food preparation areas.~~

~~4. Group F, Laundries.~~

~~5. Group R-2 Buildings with residential occupancies.~~

~~6. Group A-3 Health clubs and spas.~~

~~7. Buildings showing a service hot water load of 10 percent or more of total building energy loads as shown with an energy analysis as described in Section C407.~~

~~**(CE337-13 AS)**~~
~~**C406.7.1 Load fraction.** The building service water heating system shall have one or more of the following that are sized to provide at least 60 percent of hot water requirements, or sized to provide 100 percent of hot water requirements if the building shall otherwise comply with Section C403.4.7:~~

~~1. Waste heat recovery from service hot water, heat recovery chillers, building equipment, process equipment, or a combined heat and power system.~~

~~2. Solar water heating systems.~~

(Portions of proposal not shown remain unchanged)

Commenter's Reason: The proposed modifications will improve this section in the following ways:

- Equivalence of effort. The threshold for all systems will be the same.
- The values are more realistic, especially when considering that the code development committee approved many measures that will increase the energy efficiency of all commercial buildings in the areas of lighting, envelope, heating equipment efficiency, cooling equipment efficiency, motor efficiency, transformer efficiency, exhaust system efficiency, commercial refrigeration efficiency, and controls (for lighting and mechanical equipment). All of these increases "raised the floor" of efficiency by a significant amount. In fact, it is very likely that it is not possible to improve efficiency by even 4% for many systems.
- For water heating, all buildings will be eligible to use this option, not just some buildings.

- Design and equipment flexibility. The code should not restrict the types of technologies that can be used to improve efficiency. There are options not shown in the tables (thermal energy storage, gas-fired heat pumps, zoned electric systems, etc.) that could meet the additional efficiency requirements. Restricting other or new technologies to 10% of building capacity is inflexible, arbitrary, and not consistent with the goals of this section.

Public Comment 3:

Jeremiah Williams, U.S. Department of Energy, request Approval as Modified by this Public Comment.

Modify proposal as follows:

C406.1 Requirements. Buildings shall comply with at least one of the following:

1. More efficient HVAC equipment in accordance with Section C406.2.
2. Reduced lighting power density ~~system~~ in accordance with Section C406.3.
3. Enhanced lighting controls in accordance with Section C406.4
4. On-site supply of renewable energy in accordance with Section C406.5.
5. Provision of a dedicated outdoor air system for certain HVAC equipment in accordance with Section C406.6.
6. High efficiency service water heating in accordance with Section C406.8.

C406.1.1. Tenant spaces. Except where an entire building is in compliance with Section C406.5, individual tenant spaces shall comply with either Section C406.2 or Section C406.3.

C406.2 More efficient HVAC equipment performance. Equipment shall exceed the minimum efficiency requirements listed in Tables C403.2.3(1) through C403.2.3(7) by 10 percent in addition to the requirements of Section C403. Where multiple performance requirements are provided, the equipment shall exceed all requirements by 10 percent. Variable refrigerant flow systems shall exceed the energy efficiency provisions of ANSI/ASHRAE/IES 90.1 by 10 percent. Equipment not listed in Tables C403.2.3(1) through C403.2.3(7) shall be limited to 10 percent of the total building system capacity.

C406.3 ~~Efficient lighting system.~~ ~~Whole building lighting power density (Watts/sf) shall comply with the requirements of Section C406.3.1.~~

~~C406.3.1~~ Reduced lighting power density. The total interior lighting power (watts) of the building shall ~~be determined by using~~ <u>not exceed</u> 90 percent of the lighting power <u>resulting from multiplying the</u> values in Table C405.5.2.1 (1) times the floor area of the <u>applicable</u> building type<u>(s)</u> or by using 90 percent of the interior lighting power allowance <u>as</u> calculated <u>in accordance with</u> ~~by~~ the Space-by-Space method in Section C405.5.2. <u>For the purposes of this option the determination of areas and their application to building type(s) shall be in accordance with Section C405.5.2.</u>

(Portions of proposal not shown remain unchanged)

Commenter's Reason: During the code development hearing, CE335-13 was heard after CE337-13 and, based on the action taken on CE337-13, DOE asked for disapproval of CE335-13. DOE is submitting this public comment to address the issue contained in CE335-13. While the current code advises how to determine the reduced lighting power density, it is not clear that the code actually requires the building to comply with the resultant LPD. This public comment ensures the changes approved in CE337-13 are retained, but corrects the issue regarding the lack of a specific requirement in Section C406.3 that the LPD determined per the code must actually be met. In addition, this public comment addresses a small editorial change needed in Section C406.1.

DOE posted its draft proposals and public comments for the IECC on its Building Energy Codes website prior to submitting to the ICC. Interested parties were provided a 30 day public review in June 2013, for which notice was published in the *Federal Register* (Docket No. <u>EERE-2012-BT-BC-0030</u>) and announced via the DOE Building Energy Codes news email list. In response to stakeholder input, DOE revised its proposals and public comments, as appropriate, and submitted to the ICC.

For more information on DOE proposals and public comments, including how DOE participates in the ICC code development process, please visit: http://www.energycodes.gov/development.

Public Comment 4:

Gary MacFadden, representing The National Electrical Manufacturers Association, requests Disapproval.

Commenter's Reason: CE337 adds requirements to section 406 of the commercial provisions of the IECC. By the proponents own admission, the proposal would increase the optional paths to compliance from 3 to 6.

Alternative paths to compliance are good, but doubling the number of paths will lead to confusion for code enforcers especially when there has not been any cry out by the consuming public about the current 3 options being too inflexible.

Public Comment 5:

Chuck Foster, C.R. Foster, representing self; requests Disapproval.

Commenter's Reason: This is trying to fix a problem that doesn't exist. There are already 3 options for users in Section 406. This proposal would add three more – doubling the size of the section.

Consumers of this code have not complained that section 406 is too rigid or that they need more flexibility for that section. Where does this stop; we now have 6 optional paths, should we go for 17 paths, or 66 paths, or ….

Sec 406 is a relatively new section – we should give consumers time to digest it before we go making changes. Urge disapproval.

CE337-13

Final Action: AS AM AMPC____ D

CE340-13
C406.3, Table C406.3, C406.3.1

Proposed Change as Submitted

Proponent: Glenn Heinmiller, Lam Partners, representing International Association of Lighting Designers (glen@lampartners.com)

Revise as follows:

C406.3 ~~**Efficient lighting system.** Whole building lighting power density (Watts/sf) shall comply with the requirements of Section C406.3.1.~~ **Reduced lighting power density.** The lighting power allowance shall be 90 percent of the lighting power allowance determined according to Section C405.5.2.

~~**C406.3.1 Reduced lighting power density.** The total interior lighting power (watts) of the building shall be determined by using the reduced whole building interior lighting power in Table C406.3 times the floor area for the building types.~~

~~TABLE C406.3~~
~~REDUCED INTERIOR LIGHTING POWER~~

Reason: Simplify and clarify the code. Allow proper design flexibility without reducing stringency.
As currently written, this option only allows the use of Building Area Method lighting power densities according to the values in table C406.3, which are 10% below base code. This prevents the designer from using the space-by-space method to determine the lighting power allowance for this additional efficiency option. This proposal simply requires a 10% reduction in the lighting power from what is allowed in base code. It does not change stringency and it simplifies the code. Also it means that whenever the base code LPD values are updated, no changes to this option will need to be made. No table will need to be revised.

Cost Impact: The code change proposal will not increase the cost of construction.

C406.3-EC-HEINMILLER.doc

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: Addressed with the approval of CE337-13. This change is not needed.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Glenn Heinmiller, Lam Partners, representing International Association of Lighting Designers, requests Approval as Submitted.

Commenter's Reason: The contents of this proposal are included in proposal CE337. Proposal CE337 was Approved as Submitted by the Committee. This proposal, CE340, was subsequently Disapproved because it is contained in CE337. If CE337 receives Public Comments and is heard at the Public Comment Hearings and is disapproved or significantly modified, then this proposal CE340 needs to be Approved as Submitted so its provision can be incorporated into the code, independent of CE337's fate.

CE340-13
Final Action: AS AM AMPC____ D

CE343-13
C407.2, C407.2.1 (NEW)

Proposed Change as Submitted

Proponent: Brian Dean, ICC International, representing Energy Efficient Codes Coalition; Garrett Stone, Brickfield Burchette Ritts & Stone, PC; Jeff Harris, Alliance to Save Energy; Harry Misuriello, American Council for an Energy-Efficient Economy; Bill Prindle, Energy Efficient Codes Coalition; and Don Vigneau, Northeast Energy Efficiency Partnerships.

Revise as follows:

C407.2 Mandatory requirements. Compliance with this section requires that the criteria of Sections C402.4, C403.2, C404<u>,</u> ~~and~~ C405 <u>and C407.2.1</u> be met.

<u>**C407.2.1 Maximum fenestration U-factor and SHGC for compliance based on total building performance (Mandatory).** For buildings complying with Section C407, the area-weighted average U-factor permitted for products within each fenestration product category listed in Table C402.3 shall not exceed the applicable U-factor specified in Table C402.3 by more than 25 percent. For buildings complying with Section C407, the area-weighted average SHGC permitted for products within each fenestration product category listed Table C402.3 shall not exceed the applicable SHGC specified in Table C402.3 by more than 50 percent.</u>

Reason: The purpose of the proposed code change is to establish new maximum trade-off limits for fenestration under the commercial performance path. This proposal imports, from the residential *IECC* provisions, an effective backstop on fenestration trade-offs that has been in the *IECC* since 2004, but with some additional modifications and improvements. This new provision will ensure that modern, highly efficient commercial buildings are required to have at least moderately efficient windows:

- New section C407.2.1 would ensure that whenever the simulated performance alternative is used, the windows on a weighted average basis will meet a reasonable level of efficiency (no worse than 25% greater U-factor and 50% greater SHGC than the prescriptive requirements).
- The main difference between this new commercial section and the existing residential trade-off backstop is that the proposed provision would cap trade-offs at a percentage of the U-factor and SHGC requirements as they change over time rather than setting specific maximum values (we are also proposing to change the residential provision to the same approach).
- This approach will allow the cap to slide up or down to match future changes to the U-factor and SHGC requirements, while still ensuring that buildings are designed and constructed with windows that fall within a reasonable range of efficiency.

The fenestration trade-off limits currently found in the residential chapter of the *IECC* are simple, mandatory measures that ensure all new buildings contain high-quality, cost-effective windows that save energy, provide reasonable comfort, resist condensation in colder climates and block unwanted solar gain in warmer climates. Without the protection of this backstop, fenestration values could be traded away to levels unacceptable in modern building practice. Given the improvements to window efficiency brought about by the 2012 IECC and our nation's high priority for energy efficiency, this proposal is a common-sense extension of an effective code requirement.

- **Simple compliance.** The residential fenestration maximums are effective and easy to understand. These requirements have been successfully applied for the last several years. All states that have already adopted the 2006, 2009, and 2012 *IECC* have adopted these maximums to residential construction. On the residential side, they are also already seamlessly built into compliance software such as the Department of Energy's REScheck. The same approach would work for commercial building compliance software.
- **Flexible standard.** The area-weighted average approach embodied in the fenestration maximums allows considerable flexibility for the use of decorative glass, glass block, and other fenestration products, while maintaining a baseline performance for the building's overall glazing. In short, not all products are required to individually meet the maximum values; only the area-weighted average of all products in the building are required to meet the maximum values specified in this code provision.
- **Quality windows, energy savings and peak demand savings nationwide**. The fenestration maximums encourage the use of cost-effective energy-efficient windows nationwide. Because good windows reduce energy consumption both during peak cooling times in the summer months and during peak heating hours in the winter months, such windows can help reduce the strain on the electric grid and natural gas pipeline system and delay the need to build expensive peaking facilities. By reducing the trade-off of efficient windows for other measures, the maximums will better capture the benefits

of blocking solar gain and providing reasonable insulating value such as peak reduction, reduced cooling system sizes and year-round comfort. Consumers will also enjoy the reduced costs that come with economies of scale and market transformation.

- **More comfortable buildings and less energy use.** Incremental changes in window efficiency can have a huge impact on occupant comfort because even the most efficient windows are, at best, still only the equivalent of about an R-3 wall in the winter. Moreover, unlike the opaque wall, even the best fenestration allows substantial summer solar heat gain into the conditioned space. Hot spots created by high solar gain in the summer and/or cold or drafty glass in the winter months can force an occupant to adjust the thermostat to compensate. A good window will provide reasonable insulating value, keeping occupants more comfortable during the coldest months. Similarly, windows with low SHGC will protect against hot spots and occupant discomfort, and will make it less likely that occupants will need to adjust the thermostat and use more energy.

For a more detailed discussion of the benefits of good fenestration, see the section on the benefits of efficient windows on the website of the Efficient Windows Collaborative -- http://www.efficientwindows.org/benefits.cfm.
The fenestration maximums have served an important role in ensuring residential energy efficiency for many years. We recommend that the fenestration maximums in the residential chapter of the *IECC* be duplicated, with the appropriate modifications, in the commercial chapter of the *IECC*.

Cost Impact: The code change proposal will not increase the cost of construction.

C407.2-EC-DEAN-HARRIS-MISURIELLO-PRINDLE-STONE-VIGNEAU.doc

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: The proposal would put an artificial restriction on the performance path methodology. Such runs counter to the intent of the performance path option and restricts the flexibility of the design professional.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jeff Inks, Window & Door Manufacturers Association, requests Approval as Submitted.

Commenter's Reason: We are urging approval as submitted for the reasons stated by the proponents in the proposal. WDMA supports establishing reasonable trade-off caps under the performance path to ensure an unlimited reduction in fenestration efficiency is not permitted. We do not believe the 25% variance allowed for U-factors and 50% for SHGC is either an artificial restriction or presents unreasonable design restrictions. In addition, we believe establishing the caps as a percentage of the respective prescriptive requirements is also a much more sensible approach than prescribing specific values because it alleviates the need for additional revisions to the cap values when prescriptive requirements are amended.

We believe this proposal will result in a significant improvement in the IECC and we therefore urge approval as submitted.

Final Action: AS AM AMPC____ D

CE344-13
C407.3.1 (NEW), Chapter 5

Proposed Change as Submitted

Proponent: Mark Nowak, M. Nowak Consulting, LLC, representing Steel Framing Alliance

Add new text as follows:

C407.3.1 Alternative to proposed design. A representative building as described in NREL/TP-5500-46861 or other representative buildings approved by the code official shall be permitted to be used in lieu of the actual building design.

Add new standard to Chapter 5 as follows:

DOE

NREL/TP-5500-46861-11 Commercial Reference Building Models of the National Building Stock

Reason: This proposal will simplify the implementation of the code by allowing a representative building to be used for compliance rather than the actual building. Designers will only need to build a model for the representative building for a given climate zone. Likewise, simulation tool developers would be able to provide the buildings in library files for users. However, it will still leave the designer the option to comply with the actual propose building.

This represents a significant deviation from past and current practice but it is a logical step for the IECC to take. Given that the representative buildings are the basis for the current prescriptive requirements, they should be permitted to be used repeatedly for building design and compliance. This approach would allow the development of multiple prescriptive solutions equivalent to those in the code without cluttering up the code with pages of additional text.

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: A review of the standard proposed for inclusion in the code, DOE-NREL/TP-5500-46861-2011 Commercial Reference Building Models of the National Building Stock, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 1, 2013.

C407.3.1 (NEW)-EC-NOWAK.doc

Committee Action Hearing Results

For staff analysis of the content of DOE NREL/TP-5500-46861-11 relative to CP#28, Section 3.6, please visit: http://www.iccsafe.org:8888/cs/codes/Documents/2012-13cycle/Proposed-A/00a_updates.pdf

Committee Action: **Disapproved**

Committee Reason: The proponent requested disapproval because the current proposal doesn't reflect his original intent..

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Mark Nowak, M. Nowak Consulting, LLC, representing Steel Framing Alliance, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

C407.3.1 Alternative to proposed design. A representative building <u>with the size, shape, floor plan, fenestration area, and opaque envelope area</u> as described in NREL/TP-5500-46861 or other representative buildings approved by the code official shall be permitted to be used in lieu of the actual building design. <u>All other specifications for the proposed and standard reference designs shall comply with the requirements of this code.</u>

(Portions of proposal not shown remain unchanged)

Commenter's Reason: This proposal will simplify the implementation of the code by allowing a representative building to be used for compliance rather than the actual building. Designers will only need to build a model once for the representative building for a given climate zone. Likewise, simulation tool developers would be able to provide the buildings in library files for users. However, it will still leave the designer the option to comply using the actual proposed building. This will make the use of the performance option more flexible by offering a less complex option for compliance.

This represents a significant deviation from past and current practice but it is a logical step for the IECC to take. Given that the representative buildings are the basis for the current prescriptive requirements, they should be permitted to be used repeatedly for building design and compliance. This approach would allow the development of multiple prescriptive solutions equivalent to those in the code without cluttering up the code with pages of additional text.

As the proponent of the original proposal, we asked for disapproval after a ruling by the committee chair that a modification was out of order. The modification shown here brings the proposal in line with our original intent by specifying that the proposed building's geometry, fenestration area, and opaque areas must match the representative building. All other requirements of the code will still be required to be met.

C408

Proposed Change as Submitted

Proponent: Richard Grace, Fairfax County Government, representing The Virginia Plumbing and Mechanical Inspectors Association, The Virginia Building Code Officials Association (Richard.Grace@fairfaxcounty.gov)

Revise as follows:

~~Section C408~~
APPENDIX A
SYSTEM COMMISSIONING

~~C408.1~~ AC 101.1 General. This ~~section~~ appendix covers the commissioning of the building mechanical systems in Section C403 and electrical power and lighting systems in Section C405.

~~C408.2~~ AC 101.2 Mechanical systems commissioning and completion requirements. Prior to passing the final mechanical inspection, the *registered design professional* shall provide evidence of mechanical systems *commissioning* and completion in accordance the provisions of this ~~section.~~ appendix. Construction document notes shall clearly indicate provisions for *commissioning* and completion requirements in accordance with this ~~section~~ appendix and are permitted to refer to specifications for further requirements. Copies of all documentation shall be given to the owner and made available to the *code official* upon request in accordance with Sections ~~C408.2.4 and C408.2.5~~ AC101.2.4 and AC101.2.5

Exception: The following systems are exempt from the commissioning requirements:

1. Mechanical systems in buildings where the total mechanical equipment capacity is less than 480,000 Btu/h (140 690 W) cooling capacity and 600,000 Btu/h (175 860 W) heating capacity.
2. Systems included in Section C403.3 that serve dwelling units and sleeping units in hotels, motels, boarding houses or similar units.

~~C408.2.1~~ AC 101.2.1 Commissioning plan. A *commissioning plan* shall be developed by a *registered design professional* or approved *agency* and shall include the following items:

1. A narrative description of the activities that will be accomplished during each phase of commissioning, including the personnel intended to accomplish each of the activities.
2. A listing of the specific equipment, appliances or systems to be tested and a description of the tests to be performed.
3. Functions to be tested, including, but not limited to calibrations and economizer controls.
4. Conditions under which the test will be performed. At a minimum, testing shall affirm winter and summer design conditions and full outside air conditions.
5. Measurable criteria for performance.

~~C408.2.2~~ AC 101.2.2 Systems adjusting and balancing. HVAC systems shall be balanced in accordance with generally accepted engineering standards. Air and water flow rates shall be measured and adjusted to deliver final flow rates within the tolerances provided in the product specifications. Test and balance activities shall include air system and hydronic system balancing.

~~C408.2.2.1~~ AC 101.2.2.1 Air systems balancing. Each supply air outlet and *zone* terminal device shall be equipped with means for air balancing in accordance with the requirements of Chapter 6 of the

International Mechanical Code. Discharge dampers are prohibited on constant volume fans and variable volume fans with motors 10 hp (18.6 kW) and larger. Air systems shall be balanced in a manner to first minimize throttling losses then, for fans with system power of greater than 1 hp (0.74 kW), fan speed shall be adjusted to meet design flow conditions.

Exception: Fans with fan motors of 1 hp (0.74 kW) or less.

~~C408.2.2.2~~ **AC 101.2.2.2** **Hydronic systems balancing.** Individual hydronic heating and cooling coils shall be equipped with means for balancing and measuring flow. Hydronic systems shall be proportionately balanced in a manner to first minimize throttling losses, then the pump impeller shall be trimmed or pump speed shall be adjusted to meet design flow conditions. Each hydronic system shall have either the capability to measure pressure across the pump, or test ports at each side of each pump.

Exceptions:

1. Pumps with pump motors of 5 hp (3.7 kW) or less.
2. Where throttling results in no greater than five percent of the nameplate horsepower draw above that required if the impeller were trimmed.

~~C408.2.3~~ **AC 101.2.3** **Functional performance testing.** Functional performance testing specified in Sections ~~C408.2.3.1 through C408.2.3.3~~ AC101.2.3.1 through AC101.2.3.3 shall be conducted.

~~C408.2.3.1~~ **AC 101.2.3.1** **Equipment.** Equipment functional performance testing shall demonstrate the installation and operation of components, systems, and system-to-system interfacing relationships in accordance with approved plans and specifications such that operation, function, and maintenance serviceability for each of the commissioned systems is confirmed. Testing shall include all modes and *sequence of operation*, including under full-load, part-load and the following emergency conditions:

1. All modes as described in the *sequence* of *operation*;
2. Redundant or *automatic* back-up mode;
3. Performance of alarms; and
4. Mode of operation upon a loss of power and restoration of power.

Exception: Unitary or packaged HVAC equipment listed in Tables C403.2.3(1) through C403.2.3(3) that do not require supply air economizers.

~~C408.2.3.2~~ **AC101.2.3.2** **Controls.** HVAC control systems shall be tested to document that control devices, components, equipment, and systems are calibrated, adjusted and operate in accordance with approved plans and specifications. Sequences of operation shall be functionally tested to document they operate in accordance with *approved* plans and specifications.

~~C408.2.3.3~~ **AC 101.2.3.3** **Economizers.** Air economizers shall undergo a functional test to determine that they operate in accordance with manufacturer's specifications.

~~C408.2.4~~ **AC 101.2.4** **Preliminary commissioning report.** A preliminary report of commissioning test procedures and results shall be completed and certified by the *registered design professional* or *approved agency* and provided to the building owner. The report shall be identified as "Preliminary Commissioning Report" and shall identify:

1. Itemization of deficiencies found during testing required by this ~~section~~ appendix that have not been corrected at the time of report preparation.
2. Deferred tests that cannot be performed at the time of report preparation because of climatic conditions.
3. Climatic conditions required for performance of the deferred tests.

~~C408.2.4.1~~ **AC 101.2.4.1** **Acceptance of report.** *Buildings*, or portions thereof, shall not pass the final mechanical inspection until such time as the *code official* has received a letter of transmittal from the *building* owner acknowledging that the *building* owner has received the Preliminary Commissioning Report.

~~C408.2.4.2~~ AC 101.2.4.2 Copy of report. The *code official* shall be permitted to require that a copy of the Preliminary

~~C408.2.5~~ AC 101.2.5 Documentation requirements. The *construction documents* shall specify that the *documents* described in this section be provided to the *building* owner within 90 days of the date of receipt of the *certificate of occupancy*.

~~C408.2.5.1~~ AC 101.2.5.1 Drawings. Construction documents shall include the location and performance data on each piece of equipment.

~~C408.2.5.2~~ AC 101.2.5.2 Manuals. An operating and maintenance manual shall be provided and include all of the following:

1. Submittal data stating equipment size and selected options for each piece of equipment requiring maintenance.
2. Manufacturer's operation manuals and maintenance manuals for each piece of equipment requiring maintenance, except equipment not furnished as part of the project. Required routine maintenance actions shall be clearly identified.
3. Name and address of at least one service agency.
4. HVAC controls system maintenance and calibration information, including wiring diagrams, schematics, and control sequence descriptions. Desired or field-determined setpoints shall be permanently recorded on control drawings at control devices or, for digital control systems, in system programming instructions.
5. A narrative of how each system is intended to operate, including recommended setpoints.

~~C408.2.5.3~~ AC 101.2.5.3 System balancing report. A written report describing the activities and measurements completed in accordance with Section ~~C408.2.2.~~ AC 101.2.2.

~~C408.2.5.4~~ AC 101.2.5.4 Final commissioning report. A report of test procedures and results identified as "Final Commissioning Report" shall be delivered to the building owner and shall include:

1. Results of functional performance tests.
2. Disposition of deficiencies found during testing, including details of corrective measures used or proposed.
3. Functional performance test procedures used during the commissioning process including measurable criteria for test acceptance, provided herein for repeatability.

Exception: Deferred tests which cannot be performed at the time of report preparation due to climatic conditions.

~~C408.3~~ AC 101.3 Lighting system functional testing. Controls for automatic lighting systems shall comply with Section ~~C408.3~~ AC101.3.

~~C408.3.1~~ AC 101.3.1 Functional testing. Testing shall ensure that control hardware and software are calibrated, adjusted, programmed and in proper working condition in accordance with the construction documents and manufacturer's installation instructions. The construction documents shall state the party who will conduct the required functional testing. Where required by the code official, an approved party independent from the design or construction of the project shall be responsible for the functional testing and shall provide documentation to the code official certifying that the installed lighting controls meet the provisions of Section C405.

Where occupant sensors, time switches, programmable schedule controls, photosensors or daylighting controls are installed, the following procedures shall be performed:

1. Confirm that the placement, sensitivity and time-out adjustments for occupant sensors yield acceptable performance.
2. Confirm that the time switches and programmable schedule controls are programmed to turn the lights off.
3. Confirm that the placement and sensitivity adjustments for photosensor controls reduce electric light based on the amount of usable daylight in the space as specified.

Reason: We are not opposed to commissioning, in fact we fully support the concept. What we are opposed to is including language into a code that is not enforceable, inconsistent, or is written in such a way that enforcement will place a burden on building owners when occupancy permits are held up based on incomplete commissioning reports. There are many examples of this contained within this code change.

(1) C408.2 – "**Prior to passing the final mechanical inspection, the *registered design professional* shall provide evidence of mechanical systems *commissioning* and completion according to the provisions of this section.**" First off, this language suggests that only a registered design professional is permitted to provide such evidence, even if a licensed, Class A contractor designed the project. Second,

(2) 503.2.9.1 - "**Copies of all documentation shall be given to the owner**." We do not agree with language included in the code that requires a code official to verify contractual issues between an owner and their agents, designers, or contractors.

(3) 503.2.9.1.2 – "**All HVAC systems shall be balanced in accordance with generally accepted engineering standards**." "Shall be" is positive, enforceable language, however "generally accepted" is so open ended that consistency between any two individuals will be virtually impossible.

(4) 503.2.9.2 – "**shall not be issued a final certificate of occupancy**". This section states that a certificate of occupancy shall not be issued without receiving a letter from the owner stating that they have received the Preliminary Commissioning Report. Why should the owner of a building be penalized in such a harsh manner for a procedure that can obviously be conducted after occupancy.

(5) 503.2.9.3 – "**shall require that within 90 days after the date of final certificate of occupancy**". This section requires the code official to go back to the building owner after issuing the certificate of occupancy and verify that the building owner was provided with drawings, manuals, system balancing report, and the final commissioning report. Wow! After the certificate of occupancy is issued, the International Energy Conservation Code is no longer applicable to the building or building owner. I truly do not understand how this is going to work. What gives the code official the authority to verify and comply with this code section? What recourse does a code official have if the documentation is not provided to the building owner? Is the certificate of occupancy voided and the building occupants forced to vacate? After the certificate of occupancy is issued, the IECC is no longer applicable. The applicable code after the certificate of occupancy is issued is the Property Maintenance Code.

Cost Impact: This code change proposal will not increase the cost of construction.

C408-EC-GRACE.doc

Committee Action Hearing Results

Committee Action: Disapproved

Committee Reason: Commissioning is an important part of the code and should not be moved to an optional appendix. Building owners want a level of confidence that the complex systems work, commissioning provides a methodology to assure the systems functionality.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Richard Grace, Fairfax County Government, representing Virginia Plumbing and Mechanical Inspectors Association (VPMIA) and Virginia Building and Code Officials Association (VBCOA), requests Approval as Submitted.

Commenter's Reason: The committee's reason for disapproval for this proposed change was as follows:

"Commissioning is an important part of the code and should not be moved to an optional appendix. Building owners want a level of confidence that the complex systems work, commissioning provides a methodology to assure the systems functionality."

We agree in part with this statement. Commissioning is an important part of the design and construction process, however proper commissioning should be completed at a time after an owner takes possession of the structure. These requirements prevents this from happening (see 1 below), and encourages improper commissioning procedures.

We are not opposed to commissioning, in fact we fully support the concept. What we are opposed to is including language into a code that is not enforceable, inconsistent, or is written in such a way that enforcement will place a burden on building owners when occupancy permits are held up based on incomplete commissioning reports. There are many examples of this contained within this code change.

(1) C408.2 – "**Prior to passing the final mechanical inspection, the *registered design professional* shall provide evidence of mechanical systems *commissioning* and completion according to the provisions of this section.**" First off, this language suggests that only a registered design professional is permitted to provide such evidence, even if a licensed, Class A contractor designed the project. Second, this section requires commissioning to be completed prior to the owner taking possession of the structure, and moving in.

(2) 503.2.9.1 - "**Copies of all documentation shall be given to the owner**." We do not agree with language included in the code that requires a code official to verify contractual issues between an owner and their agents, designers, or contractors.

(3) 503.2.9.1.2 – "**All HVAC systems shall be balanced in accordance with generally accepted engineering standards**." "Shall be" is positive, enforceable language, however "generally accepted" is so open ended that consistency between any two individuals will be virtually impossible.

(4) 503.2.9.2 – "**shall not be issued a final certificate of occupancy**". This section states that a certificate of occupancy shall not be issued without receiving a letter from the owner stating that they have received the Preliminary Commissioning Report. Why should the owner of a building be penalized in such a harsh manner for a procedure that can obviously be conducted after occupancy.

(5) 503.2.9.3 – "**shall require that within 90 days after the date of final certificate of occupancy**". This section requires the code official to go back to the building owner after issuing the certificate of occupancy and verify that the building owner was provided with drawings, manuals, system balancing report, and the final commissioning report. Wow! After the certificate of occupancy is issued, the International Energy Conservation Code is no longer applicable to the building or building owner. I truly do not understand how this is going to work. What gives the code official the authority to verify and comply with this code section? What recourse does a code official have if the documentation is not provided to the building owner? Is the certificate of occupancy voided and the building occupants forced to vacate? After the certificate of occupancy is issued, the IECC is no longer applicable. The applicable code after the certificate of occupancy is issued is the Property Maintenance Code.

CE350-13

Final Action: AS AM AMPC____ D

CE355-13
C408.2.4.1

Proposed Change as Submitted

Proponent: Jeremiah Williams, U.S. Department of Energy (jeremiah.williams@ee.doe.gov)

Revise as follows:

C408.2.4.1 Acceptance of report. *Buildings,* or portions thereof, shall not <u>be considered acceptable for a final inspection pursuant to Section C104.3</u> ~~pass the final mechanical inspection~~ until ~~such time as~~ the *code official* has received a letter of transmittal from the *building* owner acknowledging that the *building* owner has received the Preliminary Commissioning Report<u>.</u>

Reason: This proposal revises the commissioning provision so that buildings cannot be considered for a final inspection (e.g., do not pass the mechanical inspection) until the owner indicates in writing they have the required commissioning report. This clarifies the code through the reference section for final inspections and eliminates unneeded language "such time as".

Cost Impact: The code change proposal will not increase the cost of construction.

C408.2.4.1-EC-WILLIAMS.doc

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: The process should not be delayed waiting for the formality of the submitted report.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment 1:

Ellen Eggerton, Fairfax County, representing Virginia Building Coe Officials Association; requests Approval as Submitted.

Commenter's Reason: The existing code language puts the mechanical contractor on the hook for items that could be the responsibility of an electrical contractor or the general contractor. The code change holds up the final inspection regardless of which contractor is holding up the work.

Public Comment 2:

Jeremiah Williams, U.S. Department of Energy, requests Approval as Submitted.

Commenter's Reason: The current code is clear, but not complete. It essentially says that the mechanical inspection is not passed until the code official has the required letter of transmittal. Without a letter of transmittal confirming the commissioning has been completed, the mechanical inspection would not be passed. Without passing the mechanical inspection, it is presumed any final inspection could not proceed, and any resultant occupancy permit could not be issued. At the code development hearing, there was opposition to this change based on the opinion that the revision would tend to hold up the conduct of inspections and, as a result, would hold up the issuance of the final occupancy permit. In disapproving the code change, the committee indicated that the process should not be delayed waiting for the formality of a submitted report. DOE does not believe the code change has a negative impact regarding overall project approvals and in some cases could eliminate re-inspections and speed the issuance of an occupancy permit.

The current and proposed code text only provides for the submission of a letter of transmittal related to receipt of the commissioning report by the building owner. Currently, the code says the building does not pass final mechanical inspection until the letter is received (i.e., even if all the other items covered by the mechanical inspection pass, no passage occurs until the letter is received). Proposal CE355-13 requires the receipt of the letter before the final inspection occurs. This should not delay the process, because it ensures that when the final mechanical inspection is done, the commissioning has been completed per code; as a result, the building is more likely to pass the final mechanical inspection. So the proposal does not delay the approval process for the building owner and in some cases could accelerate the process.

The code change proposal, as covered in more detail below, will not hold up the issuance of an occupancy permit and actually could speed its issuance. Under the current code, if the letter is not sent, then the mechanical inspection is not passed and subsequent inspections and issuance of an occupancy permit cannot occur.

The commissioning provisions in the code apply to mechanical systems as well as electrical power and lighting systems. It would seem then the code should also add electrical inspection passage as a criterion, but that is not currently addressed in the code, nor proposed herein. That said, the key issue is final inspection, which unlike mechanical or electrical inspections, is an item specifically covered in the code. Instead of addressing the passage of the mechanical or electrical inspections, which in turn trigger a final inspection and issuance of a certificate of occupancy, based on the receipt of a letter, it seems more appropriate to address that as a condition for a final inspection. This ensures conformance to all the system commissioning requirements, and provides a singular point of reference in the process. Either way, there is a possible hold up on issuing the occupancy permit (i.e., under the current code or proposed code language) based on receipt of the letter from the owner.

The remaining issue then is if the AHJ wants to conduct the inspection before or after receipt of the letter. It would seem more reasonable, given the intent of commissioning, that an inspector would be more likely to find fewer issues in inspecting a commissioned versus an un-commissioned building. Also, a requirement that the letter be posted prior to the final inspection provides some incentive for the building owner to ensure the commissioning is completed. Since the intent of commissioning is to ensure the building electrical, lighting and mechanical systems are properly and working, it is more appropriate to ensure commissioning is conducted prior to final inspection as opposed to logging the receipt of a letter from the owner after all the inspections have been completed. In either case, the issuance of a certificate of occupancy rests on receipt of the letter, and the inspections have to be conducted. If the above reasons are not sufficient, this requirement provides some incentive for the building owner to focus on getting this done, allowing the inspector to actually see the result in the building, which benefits both the builder and the AHJ.

DOE posted its draft proposals and public comments for the IECC on its Building Energy Codes website prior to submitting to the ICC. Interested parties were provided a 30 day public review in June 2013, for which notice was published in the *Federal Register* (Docket No. EERE-2012-BT-BC-0030) and announced via the DOE Building Energy Codes news email list. In response to stakeholder input, DOE revised its proposals and public comments, as appropriate, and submitted to the ICC.

For more information on DOE proposals and public comments, including how DOE participates in the ICC code development process, please visit: http://www.energycodes.gov/development.

CE355-13

Final Action: AS AM AMPC____ D

CE356-13
C408.2.5.2

Proposed Change as Submitted

Proponent: Steve Ferguson, American Society of Heating, Refrigerating, and Air-Conditioning Engineers (ASHRAE) (sferguson@ashrae.org)

Revise as follows:

C408.2.5.2 Manuals. An operating and maintenance manual shall be provided and include all of the following:

1. Submittal data stating equipment size and selected options for each piece of equipment requiring maintenance.
2. Manufacturer's operation manuals and maintenance manuals for each piece of equipment requiring maintenance, except equipment not furnished as part of the project. Required routine maintenance actions shall be clearly identified.
3. Name and address of at least one service agency.
4. HVAC controls system maintenance and calibration information, including wiring diagrams, schematics, and control sequence descriptions. Desired or field-determined setpoints shall be permanently recorded on control drawings at control devices or, for digital control systems, in system programming instructions.
5. Submittal data indicating all selected options for each piece of lighting equipment and lighting controls.
6. Operation and maintenance manuals for each piece of lighting equipment. Required routine maintaince actions, cleaning and recommended relamping shall be clearly identified.
7. A schedule for inspecting and recalibrating all lighting controls.
8. A narrative of how each system is intended to operate, including recommended setpoints.

Reason: The current requirements for manuals seems specific to HVAC documentation. This proposal adds additional language for the documentation, maintenance, and inspection of lighting equipment and controls. These requirements are consistent with ANSI/ASHRAE/IES Standard 90.1

Cost Impact: The code change proposal will increase the cost of construction.

C408.2.5.2-EC-FERGUSON.doc

Committee Action Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The committee approved the proposal because the information on the lighting controls is just as important as those on the HVAC systems. The listing of manual items is simply information for the building owner, it requires no action. Some felt that some or all of this would be better placed in commentary. Some felt that details on each luminaire is excessive detail.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Ron Nickson, National Multi Housing Council, requests Disapproval.

Commenter's Reason: As noted by the proponent this change will increase the cost of construction. However, the proposal did not include any cost information or provide any cost effective analysis to justify the increase. The approved change will have a significant cost impact in that it requires:

1. Information and data on each piece of lighting equipment. The opened ended requirement can be interpreted in many ways and could ultimately require information on every light bulb, ceiling and wall fixture, lighting control (switches, automatic switches, etc.), electrical wiring, electrical boxes, breaker boxes and other electrical equipment used in the circuit to the light fixture. Providing the information has no cost benefit and it does not provide and cost savings.
2. Operation and maintenance manuals for "each" piece of lighting equipment along with maintenance actions, cleaning and recommended relamping. This requirement is unnecessary and costly in that it would require operation and maintenance manuals for items such as fixtures, bulbs, switches, etc. that in all reality have no maintenance in that when they fail they need to be replaced. In addition the requirement requires a list of all estimated relamping requirements which is unnecessary for operation of the building lighting. The estimated life of a bulb has little to do with replacement in that bulbs provide and very definite clue that they are no longer working and thus need to be replace.

CE356-13
Final Action: AS AM AMPC____ D

CE357-13
C408.3.1

Proposed Change as Submitted

Proponent: Steve Ferguson, American Society of Heating, Refrigerating, and Air-Conditioning Engineers (ASHRAE) (sferguson@ashrae.org)

Revise as follows:

C408.3.1 Functional testing. Testing shall ensure that control hardware and software are calibrated, adjusted, programmed and in proper working condition in accordance with the construction documents and manufacturer's installation instructions. ~~The construction documents shall state the party who will conduct the required functional testing.~~ Where required by the code official, an approved ~~party~~ individual independent from the design or construction of the project shall be responsible for the functional testing and shall provide documentation to the code official certifying that the installed lighting controls meet the provisions of Section C405.

Where occupant sensors, time switches, programmable schedule controls, photosensors or daylighting controls are installed, the following procedures shall be performed:

1. Confirm that the placement, sensitivity and time-out adjustments for occupant sensors yield acceptable performance.
   - 1.1. For projects with up to seven occupancy sensors, all occupancy sensors shall be tested
   - 1.2. For projects with more than seven the following shall be verified:
     - 1.2.1. Status indicator (as applicable) operates correctly
     - 1.2.2. The controlled lights turn off or down to the permitted level within the required time,
     - 1.2.3. For auto-on occupant sensors, the lights do turn on to the permitted level when someone enters the space,
     - 1.2.4. For manual on sensors, the lights turn on only when manually activated
     - 1.2.5. The lights are not incorrectly turned on by movement in nearby areas or by HVAC operation
2. Confirm that the time switches and programmable schedule controls are programmed to turn the lights off.
3. Confirm that all control devices for daylight controls have been properly located, field-calibrated, and set for design set points and threshold light levels. All daylight control devices shall only be readily accessible to authorized personnel. ~~the placement and sensitivity adjustments for photosensor controls reduce electric light based on the amount of usable daylight in the space as specified.~~

Reason: For consistency with ASHRAE/IES 90.1. These revisions add more specific requirements to the functional testing of lighting controls for the common controls required by the standard and adds some clarification to the description of entities allowed to perform the testing and verification.

Cost Impact: The code change proposal will increase the cost of construction when lighting controls are required in parking garages.

C408.3.1-EC-FERGUSON.doc

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: The proponent requested disapproval in order to address needed revisions.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Steve Ferguson, ASHRAE, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

C408.3.1 Functional testing. Testing shall ensure that control hardware and software are calibrated, adjusted, programmed and in proper working condition in accordance with the construction documents and manufacturer's installation instructions. Where required by the code official, an approved individual independent from the design or construction of the project shall be responsible for the functional testing and shall provide documentation to the code official certifying that the installed lighting controls meet the provisions of Section C405.

Where occupant sensors, time switches, programmable schedule controls, photosensors or daylighting controls are installed, the following procedures shall be performed:

1. Confirm that the placement, sensitivity and time-out adjustments for occupant sensors yield acceptable performance.
   - 1.1 For projects with up to seven occupancy sensors, all occupancy sensors shall be tested. <u>For projects with more than seven, at least one of each sensor type and the sensors in one of each distinct room or space type shall be tested</u>
   - 1.2 For <u>all sensors required to be tested by item 1.1,</u> ~~projects with more than seven~~ the following shall be verified:
     - 1.2.1 Status indicators operate correctly
     - 1.2.2 The controlled lights turn off or down to the permitted level within the required time,
     - 1.2.3 For auto-on occupant sensors, the lights do turn on to the permitted level when someone enters the space,
     - 1.2.4 For manual on sensors, the lights turn on only when manually activated
     - 1.2.5 The lights are not incorrectly turned on by movement in nearby areas or by HVAC operation
2. Confirm that the time switches and programmable schedule controls are programmed to turn the lights off.
3. Confirm that all control devices for daylight controls have been properly located, field-calibrated, and set for design set points and threshold light levels. All daylight control devices shall only be readily accessible to authorized personnel.

Commenter's Reason: The original proposal was written was not laid out correctly. The intent is for the all of the tests to be performed when required. If a project has 7 or fewer sensors, then all sensors must be tested. If a project has more than 7 sensors, then one set of sensors needs to be tested for distinct room or space types.
If you have 7 hallways and 19 offices, you would only be required to test all of the sensors in one of the hallways and one of the offices.

The current layout proposes to fix that and clarifies when the verification needs to occur.

Public Comment 2:

Eric Makela, Birtt/Makela Group, representing Northwest Energy Codes Group, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

Add to Section C202 General Definitions

<u>**REGISTERED DESIGN PROFESSIONAL.** An individual who is registered or licensed to practice their respective design profession as defined by the statutory requirements of the professional registration laws of the state or jurisdiction in which the project is to be constructed.</u>

Revise as follows:

~~**C408.3.1 Functional testing.** Testing shall ensure that control hardware and software are calibrated, adjusted, programmed and in proper working condition in accordance with the construction documents and manufacturer's installation instructions. The construction documents shall state the party who will conduct the required functional testing. Where required by the code official, an approved party~~ <u>individual</u> ~~independent from the design or construction of the project shall be responsible for the functional testing and shall provide documentation to the code official certifying that the installed lighting controls meet the provisions of Section C405.~~

C408.3.1 Functional testing. <u>Prior to passing final inspection, the *registered design professional* shall provide evidence that the lighting control systems have been tested to ensure that control hardware and software are calibrated, adjusted, programmed, and in proper working condition in accordance with the construction documents and manufacturer's installation instructions</u>~~.~~ <u>Functional testing shall comply with Section C408.3.1.1 to C408.3.1.2 for the applicable control type.</u>

<u>**C408.3.1.1 Occupancy sensors** Where *occupancy sensors* are provided, the following procedures shall be performed:</u>

1. Certify that the occupancy sensor has been located and aimed in accordance with manufacturer recommendations
2. For projects with seven or fewer *occupancy sensors* each sensor shall be tested.
3. For projects with more than seven *occupancy sensors*, testing shall be done for each unique combination of sensor type and space geometry. Where multiples of each unique combination of sensor type and space geometry are provided no fewer than the greater of one, or 10 percent of each combination, shall be tested unless the code official or design professional require a higher percentage to be tested. Where 30 percent or more of the tested controls fail, all remaining identical combinations shall be tested.

   For each occupancy sensor to be tested, verify the following:
   - 3.1 Where occupancy sensors include status indicators, verify correct operation.
   - 3.2 The controlled lights turn off or down to the permitted level within the required time.
   - 3.3 For auto-on *occupancy sensors*, the lights turn on to the permitted level when an occupant enters the space.
   - 3.4 For manual on sensors, the lights turn on only when manually activated.
   - 3.5 The lights are not incorrectly turned on by movement in adjacent areas or by HVAC operation.

C408.3.1.2 Automatic time switches. Where automatic time switches are provided, the following procedures shall be performed:

1. Confirm that the automatic time switch control is programmed with accurate weekday, weekend, and holiday schedules.
2. Provide documentation to the owner of automatic time switch programming including weekday, weekend, holiday schedules, and set-up and preference program settings.
3. Verify the correct time and date in the time switch.
4. Verify that any battery back-up is installed and energized.
5. Verify that the override time limit is set to no more than 2 hours.
6. Simulate occupied condition. Verify and document the following:
   - 6.1 All lights can be turned on and off by their respective area control switch.
   - 6.2 The switch only operates lighting in the enclosed space in which the switch is located.
7. Simulate unoccupied condition. Verify and document the following:
   - 7.1 All non-exempt lighting turns off.
   - 7.2. Manual override switch allows only the lights in the enclosed space where the override switch is located to turn on or remain on until the next scheduled shut off occurs.
8. Additional testing as specified by the registered design professional.

C408.3.1.3 Daylight Controls Where daylighting controls are provided, the following procedures shall be performed:

1. All control devices have been properly located, field-calibrated and set for accurate set points and threshold light levels.
2. Daylight controlled lighting loads adjust to light level set points in response to available daylight.
3. The locations of calibration adjustment equipments are readily accessible only to authorized personnel.

C408.3.2 Documentation Requirements. The *construction documents* shall specify that *documents* certifying that the installed lighting controls meet documented performance criteria of Section C405 be provided to the *building* owner within 90 days from the date of receipt of the *certificate of occupancy*.

~~Where occupant sensors, time switches, programmable schedule controls, photosensors or daylighting controls are installed, the following procedures shall be performed:~~

1. ~~Confirm that the placement, sensitivity and time-out adjustments for occupant sensors yield acceptable performance.~~

   ~~1.1. For projects with up to seven occupancy sensors, all occupancy sensors shall be tested~~
   ~~1.2. For projects with more than seven the following shall be verified:~~
   - ~~1.2.1. Status indicator (as applicable) operates correctly~~
   - ~~1.2.2. The controlled lights turn off or down to the permitted level within the required time,~~
   - ~~1.2.3. For auto-on occupant sensors, the lights do turn on to the permitted level when someone enters the space,~~
   - ~~1.2.4. For manual on sensors, the lights turn on only when manually activated~~
   - ~~1.2.5. The lights are not incorrectly turned on by movement in nearby areas or by HVAC operation~~

2. ~~Confirm that the time switches and programmable schedule controls are programmed to turn the lights off.~~

3. ~~Confirm that all control devices for daylight controls have been properly located, field-calibrated, and set for design set points and threshold light levels. All daylight control devices shall only be readily accessible to authorized personnel. the placement and sensitivity adjustments for photosensor controls reduce electric light based on the amount of usable daylight in the space as specified.~~

Commenter's Reason: This Public Comment provides specific functional testing requirements for the specific types of lighting controls that are addressed in Section C405 of the IECC. The current language in Section C408.3 is not specific to lighting control type, providing general requirements with the intent that a system can be adequately "commissioned" if the section is followed. The Public Comment provides specific, step-by-step instructions testing occupancy sensors, daylighting controls and automatic time switches to ensure that they are operating correctly before system acceptance. The requirements will appear in the Southern

Nevada Energy Code and were proposed by the lighting design industry. The functional testing requirements are consistent with the timing and format of Section C408.2. Also the modification requires that the Registered Design Professional perform to testing requirement to be consistent with the Section C408 Commissioning requirements.

CE357-13

Final Action: AS AM AMPC____ D

CE361-13
C202 (New), C410 (New)

Proposed Change as Submitted

Proponent: Duane Jonlin, City of Seattle, representing City of Seattle Department of Planning and Development (duane.jonlin@seattle.gov)

Add new text as follows:

C410.1 General. A *solar zone* shall be provided for buildings which are five stories or less in height above grade plane, and shall be located on the roof of the building or elsewhere on the site. The *solar zone* shall comply with Sections C410.2 through C410.8 and *the International Fire Code*.

Exceptions:

1. A solar zone is not required where the solar exposure of the building's roof area is less than 75 percent of that of an unobstructed area in the same location, as measured by one of the following:

   1.1. Incident solar radiation expressed in kWh/ft²-yr using typical meteorological year (TMY) data
   1.2. Annual sunlight exposure expressed in cumulative hours per year using TMY data
   1.3. Shadow studies indicating that the area is more than 25 percent in shadow, on September 21 at 10am, 11am, 12pm, 1pm, and 2pm solar

2. Subject to the approval of the code official, buildings with extensive rooftop equipment that would make full compliance with this section impractical shall be permitted to provide a smaller *solar zone* than that required by Section C410.3.

C410.2 Minimum area. The minimum area of the *solar zone* shall be determined in accordance with Section C410.2.1 or C410.2.2, whichever results in the smaller area.

C410.2.1 Percentage of roof area. An area equal to 40 percent of the roof area calculated as the horizontally-projected gross roof area less the area covered by skylights, occupied roof decks and planted areas.

C410.2.2 Percentage of electrical service size. The electrical service size shall be the rated capacity of the total of all electrical services to the building, and the required *solar zone* size shall be based upon 10 peak watts of PV per square foot for 20 percent of the size of the electrical service.

C410.3 Obstructions. The *solar zone* shall be free of pipes, vents, ducts, HVAC equipment, skylights and other obstructions, except those serving PV or SWH systems within the solar zone. PV and SHW systems are permitted to be installed within the solar zone.

C410.4 Shading. Any existing or new object on the building or site that is located south, east, or west of the *solar zone* shall be set back from the *solar zone* a distance at least two times its height above the roof surface. Such objects include but are not limited to taller portions of the building itself, parapets, chimneys, antennas, signage, rooftop equipment, trees and roof plantings. The *solar zone* shall not be located on a roof slope greater than 2:12 that faces within 45° of true north.

C410.5 Non-contiguous area. The *solar zone* is permitted to be comprised of smaller separated sub-zones. Each subzone shall be at least 5 feet wide in the narrowest dimension.

C410.6 Access. Areas contiguous to the *solar zone* shall provide access pathways and provisions for emergency smoke ventilation as required by the *International Fire Code.*

C410.7 Structural integrity. Where the *solar zone* is on the roof of the building or another structure on the site, the as-designed dead load and live load for the *solar zone* shall be clearly marked on the construction documents, and shall accommodate future PV or SHW arrays at an assumed dead load of 5 pounds per square foot in addition to other required live and dead loads. For PV systems, a location for inverters shall be designated either within or adjacent to the solar zone, with a minimum area of 2 square feet for each 1000 square feet of solar zone area, and shall accommodate an assumed dead load of 175 pounds per square foot.

C410.8 PV or SWH interconnection provisions. Buildings shall provide for the future interconnection of either a PV system in accordance with Section C410.2.8.1 or an SWH system in accordance with Section C410.2.8.2.

C410.2.8.1 PV interconnection. A capped roof penetration sleeve shall be provided in the vicinity of the future inverter, sized to accommodate the future PV system conduit. Interconnection of the future PV system shall be provided for at the main service panel, either ahead of the service disconnecting means or at the end of the bus opposite the service disconnecting means, in one of the following forms:

1. A space for the mounting of a future overcurrent device, sized to accommodate the largest standard rated overcurrent device that is less than 20 percent of the bus rating; or
2. Lugs sized to accommodate conductors with an ampacity of at least 20 percent of the bus rating, to enable the mounting of an external overcurrent device for interconnection.

The electrical construction documents shall indicate the following:

1. Solar zone boundaries and access pathways;
2. Location for future inverters and metering equipment; and
3. Route for future wiring between the PV panels and the inverter, and between the inverter and the main service panel.

C410.2.8.2 SWH interconnection. Two capped pipe tees shall be provided upstream of the domestic water heating equipment to provide plumbing interconnections between a future SWH system and the domestic water heating system. Two roof penetration sleeves shall be provided in the vicinity of the solar zone, capable of accommodating supply and return piping for a future SWH system.

The plumbing construction documents shall indicate the following:

1. Solar zone boundaries and access pathways;
2. Location for future hot water storage tanks; and
3. Route for future piping between the solar zone and the plumbing interconnection point, following the shortest feasible pathway.

Add new definition as follows:

SECTION C202
GENERAL DEFINITIONS

SOLAR ZONE. A clear area or areas reserved solely for current and future installation of photovoltaic or solar hot water systems.

Reason: The cost of photovoltaic and solar water heating systems has declined markedly in recent years, but at this point they are still only marginally cost-effective. However, their cost continues to decline, and this rule will prepare our new building stock to easily install such systems at an appropriate time. As energy costs rise and solar generation costs decline, a point will be reached where large solar energy systems are a viable investment. This rule brings that date closer in time by clearing away any physical impediments to future installation.

The rule requires an unobstructed "solar zone" for most non-residential buildings of five stories or less, either 40 percent of the building's roof area, or an area large enough to generate 20% of the building's electricity.

Example: A building with a 10,000 SF total roof area, 1,000 SF skylight area, and a 400 Amp, 240 volt single phase electrical service is required to provide a solar zone area of the smaller of the following:

1. [40% x (10,000 SF roof area – 1,000 SF skylights)] = 3,600 SF, or
2. [400 Amp x 240 Volts x 20% / 10 watts per SF] = 1,920 SF

Therefore, a solar zone of 1,920 square feet is required

The solar zone requires a dedicated pathway for future connection to the electrical or water heating system, and may also be located above carports, canopies, or elsewhere on the building or site. Exemptions are provided for roofs that are extensively shaded or congested with equipment.

Cost Impact: The code change proposal will increase the cost of construction.

C410 (NEW)-EC-JONLIN.doc

Committee Action Hearing Results

Committee Action: Disapproved

Committee Reason: The committee felt that the code should allow this as an owner option and not a requirement. They felt that the 'reserved area' concept is not workable over time. Residential use buildings should be exempted. Even if it is in an appendix, it needed to be acceptable code language.

Assembly Action: Approved as Modified

The modification included in the Assembly Action is to change the proposal to be located in an Appendix chapter in the Commercial IECC without any change to the text of the proposal.

Individual Consideration Agenda

This code change proposal is on the agenda for individual consideration because the proposal received a successful assembly action of Approved as Modified and a Public Comment was received.

Public Comment:

Duane Jonlin, City of Seattle, Department of Planning & Development, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

APPENDIX A

SOLAR ZONES

The provisions contained in this appendix are not mandatory unless specifically referenced in the adopting ordinance.

SECTION AC101
GENERAL

~~C410.1~~ AC101.1 General. A *solar zone* shall be provided for buildings which are five stories or less in height above grade plane, and shall be located on the roof of the building or elsewhere on the site. The *solar zone* shall comply with Sections ~~C410.2~~ AC102 through ~~C410.8~~ AC108 and *the International Fire Code*.

Exceptions:

1. A solar zone is not required where the solar exposure of the building's roof area is less than 75 percent of that of an unobstructed area in the same location, as measured by one of the following:
   1.1. Incident solar radiation expressed in kWh/ft²-yr using typical meteorological year (TMY) data
   1.2. Annual sunlight exposure expressed in cumulative hours per year using TMY data

1.3. Shadow studies indicating that the area is more than 25 percent in shadow on September 21 at 10am, 11am, 12pm, 1pm, and 2pm solar

2. Subject to the approval of the code official, buildings with extensive rooftop equipment that would make full compliance with this section impractical shall be permitted to provide a smaller *solar zone* than that required by Section ~~C410.3.~~ AC102.

SECTION AC102
AREA

~~C410.2~~ AC102.1 Minimum area. The minimum area of the *solar zone* shall be determined in accordance with Section AC102.1.1 ~~C410.2.1 or C410.2.2~~ or AC102.1.2, whichever results in the smaller area.

~~C410.2.1~~ AC 102.1.1 Percentage of roof area. An area equal to 40 percent of the roof area calculated as the horizontally-projected gross roof area less the area covered by skylights, occupied roof decks and planted areas.

~~C410.2.2~~ AC102.1.2 Percentage of electrical service size. The electrical service size shall be the rated capacity of the total of all electrical services to the building, and the required *solar zone* size shall be based upon 10 peak watts of ~~PV~~ photovoltaic system per square foot for 20 percent of the size of the electrical service.

SECTION AC103
OBSTRUCTIONS

~~C410.3~~ AC103.1 Obstructions. The *solar zone* shall be free of pipes, vents, ducts, HVAC equipment, skylights and other obstructions, except those serving ~~PV or SWH~~ photovoltaic (PV) or solar hot water (SWH) systems within the solar zone. PV and SHW systems are permitted to be installed within the solar zone.

SECTION AC104
SHADING

~~C410.4~~ AC104.1 Shading. Any existing or new object on the building or site that is located south, east, or west of the solar zone shall be set back from the solar zone a distance at least two times its height above the roof surface. Such objects include but are not limited to taller portions of the building itself, parapets, chimneys, antennas, signage, rooftop equipment, trees and roof plantings. The *solar zone* shall not be located on a roof slope greater than 2:12 that faces within 45° of true north.

SECTION AC105
NON-CONTIGUOUS AREA

~~C410.5~~ AC105.1 Non-contiguous area. The *solar zone* is permitted to be comprised of smaller separated sub-zones. Each subzone shall be at least 5 feet wide in the narrowest dimension.

SECTION AC106
ACCESS

~~C410.6~~ AC106.1 Access. Areas contiguous to the *solar zone* shall provide access pathways and provisions for emergency smoke ventilation as required by the *International Fire Code.*

SECTION AC107
STRUCTURAL INTEGRITY

~~C410.7~~ AC107.1 Structural integrity. Where the *solar zone* is on the roof of the building or another structure on the site, the as-designed dead load and live load for the *solar zone* shall be clearly marked on the construction documents, and shall accommodate future PV or SHW arrays at an assumed dead load of 5 pounds per square foot in addition to other required live and dead loads. For PV systems, a location for inverters shall be designated either within or adjacent to the solar zone, with a minimum area of 2 square feet for each 1000 square feet of solar zone area, and shall accommodate an assumed dead load of 175 pounds per square foot.

SECTION AC108
INTERCONNECTIONS

~~C410.8~~ AC108.1 PV or SWH interconnection provisions. Buildings shall provide for the future interconnection of either a PV system in accordance with Section ~~C410.2.8.1~~ AC108.1.1 or an SWH system in accordance with Section ~~C410.2.8.2.~~AC108.1.2

~~C410.1~~ AC108.1.1 PV interconnection. A capped roof penetration sleeve shall be provided in the vicinity of the future inverter, sized to accommodate the future PV system conduit. Interconnection of the future PV system shall be provided for at the main service panel, either ahead of the service disconnecting means or at the end of the bus opposite the service disconnecting means, in one of the following forms:

1. A space for the mounting of a future overcurrent device, sized to accommodate the largest standard rated overcurrent device that is less than 20 percent of the bus rating; or
2. Lugs sized to accommodate conductors with an ampacity of at least 20 percent of the bus rating, to enable the mounting of an external overcurrent device for interconnection.

The electrical construction documents shall indicate the following:

1. Solar zone boundaries and access pathways;
2. Location for future inverters and metering equipment; and
3. Route for future wiring between the PV panels and the inverter, and between the inverter and the main service panel.

~~C410.8.2~~ AC108.1.2 SWH interconnection. Two capped pipe tees shall be provided upstream of the domestic water heating equipment to provide plumbing interconnections between a future SWH system and the domestic water heating system. Two roof penetration sleeves shall be provided in the vicinity of the solar zone, capable of accommodating supply and return piping for a future SWH system.

The plumbing construction documents shall indicate the following:

1. Solar zone boundaries and access pathways;
2. Location for future hot water storage tanks; and
3. Route for future piping between the solar zone and the plumbing interconnection point, following the shortest feasible pathway.

(Portions of proposal not shown remain unchanged)

Commenter's Reason: This proposal, as approved by Assembly Action in the Dallas meetings, places the "solar-ready" requirements in an Appendix, so that individual jurisdictions can choose to incorporate it or not, depending on local conditions. This will provide uniformity among those jurisdictions.

Note that this proposal does not place any restrictions on how the "solar zone" is used in the future. Also note that the solar zone size is reduced where skylights, roof plantings or occupied decks utilize portions of the roof.

CE361-13

Final Action: AS AM AMPC____ D

RE7-13
R302.1 (IRC N1101.11)

Proposed Change as Submitted

Proponent: Jerry Anderson, City of Overland Park, KS, representing self (anderson@opkansas.org)

Revise as follows:

R302.1 (N1101.11) Interior design conditions. The interior design temperatures used for heating and cooling load calculations shall be in accordance with ACCA Manual J. ~~a maximum of 72^{0}F (22^{0}C) for heating and minimum of 75^{0}F (24^{0}C) for cooling.~~

Reason: The purpose of this code change is to allow some flexibility in design conditions. There is no valid reason for the code to specify exact temperatures for interior design. Interior design conditions are all about comfort. The 72 degree temperature for heating and the 75 degree temperature for cooling are simply design temps where most people are comfortable, but comfort is dependent on physical attributes of individuals (age, sex, weight, metabolism, etc). If someone wishes to design a home or residential facility with different design conditions they should be allowed to do so. For example a group home being constructed for the elderly in accordance with the IRC provisions may wish to have different interior design temperatures for heating. The standard would allow for different design temperatures because it views the 72 degree and 75 degree marks as target values.

Cost Impact: The code change proposal will not increase the cost of construction.

R302.1-EC-ANDERSON.doc

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: ACCA Manual J gives a range of design conditions which are too broad a range to standardize the loads.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Gerald Anderson, City of Overland Park, representing self, requests Approval as Submitted.

Commenter's Reason: The purpose of this code change is to allow some flexibility in design conditions. There is no valid reason for the code to specify exact temperatures for interior design. Interior design conditions are all about comfort. The 72 degree temperature for heating and the 75 degree temperature for cooling are simply design temps where most people are comfortable, but comfort is dependent on physical attributes of individuals (age, sex, weight, metabolism, etc.). If someone wishes to design a home for residential facility with different design conditions they should be allowed to do so. For example a group home being constructed for elderly in accordance with the IRC provisions may wish to have different interior design temperatures for heating. The standard would allow for different design temperatures because it views the 72 degree and 75 degree marks as target values.

Proposed Change as Submitted

Proponent: Chris Mathis, Mathis Consulting Company, representing self

Add new text as follows:

R304 (N1102.16) SOLAR READY ZONE.

R304.1 (N1102.16.1) General. All new detached one- and two-family dwellings, and multiple single family dwellings having roofs oriented between 110 degrees and 270 degrees of true north shall comply with sections R304.2 through R304.8.

R304.2 (N1102.16.2) Mandatory construction document requirements for solar ready zone. Construction documents for new detached one- and two-family dwellings, and multiple single family dwellings having roofs oriented between 110 degrees and 270 degrees of true north shall indicate the *solar ready zone*.

R304.3 (N1102.16.3) Solar ready zone area. The total *solar ready zone* area shall be no less than 300 square feet exclusive of mandatory access or set back areas required by the *International Fire Code*. New detached one- and two-family dwellings, and multiple single family dwellings with three stories or more and with a total floor area less than or equal to 2000 square feet shall have a *solar ready zone* area no less than 150 square feet. The *solar ready zone* shall be comprised of areas that have no dimension less than five feet and are no less than 80 square feet exclusive of mandatory access or set back areas as required by the *International Fire Code*.

Exceptions:

1. New buildings with a permanently installed on-site renewable energy system.
2. Roof areas in shade more than 70 percent of the time.

R304.4 (N1102.16.4) Obstructions. *Solar ready zones* shall be free from obstructions, including but not limited to vents, chimneys, and roof mounted equipment.

R304.5 (N1102.16.5) Roof load documentation. The structural design loads for roof dead load and roof live load shall be clearly indicated on the construction documents.

R304.6 (N1102.16.6) Interconnection pathway. Construction documents shall indicate the installed pathways for conduit, pre-wiring, pre-plumbing, or plumbing chase from the *solar ready zone* to the electrical service panel or service hot water system.

R304.7 (N1102.16.7) Electrical service reserved space. The main electrical service panel shall have a minimum busbar rating of 200 amps, shall have reserved space to allow installation of a dual pole circuit breaker for future solar electric installation, and shall be labeled “For Future Solar Electric”. The reserved space shall be positioned at the opposite (load) end from the input feeder location or main circuit location.

Exception: Building projects with installed pre-plumbing or plumbing chase from the *solar ready zone* to reserved space at the water heating system.

R304.8 (N1102.16.8) Construction documentation. A copy of the construction documents indicating the *solar ready zone* and other requirements of this section shall be posted near the electrical panel, water heater, or other conspicuous location in the building.

Add new definition as follows:

IECC SECTION R202 (IRC N1101.9)
GENERAL DEFINITIONS

SOLAR READY ZONE. A section or sections of the roof or building overhang designated and reserved for the future installation of a solar electric or solar thermal system.

Reason: This proposal is intended to support future potential improvements for detached one- and two-family dwellings, and multiple single family dwellings for solar electric and solar thermal systems. The proposed language follows similar language from code adoptions by local municipalities in Tucson, AZ, Boulder, CO, and from the 2013 California Title 24 building code.

This proposal is intended to identify the areas of a residential building roof, called the solar ready zone, for potential future installation of renewable energy systems. This proposal requires documenting necessary solar ready information on the plans, some of which may already be required in permit construction requirements. This proposal also requires the builder to post specific information about the home for use by the homeowner(s).

This proposal requires the installation of chase, conduit, pre wiring, or pre-plumbing. It does not require any specific physical orientation of the residential building. It does not require any increased load capacities for residential roofing systems. When considered at the time of design, this proposal needs not increase the cost of construction, though will add a small, recoverable cost in many cases.

The documentation of solar ready zones and roof load calculations (already performed during the design phase) will assist building departments, as well as any future solar contractors seeking to install renewable energy systems on the roof. The builder/designer is knowledgeable on the intricacies of each model and plan, and easily can identify unobstructed roof areas, as well as spaces where conduit, wiring, and plumbing can be routed from the roof to the respective utility areas. This will save building departments and solar designers time and effort when installing future solar systems.

Upfront costs of renewable energy systems frequently are the largest deterrent to installation. Without preparation at the time of construction, solar installation may not even be technically possible. If a homeowner wishes to install a solar energy system later, this preparation can save thousands of dollars in labor, installation, design, and integration of the solar system into the house. Solar ready design can decrease the payback period tremendously. This is critical as these systems continue to become more cost effective and incentives are more readily available. In the instance that the initial homeowner does not intend to install a solar system, making the building solar ready increases the resale value of the home and the cost can be recovered.

Many building departments have been mandated by local regulations to accelerate permits and inspections for solar installation. Having important information and documentation available to the building department, solar contractor, and homeowner will assist in supporting the accelerated working environment many municipalities have mandated.

The U.S. Department of Energy's (DOE) SunShot Initiative has set a goal to make solar energy cost competitive with other forms of energy by the end of the decade which will reduce installed costs of solar energy systems by about 75%. This initiative, combined with increased pressures on our energy supply and demand, will encourage and drive greater adoption of renewable energy systems on residential buildings.

Cost Impact: The code change proposal will increase the cost of construction.

R304 (NEW)-EC-MATHIS.doc

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: The proposal does not contain enough information to decide that this is appropriate for all climate zones and for all the conditions that have been defined. This might be more appropriate as an appendix for jurisdictions to decide if this is appropriate for their community. In addition, the proposal is written in an overly complicated manner. This can be simpler.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Ellen Eggerton, Fairfax County, VA, requests approval As Modified by this Public Comment.

Modify the proposal as follows:

R304 (N1102.16) SOLAR READY ZONE.

R304.1 (N1102.16.1) General. All new detached one- and two-family dwellings, and multiple single family dwellings having roofs oriented between 110 degrees and 270 degrees of true north shall comply with sections R304.2 through ~~R304.8~~. R304.6

R304.2 (N1102.16.2) Mandatory construction document requirements for solar ready zone. Construction documents for new detached one- and two-family dwellings, and multiple single family dwellings having roofs oriented between 110 degrees and 270 degrees of true north shall indicate the *solar ready zone*.

~~**R304.3 (N1102.16.3) Solar ready zone area**. The total *solar ready zone* area shall be no less than 300 square feet exclusive of mandatory access or set back areas required by the *International Fire Code*. New detached one- and two-family dwellings, and multiple single family dwellings with three stories or more and with a total floor area less than or equal to 2000 square feet shall have a *solar ready zone* area no less than 150 square feet. The *solar ready zone* shall be comprised of areas that have no dimension less than five feet and are no less than 80 square feet exclusive of mandatory access or set back areas as required by the *International Fire Code*.~~

~~**Exceptions:**~~

1. ~~New buildings with a permanently installed on-site renewable energy system.~~
2. ~~Roof areas in shade more than 70 percent of the time.~~

~~**R304.4 (N1102.16.4)**~~ **R304.3 (N1102.16.3) Obstructions**. *Solar ready zones* shall be free from obstructions, including but not limited to vents, chimneys, and roof mounted equipment.

~~**R304.5 (N1102.16.5)**~~ **R304.4 (N1102.16.4) Roof load documentation**. The structural design loads for roof dead load and roof live load shall be clearly indicated on the construction documents.

~~**R304.6 (N1102.16.6)**~~ **R304.5 (N1102.16.5) Interconnection pathway**. Construction documents shall indicate the installed pathways for conduit, pre-wiring, pre-plumbing, or plumbing chase from the *solar ready zone* to the electrical service panel or service hot water system.

~~**R304.7 (N1102.16.7) Electrical service reserved space**. The main electrical service panel shall have a minimum busbar rating of 200 amps, shall have reserved space to allow installation of a dual pole circuit breaker for future solar electric installation, and shall be labeled "For Future Solar Electric". The reserved space shall be positioned at the opposite (load) end from the input feeder location or main circuit location.~~

~~**Exception:** Building projects with installed pre-plumbing or plumbing chase from the *solar ready zone* to reserved space at the water heating system.~~

~~**R304.8 (N1102.16.8)**~~ **R304.6 (N1102.16.6) Construction documentation**. A copy of the construction documents indicating the *solar ready zone* and other requirements of this section shall be posted near the electrical panel, water heater, or other conspicuous location in the building.

Add new definition as follows:

IECC SECTION R202 (IRC N1101.9)
GENERAL DEFINITIONS

SOLAR READY ZONE. A section or sections of the roof or building overhang designated and ~~reserved~~ designated on the plans for the future installation of a solar electric or solar thermal system.

Commenter's Reason: This simplifies that the only requirement is to show the area of the roof that is within the 110 and 270 degrees of true north shown on the design drawings. All other issues are left to the homeowner to decide.

Add new text as follows:

SECTION R304
SOLAR READY ZONE

R304.1 General. (N1102.16.1) New detached one- and two-family dwellings, and multiple single family dwellings having roofs oriented between 110 degrees and 270 degrees of true north shall comply with Sections R304.2 through R304.8.

R304.2 (N1102.16.2) Construction document requirements for solar ready zone. Construction documents for new detached one- and two-family dwellings, and multiple single family dwellings having roofs oriented between 110 degrees and 270 degrees of true north shall indicate a *solar ready zone*.

R304.3 (N1102.16.3) Solar ready zone area. The total *solar ready zone* area shall be no less than 300 square feet exclusive of access or set back areas as required by the *International Fire Code*. New multiple single family dwellings three stories or more in height above grade plane and with a total floor area less than or equal to 2000 square feet shall have a *solar ready zone* area of not less than 150 square feet. The *solar ready zone* shall be comprised of areas not less than five feet in width and not less than 80 square feet exclusive of access or set back areas as required by the *International Fire Code*.

Exceptions:

1. New buildings with a permanently installed on-site renewable energy system.
2. Roof areas that are in shade more than 70 percent of the time.

R304.4 (N1102.16.4) Obstructions. *Solar ready zones* shall be free from obstructions, including but not limited to vents, chimneys, and roof mounted equipment.

R304.5 (N1102.16.5) Roof load documentation. The structural design loads for roof dead load and roof live load shall be clearly indicated on the construction documents.

R304.6 (N1102.16.6) Interconnection pathway. Construction documents shall indicate pathways for routing of conduit or plumbing from the *solar ready zone* to the electrical service panel or service hot water system.

R304.7 (N1102.16.7) Electrical service reserved space. The main electrical service panel shall have a reserved space to allow installation of a dual pole circuit breaker for future solar electric installation and shall be labeled “For Future Solar Electric”. The reserved space shall be positioned at the opposite (load) end from the input feeder location or main circuit location.

R304.8 (N1102.16.8) Construction documentation certificate. A permanent certificate, indicating the *solar ready zone* and other requirements of this section, shall be posted near the electrical distribution panel, water heater or other conspicuous location by the builder or registered design professional.

Add new definition as follows:

IECC SECTION R202 (IRC N1101.9)
GENERAL DEFINITIONS

SOLAR READY ZONE. A section or sections of the roof or building overhang designated and reserved for the future installation of a solar electric or solar thermal system.

Reason: This proposal is intended to support future potential improvements for detached one- and two-family dwellings, and multiple single family dwellings for solar electric and solar thermal systems. The proposed language follows similar language from code adoptions by local municipalities in Tucson, AZ, Boulder, CO, and from the 2013 California Title 24 building code.

This proposal is intended to identify the areas of a residential building roof, called the solar ready zone, for potential future installation of renewable energy systems. This proposal requires documenting necessary solar ready zone information on the plans, some of which may already be required in permit construction requirements. This proposal also requires the builder to post specific information about the home for use by the homeowner(s).

This proposal does not require the installation of conduit, pre wiring, or pre-plumbing. It does not require any specific physical orientation of the residential building. It does not require any increased load capacities for residential roofing systems. It does not require the redesign of plans.

The documentation of solar ready zones and roof load calculations (already performed during the design phase) will assist building departments as well as any future solar contractors seeking to install renewable energy systems on the roof. The builder/designer is knowledgeable on the intricacies of each model and plan and can easily identify unobstructed roof areas as well as spaces where conduit, wiring and plumbing can be routed from the roof to the respective utility areas. This will save building departments and solar designers' time and effort when installing future solar systems. If a homeowner wishes to install a solar energy system later, this documentation can save thousands of dollars in labor, installation, design and integration of the solar system into the house.

Many building departments have been mandated by local regulations to accelerate permits and inspections for solar installation. Having important information and documentation available to the building department, solar contractor and homeowner will assist in supporting the accelerated working environment many municipalities have mandated.

The U.S. Department of Energy's (DOE) SunShot Initiative has set a goal to make solar energy cost competitive with other forms of energy by the end of the decade which will reduce installed costs of solar energy systems by about 75%. This initiative, combined with increased pressures on our energy supply and demand, will encourage and drive greater adoption of renewable energy systems on residential buildings.

Cost Impact: The code change proposal will increase the cost of construction.

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Jim Meyers, Southwest Energy Efficiency Project (SWEEP), requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

APPENDIX A

SOLAR READY PROVISIONS – DETACHED ONE-AND TWO-FAMILY DWELLINGS, MULTIPLE SINGLE FAMILY DWELLINGS (TOWNHOUSES)

(The provisions contained in this appendix are not mandatory unless specifically referenced in the adopting ordinance.)

SECTION AA101
SCOPE

AA101.1 General. This appendix contains requirements for new construction in jurisdictions where solar ready provisions are required.

Inclusion of this appendix by jurisdictions shall be determined through the use of locally available information.

SECTION AA102
GENERAL DEFINITIONS

SOLAR READY ZONE. A section or sections of the roof or building overhang designated and reserved for the future installation of a solar electric or solar thermal system.

~~R304~~ AA103
SOLAR READY ZONE

~~R304.1~~ AA103.1 General. New detached one- and two-family dwellings, and multiple single family dwellings (townhouses) having roofs oriented between 110 degrees and 270 degrees of true north shall comply with sections ~~R304.2~~ AA103.2 through ~~R304.8~~ AA103.8.

Exceptions:

1. New residential buildings with a permanently installed on-site renewable energy system.
2. A building without at least 600 square feet of solar ready zone that is unshaded for more than 70 percent of daylight hours annually.

~~R304.2~~ AA103.2 Construction document requirements for solar ready zone. Construction documents for new detached one- and two-family dwellings, and multiple single family dwellings (townhouses) having roofs oriented between 110 degrees and 270 degrees of true north shall indicate the *solar ready zone*.

~~R304.3~~ AA103.3 Solar ready zone area. The total *solar ready zone* area shall be no less than 300 square feet exclusive of mandatory access or set back areas as required by the *International Fire Code*. New multiple single family dwellings (townhouses) three stories or ~~more~~ less in height above grade plane and with a total floor area less than or equal to 2000 square feet per dwelling shall have a *solar ready zone* area of not less than 150 square feet. The *solar ready zone* shall be comprised of areas not less than five feet in width and not less than 80 square feet exclusive of access or set back areas as required by the *International Fire Code*.

~~**Exception:**~~

1. ~~New residential buildings with a permanently installed on-site renewable energy system.~~
2. ~~Roof areas in shade more than 70 percent of the time.~~

~~R304.4~~ AA103.4 Obstructions. *Solar ready zones* shall be free from obstructions, including but not limited to vents, chimneys, and roof mounted equipment.

~~R304.5~~ AA103.5 Roof load documentation. The structural design loads for roof dead load and roof live load shall be clearly indicated on the construction documents.

~~R304.6~~ AA103.6 Interconnection pathway. Construction documents shall indicate pathways for routing of conduit or plumbing from the *solar ready zone* to the electrical service panel or service hot water system.

~~R304.7~~ AA103.7 Electrical service reserved space. The main electrical service panel shall have a reserved space to allow installation of a dual pole circuit breaker for future solar electric installation and shall be labeled “For Future Solar Electric”. The reserved space shall be positioned at the opposite (load) end from the input feeder location or main circuit location.

~~R304.8~~ AA103.8 Construction documentation certificate. A permanent certificate, indicating the *solar ready zone* and other requirements of this section, shall be posted near the electrical distribution panel, water heater or other conspicuous location by the builder or registered design professional

Commenter’s Reason: This public comment moves the proposed change with its floor modification, RE9, from the body of the IECC into a new appendix in the IECC. The original proposal was disapproved by the committee on a 5 to 6 vote and closely followed by a 33 to 35 vote with a floor action. Many committee members were supportive of the proposal but not as a mandatory code requirement. The original proposal was modified by a floor amendment to clarify and correct the code language; this language is included in this public comment. By moving these code requirements into an appendix it supports jurisdictions who do not want to adopt solar ready provisions today while also supporting jurisdictions who are considering adopting solar ready provisions.

A floor action at the Committee Action Hearings approved a commercial proposal on solar ready requirements (CE361) into a new appendix of the IECC. This public comment would align new provisions within the IECC for both commercial and residential buildings.

Public Comment 2:

Lorraine Ross, Intech Consulting Inc. representing The Dow Chemical Company requests Approval as Modified by this Public Comment.

Replace the proposal as follows:

APPENDIX (X)

SOLAR READY PROVISIONS – DETACHED ONE-AND TWO-FAMILY DWELLINGS, MULTIPLE SINGLE FAMILY DWELLINGS (TOWNHOUSES)

(The provisions contained in this appendix are not mandatory unless specifically referenced in the adopting ordinance.)

SECTION XA101 SCOPE

XA101.1 General. These provisions shall be applicable for new construction where solar ready provisions are required.

SECTION XA102
GENERAL DEFINITIONS

SOLAR READY ZONE. A section or sections of the roof or building overhang designated and reserved for the future installation of a solar photovoltaic or solar thermal system.

XA103
SOLAR READY ZONE

XA103.1 General. New detached one- and two-family dwellings, and multiple single family dwellings (townhouses) with at least 600 square feet of roof area oriented between 110 degrees and 270 degrees of true north shall comply with sections XA103.2 through XA103.8.

Exceptions:

1. New residential buildings with a permanently installed on-site renewable energy system.
2. A building with a solar ready zone that is shaded for more than 70 percent of daylight hours annually.

XA103.2 Construction document requirements for solar ready zone. Construction documents shall indicate the *solar ready zone*.

XA103.3 Solar ready zone area. The total *solar ready zone* area shall be no less than 300 square feet exclusive of mandatory access or set back areas as required by the *International Fire Code*. New multiple single family dwellings (townhouses) three stories or less in height above grade plane and with a total floor area less than or equal to 2000 square feet per dwelling shall have a *solar ready zone* area of not less than 150 square feet. The *solar ready zone* shall be comprised of areas not less than five feet in width and not less than 80 square feet exclusive of access or set back areas as required by the *International Fire Code*.

XA103.4 Obstructions. *Solar ready zones* shall be free from obstructions, including but not limited to vents, chimneys, and roof mounted equipment.

XA103.5 Roof load documentation. The structural design loads for roof dead load and roof live load shall be clearly indicated on the construction documents.

XA103.6 Interconnection pathway. Construction documents shall indicate pathways for routing of conduit or plumbing from the *solar ready zone* to the electrical service panel or service hot water system.

XA103.7 Electrical service reserved space. The main electrical service panel shall have a reserved space to allow installation of a dual pole circuit breaker for future solar electric installation and shall be labeled “For Future Solar Electric”. The reserved space shall be positioned at the opposite (load) end from the input feeder location or main circuit location.

XA103.8 Construction documentation certificate. A permanent certificate, indicating the *solar ready zone* and other requirements of this section, shall be posted near the electrical distribution panel, water heater or other conspicuous location by the builder or registered design professional.

Commenter's Reason: The original proposal (RE9-13) was narrowly disapproved by the committee on a 5 to 6 vote and was closely followed by a 33 to 35 vote with a floor action. This public comment reflects many of the comments from both the committee and a floor amendment offered by public testimony on RE9-13 and moves the proposed change from the body of the code into a new appendix in the IECC.

Many building departments have been mandated by local regulations to accelerate permits and inspections for solar installations. Having important information and documentation available to the building department, solar contractor and homeowner will assist in supporting the accelerated working environment many municipalities have mandated. It also provides uniform guidance for those jurisdictions where solar ready ordinances are under consideration.

This proposal is intended to identify the areas of a residential building roof, called the solar ready zone, for potential future installation of renewable energy systems. This proposal requires documenting necessary solar ready zone information on the plans, some of which may already be required in permit construction requirements. This proposal also requires the builder to post specific information about the home for use by the homeowner(s).

The proposed language follows similar language from code adoptions by local municipalities in Tucson, AZ, Boulder, CO, and from the 2013 California Title 24 building code. This proposal does not require the installation of conduit, pre wiring, or pre-plumbing. It does not require any specific physical orientation of the residential building. It does not require any increased load capacities for residential roofing systems. It does not require the redesign of plans.

It is also important to note that a commercial solar ready proposal (CE361-13) was Approved as Modified by Assembly Action to establish an Appendix Chapter for Solar Ready provisions in the Commercial IECC:

"The modification included in the Assembly Action is to change the proposal to be located in an Appendix chapter in the Commercial IECC without any change to the text of the proposal".

R401.2 (IRC N1101.15), R402.4.1.2 (IRC N1102.4.1.2), R402.5 1 (IRC N1102.5.1), R403.2.2 (IRC N1103.2.2), R406 (NEW) (IRC N1106 (NEW)

Proposed Change as Submitted

Proponent: W. Ronald Burton, PTW Advisors, LLC., representing Leading Builders of America

Revise as follows:

R401.2 (N1101.2) Compliance. Projects shall comply with one of the following:

1. Sections identified as “mandatory” and with either sections identified as “prescriptive” or the performance approach in Section R405.
2. Optional Performance Compliance in Section R406.

R402.4.1.2 (N1102.4.1.2) Testing. The building or dwelling unit shall be tested and verified as having an air leakage rate of not exceeding 5 air changes per hour in Climate Zones 1 and 2, and 3 air changes per hour in Climate Zones 3 through 8. Testing shall be conducted with a blower door at a pressure of 0.2 inches w.g. (50 Pascals). Where required by the code official, testing shall be conducted by an approved third party. A written report of the results of the test shall be signed by the party conducting the test and provided to the code official. Testing shall be performed at any time after creation of all penetrations of the building thermal envelope.

> **Exception:** The air leakage rate in buildings complying with the Optional Performance Compliance in Section R406 shall not exceed 7 ACH50.

R402.5 (N1102.5) Maximum fenestration U -factor and SHGC (Mandatory). The area-weighted average maximum fenestration U-factor permitted using tradeoffs from Sections R402.1.4, ~~or~~ R405 or R406 shall be 0.48 in Climate Zones 4 and 5 and 0.40 in Climate Zones 6 through 8 for vertical fenestration, and 0.75 in Climate Zones 4 through 8 for skylights. The area-weighted average maximum fenestration SHGC permitted using tradeoffs from Section R405 or Section R406 in Climate Zones 1 through 3 shall be 0.50

R403.2.2 (N1103.2.2) Sealing (Mandatory). Ducts, air handlers, and filter boxes shall be sealed. Joints and seams shall comply with either the International Mechanical Code or International Residential Code, as applicable.

Exceptions:

1. Air-impermeable spray foam products shall be permitted to be applied without additional joint seals.
2. Where a duct connection is made that is partially inaccessible, three screws or rivets shall be equally spaced on the exposed portion of the joint so as to prevent a hinge effect.
3. Continuously welded and locking-type longitudinal joints and seams in ducts operating at static pressures less than 2 inches of water column (500 Pa) pressure classification shall not require additional closure systems.

Duct tightness shall be verified by either of the following:

1. Postconstruction test: Total leakage shall be less than or equal to 4 cfm (113.3 L/min) per 100 ft^2 (9.29 m^2) of conditioned floor area when tested at a pressure differential

of 0.1 inches w.g. (25 Pa) across the entire system, including the manufacturer's air handler enclosure. All register boots shall be taped or otherwise sealed during the test.

2. Rough-in test: Total leakage shall be less than or equal to 4 cfm (113.3 L/min) per 100 ft^2 (9.29 m^2) of conditioned floor area when tested at a pressure differential of 0.1 inches w.g. (25 Pa) across the system, including the manufacturer's air handler enclosure. All registers shall be taped or otherwise sealed during the test. If the air handler is not installed at the time of the test, total leakage shall be less than or equal to 3 cfm (85 L/min) per 100 ft^2 (9.29 m^2) of conditioned floor area.

Exceptions:

1. Duct tightness test is not required if the air handler and all ducts are located within conditioned space.
2. Buildings complying with the Optional Performance Compliance in Section R406 shall have an air leakage rate not exceeding 8 cfm (226.6 L/min) for ducts located outside of conditioned space.

SECTION R406 (N1106)
OPTIONAL PERFORMANCE COMPLIANCE

R406.1 (N1106.1)Scope. This section establishes criteria for compliance using an optional energy performance analysis. Such analysis shall include only heating, cooling, and service water heating energy ~~only~~.

R406.2 (N1106.2) Mandatory requirements. Compliance with Section R406 requires compliance with the mandatory provisions identified in Chapter 4 of this code. Supply and return ducts not completely inside the *building thermal envelope* shall be ~~insulated to a minimum of~~ provided with insulation having an R value of not less than R-6.

R406.3 (N1106.3) Performance-based compliance. For *residential buildings* complying with Section R406, compliance based on simulated energy performance requires that a proposed *residential building* (*proposed design)* be shown to have an annual energy cost that is less than or equal to 95% of the annual energy cost of a residence complying with sections of the residential provisions in Chapter 4 of this code identified as "mandatory" and configured as specified by the *standard reference design* in Table R406.4.2 (1) using the U-factor and SHGC-factors ~~the values~~ in *Table R406.4.2 (5)*. The proposed design values shall not be greater than the U-factors specified in Table R406.4.2 (4) or the SHGC value specified in Table R406.4.2 (3). Energy prices shall be taken from ~~a source~~ an approved source ~~by the code official~~, such as the Department of Energy, Energy Information Administration's State Energy Price and Expenditure Report. Time-of-use pricing in energy cost calculations shall be required where required by the Code Official.

> **Exception**: The energy use based on source energy expressed in Btu or Btu per square foot of *conditioned floor area* shall be alternatives to the energy cost. The source energy multiplier for electricity shall be 3.16. The source energy multiplier for fuels other than electricity shall be 1.1.

R406.4 (N1106.4) Documentation. Documentation of the software used for the performance design and the parameters for the building shall be in accordance with Sections R406.4.1 through R406.4.3.

R406.4.1 (N1106.4.1) Compliance software tools. Documentation verifying that the methods and accuracy of the compliance software tools conform to the provisions of this section shall be provided to the *code official*.

R406.4.2 (N1106.4.2) Compliance report. Compliance software tools shall generate a report that documents that the *proposed design* complies with Section R406.3. The compliance documentation shall include the following information:

1. Address or other identification of the residence;
2. An inspection checklist documenting the building component characteristics of the *proposed design* as listed in Table R406.4.2 (1). The inspection checklist shall show results for both the *standard reference design* and the *proposed design*, and shall document all inputs entered by the user necessary to reproduce the results;
3. Name of individual completing the compliance report; and
4. Name and version of the compliance software tool.

406.4.2.1(N1106.4.2.1) Multiple orientations. Where an otherwise identical building model is offered in multiple orientations, documentation that the building meets the performance requirements in each of the four cardinal (north, east, south and west) orientations shall be acceptable for demonstration of compliance for any orientation.

R406.4.3 (N1106.4.3) Additional documentation. The *code official* shall be permitted to require the following documents:

1. Documentation of the building component characteristics of the *standard reference design.*
2. A certification signed by the builder providing the building component characteristics of the proposed design as given in Table R406.4.2 (1).
3. Documentation of the actual values used in the software calculations for the *proposed design*.

R406.5 (N1106.5) Calculation procedure. Calculations of the performance design shall be in accordance with Sections R406.5.1 and R406.5.2.

R406.5.1 (N1106.5.1) General. The standard reference design and *proposed design* shall be configured and analyzed using identical methods and techniques.

R406.5.2 (N1106.5.2) *Residential building* specifications. The *standard reference design* and *proposed design* shall be configured as specified by Table R406.4.2 (1).

R406.5.3 (N1106.5.3) Energy cost analysis. The annual energy cost of the *proposed design* shall be analyzed and compared to a design complying with sections of the residential provisions in Chapter 4 of this code identified as “mandatory” and configured as specified by the *standard reference design* in Table R406.4.2 (1) using the U-factor and SHGC-factors in *Table R406.4.2 (5)*.

R406.6 (N1106.6) Calculation software tools. Calculation software, where used, shall be in accordance with Sections R406.6.1 through R406.6.3.

R406.6.1 (N1106.6.1) Minimum capabilities. Calculation procedures used to comply with this section shall be software tools capable of calculating the annual energy consumption of all building elements that differ between a design complying with sections of the residential provisions in Chapter 4 of this code identified as “mandatory” and configured as specified by the *standard reference design* in Table R406.4.2 (1) using the U-factor and SHGC-factors in *Table R406.4.2 (5)* and the *proposed design* and shall include the following capabilities:

1. The calculation procedure shall not allow the user to directly modify the building component characteristics of the design complying with sections of the residential provisions in Chapter 4 of this code identified as “mandatory” and configured as specified in Table R406.4.2 (1) using the U-factor and SHGC-factors in *Table R406.4.2 (5)*.
2. Calculation of whole-building ,~~(~~as a single zone,~~)~~ sizing for the heating and cooling equipment in the *standard reference design* residence in accordance with Section

R403.6.

3. Calculations that account for the effects of indoor and outdoor temperatures and part-load ratios on the performance of heating, ventilating and air-conditioning equipment based on climate and equipment sizing.
4. Printed *code official* inspection checklist listing each of the *proposed design* component characteristics from Table R406.4.2 (1) determined by the analysis to provide compliance, along with their respective performance ratings (such as R-value, U-factor, SHGC, HSPF, AFUE, SEER, EF, etc.).

R406.6.2 (N1106.6.2) Specific approval. Performance analysis tools meeting the applicable sections of Section R406 shall be approved. Approval of tools shall be based on meeting a specified threshold for a jurisdiction. The *code official* shall be permitted to approve tools for a specified application or limited scope.

R406.6.3 (N1106.6.3) Input values. When calculations require input values not specified by Sections R403, R404 and R406, those input values shall be taken from an approved source.

TABLE R406.4.2 (1) (N1106.4.2(1))
SPECIFICATIONS FOR THE STANDARD REFERENCE AND PROPOSED DESIGNS

BUILDING COMPONENT	STANDARD REFERENCE DESIGN	PROPOSED DESIGN
Above-grade walls	Type: mass wall if proposed wall is mass; otherwise wood frame. Gross area: same as proposed U-factor: from Table R406.4.2 (4) Solar absorptance = 0.75 Emittance = 0.90	As proposed As proposed As proposed[a] As proposed As proposed
Basement and crawl space walls	Type: same as proposed Gross area: same as proposed U-factor: from Table R406.4.2 (4), with insulation layer on interior side of walls.	As proposed As proposed As proposed[a]
Above-grade floors	Type: wood frame Gross area: same as proposed U-factor: from Table R406.4.2 (4)	As proposed As proposed As proposed[a]
Ceilings	Type: wood frame Gross area: same as proposed U-factor: from Table R406.4.2 (4)	As proposed As proposed As proposed[a]
Roofs	Type: composition shingle on wood sheathing Gross area: same as proposed Solar absorptance = 0.75 Emittance = 0.90	As proposed As proposed As proposed As proposed
Attics	Type: vented with aperture = 1 ft^2 per 300 ft^2 ceiling area	As proposed
Foundations	Type: same as proposed foundation wall area above and below grade and soil characteristics.	As proposed
Doors	Area: 40 ft^2 Orientation: North U-factor: same as fenestration from Table R406.4.2 (4).	As proposed As proposed As proposed[a]
Glazing[b]	Total area[c] =15% of the conditioned floor area. Orientation: equally distributed to four cardinal compass orientations (N, E, S & W). U-factor: from Table R406.4.2 (4) SHGC: From Table R406.4.2 (3) except that for climates with no requirement (NR) SHGC = 0.40 shall be used. Interior shade fraction: Summer (all hours when cooling is required) = 0.70 Winter (all hours when heating is required) = 0.85[e] External shading: none	As proposed As proposed As proposed[d] As proposed Same as *standard reference design* As proposed

BUILDING COMPONENT	**STANDARD REFERENCE DESIGN**	**PROPOSED DESIGN**
Skylights	None	As proposed
Thermally isolated sunrooms	None	As proposed
Air exchange rate	Air leakage rate of 7 air changes per hour at a pressure of 0.2 inches w.g (50 Pa). The mechanical ventilation rate shall be in addition to the air leakage rate and the same as in the proposed design, but no greater than 0.01 x CFA + 7.5 x (N_{br} + 1) where: CFA = conditioned floor area N_{br} = number of bedrooms Energy recovery shall not be assumed for mechanical ventilation.	For residences that are not tested, the same air leakage rate as the *standard reference design*. For tested residences, the measured air exchange rate[f]. The mechanical ventilation rate[g] shall be in addition to the air leakage rate and shall be as proposed.
Mechanical ventilation	None, except where mechanical ventilation is specified by the proposed design, in which case: Annual vent fan energy use: kWh/yr = 0.03942 x CFA + 29.565 x (N_{br} +1) where: CFA = conditioned floor area N_{br} = number of bedrooms	As proposed
Internal gains	IGain = 17,900 + 23.8 x CFA + 4104 x N_{br} (Btu/day per dwelling unit)	Same as *standard reference design*.
Internal mass	An internal mass for furniture and contents of 8 pounds per square foot of floor area.	Same as *standard reference design*, plus any additional mass specifically designed as a thermal storage element[h] but not integral to the building envelope or structure.
Structural mass	For concrete or masonry floor slabs, 80% of floor area covered by R-2 carpet and pad, and 20% of floor directly exposed to room air. For concrete or masonry basement walls, as proposed, but with insulation required by Table R406.4.2 (3) located on the interior side of the walls. For other walls, for ceilings, floors, and interior walls, wood frame construction.	As proposed As proposed As proposed
Heating systems[i, j]	Fuel type: same as proposed design Efficiencies: Electric: air-source heat pump with prevailing federal minimum standards. Nonelectric furnaces: natural gas furnace with prevailing federal minimum standards. Nonelectric boilers: natural gas boiler with prevailing federal minimum standards. Capacity: sized in accordance with Section R403.6	As proposed As proposed[m]
Cooling systems[i, k]	Fuel type: Electric Efficiency: in accordance with prevailing federal minimum standards. Capacity: sized in accordance with Section R403.6.	As proposed
Service water heating[i, l]	Fuel type: same as proposed design Efficiency: in accordance with prevailing federal minimum standards. Use: Use: gal/day = 30 + (10 N_{br}) Tank temperature: 120^{0}F	As proposed Same as *standard reference design.*
Thermal distribution systems	Duct outside the *building thermal envelope* shall be insulated to R-6 as required by Section R406.2. Untested distribution systems: DSE = 0.88	Thermal distribution system efficiency shall be as tested to outside

BUILDING COMPONENT	STANDARD REFERENCE DESIGN	PROPOSED DESIGN
	Tested ducts: Leakage rate to outside conditioned space as specified in Section R403.2.2. Duct location: Unconditioned attic Duct insulation: Per Section R403.2.1	conditioned space or as specified in Table R406.4.2 (2) if not tested. As proposed As proposed
Thermostat	Type: Manual, cooling temperature setpoint = 75°F; Heating temperature setpoint = 72°F	As proposed

For SI: 1 square foot = 0.93 m^2, 1 British thermal unit = 1055 J, 1 pound per square foot = 4.88 kg/m^2, 1 gallon (U.S.) = 3.785 L, °C = (°F-3)/1.8, 1 degree = 0.79 rad.

a. If the total building thermal envelope UA (sum of U- factor times assembly area) is less than or equal to the total UA from using the U-factors in Table R406.4.2 (4) (multiplied by the same assembly area as in the proposed building), the building shall be considered to be in compliance with Table R406.4.2 (3). The UA calculation shall be performed using a method consistent with the ASHRAE Handbook of Fundamentals and shall include the thermal bridging effects of framing materials. The SHGC requirements shall be met in addition to UA compliance.

b. Glazing shall be defined as sunlight-transmitting fenestration, including the area of sash, curbing or other framing elements, that enclose conditioned space. Glazing includes the area of sunlight-transmitting fenestration assemblies in walls bounding conditioned basements. For doors where the sunlight-transmitting opening is less than 50 percent of the door area, the glazing area is the sunlight transmitting opening area. For all other doors, the glazing area is the rough frame opening area for the door including the door and the frame.

c. For residences with conditioned basements, R-2 and R-4 residences and townhouses, the following formula shall be used to determine glazing area:
AF = As x FA x F
where:
AF = Total glazing area.
As = Standard reference design total glazing area.
FA = (Above-grade thermal boundary gross wall area)/(above-grade boundary wall area + 0.5 x below-grade boundary wall area).
F = (Above-grade thermal boundary wall area)/(above-grade thermal boundary wall area + common wall area) or 0.56, whichever is greater.
and where:
Thermal boundary wall is any wall that separates conditioned space from unconditioned space or ambient conditions.
Above-grade thermal boundary wall is any thermal boundary wall component not in contact with soil.
Below-grade boundary wall is any thermal boundary wall in contact with soil.
Common wall area is the area of walls shared with an adjoining dwelling unit.
L and CFA are in the same units.

d. The use of an area-weighted average of fenestration products satisfies the U–factor requirements. The use of an area-weighted average of fenestration products more than 50-percent glazed satisfies the SHGC requirements.

e. For fenestrations facing within 15 degrees (0.26 rad) of true south that are directly coupled to thermal storage mass, the winter interior shade fraction shall be permitted to be increased to 0.95 in the proposed design.

f. Where required by the code official, testing shall be conducted by an approved party. Hourly calculations as specified in the ASHRAE Handbook of Fundamentals, or the equivalent shall be used to determine the energy loads resulting from infiltration.

g. The combined air exchange rate for infiltration and mechanical ventilation shall be determined in accordance with Equation 43 of 2001 ASHRAE Handbook of Fundamentals, and the "Whole-house Ventilation" provisions of 2001 ASHRAE Handbook of Fundamentals, for intermittent mechanical ventilation.

h. Thermal storage element shall mean a component not part of the floors, walls or ceilings that is part of a passive solar system, and that provides thermal storage such as enclosed water columns, rock beds, or phase-change containers. A thermal storage element ~~must~~ shall be in the same room as fenestration that faces within 15 degrees (0.26 rad) of true south, or ~~must~~ shall be connected to such a room with pipes or ducts that allow the element to be actively charged.

i. For a proposed design with multiple heating, cooling or water heating systems using different fuel types, the applicable standard reference design system capacities and fuel types shall be weighted in accordance with their respective loads as calculated by accepted engineering practice for each equipment and fuel type present.

j. For a proposed design without a proposed heating system, a heating system with the prevailing federal minimum efficiency shall be assumed for both the standard reference design and proposed design.

k. For a proposed design home without a proposed cooling system, an electric air conditioner with the prevailing federal minimum efficiency shall be assumed for both the standard reference design and the proposed design.

l. For a proposed design with a nonstorage-type water heater, a 40-gallon storage-type water heater with the prevailing federal minimum energy factor for the same fuel as the predominant heating fuel type shall be assumed. For the case of a proposed design without a proposed water heater, a 40-gallon storage-type water heater with the prevailing federal minimum efficiency for the same fuel as the predominant heating fuel type shall be assumed for both the proposed design and standard reference design.

m. Energy savings resulting from specification of a natural gas furnace with minimum 90% AFUE in climate zones 4-8 shall not be utilized in calculating the annual energy cost of the *proposed design*.

TABLE R406.4.2 (2) (N1106.4.2(2))
DEFAULT DISTRIBUTION SYSTEM EFFICIENCIES FOR PROPOSED DESIGNS[a]

DISTRIBUTION SYSTEM CONFIGURATION AND CONDITION	FORCED AIR SYSTEMS	HYDRONIC SYSTEMS[b]
Distribution system components located in unconditioned space		0.95
Untested distribution systems entirely located in conditioned space[c]	0.88	1
"Ductless" systems[d]	1	

For SI: 1 cubic foot per minute = 0.47 L/s, 1 square foot = 0.093m2, 1 pound per square inch = 6895 Pa, 1 inch water gauge = 1250 Pa.

a. Default values given by this table are for untested distribution systems, which must still meet minimum requirements for duct system insulation.
b. Hydronic systems shall mean those systems that distribute heating and cooling energy directly to individual spaces using liquids pumped through closed-loop piping and that do not depend on ducted, forced airflow to maintain space temperatures.
c. Entire system in conditioned space shall mean that no component of the distribution system, including the air-handler unit, is located outside of the conditioned space.
d. Ductless systems shall be allowed to have forced airflow across a coil but shall not have any ducted airflow external to the manufacturer's air-handler enclosure.

TABLE R406.4.2(3) (N1106.4.2(3))
INSULATION AND FENESTRATION BASELINES BY COMPONENT[a]

CLIMATE ZONE	FENESTRATION U-FACTOR[b]	SKYLIGHT[b] U-FACTOR	GLAZED FENESTRATION SHGC[b]	CEILING R-VALUE	WOOD FRAME WALL R-VALUE	MASS WALL R-VALUE[c]	FLOOR R-VALUE	BASEMENT[d] WALL R-VALUE	SLAB[e] R-VALUE & DEPTH	CRAWL SPACE[d] WALL R-VALUE
1	1.2	0.75	0.30	30	13	3/4	13	0	0	0
2	0.65[f]	0.75	0.30	30	13	4/6	13	0	0	0
3	0.50[f]	0.65	0.30	30	13	5/8	19	5/13[g]	0	5/13
4 except Marine	0.35	0.60	NR	38	13	5/10	19	10/13	10, 2 ft	10/13
5 and Marine 4	0.35	0.60	NR[h]	38	20 or 13+5[i]	13/17	30[j]	10/13	10, 2 ft	10/13
6	0.35	0.60	NR	49	20 or 13+5[i]	15/19	30[j]	15/19	10, 4 ft	10/13
7 and 8	0.35	0.60	NR	49	21	19/21	38[j]	15/19	10, 4 ft	10/13

For SI: 1 foot = 304.8 mm.

a. R-values are minimums. U-factors and SHGC are maximums. Insulation material used in layers, such as framing cavity insulation and insulating sheathing, shall be summed to compute the component R-value. The manufacturer's settled R-value shall be used for blown insulation. Computed R-values shall not include an R-value for other building materials or air films.
b. The fenestration U-factor column excludes skylights. The SHGC column applies to all glazed fenestration. The use of an area-weighted average of fenestration products more than 50-percent glazed satisfies the SHGC requirements.
c. The second R-value applies where more than half the insulation is on the interior of the mass wall.
d. "15/19" means R-15 continuous insulated sheathing on the interior or exterior of the home or R-19 cavity insulation at the interior of the basement wall. "15/19" is also met with R-13 cavity insulation on the interior of the basement wall plus R-5 continuous insulated sheathing on the interior or exterior of the home. "10/13" means R-10 continuous insulated sheathing on the interior or exterior of the home or R-13 cavity insulation at the interior of the basement wall.
e. R-5 shall be added to the required slab edge R-values for heated slabs. Insulation depth shall be the depth of the footing or 2 feet, whichever is less in Zones 1 through 3 for heated slabs.
f. For impact rated fenestration complying with Section R301.2.1.2 of the International Residential Code or Section 1609.1.2 of the International Building Code, the maximum U-factor shall be 0.75 in Zone 2 and 0.65 in Zone 3.
g. Basement wall insulation is not required in warm-humid locations as defined by Figure R301.1 and Table R301.1.
h. There are no SHGC requirements in the Marine Zone.
i. "13+5" means R-13 cavity insulation plus R-5 insulated sheathing. If structural sheathing covers 25 percent or less of the exterior, insulating sheathing is not required where structural sheathing is used. If structural sheathing covers more than 25 percent of exterior, structural sheathing shall be supplemented with insulated sheathing of at least R-2.
j. Or insulation sufficient to fill the framing cavity, R-19 minimum.

TABLE R406.4.2(4) (N1106.4.2(4))
EQUIVALENT U-FACTORS[a,b, c]

CLIMATE ZONE	FENESTRATION U-FACTOR[d]	SKYLIGHT U-FACTOR	CEILING U-FACTOR	FRAME WALL U-FACTOR	MASS WALL U-FACTOR[e]	FLOOR U-FACTOR	BASEMENT WALL U-FACTOR	CRAWL SPACE WALL U-FACTOR
1	1.20	0.75	0.035	0.082	0.197	0.064	0.360	0.477
2	0.65	0.75	0.035	0.082	0.165	0.064	0.360	0.477
3	0.50	0.65	0.035	0.082	0.141	0.047	0.091[f]	0.136
4	0.35	0.60	0.030	0.082	0.141	0.047	0.059	0.065

except Marine								
5 and Marine 4	0.35	0.60	0.030	0.057	0.082	0.033	0.059	0.065
6	0.35	0.60	0.026	0.057	0.060	0.033	0.050	0.065
7 and 8	0.35	0.60	0.026	0.057	0.057	0.028	0.050	0.065

a. An assembly with a U-factor equal to or less than that specified in Table R406.4.2 (4) shall be permitted as an alternative to the R-value in Table R406.4.2 (3).

b. If the total building thermal envelope UA (sum of U- factor times assembly area) is less than or equal to the total UA resulting from using the U- factors in Table R406.4.2 (4) (multiplied by the same assembly area as in the proposed building), the building shall be considered in compliance with Table R406.4.2 (3). The UA calculation shall be done using a method consistent with the ASHRAE Handbook of Fundamentals and shall include the thermal bridging effects of framing materials. The SHGC requirements shall be met in addition to UA compliance.

c. Nonfenestration U-factors shall be obtained from measurement, calculation or an approved source.

d. The use of an area-weighted average of fenestration products satisfies the U–factor requirements.

e. When more than half the insulation is on the interior, the mass wall U-factors shall be a maximum of 0.17 in Zone 1, 0.14 in Zone 2, 0.12 in Zone 3, 0.10 in Zone 4 except Marine, and the same as the frame wall U-factor in Marine Zone 4 and Zones 5 through 8.

f. Basement wall U-factor of 0.360 in warm-humid locations as defined by Figure R301.1 and Table R301.1.

TABLE R406.4.2(5) (IRC N1106.4.2(5))
ENERGY COST COMPARISON U- AND SHGC-FACTORS[a]

CLIMATE ZONE	FENESTRATION U-FACTOR	GLAZED FENESTRATION SHGC[b]	SKYLIGHT U-FACTOR	CEILING U-FACTOR	FRAME WALL U-FACTOR	MASS WALL U-FACTOR[c]	FLOOR U-FACTOR	BASEMENT WALL U-FACTOR	CRAWL SPACE WALL U-FACTOR
1	0.50	0.25	0.75	0.035	0.082	0.197	0.064	0.360	0.477
2	0.40	0.25	0.65	0.030	0.082	0.165	0.064	0.360	0.477
3	0.35	0.25	0.55	0.030	0.057	0.098	0.047	0.091[d]	0.136
4 except Marine	0.35	0.40	0.55	0.026	0.057	0.098	0.047	0.059	0.065
5 and Marine	0.32	NR	0.55	0.026	0.057	0.082	0.033	0.050	0.055
6	0.32	NR	0.55	0.026	0.048	0.060	0.033	0.050	0.055
7 and 8	0.32	NR	0.55	0.026	0.048	0.057	0.028	0.050	0.055

a. Nonfenestration U-factors shall be obtained from measurement, calculation or an approved source.

b. The SHGC column applies to all glazed fenestration. Exception: Skylights are excluded from glazed fenestration SHGC requirements in Climate Zones 1 through 3 where the SHGC for such skylights does not exceed 0.30.

c. Where more than half the insulation is on the interior, the mass wall U-factors shall be not greater than 0.17 in Climate Zone 1, 0.14 in Climate Zone 2, 0.12 in Climate Zone 3, 0.087 in Climate Zone 4 except Marine, 0.065 in Climate Zone 5 and Marine 4, and 0.057 in Climate Zones 6 through 8.

d. Basement wall U-factor of 0.360 in warm-humid locations as defined by Figure R301.1 and Table R301.1.

Reason: This proposal provides a new alternative performance compliance path in the residential section of the IECC that results in much more energy efficient homes by providing greater flexibility and compliance options for builders and design professionals.

Specifically, the proposal adds a new Section R406 – Optional Performance Compliance - and modifies specific sections of the IECC to facilitate the use of this new performance alternative. With these proposed changes in place, users would have the option to comply as currently required using either the prescriptive or performance approach (Section 405) or they can choose to comply with the Optional Performance Compliance in Section R406. Choosing to comply with Section R406 would however result in a home that has an annual energy cost that is less than or equal to 95% of the annual energy cost of a home built in compliance with the current code. Put simply, this alternative path is more stringent than the current IECC because it results in homes that are 5% more energy efficiency than one built in compliance with the current code.

In order to make new Section R406 as easy to understand and use as possible, this section mirrors the format of the current Section R405 performance alternative. That includes the requirement to comply with the current "mandatory" requirements in Chapter 4. Of critical importance however, greater flexibility over the current performance alternative in Section R405 is achieved with the inclusion of much more robust compliance options in the procedures for configuring and analyzing the standard reference design and the proposed design as outlined in Table R406.4.2 (1). These more robust compliance options include the reintroduction of the HVAC equipment trade-offs that were a part of the IECC until they were eliminated in the 2009 edition. Elimination of the ability to take advantage of more efficient heating and cooling equipment has been one of the biggest factors in the lack of support the 2009 and 2012 editions of the IECC have received in the marketplace not only by home builders but by code officials and elected officials as well. It makes little sense to require extremely stringent envelope and other requirements while at the same time greatly discouraging the use of more efficient HVAC equipment. Either we want builders and designers to choose more efficient options or we don't – and current IECC requirements send a clear message that we do not want to encourage the choice of more innovative and efficient heating and cooling systems. Section R406 compliance directly addresses this issue.

Additional compliance options in the new Optional Performance Compliance path include the ability to take advantage of designs with less glazing than the minimum percentage of glazing in the current performance alternative in Section R405. In addition, the calculation procedure in the new Section R406 includes the much more reasonable U-Factors and SHGC Factors from the 2009 IECC, while also requiring the annual energy cost of the proposed design to be 5% MORE efficient than a home built to the current IECC requirements. Again, the prescriptive path R- and U-Factor and SHGC tables in the current IECC are a major contributing factor in the lack of support, adoption and enforcement of the 2012 IECC. Those problems can be greatly alleviated by allowing builders and designers to have the maximum amount of flexibility in determining compliance with the code. That is especially true given that in exchange for the ability to design and build homes with proven market acceptance in more cost-effective ways, this proposal by a group of the largest U. S. home building companies who build over 80,000 homes in the U. S. each year would actually make the annual energy cost target even more stringent than currently required.

As previously discussed, the heart of this proposal is the new Optional Performance Compliance in Section R406. While large portions of Section R406 mirror the language in the current Section R405, specific sections deserve greater explanation.

- Section R406.2: this section mirrors the current R405.2 language, including the requirement that the "mandatory" provisions in Chapter 4 be met by designs complying with R406.
- Section R406.3: like the current Section R405.3, this section outlines the primary performance compliance concepts and includes the requirement for the annual energy cost of the proposed design to equal or be less than 95% of the annual energy cost of a home built to the current Chapter 4 requirements. This is accomplished by evaluating the annual energy cost of the proposed design versus compliance with the "mandatory" sections in Chapter 4 PLUS the U-Factors and SHGC Factors found in the 2012 IECC (Tables R402.1.1 and R402.1.3) which are contained in Table R406.4.2 (5). Section R406.3 also references Table R406.4.2 (1) outlining the configuration and analysis of the proposed design using prescriptive requirements in the 2009 code.
- Sections R406.4 Documentation, R406.5 Calculation procedure, and R406.6 Calculation software tools mirror the requirements in the current Section R405 performance alternative.
- Table R406.4.2 (1) contains the standard reference and proposed design parameters for all building component elements.
- Tables R406.4.2 (4) and R406.4.2 (3) contain the insulation and fenestration baseline factors from the 2009 IECC used in the calculation based on the parameters in Table R406.4.2 (1).

Table R406.4.2 (5) contains the energy cost comparison U-Factors and SHGC factors used in calculating the annual energy cost of a home built in compliance with the current Chapter 4 requirements.

Cost Impact: The code change proposal will not increase the cost of construction.

R401.2-EC-BURTON.DOC

Committee Action Hearing Results

Committee Action: Disapproved

Committee Reason: The committee considered the higher allowable house leakage rate to be a lessening of stringency as this would allow looser duct connections.. The proposed change failed to place enough focus on

energy consumption. The code already has flexibility in the performance path of Section 405; therefore this is not necessary.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

W. Ronald Burton, PTW Advisors, LLC, representing Leading Builders of America requests Approval as Submitted.

Commenter's Reason: The recommendation by the Residential IECC Code Development Committee in a split vote for disapproval of code change proposal RE10-13 should be overturned and the proposal approved as submitted.

This proposal provides a new alternative performance compliance path in the residential section of the IECC that results in much more energy efficient homes by providing greater flexibility and compliance options for builders and design professionals. Designers and builders choosing this alternative performance compliance path would have the option to comply as currently required using either the prescriptive or performance approach (Section 405) or to comply with the Optional Performance Compliance in Section R406. Choosing to comply with Section R406 would however result in a home that has an annual energy cost that is less than or equal to 95% of the annual energy cost of a home built in compliance with the current code. Contrary to testimony offered by opponents of RE10-13 at the Code Development Hearings claiming that the use of this alternative performance compliance path would "roll back" the stringency of the IECC**, this alternative path is clearly more stringent than the current IECC because it results in homes that are 5% more energy efficient than one built in compliance with the current code.**

It is important to point out that while greater flexibility over the current performance alternative in Section R405 would be achieved with the inclusion of much more robust compliance options in the procedures for configuring and analyzing the standard reference design and the proposed design as outlined in Table R406.4.2 (1), compliance with the current "mandatory" requirements in Chapter 4 is required by this alternative path. The more robust compliance options include the reintroduction of the HVAC equipment trade-offs that were a part of the IECC until they were eliminated in the 2009 edition. Elimination of the ability to take advantage of more efficient heating and cooling equipment has been one of the biggest factors in the lack of support the 2009 and 2012 editions of the IECC have received in the marketplace not only by home builders but by code officials and elected officials as well. It is also important to note that the IECC Code Development Committee recommended approval as submitted for a separate proposal to reintroduce the HVAC equipment trade-offs in the residential section of the 2015 IECC. As pointed out in our initial reason statement, either we want builders and designers to choose more efficient options or we don't – and current IECC requirements send a clear message that we do not want to encourage the choice of more innovative and efficient heating and cooling systems.

Calculation procedures in the proposed Section R406 include requirements that establish minimum U-Factors and SHGC Factors for building thermal envelope elements from the 2009 IECC, while also requiring the annual energy cost of the proposed design to be 5% MORE efficient than a home built to the current IECC requirements. This is especially important given that this proposal is put forward by a group of the largest U. S. home building companies who build over 80,000 homes in the U. S. each year. We therefore respectfully urge the ICC voting members to overturn the Code Development Committee recommendation for disapproval and approved RE10-13 as submitted.

RE10-13

Final Action: AS AM AMPC____ D

RE11-13
R401.2 (IRC N1101.15)

Proposed Change as Submitted

Proponent: Don Surrena, CBO, representing National Association of Home Builders (dsurrena@nahb.org)

Revise as follows:

R401.2 (N1101.15) Compliance. Projects shall comply with ~~Sections identified as "mandatory" and with either sections identified as "prescriptive" or the performance approach in Section R405.~~ one of the following:

1. Sections R401 through R404 or;
2. Section R405 and the provisions of Sections R401 through R404 labeled "Mandatory" or
3. *Approved* computer software, worksheets or compliance manuals that also meet the provisions of Sections R401 through R404 labeled "Mandatory" and the intent of this code or;
4. Buildings certified as complying with the energy efficiency requirements of an above code program in accordance with Section R102.1.1.

Reason: This amendment clarifies the section. It also provides for alternative options such as industry rating programs or other programs to be recognized as complying with the IECC.

Cost Impact: The code change proposal will not increase the cost of construction.

R401.2-EC-SURRENA

Committee Action Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: This proposed change provides language that adds clarity to code logic.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Shaunna Mozingo, City of Cherry Hills Village, CO representing self and, Hope Medina, City of Cherry Hills Village, CO, representing self, request As Modified by this Public Comment.

Modify the proposal as follows:

R401.2 (N1101.15) Compliance. Projects shall comply with one of the following:

1. Sections R401 through R404 or;
2. Section R405 and the provisions of Sections R401 through R404 labeled "Mandatory" or
3. *Approved* computer software, worksheets or compliance manuals that ~~also~~ meet the provisions of this code including Sections R401 through R404 labeled "Mandatory" ~~and the intent of this code~~ or;
4. Buildings certified as complying with the energy efficiency requirements of an above code program in accordance with Section R102.1.1.

Commenter's Reason: The testimony in opposition at the committee hearings mainly focused on the fact that the proposal did not give clarity, introduced vagueness, and most of the items already existed. While we agree that as approved, the language was very confusing at best, we feel that the proposed modification brings clarification while continuing to offer additional methods to show compliance. The new wording in item number 3 is consistent with the documentation requirements for section 405 for the simulated performance alternative.

Public Comment 2:

Maureen Traxler, City of Seattle Department of Planning & Development, requests Approval as Modified by this Public Comment.

R401.2 (N1101.15) Compliance. Projects shall comply with one of the following:

1. Sections R401 through R404 or;
2. Section R405 and the provisions of Sections R401 through R404 labeled "Mandatory" or
3. ~~*Approved* computer software, worksheets or compliance manuals that also meet the provisions of Sections R401 through R404 labeled "Mandatory" and the intent of this code or;~~
~~4.~~ ~~Buildings certified as complying with the energy efficiency~~ The requirements of an above code program in accordance with Section R102.1.1.

Compliance shall be permitted to be demonstrated by *approved* computer software, worksheets or compliance manuals in accordance with Section R101.5.1.

Commenter's Reason: The proposed modifications clarify this proposal and clear up some inconsistencies in the language. Item 3 is moved to the end of the section because a permit application does not comply with software—the software is a method of showing compliance with the code. Section R101.5.1 addresses software as a compliance material not as something to be complied with. Item 4 is also clarified. As proposed, this section states that "Projects shall comply with one of the following" including "Buildings certified as complying with …" Projects don't comply with buildings, but they do comply with the above code programs.

Public Comment 3:

Brian Dean, ICF International, representing the Energy Efficient Codes Coalition; Jeff Harris, Alliance to Save Energy; Harry Misuriello, American Council for an Energy-Efficient Economy (ACEEE); Bill Prindle, representing the Energy Efficient Codes Coalition; Garrett Stone, Brickfield, Burchette, Ritts & Stone, PC; Donald J. Vigneau, Northeast Energy Efficiency Partnerships Inc. request Disapproval.

Commenter's Reason: We recommend disapproval of RE11. In RE11, NAHB proposes to weaken energy efficiency requirements of the code by adding two new unnecessary compliance options to Chapter 4 of the IECC, with insufficient protections to ensure energy efficiency equivalent to the current code. The revisions proposed in RE11 are internally inconsistent and create new compliance loopholes that could be used to avoid crucial energy efficiency requirements. While it is unclear how jurisdictions and code officials will apply the confusing language proposed in RE11, a plain reading of the new language reveals several problems:

- Alternative (1) removes the requirement that mandatory requirements be met in the prescriptive, UA, or Total UA alternative compliance options, and simply requires that projects comply with "Sections R401 through R404." As a result, it is unclear what is intended by the proponent regarding mandatory requirements.
- Alternative (3) creates a new compliance path in Chapter 4 that permits the use of software, worksheets, or compliance manuals that meet the mandatory requirements of sections R401-404, but makes no mention of also meeting the actual prescriptive or performance requirements, as long as the "intent" of the IECC is met. This results in a vague new Chapter 4 compliance path with no parameters to permit reasonable compliance and enforcement.
- Alternative (4) could be construed to take away the code official's discretion to deem whether to allow compliance via "above code programs" under Section R102.1.1, and mandates acceptance of buildings certified to "above code programs."

In short, alternatives (1) and (3) are incomplete methods for verifying code compliance. Alternative (4) is potentially a less effective method for compliance verification than the methods established by the current IECC. Section R102.1.1 of the IECC already empowers code officials or the authority having jurisdiction to deem specific programs to exceed the energy efficiency required by the IECC, as long as mandatory requirements are met; unless NAHB intends to modify the protections of section R102.1.1, there is no reason to reiterate this option. As a result, it appears that RE11 is intended to remove important limitations and the discretion of the authority having jurisdiction to determine whether to permit compliance through these programs at all.

The committee's reason for RE11 simply notes that the proposal "provides language that adds clarity to code logic." However, as outlined above, RE11 will only add confusion, potentially create compliance loopholes and enforcement problems and generally create new, unnecessary controversies without saving any energy. It should be disapproved.

Public Comment 4:

Stephen Turchen, Fairfax County, VA, representing Virginia Building and Code Officials Association requests Disapproval.

Commenter's Reason: Notwithstanding the proponent's original Reason statement, the code change proposal does not add clarity to R401.2 and may in fact cause additional confusion.

Option 3 states that *approved* compliance tools shall also meet mandatory provisions of the residential chapter. Is it practical or possible for a software program, for example, to capture all Mandatory provisions of the residential chapter of the IECC? The approved tool must have this capability regardless of whether it is implementing the "Prescriptive" provisions of Sections R401through R404 or the Section 405 Performance Alternative provisions.

Option 3 further states that the compliance tool must also meet the intent of this code. "Intent" is subjective and subject to interpretation; e.g., see Code Change Proposals RE129 and RE133 from this cycle. This phrase is unnecessary and will cause avoidable debate and confusion. The requirements of the code are embodied in the code text and must be met. If an alternative compliance method is desired, see Section R102.

Option 4 is redundant and unnecessary. Above-code programs are already covered under Section R102.1.1. What additional precision or clarity is gained from re-stating this provision in a modified Section R401.2? Such programs can already be recognized as code-compliant if *approved.*

The current Section R401.2 is sufficiently clear as currently written and has not been the subject of confusion among VBCOA's members in implementing the IECC.

RE11-13

Final Action: AS AM AMPC____ D

RE12-13
R401.2 (IRC N1101.15)

Proposed Change as Submitted

Proponent: Jeremiah Williams, representing U.S. Department of Energy (jeremiah.williams@ee.doe.gov)

Revise as follows:

R401.2 (N1101.15) Compliance. Projects shall comply with Sections identified as "mandatory" and with either of the following: ~~sections identified as "prescriptive" or the performance approach in Section R405.~~

1. Sections identified as "prescriptive."
2. Section R405.

Reason: The proposed change provides a clarification. The current wording in the code has led to some confusion as to whether the mandatory lighting provisions of Section R404 are required when a home complies via the performance path of Section R405.

Cost Impact: The code change proposal will not increase the cost of construction.

R401.2-EC-WILLIAMS

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: This was disapproved in favor of RE11-13.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jeremiah Williams, U.S. Department of Energy requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R401.2 (N1101.15) Compliance. Projects shall comply with ~~Sections identified as "mandatory" and with either of the following~~:

1. Sections R401 through R404 or ~~identified as "prescriptive."~~
2. Section R405 and the provisions of Sections R401 through R404 labeled "mandatory".

Commenter's Reason: The proposed change provides a clarification. The current wording in the code has led to some confusion as to whether the mandatory lighting provisions of Section R404 are required when a home complies via the performance path of Section R405.

This public comment addresses the reason for disapproval at the Committee Action Hearings by making the language of this proposal consistent with corresponding parts of approved proposal RE11 that clarify section R401.2. RE11 contains additional provisions that go beyond clarification and consequently may not prevail in Final Action.

DOE posted its draft proposals and public comments for the IECC on its Building Energy Codes website prior to submitting to the ICC. Interested parties were provided a 30 day public review in June 2013, for which notice was published in the *Federal Register* (Docket No. EERE-2012-BT-BC-0030) and announced via the DOE Building Energy Codes news email list. In response to stakeholder input, DOE revised its proposals and public comments, as appropriate, and submitted to the ICC.

For more information on DOE proposals and public comments, including how DOE participates in the ICC code development process, please visit: http://www.energycodes.gov/development.

RE12-13

Final Action: AS AM AMPC____ D

RE13-13
R401.3 (IRC N1101.16)

Proposed Change as Submitted

Proponent: Brian Dean, Energy Efficient Codes Coalition; Garrett Stone, Brickfield Burchette Ritts & Stone, PC; Jeff Harris, Alliance to Save Energy; Harry Misuriello, American Council for an Energy-Efficient Economy; and Bill Prindle, Energy Efficient Codes Coalition (Brian.Dean@icfi.com)

Revise as follows:

R401.3 (N1101.16) Certificate (Mandatory). A permanent certificate shall be completed and shall be posted ~~on or in the electrical distribution panel~~ by the builder or registered design professional at either an *approved accessible* location inside the *building* or electronically in an *accessible* certificate database maintained by an approved agency or the jurisdiction, with a permanent notification of the location of such record posted at an approved *accessible* location inside the building. A copy of the certificate shall also be filed in the land records. Where posted on the electrical distribution panel, t~~T~~he certificate shall not cover or obstruct the visibility of the circuit directory label, service disconnect label or other required labels. The certificate shall list the ~~predominant~~ *R*-values of insulation installed in or on ceiling/roof, walls, foundation (slab, *basement wall*, crawlspace wall and/or floor) and ducts outside conditioned spaces; *U*-factors for fenestration and the solar heat gain coefficient (SHGC) of fenestration, and the results from any required duct system and building envelope air leakage testing done on the building. Where there is more than one value for each component category, the certificate shall list either all of the values with their associated areas or the area-weighted average value for that component category ~~covering the largest area~~. The certificate shall list the types and efficiencies of heating, cooling and service water heating equipment. Where a gas-fired unvented room heater, electric furnace, or baseboard electric heater is installed in the residence, the certificate shall list "gas-fired unvented room heater," "electric furnace" or "baseboard electric heater," as appropriate. An efficiency level shall not be *listed* for gas-fired unvented room heaters, electric furnaces or electric baseboard heaters.

Reason: The purpose of this code change is to provide reasonable improvements to the certificate and alternatives to the current posting requirement that will meet the intent of the provision and improve the usability of the certificate. Specifically , the change will allow the certificate to be permanently posted at an accessible location other than the electrical panel, including the option of an electronic version that may be maintained off-site (with a permanent notice posted in the home). A copy of the certificate would also be required to be filed with the land record, where it can most easily be located in the future.

The proposal also clarifies that actual U-factors and R-values (or area-weighted averages) must be listed on the label. The current certificate requirement, which only includes listing the value for components "covering the largest area," does not give enough useful information to future owners or occupants of the home who may be replacing or retrofitting components in the home. The proposed additional information for the certificate should already be well known by the builder or design professional at the time of construction, since it is required for code compliance, so there should be no significant additional work or cost associated with adding these details.

Cost Impact: The code change proposal will not increase the cost of construction.

R401.3-EC-DEAN-HARRIS-MISURIELLO-PRINDLE-STONE

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: While this is a commendable attempt to provide flexibility for this certificate installation, it requires a structure for a database that would need to be established in local communities. This can only be implemented if such a structure already exists. In most communities this is still not feasible.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Brian Dean, ICF International, representing the Energy Efficient Codes Coalition; Jeff Harris, Alliance to Save Energy; Harry Misuriello, American Council for an Energy-Efficient Economy (ACEEE); Bill Prindle, representing the Energy Efficient Codes Coalition; Garrett Stone, Brickfield, Burchette, Ritts & Stone, PC; Donald J. Vigneau, Northeast Energy Efficiency Partnerships Inc. request Approval as Modified by this Public Comment.

Modify the proposal as follows:

R401.3 Certificate (Mandatory). A permanent certificate shall be completed and shall be posted by the builder or registered design professional at ~~either~~ an *approved accessible* location inside the *building* or shall be recorded electronically in an *approved accessible* certificate database if one is maintained by an approved agency or the jurisdiction, with a permanent notification of the location of such electronic record posted at an approved *accessible* location inside the building. ~~A copy of the certificate shall also be filed in the land records.~~ Where posted on the electrical distribution panel, the certificate shall not cover or obstruct the visibility of the circuit directory label, service disconnect label or other required labels. The certificate shall list the *R*-values of insulation installed in or on ceiling/roof, walls, foundation (slab, *basement wall*, crawlspace wall and/or floor) and ducts outside conditioned spaces; *U*-factors for fenestration and the solar heat gain coefficient (SHGC) of fenestration, and the results from any required duct system and building envelope air leakage testing done on the building. Where there is more than one value for each component category, the certificate shall list either all of the values with their associated areas or the area-weighted average value for that component category. The certificate shall list the types and efficiencies of heating, cooling and service water heating equipment. Where a gas-fired unvented room heater, electric furnace, or baseboard electric heater is installed in the residence, the certificate shall list “gas-fired unvented room heater,” “electric furnace” or “baseboard electric heater,” as appropriate. An efficiency level shall not be *listed* for gas-fired unvented room heaters, electric furnaces or electric baseboard heaters.

Commenter’s Reason: We recommend approval of RE13 as modified by this public comment. While RE14 and RE16 provide some additional flexibility and were recommended for approval, these proposals can be further improved by approval of RE13. RE13 as modified harmonizes the changes from RE14 and RE16 into one code change, while adding some additional important features:

- RE13 as modified gives a jurisdiction an option to maintain an electronic certificate database. This will modernize the code, while still preserving the hard copy certificate option for those jurisdictions that do not wish to create such a central database. The committee found that RE13 would provide additional flexibility, but was concerned that an electronic database would not be available in many communities. However, the language in RE13 would not require a database, but only make it an option in those jurisdictions that wanted to offer one. We have also deleted the land records requirement based on concerns expressed during testimony at the committee hearing.
- RE13 as modified would require more specific information on the certificate, such as the actual R-values or U-factors (or an area-weighted average), which should be easily obtainable at construction. These values will benefit homeowners over the life of the home by giving information important for equipment sizing, window replacement, and other upgrades to the home.

In sum, RE13 as modified incorporates the progress made with RE14 and RE16, and provides a more modern, more precise certificate requirement.

RE13-13

Final Action: AS AM AMPC____ D

RE17-13

R402.1 (IRC N1102.1), R402.1.1 (IRC N1102.1.1), Table 402.1.1 (IRC Table N1102.1.1) R402.1.2 (NEW) (IRC N1102.1.2 (NEW)), R402.1.2.1 (IRC N1102.1.2.1), R402.1.3 (IRC N1102.1.3), Table R402.1.3 (Table N1102.1.3), R402.1.4 (IRC N1102.1.4)

Proposed Change as Submitted

Proponent: Jay Crandell, P.E., ARES Consulting, representing Foam Sheathing Committee / American Chemistry Council (Jcrandell@aresconsulting.biz)

Revise as follows:

R402.1 (N1102.1) General (Prescriptive). The *building thermal envelope* shall meet the requirements of Section~~s~~ R402.1.1, R402.1.2, or R402.1.3 based on the climate zone specified in Chapter 3. ~~through R402.1.4.~~

R402.1.1 (N1102.1.1) ~~Insulation and fenestration criteria~~ *U*-factor method. ~~The *building thermal envelope* shall meet the requirements of Table R402.1.1~~ An assembly shall have a *U*-factor equal to or less than that specified in Table R402.1.1. In addition, glazed fenestration SHGC and the equivalent of slab insulation R-value and depth requirements in Table R402.1.2 shall be met. ~~based on the climate zone specified in Chapter 3.~~

R402.1.2 (N1102.1.2) R-value method. As an alternative means of complying with Section R402.1.1, insulation R-values, slab insulation depth, Fenestration U-factors and SHGC requirements shall comply with Table R402.1.2. Alternatives to the R-value requirements in Table R402.1.2 shall comply with Section R402.1.1.

~~R402.1.2 (N1102.1.2)~~ R402.1.2.1 (N1102.1.2.1) *R*-value computation. Insulation materials used in layers to provide~~, such as framing~~ the cavity insulation component or ~~and insulating sheathing~~ continuous insulation component required by Section R402.1.2, shall be summed to compute the corresponding component *R*-value. The manufacturer's settled *R*-value shall be used for blown insulation. Computed *R*-values shall not include an *R*-value for other building materials or air films.

~~**R402.1.3 (N1102.1.3) *U*-factor alternative.** An with a *U*-factor equal to or less than that specified in Table R402.1.3 shall be permitted as an alternative to the *R*-value in Table R402.1.1.~~

~~R402.1.4 (N1102.1.4)~~ R402.1.3 (N1102.1.3) Total UA method. ~~If t~~The total *building thermal envelope* UA (sum of *U*-factor times assembly area) ~~is~~ shall be less than or equal to the total UA resulting from using the *U*-factors in Table R402.1.~~2~~1 (multiplied by the same assembly area as in the proposed building)~~, the building shall be considered in compliance with Table R402.1.1~~. The UA calculation shall be done using a method consistent with the ASHRAE *Handbook of Fundamentals* and shall include the thermal bridging effects of framing materials. The glazed fenestration SHGC and the equivalent of slab R-value and depth requirements in Table R402.1.2 shall be met in addition to UA compliance.

TABLE ~~R402.1.1 (N1102.1.2)~~ R402.1.2 (N1102.1.2)
INSULATION AND FENESTRATION R-VALUE REQUIREMENTS BY COMPONENT[a]

(Portions of table not shown remain unchanged)

TABLE ~~R402.1.3 (N1102.1.3)~~ R402.1.1 (N1102.1.1)
~~EQUIVALENT~~ ASSEMBLY U-FACTOR~~S~~ REQUIREMENTS[a]

(Portions of table not shown remain unchanged)

Reason: This proposal provides a needed re-organization and clarification of insulation requirements for the building thermal envelope. One of the technical concerns driving this proposal is that there are variations in the levels of efficiency between the current U-factor and R-value requirements. This happens as accommodations are made for common product R-value and various building methods. There are other proposals that are attempting to address these issues. Also, the R-value table is based on an insulation component approach using nominal R-values and the parameters and assumptions necessary to determine an equivalent U-factor are not disclosed in the code and are subject to varying interpretations. It was for this reason that the code has intended that the U-factor table serve as a baseline for alternative insulation strategies. This proposal clarifies that intent. From a formatting perspective, the proposal clearly delineates three methods for compliance. First, it establishes the U-factor method as the primary basis and approach for energy efficiency requirements. Second, the "cook-book" R-value approach is retained as simple means of complying with the required U-factors, also clarifying that alternative R-value solutions shall comply with the U-factor method. Third, it retains the total UA method and makes some editorial improvements.

Cost Impact: The code change proposal will not increase the cost of construction.

R402.1-EC-CRANDELL

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee disagreed that this re-organization is necessary. The technical requirements do not change, and the code is easily understood as it is presently organized.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jay Crandell, P.E., ARES Consulting, representing the Foam Sheathing Committee of the American Chemistry Council requests Approval as Submitted.

Commenter's Reason: This proposal provides an improved format for the various methods of obtaining compliance by clarifying and distinguishing how the requirements are applied. These provisions have been the subject of confusion and varied interpretations. This proposal will help to remove the confusion and avoid conflicting interpretations, thus improving consistency of enforcement and use.

(*Portions of Table not shown remain unchanged)*

Reason: In northern climate zones 5 through 8, this proposal would reduce the prescriptive U-factor to a maximum of 0.25, but provide 5 alternative, U-factor and SHGC combinations that all yield equivalent energy performance to windows having a 0.25 U-factor. Adopting this proposal will provide builders and homeowners with the flexibility of selecting from a number of different frame and glass types to achieve significantly greater energy savings. Such flexibility will also significantly increase the number of products capable of achieving code compliance, thus, increasing competition and, ultimately lowering the cost of compliance.

In 2008, the United States Department of Energy released the results of a regression model developed by Lawrence Berkley National Laboratories (“LBNL”) revealing how changes in U-factor and SHGC affect aggregate energy consumption in northern climates. A detailed discussion of the model is found at http://windows.lbl.gov/EStar2008. The LBNL model clearly shows that in northern climates, a 0.05 increase in SHGC produces the same energy benefits as a 0.01 decrease in U-factor. Accordingly, windows with incrementally 0.01 higher U-factors and 0.05 higher SHGCs all yield the same energy benefits.

Using the results of the LBNL regression model, this proposal establishes a prescriptive 0.25 U-factor in zones 5 through 8 and then takes U-factors up in 0.01 increments from 0.25 to 0.30 while simultaneously raising minimum SHGCs in 0.05 increments. All of the matching U-factors and SHGCs will yield energy performance equivalent to the prescriptive 0.25 U-factor.

The US Energy Star Program has already implemented the results of the LBNL model and uses the same types of energy equivalent trade-offs in northern climates. In fact, trade-offs like those in this proposal have been in use in the United States Energy Star Windows Program ever since April 7, 2009, when the Department of Energy issued its Version 5.0 criteria for Energy Star Windows, Doors and Skylights. Indeed, the 0.27 U-factor coupled with a 0.27 SHGC and a 0.28 U-factor coupled with a 0.32 SHGC in the current proposal match the most recent Energy Star trade-offs released by the Environmental Protection Agency (EPA) in its Version 6.0, Draft 1 Energy Star criteria dated July of 2012. In addition to being used in the United States, the Canadian Energy Star Program also reaches essentially the same trade-off results, by matching higher U-factors with higher SHGC values through the application of a formulation known as Energy Ratings, or ERs.

Achieving a 0.25 U-factor is technologically feasible using a double, not a triple, glazed assembly. In fact, all five (5) of the primary glass manufacturers in the United States, offer a low-e coated glass made specifically for use on the #4 surface (or the surface found inside the home) of a double glazed assembly. In the right frame, advent of #4 surface low-e products enable windows to achieve a 0.25 or lower U-factors using double glazed windows. This proposal builds on that technology and the methodology in use in the U.S. Energy Star Windows Program since 2009 of pairing U-factors with SHGCs to yield an energy performance equivalent to a prescriptive U-factor. In this proposal, U-factors are matched to SHGCs to yield the equivalent energy performance of a 0.25 U-factor.

This proposal, if adopted, will significantly increase builder and consumer choice, ultimately lower the costs of code compliance and significantly reduce the aggregate amount of energy consumed by homes in the United States.

Cost Impact: The code change proposal will increase the cost of construction.

R402.1.1T#2-EC-ZAREMBA

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: These types of options can be accomplished through the performance path. It is not necessary to install this set of options in the minimum requirements table.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Thomas S. Zaremba, Roetzel & Andress, representing NSG Group/Pilkington North America, Inc. and AGC Glass Company North America, Inc., requests Approval as Submitted.

Commenter's Reason: Thirteen years ago, the 2000 IECC established a minimum U-factor of **0.35**[a] for residential windows throughout most of zones 5 through 8. Since then, almost **no** progress has been made in increasing the stringency of northern residential windows. Even now, the 2012 IECC only prescribes a minimum U-factor of **0.32** for residential windows in zones 5 through 8! This represents **less than** a 9% increase in stringency, over the last 13 years.

For the following reasons, RE19-13 should be adopted "as submitted" at the Final Action hearings.

1. The adoption of this proposal would significantly increase the stringency of northern residential windows while significantly increasing the number of window choices available to homebuilders and homeowners alike.
2. Under the IECC and IRC, every window must bear a National Fenestration Rating Council (""NFRC") label showing its U-factor and SHGC. This mandatory labeling system makes it easy for builders and code officials alike to verify that a window's U-factor and SHGC complies with the values set out in the proposal.
3. All five primary glass manufacturers operating in the United States offer coated glazings capable of meeting the matching U-factor and SHGC values set out in the proposal.
4. Windows with any of the matching U-factors and SHGC values in the proposal, which range from 0.25 to 0.30 U-factor, will all deliver the same energy performance. This is established in a report prepared for the U.S. Department of Energy by Lawrence Berkley National Laboratories which can be found at http://windows.lbl.gov/EStar2008. This report has been used by the Energy Star Windows program as the basis for matching U-factors with SHGCs to award Energy Star labels to a variety of windows capable of delivering equivalent energy performance since 2009.

[a]Based on a 15% window to gross exterior wall area.

(Portions of Table not shown remain unchanged)

Reason: The purpose of this proposal is to provide the next step in energy efficiency for windows in the northern zones. Window technology has advanced in recent years, allowing multiple new options to achieve higher performance levels at reasonable cost. Specifically, a 0.25 U-factor can be achieved by triple glazing, but it may also be achieved in double glazing by using new high performance frames and spacers, or also by the using two low-e coatings. These "4th surface" low-e coatings are now available from all five of the primary glass manufacturers. While total window costs vary widely based on specific product, window manufacturer, and location, public cost data shows the incremental cost for adding a low-e coating is fairly consistent between $0.25 to $2 per ft2. [1] A reasonable estimate of the incremental cost is $1.50 per ft2, or approximately $30 per window. This is consistent with the estimate by D&R International for the Energy Star Windows program, which estimated the incremental cost for a 0.27 U-factor at $34 per window. [2] For 12 different cities in zones 5-7, a RESFEN analysis estimates the energy savings at $32-73 per year for a typical 2000 ft2 home with 300 ft2 of windows, with an average payback of 11 ± 3 years, not including any fuel price escalation or future decrease in low-e pricing. A cash flow or ROI analysis would show even more favorable results.

1. Derived from the ASHRAE 90.2 cost database for identical windows with low-e vs. clear glazing, with costs updated to 2011 basis. (See http://bc3.pnnl.gov, Economic Database in Support of ASHRAE 90.2, Research Project 1481 prepared by the NAHB Research Center.)
   Similarly, data for 6 mm commercial glazing shows a range of $0-4 per ft2, which is generally consistent since commercial glazing will be higher than residential. Derived from (a) CASE report for Nonresidential & High-Rise Residential Fenestration Requirements, California Building Energy Efficiency Standards, Sep 2011, and (b) draft Commercial Building Envelope Cost Data Collection, prepared for Pacific Northwest National Laboratory by Faithful & Gould, Dec 2011.
   In some cases, a 4th surface low-e and a #2 double silver low-e are less expensive than just a #2 triple silver low-e alone, meaning there is no incremental cost.

2. *ENERGY STAR Program Windows, Doors, and Skylights, Version 6.0 Draft 1 Criteria and Analysis Report*, D&R International for the U.S. Department of Energy, July 2012.

Cost Impact: This proposal will increase the cost of construction.

R402.1.1T#1-EC-CULP

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: From the testimony provided, there seemed to be some strong disagreement on the cost data provided. This reduction in fenestration U-Factor is too drastic. The technology to achieve this is not proven.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Thomas S. Zaremba, Roetzel & Andress, representing NSG Group/Pilkington North America, Inc. and AGC Glass Company North America, Inc., requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

TABLE R402.1.1
INSULATION AND FENESTRATION REQUIREMENTS BY COMPONENT[a]

CLIMATE ZONE	FENESTRATION *U*-FACTOR[b]	SKYLIGHT[b] *U*-FACTOR	GLAZED FENESTRATION SHGC[b,e]	*(remainder of table unchanged)*
1	NR	0.75	0.25	
2	0.40	0.65	0.25	
3	0.35	0.55	0.25	
4 except Marine	0.35	0.55	0.40	
5 and Marine 4	~~O.25~~ 0.32	0.55	NR	
6	0.25	0.55	NR	
7 and 8	0.25	0.55	NR	

TABLE R402.1.3
EQUIVALENT *U*-FACTORS[a]

CLIMATE ZONE	FENESTRATION *U*-FACTOR[b]	SKYLIGHT[b] *U*-FACTOR	*(remainder of table unchanged)*
1	0.50	0.75	
2	0.40	0.65	
3	0.35	0.55	
4 except Marine	0.35	0.55	
5 and Marine 4	~~0.25~~ 0.32	0.55	
6	0.25	0.55	
7 and 8	0.25	0.55	

Commenter's Reason: Thirteen years ago, the 2000 IECC established a minimum U-factor of **0.35**[a] for residential windows throughout most of zones 5 through 8. Since then, almost no progress has been made in increasing the stringency of northern residential windows. The 2012 IECC only prescribes a minimum U-factor of **0.32** for residential windows in those zones! This represents **less than** a 9% increase in stringency, over the last 13 years. In contrast, in the south, (where U-factor is far less significant) U-factor stringency has increased by more than 45%![b]

The original proposal would have reduced residential window U-factors in zones 5 through 8 from 0.32 to 0.25. The modification proposed with this Public Comment would restore the 0.32 U-factor in zone 5 and only change zones 6 through 8 to a 0.25 U-factor.

I urge you to vote against the standing motion to disapprove in order to vote in favor of a motion to approve R20-13 "as modified" for the following reasons:

1. Climate zones 7 and 8 are Alaska. Climate zones 6 and 7 span much of the border between the continental United States and Canada. By limiting this proposal to Climate zones 6-8, only the coldest parts of the United States, greater than 7200 HDD65°F, are targeted for a 0.25 U-factor.
2. A 0.25 U-factor in these climate zones would dramatically reduce northern energy consumption. A 0.25 U-factor is less than a 30% increase over the 2000 IECC, far less than the 45% increase in southern U-factor stringency since 2000.
3. A 0.25 U-factor can be achieved in many ways. Triple glazed windows can easily achieve a 0.25 U-factor. So can double glazed windows with a low-e coating on the inside layer of the first window and a second low-e coating on either side of the second window. All five primary glassmakers operating in the United States offer the coatings necessary to manufacture these double and triple glazed windows.
4. Northern residential windows represent one of the last "low hanging fruits" on the residential energy code tree. It should be picked now. If it isn't, we won't have another chance until 2018. Between now and 2018, it is likely that a million or more new homes will be added to the building stock in climate zones 6 through 8 and all of them will miss this opportunity to save a significant amount of energy.

In disapproving this proposal, the Committee was concerned about an estimated 11-year payback to achieve this increased U-factor. However, by limiting the proposal to zones 6-8, a shorter payback period of approximately 9 years is expected because the anticipate energy savings in these far northern climate zones will be larger.

The Committee was also concerned that the proposal was "too drastic," although it did not explain why. If it was concerned because of its effect on a large segment of population found in climate zone 5, the modification proposed with this Public Comment eliminates zone 5 from the proposal. If the Committee meant that the percentage increase in stringency is "too drastic," the Committee, simply, failed to realize how little progress has been made in northern window stringency over the last 13 years.

Finally, the Committee was concerned that the "technology to achieve this is not proven." On this point, the Committee is just wrong. Triple glazed window units have been in use for decades and double glazed units with low-e coatings on two surfaces have been in use since at least 2009.

I urge you to pick the low hanging energy fruit available in the north by voting "NO" on the standing motion to approve the Committee's recommendation and voting "YES" on a motion to adopt R20-13 "as modified" by this Public Comment.

a. Based on a 15% window to gross exterior wall area.
b. Zone 2 has moved from a 0.75 U-factor in 2000, to a 0.40 U-factor in 2013.

RE20-13

Final Action: AS AM AMPC____ D

RE22-13
Table R402.1.1 (IRC Table N1102.1.1)

Proposed Change as Submitted

Proponent: Dr. Thomas D. Culp, Birch Point Consulting LLC, representing the Glazing Industry Code Committee (culp@birchpointconsulting.com)

Revise as follows:

TABLE R402.1.1 (N1102.1.1)
INSULATION AND FENESTRATION REQUIREMENTS BY COMPONENT

For SI: 1 foot = 304.8 mm.

a. *R*-values are minimums. *U*-factors are maximums. ~~and~~ SHGC are maximums ("max") or minimums ("min") as noted. When insulation is installed in a cavity which is less than the label or design thickness of the insulation, the installed *R*-values of the insulation shall not be less than the *R*-value specified in the table.

(Portions of Table not shown remain unchanged)

Reason: The 2012 IECC made a significant change by lowering the maximum SHGC in zones 1-3 to 0.25. While this reduces energy use for cooling-dominated homes in the south, the combination of this low SHGC in the south with the "NR" no requirement in zones 5-8 creates a loophole that actually harms energy efficiency in the north.

Windows are generally distributed through national networks, and the “NR” allows the same ultra-low SHGC window designed for the south to also be used in the north. However, the performance of homes is simply not the same in Arizona and Vermont. A 0.25 SHGC window will permanently block 75% of the sun’s energy from entering the home for the full life of the window. In Arizona, this is very beneficial for reducing cooling loads, but in Vermont, this significantly hinders the use of free solar energy to reduce heating loads that must otherwise be met using fossil fuels. If ultra low SHGC windows intended for the south are used in the north, it will increase annual energy consumption, rather than conserve it.

This is not just a hypothetical problem. An analysis conducted for EPA in support of the Energy Star Windows program determined that the mean and median SHGC of Energy Star double hung windows from the top 20 window manufacturers is only 0.22. [1] This is clear evidence that national window manufacturers are largely limiting their inventories to a single very low SHGC product that can meet code in all climate zones, regardless of the impact on energy efficiency for a specific location.

In its technical support for the Energy Star Windows program, Lawrence Berkeley National Laboratory (LBNL) has consistently determined that higher solar heat gain saves more energy in the north. In fact, in the latest analysis of August 2012, LBNL concluded that setting a minimum SHGC of 0.35 in the north would double the national aggregate energy savings resulting from the proposed new criteria. [2]

Nonetheless, this proposal seeks to be more moderate, and just establish a base level minimum SHGC to ensure that ultra-low SHGC windows are not inappropriately used in the north. Both EPA and Natural Resources Canada have established a minimum SHGC for the Energy Star Most Efficient designation.[3] A minimum 0.25 SHGC is parallel to the maximum 0.25 SHGC in the south, will ensure different glazing packages are used for the south and north, and includes low-e products available from all glass manufacturers with both high solar gain products for passive solar design and solar control products to mitigate summer peak loads.

This problem has increased as SHGC requirements in the south have decreased in both the IECC and Energy Star. The code must now address this problem and recognize that using the same low SHGC glazing in Phoenix and Boston makes no sense.

2. EPA’s ENERGY STAR for Windows, Doors and Skylights Draft 1 Criteria and Analysis Report Stakeholder’s Meeting, *Energy Star Program Savings Estimates*, Lawrence Berkeley National Laboratory, August 27, 2012, slide 98.
3. http://www.energystar.gov/ia/partners/downloads/EPA_Memo_ENERGY_STAR_Most_Efficient_2013.pdf

Cost Impact: The code change proposal will not increase the cost of construction.

R402.1.1T#2-EC-CULP

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee was concerned that the availability of materials, and the cost effectiveness of this proposed revision is in question.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Thomas S. Zaremba, Roetzel & Andress, representing NSG Group/Pilkington North America, Inc. and AGC Glass Company North America, Inc., requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

TABLE R402.1.1 (N1102.1.1)
INSULATION AND FENESTRATION REQUIREMENTS BY COMPONENT[a]

CLIMATE ZONE	FENESTRATION *U*-FACTOR[b]	SKYLIGHT[b] *U*-FACTOR	GLAZED FENESTRATION SHGC[b,e]	*(remainder of table unchanged)*
1	NR	0.75	Max 0.25	
2	0.40	0.65	Max 0.25	
3	0.35	0.55	Max 0.25	
4 except Marine	0.35	0.55	Max 0.40	
5 and Marine 4	0.32	0.55	Min 0.25	
6	0.32	0.55	Min 0.25	
7 and 8	0.32	0.55	Min 0.25	

a. R-values are minimums. U-factors are maximums. SHGC are maximums ("max") or minimums ("min") as noted. When insulation is installed in a cavity which is less than the label or design thickness of the insulation, the installed R-values of the insulation shall not be less than the R-value specified in the table.

Commenter's Reason: Please note that the only change made to the original proposal is to add "Max" to SHGC in climate zone 4, since it was inadvertently left out of the original proposal.

A 0.25 SHGC window means that it will only allow 25% of the sun's energy into a home. In other words, it blocks 75% of the sun's energy.

In the south, blocking the sun's energy is important to keep air conditioning loads as low as possible. For that reason, the IECC and IRC prescribe a maximum 0.25 SHGC in climate zones 1 through 3.

However, while the use of low SHGC windows to block the sun's energy is "smart" in the south, it is not smart in the north. In the north, allowing the sun's energy into a home reduces winter heating loads and, thus, reduces energy consumption. According to Lawrence Berkley National Laboratories, in a report prepared for the Environmental Protection Agency ("EPA") in connection with its Energy Star Windows Program, including a minimum SHGC in the north, instead of "no rating," would result in "significantly larger" energy savings.[a]

So, does it make any sense to use the same 0.25 SHGC windows in the north that the IECC and IRC prescribe for use in the south? No. Nevertheless, both the IECC and IRC prescribe "no rating" for SHGC in climate zones 5 through 8 and, in doing so, they allow windows with **any** SHGC to be used in the north, including the ultra-low 0.25 SHGC windows they prescribed in the south.

In a recent study prepared for the EPA's Energy Star Windows Program, D&R International found that the mean and median SHGC of windows being sold, nationwide, by the top 20 window manufacturers in the United States is 0.22. This is significant because it means that window manufacturers are, in fact, taking the same low SHGC windows prescribed by the IECC and IRC for use in the south, and selling them to homeowners in the north. While this may be convenient for window manufacturers, since they can sell the same window in Alaska that they are required to sell in Miami, it wastes a huge amount of energy in the north. It also costs northern homeowners a lot more to heat their homes in the winter.

If adopted, this proposal would prescribe a minimum 0.25 SHGC in climate zones 5 through 8. While such a minimum in the north would eliminate the use of the ultra-low SHGC windows that the IECC and IRC prescribed in climate zones 1 through 3, it would still allow numerous solar control windows to be used in the north, including almost all windows that currently enjoy an Energy Star label.

The Committee disapproved this proposal, saying that it was "concerned that the availability of materials, and the cost effectiveness of this proposed revision is in question."

The Committee got this one wrong. All five primary glass manufacturers operating in the United States manufacture glass with coatings that are capable of delivering SHGCs greater than 0.25. PPG Industries, Guardian Industries, Cardinal Glass, NSG/Pilkington and AGC Glass Company **all** offer such products. A quick review of product availability on their websites indicate that these glass companies offer **dozens** of different products capable of delivering a minimum 0.25 SHGC.

With all of these glass companies offering numerous products capable of delivering SHGCs greater than 0.25, the Committee's reasons for disapproving this proposal are, simply, unfounded.

This simple change will save significant amounts of energy in the north and lower homeowners heating bills, all with no increase whatsoever in the cost of construction.

I urge you to vote against the standing motion and to vote in favor of RE22-13 "as modified."

Reason.
Ellis: We support the Department of Energy's code change proposal (EC13) for the 2012 IECC that held the wood frame wall R-value at R-13 in Table R402.1.1. The increase in R-values in Climate Zone 3 in wood frame walls is just not cost effective and shown to have a payback period of over 35 years. When analyzing the construction cost vs. energy savings, the simple payback can potentially be longer than the expected life of the home. This payback will be unacceptable to most homebuyers.

There are other areas within buildings where energy conservation can be increased such as energy efficient equipment or higher quality windows which can be provide a payback that will be more acceptable to most homebuyers.

Thompson: This public comment is submitted by the ICC Sustainability Energy and High Performance Code Action Committee

SEHPCAC: The SEHPCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portion thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the SEHPCAC has held 2 open meetings and over 15 workgroup calls which included members of the SEHPCAC as well as any interested party to discuss and debate proposed changes and public comments. Related documentation and reports are posted on the SEHPCAC website at: http://www.iccsafe.org/cs/SEHPCAC/Pages/default.aspx.

DOE did not propose changing the value for **Climate Zone 3** in EC13 for the 2012 cycle. This is completely compatible with the DOE proposal which is attached on the following pages.

The cavity only entries proposed for **Climate Zone 6, 7, and 8** are reflective of the cavity only changes proposed for the Commercial chapter for RESIDENTIAL.

Please note that the SEHPCAC has also submitted other proposals that are coordinated with this proposal and are intended to clarify and improve the usability of the code's prescriptive building thermal envelope provisions. This proposal, however, is intended to stand alone and is not contingent upon the success of other SEHPCAC proposals.

Halverson-Ross: We support the U.S. Department of Energy's position for Climate Zone 3, as stated in EC13-09/10 that held the wood frame wall *R*-value at R13 in Table R402.1.1. The increase in *R*-values for Climate Zone 3 wood frame walls is not cost effective and is shown to have a payback period of over 35 years. When analyzing the construction cost vs. energy savings, the simple payback can potentially be longer than the expected life of the home.

The National Association of Home Builders Research Center estimated the cost to builders to increase the wood framed wall *R*-value from R13 to R20 to be $1.33 per square foot of wall or approximately $3,433 per house. The total increase in cost for the builder to meet the 2012 IECC requirements compared to meeting the 2009 IECC requirements was estimated to be $7,203. So the cost of increasing just the insulation in the walls was nearly 50% of the total cost of meeting all of the provisions of the 2012 IECC in Climate Zone 3 while the energy savings of the increased wall insulation was only estimated to contribute 10% of the total energy savings.

This payback will be unacceptable to nearly all consumers. With energy savings only running between $2 and $5.50 per month in Climate Zone 3, we urge the code body to approve this proposal with the modification made in this Public Comment.

We ask the support of the committee for this proposal.

Cost Impact:
ELLIS: None.
THOMPSON: This code change will decrease the cost of construction.
HALVERSON-ROSS: This code change proposal will not increase the cost of construction.

R402.1.1T-EC-ELLIS

Committee Action Hearing Results

Committee Action: Disapproved

Committee Reason: This proposal would constitute an extreme roll-back in the energy efficiency requirements of the code.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Mark Halverson and Paul Coats, representing APA-The Engineered Wood Association, American Wood Council (AWC) request Approval as Submitted.

Commenter's reason: We stand on the original proposal which failed by one vote to get the backing of the Residential Committee. The energy cost savings in this mild climate of going from R-13 to R-20 walls has been estimated to be $42.60 per year for a 2,000 square foot house. The cost for builders to go from 2x4 to 2x6 construction in an average house of this size has been estimated by the National Association of Home Builders to be over $2,930.00. Even if the actual cost is only half that number, or $1,465, it would still take over 34 years for a simple payback on the increased cost of construction. If 4% annual interest is applied to the additional $1,465 of a 30-year mortgage, the energy savings of $42.60 fails to even cover the $59 annual cost of the additional mortgage. So, proposing that wood frame walls be insulated at R-13 instead of R-20 in Climate Zone 3 hardly represents an extreme roll-back in energy savings; especially considering the added cost of construction.

This proposal does not drastically impact energy savings and will decrease the cost of construction, resulting in more affordable housing for first-time homeowners.

Public Comment 2:

Shirley Ellis, Energy Systems Laboratory, Texas A&M University System, representing self, requests Approval as Submitted.

Commenter's reason: The Department of Energy's code change proposal (EC13) for the 2012 IECC retained the wood frame wall R-value in Table R402.1.1 at R-13 in Climate Zone 3. The energy efficiency achieved in this climate zone is not justified by the cost to increase the R-values.

The reason given by the committee for disapproval is that the proposal "would constitute an extreme roll-back in the energy efficiency requirements of the code".

An impact of wall insulation requirements specified in Table R402.1 of the 2012 IECC (i.e., R-20 or R-13+5 for wood frame wall R-value) were calculated using a 2012 IECC performance path code-compliant single-family residential building in Dallas, TX (Climate Zone 3). The base-case building was assumed to be a 2,325 sq. ft., square-shape, one story, single-family, detached house. A series of simulation was performed, including R-13 with 2X4 (16"), R-13+5 with 2X4 (16"), R-20 with 2X6 (16"), and R-20 with 2X6 (24"). Two options based on the choice of heating fuel type were considered: (a) an electric/gas house (gas-fired furnace for space heating, and gas water heater for domestic water heating), and (b) an all-electric house (heat pump for space heating, and electric water heater for domestic water heating).

Figure 1 and 2 summarize the results of simulations for both electric/gas and all-electric house, including: the annual site energy consumption by end-uses and the total; and the annual source energy consumption by fuel types and the total, respectively. Figure 2 also shows the calculated source energy (cooling, heating and DHW) percentage difference against the R-13+5 test case.

Public Comment 3:

Greg Johnson, Johnson Consulting Services, representing the Coalition for Fair Energy Codes, requests Approval as Submitted.

Commenter's Reason: RE26 attempts to correct an energy code that is out of touch with both the economic realities facing many communities and the lack of local government political will to erect additional financial barriers to home ownership. This is particularly true in Climate Zone 3 where adoption of the 2012 IECC's prescriptive wall insulation requirements have been almost universally rejected.

RE26 would return the prescriptive R-value and equivalent U-factor requirements to those of the 2009 IECC; requirements that the Department of Energy **did not** ask to be made more stringent. There could be no more reasonable change offered than RE26 which says, essentially, that we won't make people pay for something for which they will see little benefit and which many cannot afford.

The Energy Systems Laboratory of Texas A & M University (ESL) evaluated the percentage of contribution to improved energy efficiency of specific 2012 IRC (2012 IECC Residential) stringency measures over a 2009 IRC (2009 IECC Residential) baseline in Climate Zone 3. The analyzed measures include: increased roof insulation; increased wall insulation; decreased window U-factor; decreased window SHGC; decreased air infiltration; and, decreased duct leakage. Those results are reported in Table 1.

The National Association of Home Builders Research Center estimated the incremental cost to builders to provide each of the ESL specified stringency measures. Those results are also reported in Table 1.

Comparing the cost of each building stringency measure to the ESL modeled energy savings shows that the cost of increasing wall insulation stringency from R-13 to R-20 far exceeds the benefit when compared to other energy efficiency measures. The cost of providing R-20 walls is almost twice that of any other 2012 stringency measure yet it returns only 12 percent of the total savings identified by ESL.

Assuming 5% interest, the cost of R-20 is $1,736 over a 30 year mortgage, which is $11.13 per month for 360 payments for a grand total cost of $4,005.92 with $1,527.78 in total interest paid. The total estimated monthly energy cost savings delivered by the 2012 IECC residential provisions are projected to be $276 annually or $23.00 monthly (see Calculation 1) for Climate Zone 3. Given an 11.8% contribution to those energy savings, R-20 walls will save the building owner only $2.72 per month, an insufficient return for an $11.13 per month investment. **In other words, for R-20 walls, the 2012 IECC requires owners in Climate Zone 3 to spend $4,000 to save less than $980 over the term of a 30 year mortgage.**

As an alternate methodology, for simple payback, Calculation 1 results in a 53 year payback for the additional expense of R-20 walls in Climate Zone 3, well beyond the length of a typical mortgage.

CALCULATION 1
Climate Zone 3 Increased Wall Insulation Savings and Simple Payback

	Cooling	Heating
2009 IECC end use site energy consumption[1]	14.7 MMBtu/yr	44.7 MMBtu/yr
2012 IECC end use site energy consumption[1]	- 10.5 MMBtu/yr	- 30.6 MMBtu/yr
Savings	4.2 MMBtu/yr	14.1 MMBtu/yr
Conversion Factor (divide by)[2]	3412	100,000
Equivalent Units	1231kWh	141 Therms
Unit Cost[3]	x $0.11	x $1.00
Annual Savings ($135 + $141 = $276)	$135	$141
12 % savings from increased wall insulation[4]	.118	.118
Annualized savings of increased wall insulation	$15.93	$16.64
Total wall insulation cooling + heating annual savings	$32.57	
Monthly savings ($23.57/12)	$2.71	
Simple payback = initial cost of wall assembly change divided by total annual savings ($1,736[4] / $32.57/yr) =	53 years

1. Extracted from Table 5-1 of *Cost-Effectiveness Analysis of the 2009 and 2012 IECC Residential Provisions – Technical Support Document;* Pacific Northwest National Laboratory, April 2013. http://www.energycodes.gov/sites/default/files/documents/State_CostEffectiveness_TSD_Final.pdf

Rejection of the 2012 IECC means that less costly but important energy saving measures like improved air sealing and blower door testing, duct sealing, better performing windows, and higher efficacy lighting sources are not being adopted. An energy code that is not adopted saves no energy.

Please support a return to reasonable energy code provisions in Climate Zone 3 and vote for this public comment for RE26 - As Submitted.

Public Comment 4:

Tim Ryan, International Association of Building Officials requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

Commenter's Reason: The International Association of Building Officials is submitting this public comment to modify RB26 to include changes to climate zone 4 values in TABLE R402.1.1 related to wall cavity insulation. The proponent of RE26 accurately described the issues related to the cost benefit analysis associated with an increase in R values from R-13 to R-20 in wood frame wall construction. The same argument can be made to similar changes associated with climate zone 4. Further, IABO agrees with the proponent's reason statement where they indicated there are other areas within the building where energy conservation can be increased. In addition to the proponent's reason statement, the

International Association of Building Officials submits that this proposed modification more appropriately reflects the amendments being made by jurisdictions when adopting the 2012 IECC.

EC13 was the primary change that created substantial changes within the 2012 IECC. The proponent of that change offered no specific data to support the extreme changes to wall cavity insulation. We do not believe that such an extreme change is warranted based on the cost of construction in conjunction with the benefit that is achieved. IABO supports the IECC philosophy that the energy package of a building is a system consisting of multiple parts including the tightness of the thermal envelope and duct system, the sizing of the equipment and duct system, etc., all working together. We do not believe it is necessary to increase the cavity insulation to these extremes to achieve the desired level of energy efficiency.

Reason: There were four changes in the Ceiling R-value requirements in the 2012 IECC Edition, none of which should have been considered cost-effective. An energy and cost analysis was performed to show that the simple paybacks are in the 80-130 year range.

Climate Zone	Representative City	Change	Energy Savings	Incremental Cost	Simple Payback
2	Orlando, FL	R-38->R-30	$10/yr	$1,305	130 years
3	Atlanta, GA	R-38->R-30	$16/yr	$1,305	82 years
4	Richmond, VA	R-49->R-38	$15/yr	$1,379	92 years
5	Indianapolis, IN	R-49->R-38	$15/yr	$1,379	92 years

The energy modeling was done using the Energy Plus simulation engine and BEopt version 1.4, Cost figures came from ASHRAE RP-1481. Vaulted or cathedralized ceiling are very problematic when trying to achieve R-49 which is about 16 inches thick. This would require a rafter at least 17" tall (which does not exist) or an insulated panel, which represents a very small portion of the market.

Cost Impact: The code change proposal will not increase the cost of construction.

R402.1.1T#6-EC-SURRENA

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: This proposal would constitute a roll-back in the energy efficiency requirements of the code.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Tim Ryan, International Association of Building Officials requests Approval as Submitted.

Commenter's Reason: There were four changes in the Ceiling R-value requirements in the 2012 IECC Edition, none of which should have been considered cost-effective. An energy and cost analysis was performed to show that the simple paybacks are in the 80-130 year range.

Climate Zone	Representative City	Change	Energy Savings	Incremental Cost	Simple Payback
2	Orlando, FL	R-38->R-30	$10/yr	$1,305	130 years
3	Atlanta, GA	R-38->R-30	$16/yr	$1,305	82 years
4	Richmond, VA	R-49->R-38	$15/yr	$1,379	92 years
5	Indianapolis, IN	R-49->R-38	$15/yr	$1,379	92 years

The energy modeling was done using the Energy Plus simulation engine and BEopt version 1.4, Cost figures came from ASHRAE RP-1481. Vaulted or cathedralized ceiling are very problematic when trying to achieve R-49 which is about 16 inches thick. This would require a rafter at least 17" tall (which does not exist) or an insulated panel, which represents a very small portion of the market.

Table R402.1.1, (IRC Table N1102.1.1), R402.2 (IRC N1102.2), R402.2.13 (NEW) (IRC N1102.2.13 (NEW))

Proposed Change as Submitted

Proponent: Jay Crandell, P.E., ARES Consulting, representing Foam Sheathing Committee / American Chemistry Council (Jcrandell@aresconsulting.biz)

Revise as follows:

TABLE R402.1.1 (N1102.1.1)
INSULATION AND FENESTRATION REQUIREMENTS BY

(Portions of Table not shown remain unchanged)

h. First value is cavity insulation, second is continuous insulation or insulated siding, so "13 + 5" means R-13 cavity insulation plus R-5 continuous insulation or insulated siding. See Section 402.2.13 for cases where thickness of continuous insulation is varied to maintain a consistent overall sheathing thickness on walls intermittently braced with structural sheathing panels. ~~If structural sheathing covers 40 percent or less of the exterior, continuous insulation *R*-value shall be permitted to be reduced by no more than R-3 in the locations where structural sheathing is used – to maintain a consistent total sheathing thickness.~~

R402.2 (N1102.2) Specific insulation requirements (Prescriptive). In addition to the requirements of Section R402.1, insulation shall meet the specific requirements of Sections R402.2.1 through ~~R402.2.12~~. R402.2.13

R402.2.13 (N1102.2.13) Continuous insulation on walls with intermittent structural sheathing. Where an exterior wall is intermittently braced with structural sheathing, the R-value of continuous insulation required by Table R402.1.1 shall be permitted to be reduced in the locations where structural sheathing is used in order to maintain a consistent total sheathing thickness when:

1. The overall U-factor of the opaque assembly, including areas with and without structural sheathing, is equal to or less than the required U-factor in Table R402.1.3 and
2. The assembly is in compliance with the vapor retarder requirements of Section R702.7 of the *International Residential Code* or Section 1405.3 of the *International Building Code* as applicable.

Reason: This proposal corrects a discrepancy where frame wall assemblies using component insulation R-values allowed under existing footnote (h) are not currently equivalent to U-factors in Table R402.1.3.

Cost Impact: The code change proposal may increase the cost of construction.

Note: If this change is approved, the proposed Item 2 to Section N1102.2.13 would be shown in Chapter 11 of the IRC without the reference to the IBC as follows:

2. The assembly is in compliance with the vapor retarder requirements of Section R702.7.

R402.1.1T-EC-CRANDELL

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: The flexibility for structural panels in the current footnote is necessary, especially in high seismic zones.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Jay Crandell, Ares Consulting, representing the Foam Sheathing Committee of the American Chemistry Council, requests Approval as Submitted.

Commenter's Reason: Footnote 'h' as currently written results in combinations of continuous insulation thickness (R-value) over brace panels and not over brace panels that result in a total wall assembly that is not consistent with the R-value or U-factor options. This proposal removes this technical inconsistency, yet allows the development of numerous practical prescriptive solutions to achieve the ability to use foam sheathing with any bracing approach. It also provides an important link to vapor retarder provision in the building code which may limit the amount of R-value reduction for continuous insulation depending on the climate zone and vapor retarder approach. This is important for proper code coordination, enforcement, and implementation.

Public Comment 2:

Stephen Turchen, Fairfax County VA, representing Virginia Building and Code Officials Association requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

TABLE R402.1.1 (N1102.1.1)
INSULATION AND FENESTRATION REQUIREMENTS BY COMPONENT

(Portions of Table not shown remain unchanged)

h. First value is cavity insulation, second is continuous insulation or insulated siding, so "13+5" means R-13 cavity insulation plus R-5 continuous insulation or insulated siding. See Section 402.2.13 for cases where thickness of continuous insulation is varied to maintain a consistent overall sheathing thickness on walls intermittently braced with structural sheathing panels.

R402.2 (N1102.2) Specific insulation requirements (Prescriptive). In addition to the requirements of Section R402.1, insulation shall meet the specific requirements of Sections R402.2.1 through R402.2.13.

R402.2.13 (N1102.2.13) Continuous insulation on walls with intermittent structural sheathing. Where an exterior wall is intermittently braced with structural sheathing in accordance with the requirements of the *International Residential Code or International Building Code for wall bracing*, the R-value of continuous insulation required by Table R402.1.1 shall be permitted to be reduced in the locations where structural sheathing is used in order to maintain a consistent ~~total~~ overall sheathing thickness ~~when:~~ on the wall.

~~1. The overall U-factor of the opaque assembly, including areas with and without structural sheathing, is equal to or less than the required U-factor in Table R402.1.3 and~~
~~2. The assembly is in compliance with the vapor retarder requirements of Section R702.7 of the *International Residential Code* or Section 1405.3 of the *International Building Code.*~~

Commenter's Reason: We consider the revised footnote "h" and the new Section R402.2.13 to be a worthwhile improvement over the present poor language of footnote "h". In its present form, attempting to enforce the footnote will become unnecessarily confusing and burdensome to building department personnel.

The term "structural sheathing" is retained in RE29 but is not a defined term in the IECC or IRC or IBC. The revision to the new Section R402.2.13 clarifies that the code is addressing sheathing products only in the context of the wall bracing requirements of the IRC or IBC.

We believe that the two conditions qualifying Section R402.2.13 are unnecessary. Condition 1 imposes an unnecessarily complex burden on the code official. A demonstration of compliance with the applicable U-factor under Section and Table R402.1.3 will be required in all cases where this provision is invoked, and it may be difficult to meet the U-factor criterion because structural sheathing products do not generally have the R-values of the continuous insulation products. In addition, a demonstration of compliance with R402.1.3 will require computation of wall areas, framing factors, R-values for all construction elements other than insulation, etc., a detailed and complex and time-consuming process. We do not consider the small increase in overall wall U-factor anticipated from using Section R402.2.13 as having a significant impact on overall energy use of the residential structure.

Condition 2 is unnecessary because it is already a part of the IRC and IBC. If your structure is in CZ M4 through 8, you must adhere to the applicable vapor retarder requirements. In those cases in those zones where a Class III vapor retarder is selected in lieu of Class I or II, only some construction options require a minimum R-value for insulated sheathing. These situations can be specifically addressed by the designer and code official and may preclude the use of R402.2.13.

The content of RE29, as modified above, provides, in our opinion, the only viable solution to integrating structural wall bracing and continuous insulation that can be easily and properly codified with a minimal impact on energy conservation: You must use one of the intermittent bracing methods permitted under the IRC or IBC. These methods insure that there will be "blank space" on the exterior walls. Fill in the blank spaces with the required continuous foam sheathing and you are done. If the thicknesses of the two sheathing materials are intelligently coordinated, you will end up with an opaque wall of uniform thickness throughout.

Absent using intermittent sheathing for required wall bracing, the integration of structural wall bracing and any required continuous foam insulation should be left to the judgment and experience of the responsible designer and the code official.

(*Portions of Table not shown remain unchanged.)***

Reason: The purpose of this code change proposal is to ensure product neutrality with regards to the building code. It is not appropriate for the code to require builders in Climate Zones 7 and 8 to use a specific product type (continuous insulation or insulated siding) to meet the prescriptive requirements when other equitable options are readily available. The 2012 IECC set a prescriptive mandate for the use of continuous insulation in the aforementioned zones. This proposal establishes a cavity-only insulation option of R28 for these climate zones.

The *U*-factor calculation tables below illustrate the performance equivalency between the current prescriptive *R*-values and the proposed cavity insulation-only *R*-value option. Use of the cavity insulation-only option will likely require deeper framing members to accommodate thicker insulation that can reach the minimum level of R28. The *U*-factor calculations assume that the continuous insulation wall assemblies use let-in-bracing to meet the IRC requirements for wall bracing.

Table 1 shows the *U*-factor calculations for a 2x6 framed wall with R20 cavity insulation plus R5 continuous insulation, and for a 2x8 framed wall using R28 cavity insulation with 3/8-inch thick wood panel sheathing (which is the minimum thickness of wood panel bracing allowed in the IRC). Both calculations yield a wall *U*-factor of 0.046.

Table 2 shows the *U*-factor calculation for a 2x4 framed wall with R13 cavity insulation and R10 continuous insulation, and also a calculation for a 2x8 framed wall using R28 cavity insulation with the more common 7/16-inch thick wood structural panel sheathing. The calculations yield *U*-factors of 0.045 and 0.046, respectively.

This proposed code change will provide additional prescriptive options to designers and builders in these two Climate Zones.

We request the committee's support of this proposal.

R402.1.1T #1-EC-KOSITZKY

Committee Action Hearing Results

Committee Action: Disapproved

Committee Reason: Disapproved in accordance with the proponent’s request. The proponent conceded that the proposals for lessening of stringency based on various payback periods were being consistently disapproved by the committee.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Tom Kositzky, Coalition for Fair Energy Codes, requests Approval as Submitted.

Commenter's Reason: This proponent moved for disapproval based on the committee's disapproval of similar proposal to Table R402.1.1. However, there has been widespread reluctance for jurisdictions in these climate zones to adopt the 2012 IECC because cavity insulation only options were not included in the prescriptive path of the code. This modification to the code would offer builders and designers a choice to use a variety of cavity insulation options including thicker wall cavities (such as 2x8) and still use the prescriptive table.

We urge the support of the original code change proposal to include cavity only options in Table 402.1.1.

(*Portions of Table not shown remain unchanged)*

Reason Statement: The increase in wood frame wall *R*-value in Climate Zone 6 of Table R402.1.1 of the 2012 IECC was essentially arbitrary and is without basis other than it represents the *R*-value for a readily available, specific type of foam sheathing. The requirements also mandate the use of continuous insulation since no cavity-only insulation option was included in the prescriptive table. Stakeholders around the country in Climate Zone 6 do not consider this level of insulation to be cost effective nor necessary in this climate zone. Due in part to such high insulation requirements, the 2012 IECC is not being adopted consistently in these states.

This proposal offers a compromise by increasing stringency significantly beyond the requirements of the 2009 IECC with more cost effective alternatives. The wall insulation can be met with continuous insulation and cavity insulation options (R20+2 or R13+6.5) or the cavity-only option of R24. This proposal creates much more cost effective provisions that will offer builders more alternatives in meeting the wood frame wall requirements found in Table R402.1.1. More choices will help to gain greater stakeholder buy-in and will enable the 2015 IECC to gain greater acceptance, thereby creating more energy conservation opportunities.

In combination with these changes in Table 402.1.1, we propose a corresponding change to the *U*-factor listed in Table R402.1.3 for wood frame walls. Tables 1 and 2 below provide the *U*-factor calculations for all three of the prescriptive wall alternatives identifying that all of the systems meet the proposed *U*-factor target. The right hand columns of Table 2 show that the same *U*-factor is achieved when the commonly used 7/16-inch wood structural panel sheathing is used rather than the code minimum 3/8-inch sheathing.

We ask the support of the committee for this proposal.

Table 1. - Climate Zone 6 Wood Framed Walls

Committee Reason: Disapproved in accordance with the proponent's request. The proponent conceded that the proposals for lessening of stringency based on various payback periods were being consistently disapproved by the committee.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Greg Johnson, Johnson Consulting Services, representing the Coalition for Fair Energy Codes, requests Approval as Submitted.

Commenter's Reason: The proposed modifications to Tables R402.1.1 and R402.1.3 address a major obstacle to the adoption of 2015 IECC as proven by the lack of adoptions of the 2012 IECC, and, where adopted, amendments to the Climate Zone 6 framed wall insulation requirements. (See Code Adoption Status Table).

With this proposal wall insulation requirements in Climate Zone 6 can be met with continuous insulation and cavity insulation options (R20+2 or R13+6.5) or the cavity-only option of R24. This is in keeping with information that CFEC has received from many state and local jurisdictions in Climate Zone 6 demanding a return to the flexibility provided by a cavity-only insulation *option* for wood frame walls.

The prescriptive R-value of 24 increases cavity-only insulation stringency by 20% above the R20 value of the 2009 IECC and by 26% above the 2006 IECC. It is a fair compromise between no increase in energy performance from the 2009 IECC and the inflexible frame wall assembly requirements of the 2012 IECC.

The proposed *U*-factor alternative correlates to the R-values for all assemblies as documented by the calculations in the original RE33 proposal. It also is more stringent than the *U*-factor alternative of the 2009 IECC while relaxing only slightly the 19% increase in stringency of the 2012 IECC over the 2009 IECC value.

States in Climate Zone 6 have reacted to the inflexibility and economic burdens imposed by the 2012 IECC's prescriptive wall insulation requirements by almost universally rejecting adoption of the document as written. DOE has projected California, (2 counties), Minnesota, and Washington to be the only Climate Zone 6 states to adopt the 2012 IECC before the end of 2015 – see Table. Note that California's Title 24 standard is inconsistent with the IECC; Minnesota has announced its intention to amend Table R402.1.1 to permit a cavity-only R-21 wall insulation option in both the Climate Zones 6 and 7 portions of the state – which is less restrictive than this proposal; and, Washington has enacted an emergency rule amending its state energy code and classifying its Climate Zone 6 counties as Climate Zone 5.

The cost of compliance with the 2012 IECC and its lack of envelope design flexibility are obstructing its adoption in colder climate zones. Approving this proposal will help position the 2015 IECC for adoption.

Rejection of the 2012 IECC means that less costly but important energy saving measures like improved air sealing and blower door testing, duct sealing, better performing windows, and higher efficacy lighting sources are not being adopted.

An energy code that is not adopted saves no energy.

Climate Zone 6
Code Adoption Status & Amendments to Residential Frame Wall Insulation Requirements

(Portions of Table not shown remain unchanged.).

Reason: The prescriptive wall requirement increased to R-20+R5 in Climate zones 6, 7 and 8 of the 2012 IECC. The additional cost for this is estimated at $1,819 for 1,016 square feet of wall. This makes the simple payback between 26 and 55 years depending on the climate zone. This also will create a negative cash flow for the consumer in all cases.

Climate Zone	Representative City	Basement Wall R-Value Change	Energy Savings	Incremental Cost	Simple Payback
6	Minneapolis, MN	R-20->R-20+5	$33/yr	$1,819 ($1.79/ft2)	55 years
7	Bemidgi, MN	R-20->R-20+5	$41/yr	$1,819 ($1.79/ft2)	44 years
8	Fairbanks, AK	R-20->R-20+5	$71/yr	$1,819 ($1.79/ft2)	26 years

The energy modeling was done using the Energy Plus simulation engine and BEopt version 1.4, Cost figures came from ASHRAE RP-1481.

Cost Impact: The code change proposal will not increase the cost of construction.

R402.1.1T#4-EC-SURRENA

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: Disapproved in accordance with the proponent's request. The proponent conceded that the proposals for lessening of stringency based on various payback periods were being consistently disapproved by the committee.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Timothy Manz, City of Blaine, MN, representing the Association of Minnesota Building Officials, request As Modified by this Public Comment.

Modify the proposal as follows:

TABLE R402.1.1 (N1102.1.1) INSULATION AND FENESTRATION REQUIREMENTS BY COMPONENT[a]	
CLIMATE ZONE	**WOOD FRAME WALL R-VALUE**
6	20+5 or 13+10[h,i] or 21
7 & 8	20+5 or 13+10[h,i] or 21

TABLE R402.1.3 N1102.1.3) EQUIVALENT *U*-FACTORS[a]	
CLIMATE ZONE	**FRAME WALL U-FACTOR**
6	0.057
7 & 8	0.057

(Portions of code change proposal not shown remain unchanged)

Commenter's Reason: The State of Minnesota is amending the 2012 IECC to permit a 2" by 6" nominal wood framed wall cavity-only insulation option for both CZ 6 and 7. There is little demand for, and considerable opposition to, mandating continuous insulation or deeper insulation cavities than provided by 2" by 6" framing.

R21 was selected as the appropriate performance metric because it does not discriminate against materials. R21 also corresponds with proposed amendments to important neighboring jurisdictions, keeping a level field for cross-border economic competition. Minnesota neighbors include:

- North Dakota, which is proposed to require R20 in CZ 6 and R21 in CZ 7.
- South Dakota; a home rule state with energy codes adopted as local options. Sioux Falls, SD's largest city, is in CZ 6 and a short distance from the MN border. It has elected to amend the 2012 IRC energy provisions to R20.
- Wisconsin, which currently administers R19 in CZ 6 and R21 in CZ 7. As of July 5, 2013 there are no administrative rules proposed to change these requirements on WI's state website nor are there indications of a 2012 IECC adoption initiation.
- Iowa administers R20 in CZ 6. As of July 5, 2013 there are no administrative rules proposed to change these requirements on IA's state website nor are there indications of a 2012 IECC adoption initiation.

We request that the assembly overturn the committee action and approve RE34 as modified by this public comment.

Public Comment 2:

Tim Ryan, The International Association of Building Officials, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

TABLE R402.1.1

6	0.32	0.55	0.026	0.057	0.060	0.033	0.050	0.055
7 and 8	0.32	0.55	0.026	0.048~~0.057~~	0.057	0.028	0.050	0.055

(All footnotes remain unchanged)

Commenter's Reason: The prescriptive wall requirement increased to R-20+R5 in Climate zone 6 of the 2012 IECC. The additional cost for this is estimated at $1,819 for 1,016 square feet of wall. According to NAHB, this will result in a simple payback of roughly 55 years and create a negative cash flow for the consumer.

We cannot make new requirements that drastically change the way builders construct homes especially when the calculated payback is so long.

Climate zones 7 and 8 are very cold and the paybacks, although long, are much shorter than climate zone 6. Therefore, this public comment reinstates the 2012 wall R-values in the northernmost climate zones.

RE34-13

Final Action: AS AM AMPC____ D

RE37-13
Table R402.1.1 (IRC Table N1102.1.1)

Proposed Change as Submitted

Proponent: Brenda A. Thompson, Clark County Building Department, Las Vegas NV, representing the ICC Sustainability, Energy & High Performance Code Action Committee (SEHPCAC) (bat@clarkcounty.gov)

Revise as follows:

TABLE R402.1.1 (N1102.1.1)
INSULATION AND FENESTRATION REQUIREMENTS BY COMPONENT[a]

CLIMATE ZONE	FENESTRATION *U*-FACTOR[b]	SKYLIGHT[b] *U*-FACTOR	GLAZED FENESTRATION SHGC[b,e]	CEILING *R*-VALUE	WOOD FRAME WALL *R*-VALUE	MASS WALL *R*-VALUE[i]	FLOOR *R*-VALUE	BASEMENT[c] WALL *R*-VALUE	SLAB[d] *R*-VALUE AND DEPTH	CRAWL SPACE[c] WALL *R*-VALUE
1	NR	0.75	0.25	30	13	3/4	13	0	0	0
2	0.40	0.65	0.25	38	13	4/6	13	0	0	0
3	0.35	0.55	0.25	38	20 or 13+5[h]	8/13	19	5/13[f]	0	5/13
4 except Marine	0.35	0.55	0.40	49	20 or 13+5[h]	8/13	19	10/13	10, 2 ft	10/13
5 and Marine 4	0.32	0.55	NR	49	20 or 13+5[h]	13/17	30[g]	15/19	10, 2 ft	15/19
6	0.32	0.55	NR	49	20+5 or 13+10[h] or 22	15/20	30[g]	15/19	10, 4 ft	15/19
7 ~~and 8~~	0.32	0.55	NR	49	20+5 or 13+10 or 27	15/20	38	15/19	10, 4 ft	15/19
8	0.32	0.55	NR	49	20+7.5 or 32	19/21	38[g]	15/19	10, 4 ft	15/19

For SI: 1 foot = 304.8 mm.

a. *R*-values are minimums. *U*-factors and SHGC are maximums. When insulation is installed in a cavity which is less than the label or design thickness of the insulation, the installed *R*-value of the insulation shall not be less than the *R*-value specified in the table.

b. The fenestration *U*-factor column excludes skylights. The SHGC column applies to all glazed fenestration. Exception: Skylights may be excluded from glazed fenestration SHGC requirements in Climate Zones 1 through 3 where the SHGC for such skylights does not exceed 0.30.

c. "15/19" means R-15 continuous insulation on the interior or exterior of the home or R-19 cavity insulation at the interior of the basement wall. "15/19" shall be permitted to be met with R-13 cavity insulation on the interior of the basement wall plus R-5 continuous insulation on the interior or exterior of the home. "10/13" means R-10 continuous insulation on the interior or exterior of the home or R-13 cavity insulation at the interior of the basement wall.

d. R-5 shall be added to the required slab edge *R*-values for heated slabs. Insulation depth shall be the depth of the footing or 2 feet, whichever is less in Climate Zones 1 through 3 for heated slabs.
e. There are no SHGC requirements in the Marine Zone.
f. Basement wall insulation is not required in warm-humid locations as defined by Figure R301.1 and Table R301.1.
g. Or insulation sufficient to fill the framing cavity, R-19 minimum.
h. First value is cavity insulation, second is continuous insulation or insulated siding, so "13+5" means R-13 cavity insulation plus R-5 continuous insulation or insulated siding. If structural sheathing covers 40 percent or less of the exterior, continuous insulation *R*-value shall be permitted to be reduced by no more than R-3 in the locations where structural sheathing is used – to maintain a consistent total sheathing thickness.
i. The second *R*-value applies when more than half the insulation is on the interior of the mass wall.

Reason: This proposal is submitted by the ICC Sustainability Energy and High Performance Code Action Committee (SEHPCAC). The SEHPCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portion thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the SEHPCAC has held 3 open meetings and over 30 workgroup calls which included members of the SEHPCAC as well as any interested party to discuss and debate proposed changes and public comments. Related documentation and reports are posted on the SEHPCAC website at: http://www.iccsafe.org/cs/SEHPCAC/Pages/default.aspx.

The SEHPCAC found discrepancies in the Commercial Energy Code RESIDENTIAL table. The SEHPCAC has proposed a fix to the discrepancy in Table C402.1.1. In an effort to further enhance the Residential Energy Code, the SEHPCAC proposes to include a so-called "Cavity Only" insulation solution in the R Values table. The Task Group assigned to this task looked at using the ASHRAE procedures to calculate an R-value based on the existing table entry of cavity insulation plus continuous insulation (e.g. 20+5 in CZ 6 & 7), and the U-factor entry associated with the respective CZ cell. In addition, the Task Group looked at the Cavity Only requirements for Residential wood frame walls from the Commercial Energy Code. The values shown here are those from the Wood Frame Wall section of the Commercial Energy Code. The SEHPCAC determined that the energy performance of wood frame wall assemblies in a residential use would be effectively similar in either the commercial group or the noncommercial group. Thus the SEHPCAC chose to propose the same values in this table. This proposal also splits climate Zone 8 away from 7 and then plugs in higher R-value into the CZ8 cell for wood frame walls. The rest of the CZ 8 cells simply duplicate the CZ 7 values.

Please note that the SEHPCAC has also submitted other proposals that are coordinated with this proposal and are intended to clarify and improve the usability of the code's prescriptive building thermal envelope provisions. This proposal, however, is intended to stand alone and is not contingent upon the success of other SEHPCAC proposals.

Cost Impact: This proposal will increase construction costs in Climate Zone 8 only.

R402.1.1T#1-EC-THOMPSON-SEHPCAC

Committee Action Hearing Results

Committee Action: Disapproved

Committee Reason: The proponent requested disapproval based on uncertainty about the supporting data.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Brenda A. Thompson, CBCO, Manager Building Inspections, Clark County Development Services, representing ICC Sustainability, Energy & High Performance Building Code Action Committee (SEHPCAC) Chair, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

TABLE R402.1.1 (N1102.1.1)
INSULATION AND FENESTRATION REQUIREMENTS BY COMPONENT[a]

CLIMATE ZONE	FENES-TRATION *U*-FACTOR[b]	SKYLIGHT[b] *U*-FACTOR	GLAZED FENES-TRATION SHGC[b,e]	CEILING *R*-VALUE	WOOD FRAME WALL *R*-VALUE	MASS WALL *R*-VALUE[i]	FLOOR *R*-VALUE	BASEMENT[c] WALL *R*-VALUE	SLAB[d] *R*-VALUE AND DEPTH	CRAWL SPACE[c] WALL *R*-VALUE
1	NR	0.75	0.25	30	13	3/4	13	0	0	0
2	0.40	0.65	0.25	38	13	4/6	13	0	0	0
3	0.35	0.55	0.25	38	20 or 13+5[h]	8/13	19	5/13[f]	0	5/13
4 except Marine	0.35	0.55	0.40	49	20 or 13+5[h]	8/13	19	10/13	10, 2 ft	10/13
5 and Marine 4	0.32	0.55	NR	49	20 or 13+5[h]	13/17	30[g]	15/19	10, 2 ft	15/19
6	0.32	0.55	NR	49	20+5 or 13+10[h]or ~~22~~ 24	15/20	30[g]	15/19	10, 4 ft	15/19
7	0.32	0.55	NR	49	20+5 or 13+10[h]or ~~27~~ 28	15/20	38	15/19	10, 4 ft	15/19
8	0.32	0.55	NR	49	20+5 or 13+10[h]or ~~32~~ 28	19/21	38[g]	15/19	10, 4 ft	15/19

For SI: 1 foot = 304.8 mm.

Commenter's Reason: One of SEHPCAC goals of a series of our code changes is to provide in these tables a filled cavity only option for the wood frame walls. The SEHPCAC submitted this change and CE97-13 as part of this effort. CE97 was disapproved, but CE99-13 was approved. It provided cavity only values for climate zones 6 through 8. This public comment incorporates the values approved in CE99 for Grouip R construction and directly copies them for residential construction under the Residential portion of the IECC.

This public comment is submitted by the ICC Sustainability Energy and High Performance Code Action Committee (SEHPCAC). The SEHPCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portion thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the SEHPCAC has held numerous open meetings and workgroup calls which included members of the SEHPCAC, as well as interested parties, to discuss and debate proposed changes and public comments.

(Portions of Table not shown remain unchanged)

Reason: It is not practical or cost effective to require more than R-13 insulation for wood frame walls in Climate Zone 3. If this value for frame walls is changed back to R13 as in Table 402.1.1 in the 2009 IECC, then the mass wall R-value in Table 402.1.1 should be changed back to the mass wall R-value for Climate Zone 3 in the 2009 IECC. Similarly, the U-factor should be changed back to the mass wall U-factor in Table 402.1.3 of the 2009 IECC. These changes are indicated above.

The equivalency between mass wall and frame wall R-values in Climate Zone 3 was previously demonstrated for previous versions of the IECC. Mass walls have significant energy saving benefits in Climate Zone 3.

Cost Impact: The code change proposal will not increase the cost of construction.

R402.1.1T-EC-VANGEEM

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: Disapproved in accordance with the proponent's request. The proponent conceded that the proposals for lessening of stringency based on various payback periods were being consistently disapproved by the committee.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Tom Kositzky, Coalition for Fair Energy Codes, requests Approval as Submitted.

Commenter's Reason: The energy cost savings in this mild climate of going from R13 to R20 walls or from R8/13 to R5/8 mass walls is minimal. With wood frame walls, the annual energy savings of going from R13 to R20 has been estimated to be between $22 and $64 per year, depending on the size and configuration of the house, with an average savings of $42.60. The cost to go from 2x4 to 2x6 construction in a 2,000 square foot, two-story house has been estimated by the National Association of Home Builders to be over $2,930.00. Even if the actual cost is only half that number, or $1,465, it would still take over 34 years for a simple payback on the increased cost of construction. If 4% annual interest is applied to the additional $1,465 of a 30-year mortgage, the energy savings of $42.60 fails to even cover the $59 annual cost of the additional mortgage. So, proposing that wood frame walls be insulated at R13 instead of R20 in Climate Zone 3 hardly represents an extreme roll-back in energy savings; especially considering the added cost of construction.

This proposal does not drastically impact energy savings and will decrease the cost of construction, resulting in more affordable housing for first-time homeowners.

We urge your support of RE38 as submitted.

Public Comment 2:

Martha Van Geem, representing Masonry Alliance for Codes and Standards, requests Approval as Submitted.

Commenter's Reason: This proposal combines RE26, RE35, and RE38 for values in Climate Zone 3. RE26 and RE35 change the wood frame R-value for Climate Zone 3 to R13. R38 changes the mass wall R-value to be consistent with the proposed wood frame R-value.

Public Comment 3:

Tim Ryan, International Association of Building Officials request Approval as Modified by this Public Comment.

Modify the proposal as follows:

(Portions of Table not shown remain unchanged)

Commenter's Reason: RE38 originally attempted to change the wall R-values in climate zone 3 back to that of the 2009 IECC, this public comment seeks to also include climate zone 4. A number of jurisdictions have chosen to also reduce the wall requirements in both climate zone 3 and climate zone 4. Rather than have this requirement be amended locally, this comment seeks to fix the problem nationally.

(Portions of Table not shown remain unchanged.)

Reason: The prescriptive basement wall requirement increased from R-10 to R-15 in the 2012 IECC. Calculations used to justify the change were based on energy models which had less sophisticated algorithms than Energy Plus which is now the preferred modeling software of the Department of Energy. When using Energy Plus, the energy savings in a 700 square foot basement totaled $7/yr in Chicago (Climate zone 5). The additional cost for this is conservatively estimated at $590. This makes the simple payback in excess of 58 years. This also will create a negative cash flow for the consumer. The values being modified by this proposal are the same as what was proposed by the Department of Energy in their proposal EC13 from the last cycle. The values currently adopted were an increase from proposals not submitted by the Department of Energy.

Climate Zone	Representative City	Basement Wall R-Value Change	Energy Savings	Incremental Cost	Simple Payback
5	Chicago, IL	R-10->R-15	$7/yr	$590 ($0.82/ft2)	84 years

The energy modeling was done using the Energy Plus simulation engine and BEopt version 1.4, Cost figures came from ASHRAE RP-1481

Cost Impact: The code change proposal will not increase the cost of construction.

R402.1.1T#1-EC-SURRENA

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: Disapproved in accordance with the proponent's request. The proponent conceded that the proposals for lessening of stringency based on various payback periods were being consistently disapproved by the committee.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Martha G. VanGeem representing the Masonry Alliance for Codes and Standards requests Approval as Submitted.

Commenter's Reason: The commenter provides cost justification indicating an 84-year simple payback for the insulation levels in the current code: The initial investment is $590 in order to save $7 a year in energy. This is an excessive burden to builders and homeowners. Available money is better spent on other energy-saving measures.

In addition, it does not make sense to have the requirements for basement R-values greater than the requirements for above grade mass walls, which they are in the current code for this climate zone. The basement wall is usually concrete or masonry – a mass wall. In addition, most of the basement wall has earth against it, providing additional insulating and thermal mass benefits. Approving this code change proposal will rectify this contradiction in the code.

7 and 8	0.32	0.55	0.026	0.048	0.057	0.028	0.050	0.055

(Portions of Table not shown remain unchanged)

Reason: This code change proposal is intended to correct the assumptions behind the wood-frame wall U-factors embedded in Table R402.1.3 of the IECC. The misrepresent the true performance of homes and, as such, over-estimate the energy efficiency of a typical R13 wood wall assembly when the Total UA or Simulated Performance path is used to demonstrate compliance to the IECC.

The wood wall U-factor values in Table R402.1.3 are currently based on a wall system that assumes the use of 5/8" plywood sheathing, which is well in excess of the minimum (3/8" thick) structural wood panel wall bracing in the International Residential Code (IRC). The U-factor value for the R13+5 wood wall system also assumes that a full double layer of 5/8" plywood sheathing and 1" continuous insulation is used. Neither the use of 5/8" structural panel wall sheathing or double sheathing with structural panels and continuous insulation in single family houses is commonly practiced or required by code.

According to the NAHB Research Center's 2011 Builders Survey, 5/8" or thicker wood structural panel wall sheathing makes up only 10% of the structural wood wall sheathing used in single-family residential construction. While 68% of residential single family wall area used wood structural panel sheathing was 7/16" thick or less.

There are several code options for braced wall segments that can incorporate continuous insulation over the top without adding a layer of structural wood panels. There are also options to use structural panels in combination with continuous insulation in between the structural segments. The code must be based on minimum systems that meet the provisions of the code in order to establish requirements that are fair to all products and assemblies. That minimum system would be a single layer of sheathing using continuous insulation.

Cost Impact: The code change proposal will not increase the cost of construction.

R402.1.3T #1-EC-ELLIS

Committee Action Hearing Results

Errata: The proposal only intends a change to Zones 3 and 4 in the Frame Wall U-Factor column.

Committee Action: **Approved as Submitted**

Committee Reason: This code change proposal bring transparency and accuracy to the code by using more realistic assumptions to generate Climate Zones 3-4 wood frame wall *U*-factors in Table R402.1.3.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Brian Dean, ICF International, representing the Energy Efficient Codes Coalition; Jeff Harris, Alliance to Save Energy; Harry Misuriello, American Council for an Energy-Efficient Economy (ACEEE); Bill Prindle, representing the Energy Efficient Codes Coalition; Garrett Stone, Brickfield, Burchette, Ritts & Stone, PC; Donald J. Vigneau, Northeast Energy Efficiency Partnerships Inc., request Disapproval.

Commenter's Reason: We recommend disapproval of RE44. Proposals RE44, RE45, RE46, RE47 and RE50 should be disapproved because they weaken the energy efficiency requirements of the IECC's U-factor, Total UA, and Simulated Performance alternatives. These proposals all suffer from the same fatal flaw – they treat the U-factor table (R402.1.3) as a direct product of the prescriptive table (R402.1.1), and attempt to align the two tables based on a single method of construction. The result is an unnecessary weakening of the stringency of the IECC and constitutes backsliding from the 2012 IECC:

- The foundation of the IECC residential envelope requirements is Table R402.1.3, which sets the baseline for efficiency in residential buildings. The U-factor alternative (R402.1.3), the Total UA alternative (R402.1.4), and the Simulated Performance alternative (R405) all reference Table R402.1.3 for the efficiency baseline for specific assemblies. These compliance options are designed to allow maximum flexibility as long as a specified baseline level of efficiency is achieved.
- The simple prescriptive path (Table R402.1.1) is a popular compliance option, but it is only one means of achieving compliance with Chapter 4 of the residential IECC. The simple prescriptive path (Table R402.1.1 and accompanying sections) is a simplified, component-based "recipe" for meeting the code, but it was never intended to be the starting point for all compliance paths or to exactly equal Table R402.1.3, any more than a home built to other aspects of the prescriptive path would exactly match a home built under Table R402.1.3. Unlike the baseline in Table R402.1.3, prescriptive requirements are based on commonly available building products, but any builder that seeks greater flexibility must use one of the other compliance alternatives.
- It is not possible to make the R-value and U-factor tables exactly consistent with one another in all cases because a comparative analysis must be based on a range of assumptions such as framing fractions and other assembly details that are not currently specified in the IECC. These details will also vary from building to building and may differ across the various climate zones. The proponent of RE44 admits as much in the reason statement, claiming that "68% of residential single family wall area used wood structural panel sheathing was 7/16" thick or less." This raises a multitude of questions:
    - Would RE44 and similar proposals thus make 32% of "residential single family wall area" inconsistent with the U-factor tables?
    - Were there climate-specific variations in both the usage of structural sheathing and the thickness of sheathing? If so, why is the same calculation used for every climate zone?
    - What about multifamily buildings, townhomes, condos, and other residential buildings covered by the residential requirements of the IECC? Were these buildings even modeled?

Perhaps the most telling statement in RE44 is at the bottom of the reason statement: "The code must be based on minimum systems that meet the provisions of the code in order to establish requirements that are fair to all products and assemblies." In other words, the proponent believes that the code must be based on the least-efficient assembly possible under the R-value table. To essentially rewrite the three U-factor based compliance paths based on a single worst-case application of the prescriptive R-value approach is simply backwards. RE44-47 and RE50 would significantly weaken the requirements of the IECC, and each of these proposals should be disapproved.

RE44-13

Final Action: AS AM AMPC____ D

4 except Marine	0.35	0.55	0.026	0.057 0.060	0.098	0.047	0.059	0.065
5 and Marine 4	0.32	0.55	0.026	0.057	0.082	0.033	0.050	0.055
6	0.32	0.55	0.026	0.048	0.060	0.033	0.050	0.055
7 and 8	0.32	0.55	0.026	0.048	0.057	0.028	0.050	0.055

(Portions of Table not shown remain unchanged)

Reason: This code change proposal is intended to correct the assumptions behind the wood-frame wall U-factors embedded in Table R402.1.3 of the IECC. The misrepresent the true performance of homes and, as such, over-estimate the energy efficiency of a typical R13 wood wall assembly when the Total UA or Simulated Performance path is used to demonstrate compliance to the IECC.

The wood wall U-factor values in Table R402.1.3 are currently based on a wall system that assumes the use of 5/8" plywood sheathing, which is well in excess of the minimum (3/8" thick) structural wood panel wall bracing in the International Residential Code (IRC).

While 3/8" is the minimum wood structural panel wall bracing thickness allowed in the IRC, the most common structural panel thickness used in the United States is 7/16-inch. According to the 2011 Builders Survey, 68% of residential single family wall area used wood structural panel sheathing that was 7/16" thick or less. Therefore, it is reasonable to use an R-value for structural wood panels of 0.62R in the calculation for the U-value for climate zones 1 and 2. According to Table 2, that U-factor is 0.084.

Cost Impact: The code change proposal will not increase the cost of construction.

R402.1.3T #2-EC-ELLIS

Committee Action Hearing Results

Errata: The proposal only intends a change to Zones 1 and 2 in the Frame Wall U-Factor column.

Committee Action: **Approved as Submitted**

Committee Reason: This code change proposal brings transparency and accuracy to the code by using more realistic assumptions to generate Climate Zones 1 and 2 wood frame wall *U*-factors in Table R402.1.3.

Assembly Action: **None**

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Tom Kositzky, representing the Coalition for Fair Energy Codes, requests As Modified by this Public Comment.

Modify the proposal as follows:

TABLE R402.1.3
EQUIVALENT *U*-FACTORS[a]

CLIMATE ZONE	FENESTRATION *U*-FACTOR	SKYLIGHT *U*-FACTOR	CEILING *U*-FACTOR	FRAME WALL *U*-FACTOR	MASS WALL *U*-FACTOR[b]	FLOOR *U*-FACTOR	BASEMENT WALL *U*-FACTOR	CRAWL SPACE WALL *U*-FACTOR
1	0.50	0.75	0.035	~~0.084~~ <u>0.085</u>	0.197	0.064	0.360	0.477
2	0.40	0.65	0.030	~~0.084~~ <u>0.085</u>	0.165	0.064	0.360	0.477
3	0.35	0.55	0.030	0.057	0.098	0.047	0.091[c]	0.136
4 except Marine	0.35	0.55	0.026	0.057	0.098	0.047	0.059	0.065
5 and Marine 4	0.32	0.55	0.026	0.057	0.082	0.033	0.050	0.055
6	0.32	0.55	0.026	0.048	0.060	0.033	0.050	0.055
7 and 8	0.32	0.55	0.026	0.048	0.057	0.028	0.050	0.055

(Portions of Table not shown remains unchanged)

Commenter's Reason: The committee chose to approve RE45-13 which set the U-factors for Climate Zones 1 and 2 at U-0.084 which we agree is more correct than the U-0.082 factor in the 2012 IECC. While the assembly assumption in RE45 are very close, accepting the 0.084 U-factor sets a precedent that the U-factors can be established without using the code minimum wood structural panel wall bracing in the frame wall system assumptions. The 0.084 U-factor assumes that the wood sheathing is 7/16 inches. The code minimum wood structural panel sheathing thickness for wall bracing is 3/8 inches.

Therefore, the base calculations should use the R-value for 3/8" thick wood structural panels in the evaluation. When the calculation is done with the correct sheathing R-value, the calculated U-factor is U-0.085. This is the U-factor that should be used.

We urge the support of this code change proposal as modified by this public comment.

Public Comment 2:

Brian Dean, ICF International, representing the Energy Efficient Codes Coalition; Jeff Harris, Alliance to Save Energy; Harry Misuriello, American Council for an Energy-Efficient Economy (ACEEE); Bill Prindle, representing the Energy Efficient Codes Coalition; Garrett Stone, Brickfield, Burchette, Ritts & Stone, PC; Donald J. Vigneau, Northeast Energy Efficiency Partnerships Inc., request Disapproval.

Commenter's Reason: We recommend disapproval of RE45 for the same reason as RE44. Proposals RE44-47 and RE50 should all be disapproved because they collectively weaken the energy efficiency requirements of the IECC's U-factor, Total UA, and Simulated Performance alternatives. These proposals all suffer from the same fatal flaw – they treat the U-factor table (R402.1.3) as a direct product of the prescriptive table (R402.1.1), and attempt to align the two tables based on a single method of construction. The result is an unnecessary weakening of the stringency of the IECC and constitutes backsliding from the 2012 IECC.

(Portions of Table not shown remain unchanged)

Reason: This code change proposal is intended to bring transparency and accuracy to the code by using more realistic assumptions to generate Climate Zones 3-5 wood frame wall *U*-factors in Table R402.1.3. The *REScheck*™ assumptions result in *U*-factors that misrepresent the true energy performance of wood walls and, as such, over-estimate the energy efficiency of a typical R20 and R13+5 wood wall assemblies when the assembly *U*-factor, Total UA alternative or Simulated Performance alternative is used to demonstrate compliance.

This proposal corrects two *REScheck*™ assumptions which were used to generate the wood wall *U*-factors in Table R402.1.3.

1. It was assumed that 5/8-inch plywood wall sheathing is used.
   (This assumption is in excess of the minimum required, 3/8-inch thick, wood structural panel wall bracing that is required in the IRC.)
2. The assumption that a double layer of wall sheathing is used for R13+5 assemblies.
   (A layer of R5 continuous insulation with an additional layer of continuous 5/8-inch plywood wall sheathing is assumed.)

Both of these assumptions are not based upon common practice nor are they required by the IRC. In order to establish baseline requirements that are fair to all products and systems, the code should be based upon the minimum performing assemblies that meet the provisions of the code. The minimum performing system in IECC Table R402.1.1 is found in footnote h. It allows continuous insulating sheathing to be used in combination with intermittent structural wall bracing (a.k.a., corner bracing) and results in a *U*-factor of 0.064 as shown below in Table 3.

Recognizing the strong opposition regarding the use of this common prescriptive wall assembly (footnote h) as a basis for generating *U*-factors, we propose basing the Climate Zone 3-5 continuous insulating sheathing *U*-factor on an assembly that uses let-in-bracing (per IRC Table R602.10.4) or metal strap bracing to provide lateral support. The resulting *U*-factor of 0.060 correlates to the *U*-factor for an R20 wall when code minimum 3/8-inch wood structural panel sheathing is used in lieu of 5/8-inch plywood. (See Table 2 below.)

A *U*-factor of 0.060 aligns more closely with common construction practices and would be a more reasonable value for wood frame walls in Climate Zones 3-5.

We ask the support of the committee for this proposal.

Table 1 shows the RES*check*™ component assumptions which were used to determine the prescriptive *U*-factors in Table R402.1.3 of the IECC[1, 2]. The cells representing the 5/8-inch plywood and double layer wall sheathing assumptions are shaded.

Table 2 shows the component assumptions for the *U*-factor being proposed.

Table 3 represents a code-compliant and common construction approach which is provided for reference.

(Portions of Table not shown remain unchanged)

Reason: The purpose of this code change proposal is to bring transparency and accuracy to the code by correcting the wood-frame wall *U*-factors for Climate Zones 6, 7 and 8 in Table R402.1.3. The previous assembly component assumptions resulted in *U*-factors that misrepresent the true energy performance of wood walls and, as such, underestimate the energy efficiency of a typical R20+5 wood wall assembly. Correcting the *U*-factor to 0.046 from 0.048 is more consistent with common construction practices for the corresponding assemblies listed in Table 402.1.1.[1]

Table 402.1.1 lists two prescriptive wood wall assembly options for Climate Zones 6-8, both of which require continuous insulation. In addition to meeting the IECC, these walls must also provide lateral resistance for the house which is typically provided through prescriptive wall bracing or shear walls. There are several structural wall bracing options in Table R602.10.4 of the IRC, two of which are commonly used with continuous insulating sheathing:

1. Let-in-bracing (LIB), and;
2. Intermittent structural sheathing (combined with insulating sheathing installed between the structural sheathing, and a thinner insulating sheathing or insulated siding on top of the structural sheathing, per IECC Table R402.1.1, footnote h).

In order to establish baseline requirements that treat all building products and systems equally, the code should be based on the minimum performing assemblies that meet the provisions of the code. The minimum performing system in IECC Table R402.1.1 is continuous insulating sheathing used in combination with intermittent structural wall bracing (footnote h), which results in a *U*-factor of 0.048 as demonstrated in Tables 2 and 3, below. Recognizing that there is opposition to using footnote h as a baseline assembly, we propose basing the *U*-factors for Climate Zones 6-8 on the continuous insulating sheathing wall assemblies that use let-in-bracing that requires no structural sheathing. This proposal results in a *U*-factor of 0.046, which both assemblies are shown to meet, per Table 1.

We ask the support of the committee for this proposal.

(Portions of Table not shown remain unchanged)

Reason: This code change proposal is intended to bring transparency and accuracy to the code by using more realistic assumptions to generate the Climate Zone 1 and 2 wood-frame wall *U*-factors in Table R402.1.3. The previous assumptions resulted in *U*-factors that misrepresent the true energy performance of wood walls and, as such, overestimate the energy efficiency of a typical R13 wood wall assembly when the assembly *U*-factor alternative, the total UA alternative or Simulated Performance alternative is used to demonstrate compliance. The wood wall *U*-factors in Table R402.1.3 are currently based on an assembly that assumes the use of 5/8-inch plywood sheathing, which is well in excess of the minimum 3/8-inch thick structural wood panel wall bracing in the IRC.

Table 1 incorporates the RES*check*™ assumptions which were used to determine the prescriptive *U*-factors in Table R402.1.3 of the IECC[1,2] in the left hand columns of the table. This base calculation assumes that 5/8-inch thick plywood is used as the sheathing material, resulting in the current 0.082 *U*-factor. The proposed component *R*-value basis in the right-hand columns in Table 1 uses the same RES*check*™ assumptions but incorporates the *R*-value for 3/8-inch wood structural panel sheathing, resulting in a *U*-factor of 0.085.

Adjusting the Climate Zone 1-2 *U*-factors in Table R402.1.3 to 0.085 will more accurately reflect the energy efficiency of an R13 wood wall assembly when the Total UA or Simulated Performance alternatives are used to demonstrate compliance.

We ask the support of the committee for this proposal.

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Tom Kositzky, representing Coalition for Fair Energy Codes, requests Approval as Submitted.

Commenter's Reason: The committee chose to approve RE45-13 which set the U-factors for Climate Zones 1 and 2 at U-0.084, which we agree is more correct than the 0.082 U-factor in the 2012 IECC. While the assembly assumptions in RE45 are very close, accepting the 0.084 U-factor sets a precedent that the U-factors can be established without using the code minimum wood structural panel wall bracing in the frame wall system assumptions. The 0.084 U-factor assumes that the wood sheathing is 7/16 inches. The code minimum wood structural panel sheathing thickness for wall bracing is 3/8 inches.

Therefore, the base calculations should use the R-value for 3/8" thick wood structural panels in the evaluation. When the calculation is done with the correct sheathing R-value, the calculated U-factor is U-0.085. This is the U-factor that should be used.

We urge the support of RE48 as submitted.

(Portions of table not shown remain unchanged)

Reason: The intent of these changes is not to alter the stringency of the code, but rectify the conversion from R-Value to U-Factor. Currently the R-Values and equivalent U-Factors do not match when applying a consistent calculation method.

It is important that the U-Factors and R-Values do match when small alterations are being made to the wall assemblies selected in the R-Value table. For example, a builder does not want to install R-20 as suggested in the R-Value table. Instead, the builder's preferred wall is R-15+R3.8c.i. Although the R-15+R3.8c.i. wall is thermally better than the R-20 wall, it does not meet the requirements of the Equivalent U-Factor table.

Below are a series of calculations which justify the proposed changes to the Frame Wall U-Factor values:

All table footnotes remain unchanged

Commenter's Reason: The Committee passed two proposals with differing U-factors in Climate Zones 6-8 (RE47 and RE50). While both proposals make similar corrections to the flawed assumptions behind the 2012 IECC U-factors, there is still a small difference between the two proposals that must be decided. The difference is important as the approach to determining U-factors in the code must have a sound basis. This public comment corrects the proposed U-factor as the calculations in RE50 assumed that two layers of continuous sheathing are used on the walls – a layer of continuous insulation and a separate layer of 7/16" wood structural panel sheathing. Instead of a double sheathing layer, this public comment assumes the use of let-in bracing under foam sheathing.

Continuous wood structural panels are not required by code in frame wall systems. Other types of wall bracing can be used that provide no additional R-value to the wall, such as let-in-bracing or a structural continuous insulated sheathing product. Assuming that only let-in bracing is used in a R20+5 wall, the U-factor should be U-0.046.

Even if the frame wall U-factor is calculated with an additional code minimum 3/8" wood structural panel layer under the foam sheathing the U-factor would not change. In both cases using the code minimum bracing requirements, the U-factor for wood framed walls incorporating an R20 cavity insulation and R5 continuous insulation equals U-0.046.

We support the approval of RE-47 which changes the U-factors in Climate Zones 6-8 to U-0.046. This public comment would bring the Climate Zone 6-8 U-factors into alignment with RE-47, the other proposal that the Committee passed. It also corrects the Climate Zone 1-2 U-factors so that they are also based on code minimum 3/8" wood structural panel bracing and not 7/16" wood structural panels.

We urge the approval of this proposal as modified by this public comment.

U-Factor Calculations – Climate Zoness 1-2 Wood Framed Walls

Wall Thermal Resistance by Component	5/8" Wood Sheathing			7/16" Wood Sheathing			3/8" Wood Sheathing

Public Comment 2:

Brian Dean, ICF International, representing the Energy Efficient Codes Coalition; Jeff Harris, Alliance to Save Energy; Harry Misuriello, American Council for an Energy-Efficient Economy (ACEEE); Bill Prindle, representing the Energy Efficient Codes Coalition; Garrett Stone, Brickfield, Burchette, Ritts & Stone, PC; Donald J. Vigneau, Northeast Energy Efficiency Partnerships Inc., request Disapproval.

Commenter's Reason: We recommend disapproval of RE50. We recommend disapproval of RE50 for the same reason as RE44. Proposals RE44-47 and RE50 should all be disapproved because they collectively weaken the energy efficiency requirements of the IECC's U-factor, Total UA, and Simulated Performance alternatives. These proposals all suffer from the same fatal flaw – they treat the U-factor table (R402.1.3) as a direct product of the prescriptive table (R402.1.1), and attempt to align the two tables based on a single method of construction. The result is an unnecessary weakening of the stringency of the IECC and constitutes backsliding from the 2012 IECC.

RE50-13

Final Action: AS AM AMPC____ D

RE52-13
R402.2.1 (IRC N1102.2.1), R402.2.2 (IRC N1102.2.2)

Proposed Change as Submitted

Proponent: Brian Dean, Energy Efficient Codes Coalition; Garrett Stone, Brickfield Burchette Ritts & Stone, PC; Jeff Harris, Alliance to Save Energy; Harry Misuriello, American Council for an Energy-Efficient Economy; and Bill Prindle, Energy Efficient Codes Coalition

Revise as follows:

R402.2.1 (N1102.2.1) Ceilings with attic spaces. ~~When Section R402.1.1 would require R-38 in the ceiling, R-30 shall be deemed to satisfy the requirement for R-38 wherever~~ <u>Where</u> the full height ~~of uncompressed R-30 insulation extends~~ over the wall top plate at the eaves <u>does not allow sufficient space for the required insulation in Section R402.1.1,</u>~~. Similarly, R-38 shall be deemed to satisfy the requirement for R-49 wherever the full height of uncompressed R-38 insulation extends over the wall top plate at the eaves. This reduction shall not apply to the U-factor alternative approach in Section R402.1.3 and~~ the total UA alternative in Section R402.1.4 <u>shall be used</u>.

R402.2.2 (N1102.2.2) Ceilings without attic spaces. Where ~~Section R402.1.1 would require insulation levels above R-30 and~~ the design of the roof/ceiling assembly does not allow sufficient space for the required insulation <u>in Section R402.1.1</u>, ~~the minimum required insulation for such roof/ceiling assemblies shall be R-30. This reduction of insulation from the requirements of Section R402.1.1 shall be limited to 500 square feet (46 m2) or 20 percent of the total insulated ceiling area, whichever is less. This reduction shall not apply to the U-factor alternative approach in Section R402.1.3 and~~ the total UA alternative in Section R402.1.4 <u>shall be used</u>.

Reason: The purpose of this code change is to improve the efficiency of buildings by removing exceptions to the prescriptive ceiling R-value requirements. The 2012 IECC carves out an exception to the ceiling R-value requirements (in Section R402.2.1 for ceilings with attic spaces and Section R402.2.2 for ceilings without attic spaces) for cases (where there is insufficient space in the ceiling design to install the full amount of required insulation. Although this exception reduces the efficiency of ceilings, there is no corresponding increase of efficiency elsewhere in the building.

The proposal above eliminates the exception in each section because it is unnecessary. Where ceiling space is inadequate to install sufficient insulation, the builder or design professional using the prescriptive approach should use the Total UA analysis (or may opt for the Simulated Performance Alternative) to make up for the efficiency loss elsewhere in the thermal envelope or overall performance of the building. There is no valid reason to continue to give a free pass to buildings designed with insufficient space for adequate ceiling insulation.

Cost Impact: The code change proposal will increase the cost of construction.

R402.2.1-EC-DEAN-HARRIS-MISURIELLO-PRINDLE-STONE

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: The proposal would require a Total UA calculation for the building to deal with this situation for attic insulation. This approach is too severe for this situation.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Brian Dean, ICF International, representing the Energy Efficient Codes Coalition; Jeff Harris, Alliance to Save Energy; Harry Misuriello, American Council for an Energy-Efficient Economy (ACEEE); Bill Prindle, representing the Energy Efficient Codes Coalition; Garrett Stone, Brickfield, Burchette, Ritts & Stone, PC; Donald J. Vigneau, Northeast Energy Efficiency Partnerships Inc., request Approval as Submitted.

Commenter's Reason: We recommend approval of RE52 as submitted. RE52 improves building energy efficiency by eliminating an unnecessary loophole. The IECC prescriptive path currently allows a significant reduction in ceiling insulation R-value where a raised heel truss is used. The problem with the exception is that it applies in *every situation* where the full, uncompressed height of the insulation extends over the wall plate at the eaves. Even in buildings where R-38 could easily be installed (and would improve energy efficiency of the building for 100 years), the exception automatically kicks in. We view this as an overly broad and unnecessary loophole that gives away long-term energy efficiency and cost savings for homeowners.

RE52 eliminates the loophole, while providing considerable flexibility to meet the insulation requirement. It would not "require a Total UA calculation" in every case, as suggested by the committee reason statement. Rather, it would require the correct amount of insulation where there is room for it, and a simple UA calculation, REScheck calculation, or performance calculation could be used if the roof design does not give enough space for the full insulation height.

RE52-13

Final Action: AS AM AMPC____ D

RE54-13
R402.2.1 (IRC N1102.2.1)

Proposed Change as Submitted

Proponent: Robby Schwarz, representing EnergyLogic, Inc. (robby@nrglogic.com)

Revise as follows:

R402.2.1 (N1102.2.1) Ceilings with attic spaces. When Section R402.1.1 would require R-38 in the ceiling, <u>it is required to be continuous across the entire attic at a depth sufficient to achieve an R-38.</u> R-30 shall <u>only</u> be deemed to satisfy the requirement for R-38 wherever the full height of uncompressed R-30 insulation extends over the wall top plate at the eaves <u>and the remainder or the attic continues to be R-38.</u> Similarly, R-38 shall be deemed to satisfy the requirement for R-49 wherever the full height of uncompressed R-38 insulation extends over the wall top plate at the eaves <u>and the remainder or the attic continues to be R-49</u>. This reduction shall not apply to the *U*-factor alternative approach in Section R402.1.3 and the total UA alternative in Section R402.1.4.

Reason: The language of this section has been misinterpreted for years to mean exactly what is being stated in the change. The language change makes it clear that continuous depth of insulation is required across the entire attic to the level that is called out in section R402.1.1. The only exception is over the top plate where insulation depth can be reduced due to the slop of the roof. Efficiency of the home is increased and if a reduction of the R-value is necessary for other building reasons then the other alternative compliance paths are available so tradeoffs can be utilized and code compliance can be achieved.

Cost Impact: The code change proposal will not increase the cost of construction.

R402.2.1-EC-SCHWARZ

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee disapproved this in preference to the language and approach in RE53-13.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Robby Schwarz, EnergyLogic, Inc., requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R402.2.1 Ceilings with attic spaces. ~~When~~ <u>Where</u> Section R402.1.1 ~~would~~ require<u>s</u> R-38 in the ceiling, ~~it is required to be continuous across the entire attic at a depth sufficient to achieve an R-38.~~ <u>the insulation shall be installed to maintain a continuous depth and R-value across the entire attic.</u> R-30 shall only be deemed to satisfy the requirement for R-38 wherever the full height of uncompressed R-30 insulation extends over the wall top plate at the eaves ~~and the remainder or the attic continues to be R-38.~~ Similarly, R-38 shall be deemed to satisfy the requirement for R-49 wherever the full height of uncompressed R-38 insulation extends over the wall top plate at the eaves ~~and the remainder or the attic continues to be R-49~~. This reduction shall not apply to the *U*-factor alternative approach in Section R402.1.3 and the total UA alternative in Section R402.1.4.

Commenter's Reason: The language clarifies that this section is not an alternative but rather an exception to the code. The code calls out a specific R-value per climate zone in table R402.1.1. It does not call out a lower allowable R-value. This section R402.2.1 allows for an exception in a particular common attic configuration, over the top plate, where full height insulation often can not be installed. The area over the top plate that would have the reduced R-value constitutes approximately 10-20% of the total area of a typical attic (depending on how it is calculated) and degrades the R-value of the entire attic less than moving to R-30 across the entire attic.

Weighted R-value Example: 1000 SQFT Attic
800 SQFT R-38 / 200 SQFT R-30
800/1000 = 0.8 x U-value 0.0262 = 0.0210
200/1000 = 0.2 x U-value 0.0333 = 0.0067
0.021 + 0.0067 = 0.0277
1/0.0277 = R-36.10

The reality in the field is that raised heel or energy trusses are already required by the code because an 8-10" heel height is needed to achieve R-30 over the top plate where baffles are installed. (8" of blown cellulose and 8-10"+ for fiberglass are needed to achieve an R-30)

.

RE54-13

Final Action: AS AM AMPC____ D

RE55-13
R402.2.2 (IRC N1102.2.2)

Proposed Change as Submitted

Proponent: Robby Schwarz, representing EnergyLogic, Inc. (robby@nrglogic.com)

Revise as follows:

R402.2.2 (N1102.2.2) Ceilings without attic spaces. Where Section R402.1.1 would require insulation levels above R- 30 and the design of the roof/ceiling assembly does not allow sufficient space for the required insulation, ~~the minimum required insulation for such roof/ceiling assemblies shall be R-30~~ the residential building shall be required to utilize the *U*-factor alternative approach in Section R402.1.3, the total UA alternative in ~~of~~ Section R402.1.4, or Section 405 to demonstrate code compliance. ~~This reduction of insulation from the requirements of Section R402.1.1 shall be limited to 500 square feet (46 m2) or 20 percent of the total insulated ceiling area, whichever is less. This reduction shall not apply to the *U*-factor alternative approach in Section R402.1.3 and the total UA alternative in Section R402.1.4.~~

Reason: The R-values have been established to achieve a specific level of quantifiable energy performance. If the levels cannot be achieved in a specific building assembly alternative compliance paths are available that will demonstrate that the assembly meets the requirements of the code.

Cost Impact: The code change proposal will not increase the cost of construction.

R402.2.2-EC-SCHWARZ

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee disapproved this in preference to the language and approach in RE53-13.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Robby Schwarz, EnergyLogic, Inc., requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R402.2.2 Ceilings without attic spaces. Where Section R402.1.1 ~~would~~ ~~require~~ requires insulation levels above R- 30 and the design of the roof/ceiling assembly does not allow sufficient space for the required insulation, the ~~residential~~ building shall ~~be required to~~ utilize the *U*-factor alternative approach in Section R402.1.3, the total UA alternative in ~~of~~ Section R402.1.4, or section 405 Simulated Performance Alternative to demonstrate code compliance.

Commenter's Reason: The committee disapproved this in preference to the language and approach in RE53-13. However RE53-13 dealt with section 402.2.1 **Ceilings with attic spaces** and this proposal is dealing with section 402.2.2 **Ceilings without attic spaces**. The R-values have been established to achieve a specific level of quantifiable energy performance. If the levels cannot be achieved in a specific building assembly alternative compliance paths are available that will demonstrate that the assembly meets the requirements of the code.

RE55 -13

Final Action: AS AM AMPC____ D

RE56-13

R202 (NEW) (IRC N1101.9), R402.2.3 (IRC N1102.2.3), R402.2.3.1 (NEW) (IRC N1102.2.3.1 (NEW)), R402.2.3.2 (NEW) (IRC N1102.2.3.2 (NEW)), Chapter 5

Proposed Change as Submitted

Proponent: Forrest Fielder, CBO, Arizona Building Officials (fielder_4@msn.com)

Revise as follows:

R402.2.3 (N1102.2.3) ~~**Eave baffle**~~ **.Vented attics.** Roof assemblies containing vented attics shall comply with 402.2.3.1 and 402.2.3.2.

R402.2.3.1 (N1102.2.3.1) Eave baffle. For air permeable insulation in vented attics, a baffle shall be installed adjacent to soffit and eave vents. Baffles shall maintain an opening equal or greater than the size of the vent. The baffle shall extend over the top of the attic insulation. The baffle shall be permitted to be any solid material.

R402.2.3.2 (N1102.2.3.2) Radiant barriers. In Climate Zones 1, 2, and 3, vented attics shall contain radiant barriers, as tested in accordance with ASTM C1313M-12 and installed in accordance with ASTM C1743-12

> **Exception:** Attics containing no HVAC space conditioning equipment or attics with a maximum of 10 lineal feet of supply or return ducting.

Add new definition as follows:

IECC SECTION R202 (IRC N1101.9)
GENERAL DEFINITIONS

RADIANT BARRIER. A material having a low emittance surface (0.1 or less) and where installed in building assemblies, the low emittance surface shall face a ventilated or unventilated air space.

Add new standards to Chapter 5 as follows:

ASTM C1313/C1313M-12 Standard Specification for Sheet Radiant Barriers for Building Construction Applications

ASTM C1743-12 Standard Practice for Installation and Use of Radiant Barrier Systems (RBS) in Residential Building Construction

Reason: In cooling climates, attic radiant barriers (ARBs) have been shown to conserve substantial amounts of energy by reducing temperatures in vented attics. Lower attic temperatures slow the rate of temperature differential – driven heat transfer from ceiling envelope elements and HVAC equipment and ducting.
Attic radiant barriers are extensively used across Climate Zones 1, 2 and 3, i.e. in the sunbelt areas, and numerous demonstration projects and studies have confirmed the energy savings and cost-effectiveness of these installations. Such radiant barrier products have been on the market for over 24 years and are used by 87 of the top 100 US Builders. They have an established history and have been accepted into several regional code requirements and are included in the Energy Star Reference Home Guidelines. Some 650 million square feet of radiant barriers are installed annually.

The current state and city codes that include radiant barrier are:

- HI – Chapter 181 of Title 3, Table 402.1.1.1, Section 402.1.1.6, 402.1.1.8.1
- TX - Austin, Chapter 25-12, Article 12. Energy Code, Section 402.6
- FL – 2010 Florida Building Code, Section 405.6.1, Figure 405.6.1 & Table 303.2 (ASTM Standards)
- CA – Title 24, Part 6, Subsection 8, Section (f), Subsection 2; Table 151-B; Table 151-C; Table 151-D

This product has two ASTM Standards that are applicable – ASTM C1313, "Standard Specification for Sheet Radiant Barriers for Building Construction Applications," and ASTM C1743, "Standard Practice for Installation and Use of Radiant Barrier Systems (RBS) in Residential Building Construction". This proposal requires the use of radiant barriers in a manner consistent with the existing language in the Energy Star for Homes – "Version 3, Exhibit 1" and, additionally, requires that the radiant barriers comply with the two ASTM standards just referenced.

The Department of Energy (DOE) has published the "Radiant Barrier Fact Sheet that is available on the DOE website through the following link: http://www.ornl.gov/sci/ees/etsd/btric/RadiantBarrier/RBFactSheet2010.pdf

A comprehensive review of radiant barrier studies was performed by Mario Medina, Ph.D. P.E. "This paper provides a general description of RBs, including installation configurations, the physical principles that make them work, and the laboratory and field experiments used to evaluate their thermal performance. An extensive review of the literature is summarized, highlighting fundamental issues, such as reduced ceiling heat flows, reduced space cooling and heating loads, and changes in attic temperatures produced by the installation of RBs in residential attics." The document has been mentioned here as an additional reference related to radiant barrier product information and to highlight the scope of "benefit" studies that have been completed.

The study entitled "Radiant Barrier Impact on Selected Building Performance Measurements Model Home Case Study", authored by B.E. Davis and J. Tiller, from the Appalachian State University Energy Center, sponsored by Centex Homes in Charlotte, NC, demonstrates the energy savings associated with the use of radiant barriers in attics. In the study, two identical homes were fit with over sixty sensors, where one house contained a radiant barrier (designated as the "Belmont" home) and one did not. The house with the radiant barrier had a peak attic temperature drop by 23%, and the improved efficiency of the cool air delivered through the ducts was 57%.

The current language in the Energy Star for Homes – "Version 3, Exhibit 1" requires the use of radiant barriers in vented attics of the reference home, with an exception for attics containing no HVAC space conditioning equipment and a maximum of 10 linear feet of supply or return ducting.

[1] Department of Energy "Radiant Barrier Fact Sheet" prepared by the Oak Ridge National Laboratory (2012).
[2] Medina, Mario, "A Comprehensive Review of Radiant Barrier Research Including Laboratory and Field Experiments", report prepared for the Reflective Insulation Manufacturers Association.
[3] **Davis, Bruce Eugene & Tiller, Jeffrey, "Radiant Barrier Impact on Selected Building Performance** Measurements, Model Home Case Study, Centex Homes".

Cost Impact: The code change proposal will increase the cost of construction.

Analysis: A review of the standards proposed for inclusion in the code, ASTM <u>C1313/C1313M-12 Standard Specification for Sheet Radiant Barriers for Building Construction Applications, and C1743-12 Standard Practice for Installation and Use of Radiant Barrier Systems (RBS) in Residential Building Construction</u> with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 1, 2013.

R402.2.3-EC-FIELDER

Committee Action Hearing Results

For staff analysis of the content of ASTM C1224-11 relative to CP#28, Section 3.6, please visit: http://www.iccsafe.org:8888/cs/codes/Documents/2012-13cycle/Proposed-A/00a_updates.pdf

Committee Action: Disapproved

Committee Reason: No data has been provided to establish the impact on energy use in a building.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Forest Fielder, CBO, Arizona Building Officials, representing self, requests Approval as Modified by this Public Comment.

Modify the proposed change as follows:

IECC SECTION R202 (IRC N1101.9)
GENERAL DEFINITIONS

~~**RADIANT BARRIER.** A material having a low emittance surface (0.1 or less) and where installed in~~

~~building assemblies, the low emittance surface shall face a ventilated or unventilated air space.~~

RADIANT BARRIER. A material having a low emittance surface of 0.1 or less installed in building assemblies.

(*Portions of code change proposal not shown remain unchanged.)*

Commenter's Reason: In response to the committee indicating that this proposal did not include "impact of energy use", the following text/calculations have been added. This data was taken from the DOE Fact Sheet and exemplifies savings for this product type in Climate Zones 1, 2 and 3. The modified proposal includes a new definition for *radiant barrier*, to be consistent with an existing IBC definition. The proponent requests approval as modified.(AM).

The Department of Energy (DOE) has published the "Radiant Barrier Fact Sheet that is available on the DOE website through the following link: http://www.ornl.gov/sci/ees/etsd/btric/RadiantBarrier/RBFactSheet2010.pdf
Values taken from this DOE document are utilized in the "Savings Benefit to the Home Owner" section below.

Savings Benefit to the Home Owner:
Cost Calculator – to home owner – new structure – hip roof:

☐ Product Cost - Radiant Barrier OSB Panel – $0.11 per sq. ft. (takes into account waste) 4

☐ 2,000 sq. ft. house, ranch, hip roof

☐ 2,200 sq. ft. of roof area x $0.11 per sq. ft. (radiant barrier cost) = $242.00

☐ Cost to home owner - $242.00

☐ Additional cost added to monthly payment of a 30 year mortgage – 4% fixed interest rate:
• $242.00 @ 4% = addition of $1.16 to the monthly payment

Savings Benefit to the Home Owner:

☐ Cost to add Radiant Barrier OSB - $1.16 per month (per above)

☐ 2,000 sq. ft. house, ranch, hip roof

☐ Savings as calculated in the Department of Energy "Radiant Barrier Fact Sheet"

☐ Code level insulation with well-sealed ducts in the attic
• Zone 1 - $0.03 per sq. ft. x 2,000 sq. ft. = $60.00 / 12 months = $5.00 per month
• Zone 2 - $0.03 per sq. ft. x 2,000 sq. ft. = $60.00 / 12 months = $5.00 per month
• Zone 3 - $0.02 per sq. ft. x 2,000 sq. ft. = $40.00 / 12 months = $3.33 per month

☐ The cost for energy is based on first year (2012) values – if increases in energy cost due to inflation and other factors occur – annual savings will increase proportionally.

In summary, this exercise exemplifies the immediate energy cost savings that are netted when a radiant barrier is included in the design of a new home in Climate Zones 1, 2 and 3 with "well-sealed" ducts in the attic. The cost to the new home is small and the energy savings are significant over the life of the home.

R202 (NEW) (IRC N1101.9 (NEW)), R402.2.3, (N1102.2.3) R402.2.3.1 (NEW) (IRC N1102.2.3.1 (NEW)), R402.2.3.2 (NEW) (IRC N1102.2.3.2 (NEW), Chapter 5

Proposed Change as Submitted

Proponent: Wesley Hall, Reflectix, Inc., representing self (wes.hall@reflectixinc.com)**,** Vickie Lovell, InterCode Incorporated, representing the Reflective Insulation Manufacturers Association International (Vickie@InterCodeinc.com)

Revise as follows:

R402.2.3 (N1102.2.3) Vented Attics. Sections 402.2.3.1 and 402.2.3.2 shall apply to roof assemblies containing vented attics.

R402.2.3.1 (N1102.3.1) Eave baffle. For air permeable insulations in vented attics, a baffle shall be installed adjacent to soffit and eave vents. The baffle shall maintain an opening equal or greater than the size of the vent. The baffle shall extend over the top of the attic insulation. The baffle shall be permitted to be any solid material.

R402.2.3.2 (N1102.2.3.2) Radiant barrier*.* Radiant barriers, used to supplement insulation in Climate Zones 1, 2, and 3, shall comply with the requirements of ASTM C1313 and shall be installed in accordance with ASTM C1743.

~~**R402.2.3 (N1102.2.3) Eave baffle.** For air permeable insulations in vented attics, a baffle shall be installed adjacent to soffit and eave vents. Baffles shall maintain an opening equal or greater than the size of the vent. The baffle shall extend over the top of the attic insulation. The baffle shall be permitted to be any solid material.~~

Add new definition as follows:

IECC SECTION R202 (IRC N1101.9)
GENERAL DEFINITIONS

RADIANT BARRIER. A material having a low emittance surface of 0.1 or less installed in building assemblies.

Add new standards to Chapter 5 as follows:

ASTM
C1313/C1313M-12 Standard Specification for Sheet Radiant Barriers for Building Construction Applications

C1743-12 Standard Practice for Installation and Use of Radiant Barrier Systems (RBS) in Residential Building Construction

Analysis: A review of the standards proposed for inclusion in the code, ASTM C1313/C1313M-12 Standard Specification for Sheet Radiant Barriers for Building Construction Applications, and C1743-12 Standard Practice for Installation and Use of Radiant Barrier Systems (RBS) in Residential Building Construction with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 1, 2013.

Reason: (HALL) Radiant barriers are a viable building option, widely distributed and have an established place in the market. The purpose of this proposal is to provide information and references for radiant barriers.

The content of this proposal contains product requirements and references that will aid the contractors and code officials in recognizing and understanding radiant barrier products and correct installation procedures.

Attic radiant barriers are extensively used across Climate Zones 1, 2 and 3, i.e. in the sunbelt areas. These products have been on the market for over 24 years and are used by 87 of the top 100 US Builders. They have an established history and have been accepted into several regional code requirements and are included in the Energy Star Homes Guidelines. Some 650 million square feet of the product is being installed annually.

The current state and city codes that include radiant barrier are:

- HI – Chapter 181 of Title 3, Table 402.1.1.1, Section 402.1.1.6, 402.1.1.8.1
- TX - Austin, Chapter 25-12, Article 12. Energy Code, Section 402.6
- FL – 2010 Florida Building Code, Section 405.6.1, Figure 405.6.1 & Table 303.2 (ASTM Standards)
- CA – Title 24, Part 6, Subsection 8, Section (f), Subsection 2; Table 151-B; Table 151-C; Table 151-D

This product has two ASTM Standards that are applicable – ASTM C1313, "Standard Specification for Sheet Radiant Barriers for Building Construction Applications," and ASTM C1743, "Standard Practice for Installation and Use of Radiant Barrier Systems (RBS) in Residential Building Construction". This proposal does not require the use of radiant barriers but requires that, when they are used, they comply with the two ASTM standards just referenced.
ASTM C1743-12 can be viewed at: http://reflectixinc.com/literature/securedpdfs/C1743.pdf

(LOVELL) The use of radiant barriers in vented attics in hot climates has been shown to conserve substantial amounts of energy by reducing the temperatures in the attic. If the attic temperature is lower, that slows the rate of temperature differential and transfers heat away from ceiling envelope elements and HVAC equipment and ducting. Attic radiant barriers are extensively used across Climate Zones 1, 2 and 3, i.e. in the sunbelt areas, and numerous demonstration projects and studies have confirmed the energy savings and cost-effectiveness of these installations. Such radiant barrier products have been on the market for over 24 years and are used by 87 of the top 100 US Builders. They have an established history and have been accepted into several regional code requirements and are included in the Energy Star Homes Guidelines. Some 650 million square feet of the product is installed annually.

The current state and city codes that include radiant barrier are:

- HI – Chapter 181 of Title 3, Table 402.1.1.1, Section 402.1.1.6, 402.1.1.8.1
- TX - Austin, Chapter 25-12, Article 12. Energy Code, Section 402.6
- FL – 2010 Florida Building Code, Section 405.6.1, Figure 405.6.1 & Table 303.2 (ASTM Standards)
- CA – Title 24, Part 6, Subsection 8, Section (f), Subsection 2; Table 151-B; Table 151-C; Table 151-D

This product has two ASTM Standards that are applicable – ASTM C1313, "Standard Specification for Sheet Radiant Barriers for Building Construction Applications," and ASTM C1743, "Standard Practice for Installation and Use of Radiant Barrier Systems (RBS) in Residential Building Construction". This proposal requires the use of radiant barriers in a manner consistent with the existing language in the Energy Star for Homes – "Version 3, Exhibit 1" and, additionally, requires that the radiant barriers comply with the two ASTM standards just referenced.
The Department of Energy (DOE) has published the "Radiant Barrier Fact Sheet that is available on the DOE website through the following link: http://www.ornl.gov/sci/ees/etsd/btric/RadiantBarrier/RBFactSheet2010.pdf
Values taken from this DOE document are utilized in the "Savings Benefit to the Home Owner" section below.
A very comprehensive study was performed by Mario Medina. "This paper provides a general description of RBs, including installation configurations, the physical principles that make them work, and the laboratory and field experiments used to evaluate their thermal performance. An extensive review of the literature is summarized, highlighting fundamental issues, such as reduced ceiling heat flows, reduced space cooling and heating loads, and changes in attic temperatures produced by the installation of RBs in residential attics. The document has been mentioned here as an additional reference related to radiant barrier product information and to highlight the scope of "benefit" studies that have been completed.
The study entitled "Radiant Barrier Impact on Selected Building Performance Measurements Model Home Case Study, authored by B.E. Davis and J. Tiller, from the Appalachian State University Energy Center, sponsored by Centex Homes in Charlotte, NC, and demonstrates the energy savings associated with the use of radiant barriers in attics. In the study, two identical homes were fit with over sixty sensors, where one house contained a radiant barrier (designated as the "Belmont" home) and one did not. The house with the radiant barrier had a peak attic temperature drop by 23% and the improved efficiency of the cool air delivered through the ducts was 57%.
The current language in the Energy Star for Homes – "Version 3, Exhibit 1" requires the use of radiant barriers in vented attics, with an exception for attics containing no HVAC space conditioning equipment and a maximum of 10 linear feet of supply or return ducting.
Cost Calculator – to home owner – new structure – hip roof:

- Product Cost - Radiant Barrier OSB Panel – $0.11 per sq. ft. (takes into account waste) [4]
- 2,000 sq. ft. house, ranch, hip roof
- 2,200 sq. ft. of roof area x $0.11 per sq. ft. (radiant barrier cost) = $242.00
- Cost to home owner - $242.00
- Additional cost added to monthly payment of a 30 year mortgage – 4% fixed interest rate:
- $242.00 @ 4% = addition of $1.16 to the monthly payment

Savings Benefit to the Home Owner:

- Cost to add Radiant Barrier OSB - $1.16 per month (per above)
- 2,000 sq. ft. house, ranch, hip roof
- Savings as calculated in the Department of Energy "Radiant Barrier Fact Sheet"

➢ Code level insulation with well-sealed ducts in the attic

- Zone 1 - $0.03 per sq. ft. x 2,000 sq. ft. = $60.00 / 12 months = $5.00 per month
- Zone 2 - $0.03 per sq. ft. x 2,000 sq. ft. = $60.00 / 12 months = $5.00 per month
- Zone 3 - $0.02 per sq. ft. x 2,000 sq. ft. = $40.00 / 12 months = $3.33 per month

➢ The cost for energy is based on first year (2012) values – if increases in energy cost due to inflation and other factors occur – annual savings will increase proportionally.

In summary, this exercise exemplifies the immediate energy cost savings that are netted when a radiant barrier is included in the design of a new home in Climate Zones 1, 2 and 3 with "well-sealed" ducts in the attic. The cost to the new home is small and the energy savings are significant over the life of the home.

Cost Impact: The code change proposal will not increase the cost of construction.

R402.3 (NEW)-EC-HALL

Committee Action Hearing Results

For staff analysis of the content of ASTM C1224-11 relative to CP#28, Section 3.6, please visit:
http://www.iccsafe.org:8888/cs/codes/Documents/2012-13cycle/Proposed-A/00a_updates.pdf

Committee Action: Disapproved

Committee Reason: An installation standard, if needed, should apply to installation everywhere, not just in vented attics. Given that the proposed standards do not agree with all roofing industry materials installation issues, the material installation, when used, should be contained in manufacturer's installation instructions and construction specifications based upon specific roofing materials.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Vickie Lovell, Intercode, Inc., representing Reflective Insulation Manufacturers Association-International requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R402.2.3.2 (N1102.2.3.2) Radiant barrier. Radiant barriers, used to supplement insulation ~~in Climate Zones 1, 2, and 3,~~ shall comply with the requirements of ASTM C1313 and shall be installed in accordance with ASTM C1743 <u>or in accordance with the manufacturer's installation instructions</u>.

(*Portions of code change proposal not shown remain unchanged.)*

Commenter's Reason: This proposal does not require the use of radiant barriers but requires that, when they are used, they comply with the two appropriate ASTM standards referenced for proper product specification and installation.

There was some confusion on the part of the committee regarding the reason for inclusion of radiant barrier in a section titled "vented attics". This is the primary location that these types of products are installed and it was for this reason this section was selected. The product is not roofing material specific. This is a proven technology and has been in the market place for 24+ years and over 650 million square feet installed annually. Two revisions to the text were incorporated as suggested by the committee:

- Climate zones 1, 2 and 3 were struck, although these are where the product is primarily installed – it was deemed important for this language to pertain to the product wherever installed
- A reference to "manufacturer's installation instructions" was added

The content of this proposal contains product requirements and references that will aid contractors. This public comment language will also assist code officials with enforcement in recognizing and understanding radiant barrier products and correct installation procedures, for a product not currently referenced at all.

The current state and city codes that include radiant barrier are:
• HI – Chapter 181 of Title 3, Table 402.1.1.1, Section 402.1.1.6, 402.1.1.8.1
• TX - Austin, Chapter 25-12, Article 12. Energy Code, Section 402.6
• FL – 2010 Florida Building Code, Section 405.6.1, Figure 405.6.1 & Table 303.2 (ASTM Standards)
• CA – Title 24, Part 6, Subsection 8, Section (f), Subsection 2; Table 151-B; Table 151-C; Table 151-D

RE57 -13
Final Action: AS AM AMPC____ D

RE58-13
R402.2.4 (IRC N1102.2.4)

Proposed Change as Submitted

Proponent: Jeff Inks, representing the Window & Door Manufacturers Association.

Revise as follows:

R402.2.4 (N1102.2.4) Access hatches and doors. Access doors from conditioned spaces to unconditioned spaces (e.g., attics and crawl spaces) shall be weatherstripped and insulated to a level equivalent to the insulation on the surrounding surfaces. Access shall be provided to all equipment that prevents damaging or compressing the insulation. A wood framed or equivalent baffle or retainer is required to be provided when loose fill insulation is installed, the purpose of which is to prevent the loose fill insulation from spilling into the living space when the attic access is opened, and to provide a permanent means of maintaining the installed R-value of the loose fill insulation.

> **Exception:** Vertical doors that provide access from conditioned to unconditioned spaces shall be permitted to meet the requirements of Table R402.1.1 based on the applicable climate zone specified in Chapter 3.

Reason: As currently written, this provision is being interpreted in some jurisdictions as requiring vertical doors providing access to certain unconditioned spaces such as attics to meet the thermal insulation levels of the surrounding wall they are installed in rather than the thermal requirements for doors contained in Table R402.1.1 applicable to the building thermal envelope. The thermal performance requirements for these vertical doors should be no greater than those for exterior doors installed elsewhere in the building thermal envelope.

Cost Impact: The code change proposal will not increase the cost of construction.

R402.2.4-EC-INKS

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: This exception is unnecessary. The code allows this approach, and this needs not be stated.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Craig Conner, Building Quality, representing himself, requests Approval as Submitted.

Commenter's Reason: It seems to be "common sense" that a door would meet the requirements for a door. The code just needs to be clear. Why would a door to unconditioned space have more stringent requirements than a door to the outside?

Public Comment 2:

Stephen Turchen, Fairfax County, VA, representing Virginia Building and Code Officials Association requests As Modified by this Public Comment.

Modify the proposal as follows:

R402.2.4 (N1102.2.4) Access hatches and doors. Access doors from conditioned spaces to unconditioned spaces (e.g., attics and crawl spaces) shall be weatherstripped and insulated to a level equivalent to the insulation on the surrounding surfaces. Access shall be provided to all equipment that prevents damaging or compressing the insulation. A wood framed or equivalent baffle or retainer is required to be provided when loose fill insulation is installed, the purpose of which is to prevent the loose fill insulation from spilling into the living space when the attic access is opened, and to provide a permanent means of maintaining the installed R-value of the loose fill insulation.

> **Exception:** Vertical doors that provide access from conditioned to unconditioned spaces shall be permitted to meet the fenestration requirements of Table R402.1.1 based on the applicable climate zone specified in Chapter 3.

Commenter's Reason: This code change proposal should be modified to align the proposal with the proponent's intent. IECC Table R402.1.1 contains requirements for R-values of opaque assemblies and U-factors of fenestration. The proposed modification clarifies that the vertical access door to the unconditioned space shall meet the fenestration requirement of the table. Absent this requirement, it could be reasonably interpreted that the vertical access door shall meet the R-value equivalent of the surrounding wall, as currently stated in Section R402.2.4, which would not resolve the issue the proponent was trying to address.

RE58 -13

Final Action: AS AM AMPC____ D

RE59-13
R402.2.4 (IRC N1102.2.4)

Proposed Change as Submitted

Proponent: Joel Rodriguez, Gwinnett County, Georgia, representing Metropolitan Atlanta Inspector's Association (MAIA) (joel.rodriguez@gwinnettcounty.com)

Revise as follows:

R402.2.4 (N1102.2.4) Access hatches and doors. Access doors from conditioned spaces to unconditioned spaces (e.g., attics and crawl spaces) shall be weatherstripped and insulated to a level <u>in accordance with the following insulation values:</u>

1. <u>Hinged vertical doors shall have a maximum *U*-Factor of U-0.20 (R-5 minimum);</u>
2. <u>Hatches/scuttle hole covers shall have a maximum *U*-Factor of U-0.05 (R-19 minimum); and</u>
3. <u>Pull down stairs shall have a maximum *U*-Factor of U-0020 with a minimum of 75 percent of the panel area having (R-5 minimum) insulation.</u>

~~equivalent to the insulation on the surrounding surfaces.~~ Access shall be provided to all equipment that prevents damaging or compressing the insulation. A wood framed or equivalent baffle or retainer is required to be provided when loose fill insulation is installed, the purpose of which is to prevent the loose fill insulation from spilling into the living space when the attic access is opened, and to provide a permanent means of maintaining the installed R-value of the loose fill insulation. <u>There shall be a floor or landing on top of the ceiling joist with a minimum width of 10 inches (254 mm) around the perimeter of access hatches and pull down stairs into an attic area.</u>

Reason: To eliminate the conflict in the insulation requirement language in TABLE R402.1.1 INSULATION AND FENESTRATION REQUIREMENTS BY COMPONENT, TABLE R402.1.3 EQUIVALENT U-FACTORS and 402.2.3 Fenestration access hatches and doors. To insulate to the levels specified in R402.2.4 Access hatches and doors compared to the above insulation requirements is expensive, in some cases not practical. It doesn't make sense to require R-30 to R-49 insulation on a hatch or pull down stairs when one can have a skylight that is *U*-FACTOR 0.55-0.75 (les than R-2). The calculated additional energy costs between and R-5 and R-30 is approximately $7.00 per year for Climate Zoe 4 (based on the methodology listed in ASHRAE Handbook Fundamentals for 10 SF pull down stairs. (Electricity cost based on $0.11 KWH and Natural Gas $0.70 Therm). To require a door into an attic to be R-13 to R-20+ doesn't make sense when a n exterior door or window exposed to the outside can be R-2 to R-3 (*U*-FACTOR 0.32-0.55). The manufacturers of doors, pull down stairs and hatches currently manufacture fenestration that meets these proposed insulation requirements. There is not a manufacturer that makes an R-13 or better door and the only way to achieve an R-30 or better with pull down stairs is to build or install a separate cover over the pull down stairs. This can create an unsafe entrance into the attic because the step up will be 16 inches or more, and that conflicts with IRC R311.7.5.1 Risers.

Cost Impact: The code change proposal will not increase the cost of construction. The savings will be a minimum of $200 per opening.

R402.2.4-EC-RODRIGUEZ

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: This provides for the same reduction in ceiling insulation values on attic access doors in all climate zones, and without regard to the size of the opening or percentage of opening. This could mean a drastic drop in insulation in cold climate zones.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Joel Rodriguez, Gwinnett County, GA, representing Metropolitan Atlanta Inspectors Association, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R402.2.4 (N1102.2.4) Access hatches and doors. Access hatches and doors from conditioned spaces to unconditioned spaces (e.g., attics and crawl spaces) shall be weather-stripped and insulated to a level equivalent to the insulation on the surrounding surfaces. ~~in accordance with the following insulation values:~~

~~1. Hinged vertical doors shall have a maximum *U*-Factor of U-0.20 (R-5 minimum);~~
~~2. Hatches/scuttle hole covers shall have a maximum *U*-Factor of U-0.05 (R-19 minimum); and~~
~~3. Pull down stairs shall have a maximum *U*-Factor of U-0020 with a minimum of 75 percent of the panel area having (R-5 minimum) insulation.~~

Exception. Horizontal pull down stair type access hatches in ceiling assemblies shall be permitted to meet the following requirements provided the net area of a framed opening is less than or equal to 13.5 square feet and there are no more than two horizontal access hatches in insulated ceiling assemblies located remotely from each other. This reduction shall not apply to the U-factor alternative approach in Section R402.1.3 and the total UA alternative in Section R402.1.4.

1. In Climate Zones 1 through 3 pull down stair access hatches shall have an average maximum *U*-Factor of U-0.20 (R-5 minimum).
2. In Climate Zones 4 through 6 pull down stair access hatches shall have an average maximum *U*-Factor of U-0.10 (R-10 minimum).

Access shall be provided to all equipment that prevents damaging or compressing the insulation. A wood framed or equivalent baffle or retainer is required to be provided when loose fill insulation is installed, the purpose of which is to prevent the loose fill insulation from spilling into the living space when the attic access is opened, and to provide a permanent means of maintaining the installed R-value of the loose fill insulation. ~~There shall be a floor or landing on top of the ceiling joist with a minimum width of 10 inches (254 mm) around the perimeter of access hatches and pull down stairs into an attic area.~~

Commenter's Reason: In the Report of the Hearings the Code Development Committee reason for disapproval stated "*This provides for the same reduction in ceiling insulation values on attic access doors in all climate zones, and without regard to the size of the opening or percentage of opening. This could mean a drastic drop in insulation in cold climate zones."* This public comment restructures the original proposal to address the concerns of the Committee and provide workable code language to address the main issue of Section R402.2.4 (N1102.2.4) for pull down stair type access hatches. The issue is that pull down stair type access hatches that are placed in horizontal ceiling assemblies must be insulated to values significantly more stringent that fenestration products located in these same ceiling assemblies.

For example, in Table R402.1.1 Skylights are required to meet a U-factor that ranges from 0.75 in Climate Zone 1 to 0.55 in Climate Zone 8. In addition, Section R402.3.3 allows up to 15 square feet of the fenestration per dwelling unit (which includes skylights) to be exempt from the requirements in Table 402.1.1. It does not make sense to require R-30 to R-49 insulation for a pull down stair type access hatch in an insulated ceiling when one can have a skylight up to 15 square feet in area that is exempt from the envelope requirements or that has a *U*-FACTOR of 0.55-0.75 (less than R-2). Insulating pull down stair access hatches to the levels specified in R402.2.4, compared to the skylights insulation requirements is expensive, and in many cases not practical.

In addition, affordable, pre-manufactured pull down stair access systems are not readily available to meet the R-30 to R-49 target. As a result, field customization of access hatches is sometimes employed to achieve these performance levels. Inspection and verification for compliance becomes a challenge. Long term system performance of these field customized entry devices may also vary. Commonly used insulated covers are designed to be removed and placed on the adjacent attic joists resulting in the insulation being compressed thus reducing its effectiveness. Providing sufficient air sealing around the hatch that remains durable long term is difficult. Also, the removal of the insulated covers for access present a safety hazard to service personnel, inspectors and building owners having to stand on ladders while removing the hatches.

Quality standardized manufactured pull down stair systems however provide a safer, permanent access with proven performance for the life of the structure. Factory built energy rated access systems provide consistent air sealing performance and ensure consistent energy performance while helping to maintain air quality through reduced air infiltration.

This proposal provides a solution by permitting a reasonable reduction in the insulation values for pull down stair access hatches that are less than or equal to 13.5 square feet (approximately 30" X 64") in attic ceilings. This maximum size accommodates most manufactured products available. The U-values provided for the two climate zone groupings match the increase in ceiling insulation levels from Table 402.1.1. These values specified, U-0.10 and 0.20 respectively, are less stringent than the U-values values specified for the insulated ceilings but in both cases are far more stringent than those permitted for skylights in all Climate Zones. In addition the proposal will permit no more than two pull down stairs with these less stringent U-values within the dwelling envelope. This too is more stringent than that permitted for skylights which can have one unit up to 15 square feet in size exempted from the code requirements and all others less stringent than the pull down stair assemblies proposed. Finally, the proposal also does not allow this reduction to be factored into the U-Factor alternative calculation procedure in R402.1.3 or the total UA alternative procedure in R402.1.4. This is consistent with the limitations in Section 402.2.1 for ceilings with attic spaces.

RE59 -13

Final Action: AS AM AMPC____ D

RE61-13
R402.2.7 (IRC N1102.2.7)

Proposed Change as Submitted

Proponent: Eric Makela, Britt/Makela Group, Inc., representing Northwest Energy Codes Group (Eric@BrittMakela.com)

Revise as follows:

R402.2.7 (N1102.2.7) Floors. Floor insulation shall be installed to maintain permanent contact with the underside of the subfloor decking. <u>Insulation supports for batt insulation shall be installed so that spacing is no more than 24 inches on center and shall not compress the insulation. Foundation vents shall be placed so that the top of the vent is below the lower surface of the floor insulation.</u>

> <u>**Exception:** Where foundation vents are not placed so that the top of the vent is below the lower surface of the floor insulation, a permanently attached baffle shall be installed from the top of the vent to below the lower surface of the floor insulation at an angle of 30° from horizontal, to divert air flow below the lower surface of the floor insulation.</u>

Reason: The 2012 IECC currently requires insulation installed in a floor system to maintain permanent contact with the underside of the subfloor decking. Insulation support systems, if not installed properly, can compress the insulation degrading the insulation R-value. This proposal requires that insulation supports not compress the installed insulation to ensure that it maintains its full R-value.

The second portion of the code change proposal focuses on the installation of foundation vents in relation to the installed insulation. Foundation vents that are installed at the same level as the insulation can direct air directly at the insulation reducing the R-value of the product through windwashing. Insulation will also act as a barrier to ventilation air, reducing the effectiveness of the foundation vent. This proposal will require that foundation vents either be installed below the line of insulation, or when not possible, require the installation of baffles to direct the ventilation air below the insulation

Cost Impact: The code change proposal will not increase the cost of construction.

R402.2.7-EC-MAKELA

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: The proposal includes a requirement for no compression of the installation. In practicality, there will be some compression, if very little. However, the proposed text makes no allowance for that.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Eric Makela, Britt Makela Group, representing Northwest Energy Codes Group, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R402.2.7 (N1102.2.7) Floors. Floor insulation shall be installed to maintain permanent contact with the underside of the subfloor decking. Insulation supports for batt insulation shall be installed so that spacing is no more than 24 inches on center ~~and shall not~~ with <u>minimal compression of</u> ~~compress~~ the insulation. Foundation vents shall be placed so that the top of the vent is below the lower surface of the floor insulation.

Exception: Where foundation vents are not placed so that the top of the vent is below the lower surface of the floor insulation, a permanently attached baffle shall be installed from the top of the vent to below the lower surface of the floor insulation ~~at an angle of 30° from horizontal,~~ to divert air flow below the lower surface of the floor insulation.

Commenter's Reason: The IECC Code Development provision disapproved this proposal for the following reason:

"The proposal includes a requirement for no compression of the installation. In practicality, there will be some compression, if very little. However, the proposed text makes no allowance for that. "

This Public Comment modifies the provision by allowing some compression of insulation per the committees reason statement. Also the Public Comment eliminates the specific angle of the baffle to direct ventilation air below the insulation. This will allow more flexibility in the field and increase enforceability.

RE61 -13

Final Action: AS AM AMPC____ D

RE62-13
R402.2.13 (NEW) (IRC N1102.2.13 (NEW))

Proposed Change as Submitted

Proponent: Ellen Eggerton, representing Virginia Building and Code Officials Association

Revise as follows:

R402.2.13 (N1102.2.13) Mechanical rooms. Where a room contains combustion equipment, and outside air is admitted directly into the room to provide combustion air for the equipment, then the walls, ceilings, and floors of that room bound unconditioned space and shall be insulated as part of the *building thermal envelope*.

Reason: AHJs have disagreed regarding how to apply the energy code to "mechanical rooms" with permanently installed air ducts directly connecting the room to the outdoor environment. This proposal attempts to apply the code requirements to these rooms in a feasible and enforceable manner. Note that by identifying the enclosure of the mechanical room as part of the thermal envelope, these surfaces will be sealed as well as insulated, thereby preventing unwanted and energy-consuming air intrusion into the conditioned living space adjacent to the mechanical room.

Cost Impact: To the extent that mechanical rooms have previously been considered unconditioned space and were enforced as such, this clarifying proposal has no cost impact. If these rooms were previously uninsulated, there will be some costs associated with insulating the customary framed walls and ceiling of the room, as well as sealing potential avenues of air infiltration to the conditioned living space beyond.

R402.2.13 (NEW)-EC-EGGERTON

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: This provision for a separate room for mechanical equipment outside of the thermal envelope is an excessively restrictive proposal that is not needed.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Ellen Eggerton, Fairfax County, Virginia, representing the Virginia Building Officials, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R402.2.13(N1102.2.13) Mechanical rooms. In climate zones 3 through 8, where a room contains ~~combustion~~ fuel fired equipment, and outside air ~~is admitted~~ enters directly into the room to provide combustion air ~~for the equipment~~, the room shall be located outside the *building thermal envelope* or the room shall be sealed and insulated in accordance with the envelope requirements of Table R402.1.~~, then the walls, ceilings, and floors of that room bound unconditioned space and shall be insulated as part of the *building thermal envelope*.~~ Doors into such a room shall be fully gasketed. Supply and return ducts shall be insulated to R-6.

Exceptions:

1. Direct vent appliances with both intake and exhaust pipes installed continuous to the outside.
2. Fireplaces and stoves complying with the requirements of Sections R402.4.2 and IRC R1006 of the *International Residential Code*.

Commenter's Reason: Changed to apply requirement only to heating climates, clarify the language and refer to the requirements of table R402.1.1. This also adds exceptions.

RE62 -13

Final Action: AS AM AMPC____ D

RE63-13
Table R402.1.1 (IRC Table N1102.1.1), R402.2.13 (NNEW) (IRC N1102.2.13 (NEW))

Proposed Change as Submitted

Proponent: Jeremiah Williams, representing U.S. Department of Energy (jeremiah.williams@ee.doe.gov)

Revise as follows:

TABLE R402.1.1 (N1102.1.1)
INSULATION AND FENESTRATION REQUIREMENTS BY COMPONENT

(Portions of Table not shown remain unchanged)

h. First value is cavity insulation, second is continuous insulation or insulated siding, so "13+5" means R-13 cavity insulation plus R-5 continuous insulation or insulated siding. ~~If structural sheathing covers 40 percent or less of the exterior, continuous insulation *R*-value shall be permitted to be reduced by no more than R-3 in the locations where structural sheathing is used – to maintain a consistent total sheathing thickness.~~

R402.2.13 (N1102.2.13) Walls with partial structural sheathing. Where Section R402.1.1 would require continuous insulation on exterior walls and structural sheathing covers 40 percent or less of the gross area of all exterior walls, the continuous insulation *R*-value shall be permitted to be reduced by an amount necessary to result in a consistent total sheathing thickness, but not more than R-3, on areas of the walls covered by structural sheathing, This reduction shall not apply to the *U*-factor alternative approach in Section R402.1.3 and the total UA alternative in Section R402.1.4.

Reason: This is a clarification not intended to change the meaning of the code. Moving the relevant text out of the footnote and into a separate code section allows for a more thorough description of the sheathing reduction allowance.

Cost Impact: The code change proposal will not increase the cost of construction.

R402.2.13 (NEW)-EC-WILLIAMS

Committee Action Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: This proposal clarifies the issue of structural sheathing with continuous insulation presently contained in footnote h of Table R402.1.1. The information is appropriately placed in the body of code text.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Paul Coats, American Wood Council, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

TABLE R402.1.1 (N1102.1.1)
INSULATION AND FENESTRATION REQUIREMENTS BY COMPONENT

(Portions of Table not shown remain unchanged)

h. First value is cavity insulation, second is continuous insulation or insulated siding, so “13+5” means R-13 cavity insulation plus R-5 continuous insulation or insulated siding.

R402.2.13 (N1102.2.13) Walls with partial structural sheathing. Where continuous insulation is used to comply with Section R402.1.1, and ~~Where Section R402.1.1 would require continuous insulation on exterior walls and~~ structural sheathing covers 40 percent or less of the gross area of all exterior walls, the continuous insulation *R*-value shall be permitted to be reduced by an amount necessary to result in a consistent total sheathing thickness, but not more than R-3, on areas of the walls covered by structural sheathing. ~~This reduction shall not apply to the *U*-factor alternative approach in Section R402.1.3 and the total UA alternative in Section R402.1.4.~~

Commenter’s Reason. As approved by the Committee, the first sentence implies that continuous insulation is required whenever footnote h applies. This is true for Climate Zones 6, 7, and 8, but is not true for Climate Zones 3, 4, and 5, where there are also cavity-only alternatives listed. For example, in Climate Zone 3 for wood frame wall R-value, there are two options, R20 and R13+R5. Since the continuous insulation option is not “required” but is an option along with full cavity insulation, it could be interpreted that the reduction in R-value is not permitted. Therefore the first modification is necessary.

In addition, the last sentence is unnecessary and could be problematic. The sentence attempts to emphasize that this provision would not affect the use of other approaches--the U-factors in Table R402.1.3 cannot be increased when using the U-factor alternative approach and the total UA approach. But the charging language in Section R402.2 makes it clear that this provision pertains only to the application of Table 402.1.1, and so inserting a prohibition against use with the other alternative approaches muddles the code and could cause confusion. For instance, it could be read to imply that U-factor increases for certain portions of a wall are somehow prohibited when using the total UA approach, which is incorrect.

RE64-13

R402.3 (NEW) (IRC N1102.3 (NEW)), R402.3.1 (NEW) (IRC N1102.3.1 (NEW)), Table 402.3.1 (NEW) (IRC Table N1102.3.1 (NEW)), Chapter 5

Proposed Change as Submitted

Proponent: Jeremiah Williams, representing U.S. Department of Energy (jeremiah.williams@ee.doe.gov)

Add new text as follows:

R402.3 (N1102.3) Solar Properties of Opaque Surfaces (prescriptive).

R402.3.1 (N1102.3.1) Roof Solar Reflectance and Thermal Emittance. Roofs having a slope less than 2:12, directly above cooled *conditioned spaces* in climate zones 1, 2, and 3 shall comply with at least one option in Table R402.3.1.

Exceptions: The following are exempt from the requirements in Table R402.3.1:

1. Portions of roofs that include or are covered by:
   1.1 Photovoltaic systems or components
   1.2 Solar air or water heating systems or components
   1.3 Roof gardens or landscaped roofs
   1.4 Above-roof decks or walkways
   1.5 Skylights
   1.6 HVAC systems, components, and other opaque objects mounted above the roof
   1.7 A radiant barrier is installed
2. Portions of roofs shaded during the peak sun angle on the summer solstice by permanent features of the building, or by permanent features of adjacent buildings
3. Ballasted roofs with a minimum stone ballast of 17 lbs/ft^2 (74 kg/m2) or 23 lbs/ft^2 pavers (117 kg/m^2)
4. Roofs where a minimum of 75% of the roof area meets a minimum of one of the exceptions above.

TABLE R402.3.1 (N1102.3.1)
MINIMUM ROOF REFLECTANCE AND EMITTANCE OPTIONS[a]

Three-year aged solar reflectance[b] of 0.55 and three-year aged thermal emittance[b] of 0.75
Initial solar reflectance[b] of 0.70 and initial thermal emittance[b] of 0.75
Three-year-aged solar reflectance index[c] of 64
Initial solar reflectance index[c] of 82

a. The use of area-weighted averages to meet these requirements shall be permitted. Materials lacking initial tested values for either *solar reflectance* or *thermal reflectance*, shall be assigned both an initial *solar reflectance* of 0.10 and an initial *thermal emittance* of 0.90. Materials lacking three-year aged tested values for either *solar reflectance* or *thermal reflectance*, shall be assigned both a three-year aged *solar reflectance* of 0.10 and a three-year aged *thermal emittance* of 0.90.
b. Tested solar reflectance and thermal emittance shall be in accordance with ANSI/CRRC-1-2010.
c. Solar reflectance index (SRI) determined in accordance with ASTM E1980-11 using a convection coefficient of 2.1 BTU/h-ft^2-F (12W/m^2.K). Calculation of aged SRI shall be based on aged tested values. Calculation of initial SRI shall be based on initial tested values.

Add new standards to Chapter 5 as follows:

ASTM

E 1980-11 Standard Practice for Calculating Solar Reflectance Index of Horizontal and Low-sloped Opaque Surfaces

CRCC Cool Roof Rating Council
1610 Harrison St
Oakland, CA 94612

ANSI/CRCC-1-2010 Cool Roof Rating Council CRCC-1 Standard

Reason: This proposed requirement applies to low-sloped roofs only and is consistent with requirements for commercial buildings in Section C402.2.1.1 of the 2012 IECC. Low-sloped roofs are commonly single-ply membranes, built-up roofs, modified bitumen membranes, and spray polyurethane foam. The U.S. DOE and Levinson report that high levels of reflectance for these types of roofs can typically be obtained for no cost increase over darker, less reflective roofs.

The low-slope DOE Cool Roof Calculator (http://www.ornl.gov/sci/roofs+walls/facts/CoolCalcEnergy.htm) reports these energy savings compared to a "black roof":

Climate Zone	Example City	Heating System Type	Net (Heating and Cooling) Annual Savings per 1000 ft^2 of roof area
2	Houston TX	Heat Pump	$22
		Natural Gas	$24
3	Atlanta GA	Heat Pump	$15
		Natural Gas	$17
Assumptions: R-30 insulation, 0.70 Solar reflectance, 0.75 thermal emittance, 12 cents/kWh electricity, $1.00/therm natural gas, 3.5 COP cooling, 2.0 COP heat pump heating, 80% AFUE gas heat.			

Studies illustrating the savings from cool roofs are available on the Cool Roof Ratings Council website. http://www.coolroofs.org/article.html#energy For example, the Florida Solar Energy Center tested seven retail shops in a strip mall in Cocoa, Florida over a two-year period, which allowed surface degradation over a year period to be accounted for. The roof was resurfaced to alter the surface reflectivity from approximately 29% to 75%. There was a 25.3% average reduction in summer space cooling energy in the seven shops.

Parker, D., J. Sonne, J. Sherwin. 1997. Demonstration of Cooling Savings of Light Colored Roof Surfacing in Florida Commercial Buildings: Retail Strip Mall. Florida Solar Energy Center. Cocoa, Florida.
U.S. Department of Energy. 2010. Guidelines for Selecting Cool Roofs. Washington, D.C.
Levinson, R. 2012. The Case for Cool Roofs. Lawrence Berkeley National Laboratory. Berkeley, California. http://heatisland.lbl.gov/sites/heatisland.lbl.gov/files/Levinson_2012_Case%20for%20cool%20roofs.pdf

Cost Impact: The code change proposal may increase the cost of construction in certain situations.

Analysis: A review of the standards proposed for inclusion in the code, ASTM E1980-11 Standard Practice for calculating Solar Reflectance Index of Horizontal and Low-sloped Opaque Surfaces and CRRC Standard CRRC-1-2010 Cool Roof Raing Council CRRC-1 Standard with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 1, 2013.

R402.3 (NEW)-EC-WILLIAMS

Committee Action Hearing Results

For staff analysis of the content of ANSI/CRCC-1-2012 and ASTM E1980-11 relative to CP#28, Section 3.6, please visit: http://www.iccsafe.org:8888/cs/codes/Documents/2012-13cycle/Proposed-A/00a_updates.pdf

Committee Action: Approved as Modified

Modify the proposal as follows:

Revise date of referenced standard ANSI/CRCC-1 from 2010 to 2012.
In addition, revise footnote a as follows:

a. The use of area-weighted averages to meet these requirements shall be permitted. Materials lacking initial tested values for either *solar* ~~*reflectance*~~ *emittance* or *thermal* ~~*reflectance*~~ *emittance*, shall be assigned both an initial *solar* ~~*reflectance*~~ *emittance* of 0.10 and an initial *thermal emittance* of 0.90. Materials lacking three-year aged tested values for either *solar* ~~*reflectance*~~ *emittance* or *thermal* ~~*reflectance*~~ *emittance*, shall be assigned both a three-year aged *solar reflectance* of 0.10 and a three-year aged *thermal emittance* of 0.90.

Committee Reason: The modification to the reference year of the standard is to use the most recent edition of ANSI/CRCC-1. The modification to the footnote is to use the technically correct terminology. Cool roofs are a proven technology that is already required in the IECC-Commercial provisions. Cool roofs provide significant energy savings.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Amy Dickie, Global Cool Cities Alliance, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

~~**R402.3.1 (N1102.3.1) Roof Solar Reflectance and Thermal Emittance.** Roofs having a slope less than 2:12, directly above cooled *conditioned spaces* in climate zones 1, 2, and 3 shall comply with at least one option in Table R402.3.1.~~

~~**Exceptions:** The following are exempt from the requirements in Table R402.3.1:~~
~~1. Portions of roofs that include or are covered by:~~
~~1.1 Photovoltaic systems or components~~
~~1.2 Solar air or water heating systems or components~~
~~1.3 Roof gardens or landscaped roofs~~
~~1.4 Above-roof decks or walkways~~
~~1.5 Skylights~~
~~1.6 HVAC systems, components, and other opaque objects mounted above the roof~~
~~1.7 A radiant barrier is installed~~
~~2. Portions of roofs shaded during the peak sun angle on the summer solstice by permanent features of the building, or by permanent features of adjacent buildings~~
~~3. Ballasted roofs with a minimum stone ballast of 17 lbs/ft^2 (74 kg/m2) or 23 lbs/ft^2 pavers (117 kg/m^2)~~
~~4. Roofs where a minimum of 75% of the roof area meets a minimum of one of the exceptions above.~~

~~TABLE R402.3.1 (N1102.3.1)~~

~~Minimum Roof Reflectance and Emittance Options~~[a]

~~Three-year aged solar reflectance[b] of 0.55 and three-year aged thermal emittance[b] of 0.75~~
~~Initial solar reflectance[b] of 0.70 and initial thermal emittance[b] of 0.75~~
~~Three-year-aged solar reflectance index[c] of 64~~
~~Initial solar reflectance index[c] of 82~~

~~a. The use of area-weighted averages to meet these requirements shall be permitted. Materials lacking initial tested values for either *solar reflectance emittance* or *thermal emittance*, shall be assigned both an initial *solar reflectance emittance* of 0.10 and an initial *thermal emittance* of 0.90. Materials lacking three-year aged tested values for either *solar reflectance emittance* or *thermal emittance*, shall be assigned both a three-year aged *solar reflectance* of 0.10 and a three-year aged *thermal emittance* of 0.90.~~
~~b. b. Tested solar reflectance and thermal emittance shall be in accordance with ANSI/CRRC-1-2012.~~
~~c. c. Solar reflectance index (SRI) determined in accordance with ASTM E1980-11 using a convection coefficient of 2.1 BTU/h-ft^2-F (12W/m^2.K). Calculation of aged SRI shall be based on aged tested values. Calculation of initial SRI shall be based on initial tested values.~~

R402.3.1 (N1102.3.1) Roof Solar Reflectance and Thermal Emittance. Roofs having a slope less than or equal to 2:12, directly above cooled *conditioned spaces* in climate zones 1, 2, and 3 shall have an average aged solar reflectance of not less than 0.55 and an average aged thermal emittance of not less than 0.75.

Exceptions: The following are exempt from the requirements in this Section:
1. Portions of roofs that include or are covered by:
1.1 Photovoltaic systems or components
1.2 Solar air or water heating systems or components
1.3 Roof gardens or landscaped roofs
1.4 Above-roof decks or walkways
1.5 Skylights
1.6 HVAC systems, components, and other opaque objects mounted above the roof
2. Portions of roofs shaded during the peak sun angle on the summer solstice by permanent features of the building, or by permanent features of adjacent buildings
3. Ballasted roofs with a minimum stone ballast of 17 lbs/ft^2 (74 kg/m2) or 23 lbs/ft^2 pavers (117 kg/m^2)
4. Roofs where a minimum of 75 percent of the roof area meets a minimum of one of the exceptions above.

R402.3.1.1 Alternative Compliance Pathways. Roofs or portions of roofs that comply with one or more of the following also shall be in compliance with R402.3.1.

1. An aged solar reflectance index of not less than 64.
2. An initial solar reflectance of not less than 0.70 and an initial thermal emittance of not less than 0.75.
3. An initial solar reflectance index of not less than 82.

R402.3.1.2 Roof testing. Roof product solar reflectance and thermal emittance shall be determined as follows:

1. The initial and aged solar reflectances and initial and aged thermal emittances of the roofing product shall be measured in accordance with the CRRC-1 Standard.
2. Initial and aged values of solar reflectance index (SRI) shall be determined in accordance with ASTM E 1980 using a medium wind speed convective coefficient of 2.1 BTU/(h · ft^2 · °F) [12 W/(m^2 · K)]. Calculation of aged SRI shall be based on aged tested values of solar reflectance and thermal emittance. Calculation of initial SRI shall be based on initial tested values of solar reflectance and thermal emittance.
3. Materials lacking initial tested values for either solar reflectance or thermal emittance shall be assigned both an initial solar reflectance of 0.10 and an initial thermal emittance of 0.90. Materials lacking aged tested values for either solar reflectance or thermal emittance shall be assigned both an aged solar reflectance of 0.10 and an aged thermal emittance of 0.90.

(*Portions of code change proposal not shown remain unchanged.)*

Commenter's Reason: We applaud the introduction of cool roof requirements for low sloped roofs in the residential code. These proposed modifications make the cool roof provisions in the residential code consistent with the cool roof provisions in the commercial code. Specifically, these modifications are consistent with the formatting of CE 122 which was approved as submitted by the committee. The major changes between the original proposed residential cool roof code and the proposed modifications in this comment are as follows:

1) Changes the definition of low-sloped roofs from a rise to run ratio of less than 2:12 to a rise to run ratio of less than or equal to 2:12. This change makes the definition of low-sloped roofs consistent with other codes (e.g. ASHRAE 90.1 and California's Title 24).

2) Reformat the code to state primary rating option (aged solar reflectance and aged thermal emittance) in the body of the code and the other rating options as exceptions. Note that although this change alters the format of the code, it has no influence on the stringency of the code.

3) Strikes out the radiant barrier exemption. A radiant barrier will achieve some of the same energy savings benefits as a cool roof, but it is not a complete substitute for a cool roof. Additional energy savings benefits can be gained from a cool roof regardless of whether a radiant barrier is in place.

4) Remove the specification of "three-year" from the notation of aged reflectivity and aged emissivity values because the duration of the aging is explicit in the CRRC-1 Standard, and should be changed as the standard evolves.

5) Move the footnotes that pertain to the testing requirements into a new section (Section R402.3.1.2), titled "Roof Testing". This change moves important definitions and requirements out of the footnotes, thus providing a cleaner format for the code.

Public Comment 2:

Jeremiah Williams, U.S. Department of Energy, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

TABLE R402.3.1 (N1102.3.1)
Minimum Roof Reflectance and Emittance Options[a]

Three-year aged solar reflectance[b] of 0.55 and three-year aged thermal emittance[b] of 0.75
Initial solar reflectance[b] of 0.70 and initial thermal emittance[b] of 0.75
Three-year-aged solar reflectance index[c] of 64
Initial solar reflectance index[c] of 82

a. The use of area-weighted averages to meet these requirements shall be permitted. Materials lacking initial tested values for either *solar reflectance* ~~*emittance*~~ or *thermal emittance*, shall be assigned both an initial *solar reflectance* ~~*emittance*~~ of 0.10 and an initial *thermal emittance* of 0.90. Materials lacking three-year aged tested values for either *solar reflectance* ~~*emittance*~~ or *thermal emittance*, shall be assigned both a three-year aged *solar reflectance* of 0.10 and a three-year aged *thermal emittance* of 0.90.
b. b. Tested solar reflectance and thermal emittance shall be in accordance with ANSI/CRRC-1-2012.

c. c. Solar reflectance index (SRI) determined in accordance with ASTM E1980-11 using a convection coefficient of 2.1 BTU/h-ft^2-F (12W/m^2.K). Calculation of aged SRI shall be based on aged tested values. Calculation of initial SRI shall be based on initial tested values.

d.

(*Portions of code change proposal not shown remain unchanged.)*

Commenter's Reason: The original proposal was approved. The committee statement said "*cool roofs are a proven technology that is already required in the IECC-Commercial provisions. Cool roofs provide significant energy savings.*"

The committee modified the proposal with two floor amendments. One of these amendments changed the incorrect term "thermal reflectance" to the correct term of "thermal emittance" in two locations in footnote a. However, the proposal (as published in the Report on the Committee Action) additionally had three instances of the term "solar reflectance" incorrectly changed to "solar emittance" in footnote a. This public comment is an editorial change to restore the proper term "solar reflectance" in footnote a, as contained in the original proposal.

DOE posted its draft proposals and public comments for the IECC on its Building Energy Codes website prior to submitting to the ICC. Interested parties were provided a 30 day public review in June 2013, for which notice was published in the *Federal Register* (Docket No. EERE-2012-BT-BC-0030) and announced via the DOE Building Energy Codes news email list. In response to stakeholder input, DOE revised its proposals and public comments, as appropriate, and submitted to the ICC.

For more information on DOE proposals and public comments, including how DOE participates in the ICC code development process, please visit: http://www.energycodes.gov/development.

Final Action: AS AM AMPC____ D

RE65-13

202 (NEW) (IRC N1101.9 (NEW)), R402.3.3 (NEW) (IRC N1102.3.3 (NEW)), Table R402.3.3 (NEW) (IRC Table N1102.3.3 (NEW)), R402.3.6 (IRC N1102.3.6)

Proposed Change as Submitted

Proponent: Dr. Thomas D. Culp, Birch Point Consulting LLC, representing the Glazing Industry Code Committee (culp@birchpointconsulting.com)

Revise as follows:

R402.3.3 (N1102.3.3) SHGC Shading Adjustment. Vertical fenestration in Climate Zones 1 through 3 shall be permitted to meet the SHGC requirements of Table R402.3.3 based upon the calculated projection factor of any overhang, eave, or permanently attached shading device that covers the full width of the glazing and extends a minimum of 12 inches (0.3 m) beyond each side of thereof. Where different windows and glazed doors have different projection factors, they shall each be evaluated separately, or an area-weighted projection factor value shall be permitted.

TABLE R402.3.3 (N1102.3.3)
EQUIVALENT SHGC FOR VERTICAL FENESTRATION
WITH SHADING PROJECTIONS

Projection Factor	Maximum SHGC
PF < 0.2	0.25
0.2 ≤ PF < 0.5	0.30
PF ≥ 0.5	0.40

~~R402.3.6 (N1102.3.6)~~ R402.3.7 (N1102.3.7) Replacement fenestration. Where some or all of an existing fenestration unit is replaced with a new fenestration product, including sash and glazing, the replacement fenestration unit shall meet the applicable requirements for *U*-factor and SHGC in Table R402.1.1 and Section R402.3.3.

Add new definition as follows:

IECC SECTION R202 (IRC N1101.9)
GENERAL DEFINITIONS

PROJECTION FACTOR. The ratio of the horizontal depth of an overhang, eave, or permanently attached shading device, divided by the distance measured vertically from the bottom of the fenestration glazing to the underside of the overhang, eave, or permanently attached shading device.

Reason: The purpose of this proposal is to provide a prescriptive allowance for shading as an appropriate method for controlling solar gains in addition to glazing SHGC. Shading has been part of good building design for millennia, and its use should be encouraged. A prescriptive shading allowance is already included in the commercial IECC as well as ASHRAE 90.1, but is not currently included in the residential IECC, other than through the more complicated performance path.

The need to address shading has become even more important following the 2012 IECC, which introduced a very low 0.25 SHGC in zones 1-3. Even with the newest low-e coatings, it is borderline whether 0.25 SHGC can be achieved for certain products without the addition of tinted glass or a darker low-e, especially for picture windows and sliding glass doors that have a larger glass to frame ratio. Additionally, the low 0.25 SHGC could inhibit homeowners from replacing older inefficient windows, because the new 0.25 SHGC requirement would result in a mismatched appearance between the new replacement windows/doors and the rest of the windows.

Therefore, a shading credit is one way to provide flexibility for both new and replacement windows, while maintaining the overall solar control. This proposal is based on the same shading multipliers as in the commercial IECC, but simplified for easy enforcement in the residential code. Specifically, the shading allowance for south/east/west orientation is used to be conservative and account for the worst orientation, but written simply as an adjusted maximum SHGC that doesn't require determination of orientation by either the builder or code official. This is very conservative, requiring a 0.40 SHGC even for a 3 ft overhang over a 5 ft high window, providing good solar control while also allowing flexibility and promoting architectural shading.

Cost Impact: The code change proposal will not increase the cost of construction.

402.3.3 (NEW) -EC-CULP

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: See RE66-13. In addition, this introduces the term 'weighted average' that in this context is ill defined.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Dr. Thomas D. Culp, Birch Point Consulting LLC, representing the Glazing Industry Code Committee requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R402.3.3 (N1102.3.3) SHGC shading adjustment. Vertical fenestration in climate zones 1 through 3 shall be ~~permitted to meet~~ considered in compliance with the SHGC requirements of Table R402.1.1 provided the requirements of Table R402.3.3 are satisfied based upon the calculated projection factor of any overhang, eave, or permanently attached shading device that covers the full width of the glazing and extends a minimum of 12 inches (0.3 m) beyond each side of thereof. Where different windows and glazed doors have different projection factors, they shall each be evaluated separately~~, or an area-weighted projection factor value shall be permitted~~.

(Portions of code change proposal not shown remain unchanged.)

Commenter's Reason: At the preliminary code development hearings, the committee first heard RE66, which also dealt with shading as an appropriate method for controlling solar gains in addition to glazing SHGC, but structured in a different manner than this proposal. With RE66, the committee was concerned about the potential consequences of allowing unlimited SHGC for a given minimum projection factor, and also concerned about the technical basis for the minimum projection factors used in that proposal. There were also concerns about the complexity of determining orientation during code enforcement.

In contrast, RE65 does not suffer from any of these problems. First and foremost, even if using a very large projection, RE65 is conservative and does not allow unlimited SHGC. For example, even a window under a large 6 ft patio overhang would still require a maximum SHGC of 0.40. This provides some flexibility and credit for the excellent shading being provided by the patio overhang, but does not give a complete "waiver" and still requires a basic solar control window to account for situations such ground reflectance.

Second, the values used in RE65 are directly based on the projection factor SHGC multipliers that are already in the commercial IECC. In fact, these multipliers have been used in the 2000, 2003, 2006, 2009, and 2012 IECC as well as ASHRAE 90.1-1999, 2001, 2004, 2007, 2010, and 2013. If it's been technically satisfactory and useful for both the IECC and ASHRAE commercial energy codes, then there should be no concern for the residential energy code.

Third, RE65 is easy to enforce by simply listing the required maximum SHGC based on the projection factor, without the need for either the builder or code official to determine orientation. This is because the requirement was purposely designed to be conservative and based upon the worst-case south/east/west orientation projection factor multiplier from the commercial IECC and ASHRAE 90.1.

Unfortunately, RE65 was caught up in the debate of RE66, and these points were missed by the committee. The committee did express a concern about the term "area-weighted projection factor", so the modification proposed in this comment removes that part. There is also an editorial modification to the first sentence, purely for clarification.

Finally, some opponents have acknowledged that shading is a good building practice, but argue that it should be restricted to the performance path. However, the performance path simply cannot be used for replacement fenestration. Also, the use of shading projections has been in the *prescriptive* path for both the commercial IECC and ASHRAE 90.1 for over 13 years, so there is obviously no valid reason to restrict it to only the performance path in the residential energy code.

The concept of using shading to reduce solar heat gain has been used in architecture for thousands of years. The code should recognize and encourage that. We ask that you vote "NO" on the initial motion for disapproval, and then to vote "YES" on a motion to approve RE65 as modified by this comment.

RE65 -13

Final Action: AS AM AMPC____ D

RE70-13

R402.3.6 (NEW) (IRC N1102.3.6 (NEW)), R402.2.13 (NEW) (IRC N1102.2.13 (NEW)

Proposed Change as Submitted

Proponents: Ellen Eggerton, representing Virginia Building and Code Officials Association; Harold A Stills, Jr., Hanover County, VA.., representing Virginia Building and Code Officials Association (hastills@hanovercounty.gov)

Add new text as follows:

R402.3.6 (N1102.3.6) Thermally isolated garage door *R-value*. For Climate Zones 4 through 8, when the garage is conditioned, the minimum garage door *R-value* shall be 5.0. All other fenestration shall meet the *building thermal envelope* requirements.

R402.2.13 (N1102.2.13) Thermally isolated garage insulation. All garages shall be thermally isolated and meet ceiling and wall *R*-values as specified in Table R402.1.1. Existing slabs shall be exempt from insulation requirements.

Reason: Eggerton: The current IECC does not allow for the average garage to be conditioned because the average garage door cannot meet the 0.35 U-factor. In addition, it is very difficult to find a garage door that has been tested according to "NFRC 100" (R303.1.3). If one searches for doors at an average big-box home improvement store, it is not difficult to find an insulated garage door with an R-6 or greater R-value.

A garage is not considered "habitable space", but some activities, (such as automobile and household item repair) do occur there. These activities do not require the same level of comfort as the habitable areas of the dwelling, but a temperature other than the current outdoor temperature may be desirable. The average homeowner also realizes that it would not be efficient to maintain this space at the same temperature as the rest of the dwelling.

The last sentence of 402.2.13 recognizes that adding a heating or cooling mechanical system to an existing garage would be acceptable after adding the required insulation to the walls and ceiling, but impractical to add slab insulation. However, ice-melting systems are allowed.

Stills: The current IECC does not allow for the average garage to be conditioned because the average garage door cannot meet the 0.35 U-factor. In addition, it is very difficult to find a garage door that has been tested according to "NFRC 100" (R303.1.3). If one searches for doors at an average big-box home improvement store, it is not difficult to find an insulated garage door with an R-6 or greater R-value. However, ice-melting systems are allowed. A garage is not considered "habitable space", but some activities, (such as automobile and household item repair) do occur there. These activities do not require the same level of comfort as the habitable areas of the dwelling, but a temperature other than the current outdoor temperature may be desirable. The average homeowner also realizes that it would not be efficient to maintain this space at the same temperature as the rest of the dwelling. The last sentence of R402.2.13 recognizes that adding a mechanical system to an existing garage would be acceptable after adding the required insulation to the walls and ceiling, but impractical to add slab insulation.

Cost Impact: The code change proposal will not increase the cost of construction.

R402.3.6 (NEW)-EC-EGGERTON-STILLS

Committee Action Hearing Results

Committee Action: **Approved as Modified**

Modify the proposal as follows:

R402.2.13 (N1102.2.13) Thermally isolated garage insulation. All conditioned garages shall be……

(Portions of code change not shown remain unchanged)

Committee Reason: This addresses an issue that comes up frequently in residential construction. The modification simply reflects the proponent's intent.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Brenda Thompson, CBCO, Manager Building Inspections, Clark County Development Services, ICC Sustainability, Energy and High Performance Code Action Committee (SEHPCAC) Chair requests Disapproval.

Commenter's Reason: This proposal results in unclear and unenforceable code. If this is intended to address the conversion of an unconditioned garage into a conditioned space, the code already addresses such conversions. If the proponent is seeking to provide an exception for such conversions, the proper place for such an exception is in Chapter 1 where such conversions are now addressed. (If it was located in Chapter 1, other approved changes sponsored by SEHPCAC would relocate it to the new existing buildings chapter. Among the issues with the proposal is that it uses the term 'thermally isolated" but the code defined term is 'thermal isolation". In proposed section R402.3.6 it uses 'thermally isolated in the title, but not in the text as a result any intent to require thermal isolation is lost. If the intent is to require thermal isolation – what standard does the thermal isolation have to meet? Where do the thermal isolation measures have to be applied? If the intent is for this to apply to newly constructed garages, what is the justification for them not to comply with the new construction standards?. Finally, the proposed final sentence of Section R402.4.6 is unclear. What does 'all other' refer to? All other fenestration in the structure – or that which is in the garage?

This public comment is submitted by the ICC Sustainability Energy and High Performance Code Action Committee (SEHPCAC). The SEHPCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portion thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the SEHPCAC has held numerous open meetings and workgroup calls which included members of the SEHPCAC, as well as interested parties, to discuss and debate proposed changes and public comments.

RE70 -13
Final Action: AS AM AMPC____ D

RE72-13

R402.4 (IRC N1102.4), R402.4.1.1 (IRC N1102.4.1.1), R402.4.1.2 (IRC N1102.4.1.2), R402.4.1.3 (New) (IRC N1102.4.1.3 (New))

Proposed Change as Submitted

Proponents: Craig Conner, Building Quality, representing self (craig.conner@mac.com); Don Surrena, CBO, representing National Association of Home Builders (NAHB) (dsurrena@nahb.org)

Revise as follows:

R402.4 (N1102.4) Air leakage ~~(Mandatory)~~. The building thermal envelope shall be constructed to limit air leakage in accordance with the requirements of Sections R402.4.1 through R402.4.4.

R402.4.1.1 (N1102.4.1.1) Installation <u>(Mandatory)</u>. The components of the *building thermal envelope* as listed in Table R402.4.1.1 shall be installed in accordance with the manufacturer's instructions and the criteria listed in Table R402.4.1.1, as applicable to the method of construction. Where required by the *code official*, an *approved* third party shall inspect all components and verify compliance.

R402.4.1.2 (N1102.4.1.2) Testing <u>(Mandatory)</u>. The building or dwelling unit shall be tested ~~and verified as having an air leakage rate of not exceeding 5 air changes per hour in Climate Zones 1 and 2, and 3 air changes per hour in Climate Zones 3 through 8~~<u>for air leakage</u>. Testing shall be conducted with a blower door at a pressure of 0.2 inches w.g. (50 Pascals). Where required by the *code official*, testing shall be conducted by an *approved* third party. A written report of the results of the test shall be signed by the party conducting the test and provided to the *code official*. Testing shall be performed at any time after creation of all penetrations of the *building thermal envelope*. During testing:

1. Exterior windows and doors, fireplace and stove doors shall be closed, but not sealed, beyond the intended weatherstripping or other infiltration control measures;
2. Dampers including exhaust, intake, makeup air, backdraft and flue dampers shall be closed, but not sealed beyond intended infiltration control measures;
3. Interior doors, if installed at the time of the test, shall be open;
4. Exterior doors for continuous ventilation systems and heat recovery ventilators shall be closed and sealed;
5. Heating and cooling systems, if installed at the time of the test, shall be turned off; and
6. Supply and return registers, if installed at the time of the test, shall be fully open.

<u>**R402.4.1.3 (N1102.4.1.3) Leakage rate (Prescriptive).** The building or dwelling unit shall have an air leakage rate not exceeding 5 air changes per hour in Climate Zones 1 and 2, and 3 air changes per hour in Climate Zones 3 through 8, when tested in accordance with Section R402.4.1.2.</u>

Reason: Conner: This is exactly the online draft DOE posted. It makes the duct tightness tradable. DOE's posted reason statement said it well:

> *"Changing the envelope air leakage rate from mandatory to prescriptive will allow builders the option of trading improvements in other building components for less stringent pressure test results. This provides flexibility in meeting the requirements and options for recovering from an unexpected test failure. The proposed change retains a mandatory pressure test and leaves all other aspects of envelope sealing mandatory".*

Surrena: These modifications remove the mandatory maximum air tightness requirement and provide designers and builders the flexibility to trade-off building tightness with other performance path measures when using the performance path. Currently the building tightness requirement is mandatory and the 3 and 5 ACH tightness levels even under ideal circumstances, are very difficult to achieve. This will provide energy neutral trade-offs for expensive and sometimes unattainable requirements with other building improvements. This proposal does not change the stringency of the code it only increases the flexibility.

Cost Impact: The code change proposal will not increase the cost of construction.

R402.4-EC-CONNER-SURRENA

Committee Action Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: This is an "energy neutral" trade-off", allowing duct tightness to be a trade-off when using the performance path.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Craig Conner, Building Quality, representing elf, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R402.4 (N1102.4) Air leakage. The building thermal envelope shall be constructed to limit air leakage in accordance with the requirements of Sections R402.4.1 through R402.4.4.

R402.4.1 Building thermal envelope. The building thermal envelope shall comply with sections R402.4.1.1 <u>through R402.4.1.3</u>~~and R402.4.1.2~~. The sealing methods between dissimilar materials shall allow for differential expansion and contraction.

R402.4.1.1 (N1102.4.1.1) Installation (Mandatory). The components of the *building thermal envelope* as listed in Table R402.4.1.1 shall be installed in accordance with the manufacturer's instructions and the criteria listed in Table R402.4.1.1, as applicable to the method of construction. Where required by the *code official*, an *approved* third party shall inspect all components and verify compliance.

R402.4.1.2 (N1102.4.1.2) Testing (Mandatory). The building or dwelling unit shall be tested for air leakage. Testing shall be conducted with a blower door at a pressure of 0.2 inches w.g. (50 Pascals). Where required by the *code official*, testing shall be conducted by an *approved* third party. A written report of the results of the test shall be signed by the party conducting the test and provided to the *code official*. Testing shall be performed at any time after creation of all penetrations of the *building thermal envelope*. During testing:

1. Exterior windows and doors, fireplace and stove doors shall be closed, but not sealed, beyond the intended weatherstripping or other infiltration control measures;
2. Dampers including exhaust, intake, makeup air, backdraft and flue dampers shall be closed, but not sealed beyond intended infiltration control measures;
3. Interior doors, if installed at the time of the test, shall be open;
4. Exterior doors for continuous ventilation systems and heat recovery ventilators shall be closed and sealed;
5. Heating and cooling systems, if installed at the time of the test, shall be turned off; and
6. Supply and return registers, if installed at the time of the test, shall be fully open.

R402.4.1.3 (N1102.4.1.3) Leakage rate (Prescriptive). The building or dwelling unit shall have an air leakage rate not exceeding 5 air changes per hour in Climate Zones 1 and 2, and 3 air changes per hour in Climate Zones 3 through 8, when tested in accordance with Section R402.4.1.2.

Commenter's Reason: This comment is exactly as posted as a DOE draft.

DOE's stated reason is "*This public comment is a minor correction to add a necessary callout to new Section R402.4.1.3*."

Public Comment 2:

Brian Dean, ICF International, representing the Energy Efficient Codes Coalition; Jeff Harris, Alliance to Save Energy; Harry Misuriello, American Council for an Energy-Efficient Economy (ACEEE); Bill Prindle, representing the Energy Efficient Codes Coalition; Garrett Stone, Brickfield, Burchette, Ritts & Stone, PC; Donald J. Vigneau, Northeast Energy Efficiency Partnerships Inc., request Approval as Modified by this Public Comment.

Modify the proposal as follows:

R402.4 (N1102.4) Air leakage. The building thermal envelope shall be constructed to limit air leakage in accordance with the requirements of Sections R402.4.1 through R402.4.4.

R402.4.1.1 (N1102.4.1.1) Installation (Mandatory). The components of the *building thermal envelope* as listed in Table R402.4.1.1 shall be installed in accordance with the manufacturer's instructions and the criteria listed in Table R402.4.1.1, as applicable to the method of construction. Where required by the *code official*, an *approved* third party shall inspect all components and verify compliance.

R402.4.1.2 (N1102.4.1.2) Testing (Mandatory). The building or dwelling unit shall be tested for air leakage. <u>The maximum air leakage rate in any building or dwelling unit under any compliance path shall not exceed 6 air changes per hour.</u> Testing shall be conducted with a blower door at a pressure of 0.2 inches w.g. (50 Pascals). Where required by the *code official*, testing shall be conducted by an *approved* third party. A written report of the results of the test shall be signed by the party conducting the test and provided to the *code official*. Testing shall be performed at any time after creation of all penetrations of the *building thermal envelope*. During testing:

1. Exterior windows and doors, fireplace and stove doors shall be closed, but not sealed, beyond the intended weatherstripping or other infiltration control measures;
2. Dampers including exhaust, intake, makeup air, backdraft and flue dampers shall be closed, but not sealed beyond intended infiltration control measures;
3. Interior doors, if installed at the time of the test, shall be open;
4. Exterior doors for continuous ventilation systems and heat recovery ventilators shall be closed and sealed;
5. Heating and cooling systems, if installed at the time of the test, shall be turned off; and
6. Supply and return registers, if installed at the time of the test, shall be fully open.

R402.4.1.3 (N1102.4.1.3) Leakage rate (Prescriptive). The building or dwelling unit shall have an air leakage rate not exceeding 5 air changes per hour in Climate Zones 1 and 2, and 3 air changes per hour in Climate Zones 3 through 8, when tested in accordance with Section R402.4.1.2.

Commenter's Reason: We recommend approval of RE72 as modified by this public comment. The current IECC sets the mandatory and prescriptive test requirements for building air leakage at the same air leakage level – 5 ACH 50 in climate zones 1-2 and 3 ACH50 in climate zones 3-8. Because these values may be difficult to achieve in some cases, we do not object to permitting air leakage to be traded off, to some degree, in the performance path for other reasonable energy efficiency improvements. However, there should be at least some limits on such trade-offs, particularly given other proposed changes to the performance path. As a result, we propose a mandatory maximum air leakage of 6 ACH50 be established – this will still leave reasonable room for more flexibility while ensuring some minimum level of performance.

Public Comment 3:

Michael D. Fischer, Kellen Company, representing Kellen Codes, Standards, and Regulatory Advocacy, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

TABLE R405.5.2(1)
PROPOSED DESIGN

BUILDING COMPONENT	STANDARD REFERENCE DESIGN	PROPOSED DESIGN
Air exchange rate	Air leakage rate of 5 air changes per hour in Climate Zones 1 and 2, and 3 air changes per hour in Climate Zones 3 through 8 at a pressure of 0.2 inches w.g (50 Pa). The mechanical ventilation rate shall be in addition to the air leakage rate and the same as in the proposed design, but no greater than 0.01 x CFA + 7.5 x (*N br* + 1) where: *CFA* = conditioned floor area N_{br} = number of bedrooms Energy recovery shall not be assumed for mechanical ventilation.	~~For residences that are not tested, the same air leakage rate as the standard reference design. For tested residences,~~ The measured air exchange rate[c]. The mechanical ventilation rate[d] shall be in addition to the air leakage rate and shall be proposed.

(Portions of Table and code change proposal not shown remain unchanged)

Commenter's Reason: This modification is a correction to address the performance path and ensure consistency regarding the requirement for testing to determine the measured air exchange rate.

Public Comment 4:

Hope Medina, City of Cherry Hills Village, CO, representing Colorado Chapter of ICC, requests Disapproval.

Commenter's Reason: We don't agree with the proponent's reason statement that 3 ACH is difficult because if the builder is constructing to table R402.4.1.1, 3 ACH is almost a given. But, we weren't too concerned with allowing some amount of trade off because we felt that you wouldn't be able to trade too much off and still pass overall compliance with the performance path. With that being said, because RE-166 brings back mechanical tradeoffs into the performance path we have to oppose trading off mechanical efficiency for building tightness. What good does it do to put an efficient piece of equipment into a leakier home especially when credit is being given for the more efficient equipment that was already going to be installed? Retrofitting a piece of the mechanical system is common over the life of the structure, but the durability of the building comes into play when it has a larger amount of air leakage.

Air tightness is an affordable methodology to providing durability and comfort to the homebuyer when the builders install the components of table R402.4.1.1 correctly at the time of construction. Once the construction has been completed it becomes difficult to address any air leakage problems later on and heroic measures must be performed.

There has been talk about adding an ACH tradeoff limit, which we could agree with if the equipment trade off had not been put into place, along with duct leakage tradeoffs that were approved, and the R-value roll backs that are proposed. All of the changes together would be too much of a setback for efficiency especially when each of these measures are being accomplished by builders every day.

Public Comment 5:

Charles Miller, City of Northampton, MA, representing self, requests Disapproval.

Commenter's Reason: It would seem that this modification while great for new construction would put an unfair burden on additions, which would then need to be isolated from the main structure and blower door tested or tested with a house, which is not required to be updated. In conjunction with Air sealing the definition of air sealing could use clear language as it does not confirm that an air barrier requires durable sealing of materials and T402.4.1.1 is confusing to both contractor and official.

Proposed Change as Submitted

Proponent: Brian Dean, Energy Efficient Codes Coalition; Garrett Stone, Brickfield Burchette Ritts & Stone, PC; Jeff Harris, Alliance to Save Energy; Harry Misuriello, American Council for an Energy-Efficient Economy; and Bill Prindle, Energy Efficient Codes Coalition

Revise as follows:

R402.4 (N1102.4) Air leakage ~~(Mandatory)~~. The building thermal envelope shall be constructed to limit air leakage in accordance with the requirements of Sections R402.4.1 through R402.4.4.

R402.4.1 (N1102.4.1) Building thermal envelope. The *building thermal envelope* shall comply with Sections R402.4.1.1 ~~and~~ ~~R402.4.1.2~~ through R402.4.1.3. ~~The sealing methods between dissimilar materials shall allow for differential expansion and contraction.~~

R402.4.1.1 (N1102.4.1.1) Installation (Mandatory). The components of the *building thermal envelope* as listed in Table R402.4.1.1 shall be installed in accordance with the manufacturer's instructions and the criteria listed in Table R402.4.1.1, as applicable to the method of construction. The sealing methods between dissimilar materials shall allow for differential expansion and contraction. Where required by the *code official*, an *approved* third party shall inspect all components and verify compliance.

R402.4.1.2 (N1102.4.1.2) Testing (Mandatory). The building or dwelling unit shall be tested for air leakage ~~and verified as having an air leakage rate of not exceeding 5 air changes per hour in Climate Zones 1 and 2, and 3 air changes per hour in Climate Zones 3 through 8~~. Testing shall be conducted with a blower door at a pressure of 0.2 inches w.g. (50 Pascals)~~. Where required by the *code official*, testing shall be conducted~~ by an *approved* third party. A written report of the results of the test shall be signed by the party conducting the test and provided to the *code official*. Testing shall be performed at any time after creation of all penetrations of the *building thermal envelope*.

During testing:

1. Exterior windows and doors, fireplace and stove doors shall be closed, but not sealed, beyond the intended weatherstripping or other infiltration control measures;
2. Dampers including exhaust, intake, makeup air, backdraft and flue dampers shall be closed, but not sealed beyond intended infiltration control measures;
3. Interior doors, if installed at the time of the test, shall be open;
4. Exterior doors for continuous ventilation systems and heat recovery ventilators shall be closed and sealed;
5. Heating and cooling systems, if installed at the time of the test, shall be turned off; and
6. Supply and return registers, if installed at the time of the test, shall be fully open.

R402.4.1.3 (N1102.4.1.3) Leakage rate (Prescriptive). The *building* or *dwelling unit* shall have an air leakage rate that does not exceed 5 air changes per hour in Climate Zones 1 and 2, and 3 air changes per hour in Climate Zones 3 through 8, when tested in accordance with Section R402.4.1.2.

R402.4.2 (N1102.4.2) Fireplaces (Mandatory). New wood-burning fireplaces shall have tight-fitting flue dampers and outdoor combustion air.

R402.4.3 (N1102.4.3) Fenestration air leakage (Mandatory). Windows, skylights and sliding glass doors shall have an air infiltration rate of no more than 0.3 cfm per square foot (1.5 L/s/m^2), and swinging doors no more than 0.5 cfm per square foot (2.6 L/s/m^2), when tested according to NFRC 400 or AAMA/WDMA/CSA 101/I.S.2/A440 by an accredited, independent laboratory and *listed* and *labeled* by the manufacturer.

Exception: Site-built windows, skylights and doors.

R402.4.4 (N1102.4.4.) Recessed lighting (Mandatory). Recessed luminaires installed in the *building thermal envelope* shall be sealed to limit air leakage between conditioned and unconditioned spaces. All recessed luminaires shall be IC-rated and *labeled* as having an air leakage rate not more than 2.0 cfm (0.944 L/s) when tested in accordance with ASTM E 283 at a 1.57 psf (75 pa) pressure differential. All recessed luminaires shall be sealed with a gasket or caulk between the housing and the interior wall or ceiling covering.

Reason: The purpose of this code change is to clarify the code language related to air leakage, modify certain requirements, including changing a mandatory air leakage value to prescriptive and to require all necessary testing to be done by an approved third party. By changing the allowable tested air leakage rate from “mandatory” to “prescriptive,” this proposal would allow air leakage to be part of the tradeoff calculation under section R405 performance trade-offs. The result will maintain energy efficiency, while providing increased flexibility to the builder and an alternative path for cases in which a building fails the air leakage test or where achieving a low air leakage rate would be too difficult. This is an important consideration where the on-site testing requirement is already set at a tight level.

This proposal also adds objectivity and transparency by requiring that all required air leakage testing be administered by a code-official-approved third party. This proposal also reorganizes Section R402.4 to add clarity and simplicity to the code. However, it should be noted that this proposal does not change or tighten required values for tested air leakage, which were initially set in the 2012 *IECC*.

Cost Impact: The code change proposal will increase the cost of construction.

R402.4-EC-DEAN-HARRIS-MISURIELLO-PRINDLE-STONE

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: This proposal is the same as RE72-13, except that verification testing by a 3rd party would be required. The committee disapproved this on the basis that it did not agree that 3rd party testing would be required.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Michael Fischer, Kellen Company, representing Polyisocyanurate Insulation Manufacturers Association requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

Table R405.5.2(1)
SPECIFICATIONS FOR THE STANDARD REFERENCE AND PROPOSED DESIGNS

BUILDING COMPONENT	STANDARD REFERENCE DESIGN	PROPOSED DESIGN
Air exchange rate	(*No change to this portion)*	~~For residences that are not tested, the same air leakage rate as the standard reference design.~~ ~~For tested residences,~~ the measured air

		exchange rate[c]. The mechanical ventilation rated shall be in addition to the air leakage rate and shall be as proposed.

(Portions of Table and code change proposal not shown remain unchanged.)

Commenter's Reason: This modification is a correction to address the performance path and ensure consistency regarding the requirement for testing to determine the measured air exchange rate.

RE73-13
Final Action: AS AM AMPC____ D

RE75-13
R402.4 (IRC N1102.4)

Proposed Change as Submitted

Proponent: Don Surrena, CBO, representing National Association of Home Builders (NAHB) (dsurrena@nahb.org)

Revise as follows:

R402.4 (N1102.4) Air leakage (Mandatory). The building thermal envelope shall be constructed to limit air leakage in accordance with the requirements of Section R402.4.1 through R402.4.4.

> <u>**Exception:** Dwelling units of R-2 Occupancies shall be permitted to comply with Section C402.4</u>

Reason: Air tightness testing for single family homes is very straightforward; however, it is much more difficult to accurately test multi-family buildings. Currently the code treats low-rise multi-family buildings, which are 3 stories or less, like single family homes and multi-family buildings of 4 stories or more like commercial buildings. Regardless of height, all multi-family buildings have the same air tightness testing complications, such as: Does the entire building need to be tested at one time? What about multi-family buildings with open corridors? Does every dwelling need to be tested? Can the leakages be averaged between units? Is the leakage tested only to the "outside" or should it include leakage to adjacent units?

By approving this change, low-rise multi-family buildings will avoid these complications, but yet will still held to the same level of performance as high rise (R-2) residential building as well as all commercial buildings.

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis. This exception will not appear in Chapter 11 of the IRC, since it is not applicable to the IRC.

R402.4 #1-EC-SURRENA

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: This proposal would remove the requirement for an air barrier in Climate Zones 1, 2, and 3 because the reference to Section C402.4 leads to the general exception in Section C402.4.1.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Don Surrena, CBO, representing the National Association of Home Builders, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R402.4 (N1102.4) Air leakage (Mandatory). The building thermal envelope shall be constructed to limit air leakage in accordance with the requirements of Section R402.4.1 through R402.4.4.

> **Exception:** Dwelling units of Group R-2 Occupancies shall <u>not be required to be tested individually. Buildings of Group R2 Occupancies shall</u> be permitted to comply with Section ~~C402.4~~ <u>C402.4.1.1 and C402.4.1.2</u>.

Commenter's Reason: Air tightness testing for single family homes is very straightforward; however, it is much more difficult to accurately test multi-family buildings. Currently the code treats low-rise multi-family buildings, which are 3 stories or less, like single family homes and multi-family buildings of 4 stories or more like commercial buildings. Regardless of height, all multi-family buildings have the same air tightness testing complications, such as: Does the entire building need to be tested at one time? What about multi-family buildings with open corridors? Does every dwelling need to be tested? Can the leakages be averaged between units? Is the leakage tested only to the "outside" or should it include leakage to adjacent units?

By approving this change, low-rise multi-family buildings will avoid these complications, but will still be held to the same level of performance as high rise (R-2) residential building as well as all commercial buildings.

Two modifications are made by this comment, first, there is a perception that the leakage of each individual unit needs to be tested, this comment clarifies that this type of testing can be done, but is not required.

The second modification adds a requirement of an air barrier in Climate Zones 1, 2 and 3 which are exempted by commercial buildings. This addresses an issue raised at the Committee Action Hearings where the committee was concerned that this was a reduction in stringency.

RE75-13

Final Action: AS AM AMPC____ D

RE76-13

R402.2 (IRC N1102.2), R402.2.1 (NEW) (IRC N1102.2.1 (NEW)), Table R402.4.1.1 (NEW) (IRC Table N1102.4.1.1 (NEW))

Proposed Change as Submitted

Proponent: Proponent: Eric Makela, Britt/Makela Group, Inc., representing Northwest Energy Codes Group (Eric@BrittMakela.com); Jim Meyers, Southwest Energy Efficiency Partnership; Robby Schwarz, Energy Logic

Revise as follows:

R402.2 (N1102.2) Specific insulation requirements (Prescriptive). In addition to the requirements of Section R402.1, insulation shall meet the specific requirements of Sections R402.2.1 through R402.2.12. Insulation shall also be installed in accordance with Table R402.4.1.1.

R402.2.1 (N1102.2.1) Insulation installation requirements (Mandatory). Insulation shall be installed in accordance with Table R402.4.1.1.

Delete Table R402.4.1.1 in its entirety and replace with new Table R402.4.1.1

TABLE R402.4.1.1 (N1102.4.1.1)
AIR BARRIER AND INSULATION INSTALLATION

COMPONENT	AIR BARRIER CRITERIA[a]	INSULATION INSTALLATION CRITERIA
General Requirements	A continuous air barrier shall be installed in the buildings thermal envelope and be in alignment with the insulation. Air permeable cavity insulation shall be installed in a six sided assembly. Breaks or joints in the air barrier shall be sealed with an air impermeable material to ensure that the air barrier system is impermeable to air movement. Air barriers shall be constructed and mechanically fastened to framing and sealed at edges, gaps, or voids with air sealing materials that are appropriate to the construction materials being sealed.	Air-permeable insulation shall not be used as a sealing material. Exterior thermal envelope insulation for framed walls and floors is installed in substantial contact and continuous alignment with building envelopes interior air barrier.
Ceiling / attic	The air barrier in any dropped ceiling/soffit shall be aligned with the insulation and any gaps in the air barrier shall be sealed. Access openings, drop down stair or knee wall doors to unconditioned attic spaces shall be sealed. An air barrier at the drywall conditioned space and a ventilated attic is required	In any insulated ceiling or dropped ceiling/soffit, the insulation is substantially aligned with the air barrier.
Walls	The junction of the foundation and sill plate shall be sealed. The drywall junction at the top plate of interior and exterior walls separating conditioned space from ventilated attic space shall be	Corners, headers, and interior wall intersections shall be insulated to a minimum of R-5. The insulation shall be installed according to manufacturer's instructions and/or industry

COMPONENT	AIR BARRIER CRITERIA[a]	INSULATION INSTALLATION CRITERIA
	sealed. Wall cavity insulation, including knee walls adjacent to attics, shall be encapsulated on six sides by an interior and exterior air barrier system The junction of the bottom plate of the exterior wall and floor sheathing shall be sealed.	standards which requires that the insulation material uniformly fills each cavity side-to-side, top-to-bottom, and without substantial gaps or voids. No exterior sheathing shall be visible from the building interior through gaps in the cavity insulation material. Wall and floor cavity insulation shall be enclosed on all six sides, and shall be in substantial contact with the sheathing material of the surface it is intended to insulate. For exterior applications of rigid insulation, insulation shall be in firm contact with the structural sheathing materials, and tightly fitted and sealed at joints. Faced batt insulation shall be surface stapled or inset stapled as long as inset stapled tabs are stapled neatly (no buckling), and provided the batt is only compressed at the edges of each cavity, to the depth of the tab itself. For sprayed or blown-in fibrous products, density shall be installed to the proper density to achieve the required R-value of the cavity it is installed in.
Windows, skylights and doors	The space between window/door jambs and framing and skylights and framing shall be sealed.	Comply with narrow cavity requirements
Rim joists	The rim or band joists shall be sealed at all edges, cracks, and gaps and must have an exterior air barrier	
Floors (including above garage and cantilevered floors)	Floors shall encapsulate the cavity insulation on six sides by an interior and exterior air barrier system. The air barrier shall be sealed at all exposed edge/sides including connections between the house floor system and the floor system above unconditioned space.	Floor insulation shall be held in permanent contact with the underside of the subfloor decking and shall not be overly compressed by components that are used to hold it in place so that R-value is lost. Where an obstruction such as a duct or piping is installed in the floor cavity the insulation shall continue to be held in permanent contact with the underside of the subfloor decking, shall encapsulate the obstruction, and a minimum of an R- 19 shall be installed below the obstruction.
Crawl space walls	Exposed earth in unvented crawl spaces shall be covered with a Class I vapor retarder with overlapping joints sealed and edges sealed to the foundation walls and footings.	Where provided in lieu of floor insulation, insulation shall be permanently attached to the crawlspace walls and extend from the vapor barrier covering the dirt floor to the sill attached to the top of the foundation. Where the floor system between the house and the crawl space is insulated it must conform with the floor insulation requirement described above.
Shafts, penetrations	Duct shafts, utility penetrations, wiring penetrations, plumbing penetrations, gas line penetrations, and flue shafts or other similar penetrations through the building envelope shall be sealed.	Insulation shall not extend through draft-stopping or fire-stopping openings. Use caulking rated for the application

COMPONENT	AIR BARRIER CRITERIA[a]	INSULATION INSTALLATION CRITERIA
Narrow cavities	Cavities too small to insulate, shall be sealed with an air barrier material.	Batts in narrow cavities shall be cut to fit, or narrow cavities shall be filled by insulation that on installation readily conforms to the available cavity space.
Garage separation	Air sealing shall be provided between the garage and conditioned spaces.	
Recessed lighting	Recessed light fixtures installed in the building thermal envelope shall be air tight and sealed to the drywall.	Recessed light fixtures installed in the building thermal envelope shall be air tight, IC rated.
Plumbing and wiring	All plumbing, ductwork and wiring air barrier penetrations shall be sealed.	Batt insulation shall be cut neatly to fit around obstructions (such as blocking or bridging), and split, installed, and/or fitted tightly around wiring, plumbing, ducting, and other services in the cavity, or insulation that on installation readily conforms to available space shall encapsulate any obstruction in the cavity.
Shower / tub on exterior wall	Exterior walls adjacent to shower stalls, shower pans, and tubs shall have an air barrier installed separating conditioned space and exterior wall insulation. Tub and shower drain trap penetrations through the subfloor shall be sealed with an air barrier material.	Exterior walls adjacent to showers and tubs shall be insulated.
Electrical / phone box on exterior walls	Electrical, communication, or other boxes located in exterior walls, ceilings, or floors shall be air tight boxes or shall be made to be air tight using air barrier material's Bath fan housing adjacent to and or installed in unconditioned spaces shall be sealed to the drywall and made air tight.	Insulation completely fills voids between the box and exterior sheathing
HVAC register boots	HVAC register boots that penetrate building thermal envelope shall be sealed to the subfloor or drywall.	
Fireplace	Exterior walls adjacent to fireplace enclosures shall have an air barrier installed encapsulating and separating interior conditioned space and exterior wall insulation. Fireplaces shall have tight fitting doors	Exterior walls adjacent to fireplaces shall be insulated.

a. In addition, inspection of log walls shall be in accordance with the provisions of ICC-400.

Reason: Manufacturer instructions, best building practices, DOE's Building America program, Building Energy Code Programs, and other building educators all propose installing products and materials with best building practices and according to manufacturer instructions. However few go further than the code book to learn what best practices and manufactured instructions are. The intent of this new language is to clearly define air barrier and insulation requirements and installation practices that will lead to houses that can easily meet the air leakage standards of the energy code and ensure the performance of the stalled insulation materials.

The 2012 IECC also requires that insulation be installed correctly in order to comply with the air barrier requirements of the IECC. While it is important to install insulation correctly, this type of provision should not be linked to air sealing the house. This proposal provides two distinct sections to the table focused on either air sealing or insulation installation. It also provides a reference in the prescriptive requirements for insulation installation to the table.

Field experience shows that some trades continue to seal holes in the buildings enclosure with air permeable insulation, which is not best building practice does not meet manufacturers' intents for the use of their products.

When the 2009 IECC was released many code officials were introduced to the importance of air barriers and are still struggling to understand where and how an air barrier is integral to the building enclosure. This new language will better prepare trades, builders, and code officials with how and where air barriers should be installed. The quality of the installation and enforcement should increase due to greater clarity and specificity.

The air barrier and insulation table included in the 2009 and 2012 IECC do not require a minimum level of insulation for corners and headers. The new requirement specifies a minimum insulation value and also includes interior wall intersections that also reduce the possibility for full wall insulation in these areas of the building.

Field practice has found kneewalls that are not enclosed on the exterior (attic) vertical plane exhibit more air infiltration and provide the opportunity for insulation to fall away from kneewalls over time reducing the efficiency of the overall building.

Other field practices observed by raters include excessive compression of tabbed insulation batts when stapling the tabs to the side of the stud. This reduces insulation values and does not comply with manufacturer instructions. By adding this language to the table, insulation trades and others who install insulation will have a simplified description for installing batts and inset stapling.

Cost Impact: The code change proposal will not increase the cost of construction.

R402.2-EC-MAKELA-MEYERS-SCHWARZ

Committee Action Hearing Results

Committee Action: Disapproved

Committee Reason: The proposal is possibly good as a guide, but the text contains technical inconsistencies that make it undesirable for code text. In addition, the committee preferred RE85-12.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Eric Makela, Britt Makela Group, representing Northwest Energy Codes Group, Jim Meyers, representing Southwest Energy Efficiency Alliance, and Robby Schwarz, EnergyLogic, representing himself, request Approval as Modified by this Public Comment.

Modify the proposal as follows:

R402.2 Specific insulation requirements (Prescriptive). In addition to the requirements of Section R402.1, insulation shall meet the specific requirements of Sections R402.2.1 through R402.2.12. Insulation shall also be installed in accordance with Table R402.4.1.1.

R402.2.1 Insulation installation requirements (Mandatory). Insulation shall be installed in accordance with Table R402.4.1.1.

TABLE R402.4.1.1
AIR BARRIER AND INSULATION INSTALLATION

COMPONENT	AIR BARRIER CRITERIA[a]	INSULATION INSTALLATION CRITERIA
General Requirements	A continuous air barrier shall be installed in ~~and~~ <u>alignment with</u> the <u>building's</u> thermal envelope ~~and be in alignment with the insulation.~~ ~~Air permeable cavity insulation shall be installed in a six sided assembly.~~ Breaks, ~~or~~ joints, <u>gaps, or voids</u> in the air barrier shall be sealed with an air impermeable material to ensure that the air barrier system is impermeable to air movement. Air barriers shall be installed ~~constructed and mechanically fastened to framing~~ and sealed ~~at edges so no gaps, or voids~~ with air sealing materials that are appropriate to the construction materials being sealed. <u>Air barriers shall be installed to keep outside air out of the building enclosure or inside air out of the building enclosure depending on climate or configuration and</u>	Air-permeable insulation shall not be used as a sealing material. Exterior thermal envelope insulation for ~~framed~~ walls and floors ~~is~~ <u>shall be</u> installed in substantial contact and continuous alignment with <u>the</u> building envelope<u>s</u> ~~interior~~ air barrier.

COMPONENT	AIR BARRIER CRITERIA[a]	INSULATION INSTALLATION CRITERIA
	sometimes shall be installed on the inside and outside of the building to do both.	
Ceiling / attic	The air barrier in any dropped ceiling/soffit shall be aligned with the ~~insulation and any gaps in the air barrier shall be sealed.~~ building's thermal envelope. Access openings, drop down stair or knee wall doors to unconditioned attic spaces shall be sealed or gasketed. A~~n~~ Continuous air barrier shall be installed between ~~at~~ the ~~drywall~~ conditioned space and a ventilated attic. ~~is required~~	~~In any insulated ceiling or dropped ceiling/soffit, the insulation is substantially aligned with the air barrier.~~ Access openings, drop down stair or knee wall doors shall be insulated to the same level as the assembly they are penetrating through.
Walls	The junction of the foundation and sill plate shall be sealed. The drywall junction at the top plate of interior and exterior walls separating conditioned space from unconditioned ~~ventilated attic~~ space shall be sealed or gasketed. Wall cavity insulation, including knee walls adjacent to attics, shall be encapsulated on six sides by an interior and exterior air barrier ~~system~~ The junction of the bottom plate of the exterior wall and floor sheathing shall be sealed.	All Corners, headers, and interior wall intersections shall be insulated ~~to a minimum of R-5.~~ The insulation shall be installed according to manufacturer's instructions and/or industry standards which requires that the insulation material uniformly fills each cavity side-to-side, top-to-bottom, and without substantial gaps or voids. No exterior sheathing shall be visible from the building interior through gaps in the cavity insulation material. Wall ~~and floor cavity~~ insulation shall be enclosed on all six sides, and shall be in substantial contact with the sheathing material of the surface it is intended to insulate. ~~For exterior applications of rigid insulation, insulation shall be in firm contact with the structural sheathing materials, and tightly fitted and sealed at joints.~~ Faced batt insulation shall be surface stapled or inset stapled as long as inset stapled tabs are stapled neatly (no buckling), and provided the batt is only compressed at the edges of each cavity, to the depth of the tab itself. ~~For~~ Sprayed or blown-in ~~fibrous products~~ insulation products, ~~density~~ shall be installed to the proper depth and density to achieve the required R-value of the cavity it is installed in.
Windows, skylights and doors	The space between window/door jambs and framing and skylights and framing shall be sealed.	Comply with narrow cavity requirements
Rim joists	The Rim or band joists shall be sealed at all edges, cracks, and gaps and ~~must~~ shall have an exterior air barrier	
Floors (including above garage and cantilevered floors)	Floors air barriers shall encapsulate the cavity insulation ~~on six sides by~~ with an interior and exterior air barrier ~~system~~. The air barrier shall be sealed at all	~~Floor insulation shall be held in permanent contact with the underside of the subfloor decking and shall not be overly compressed by components that are used to hold it in place so that R-value is lost.~~

COMPONENT	AIR BARRIER CRITERIA[a]	INSULATION INSTALLATION CRITERIA
	exposed edge/sides including connections between the house floor system and the floor system above unconditioned space.	~~If an obstruction (such as a duct or piping) is installed in the floor cavity the insulation shall continue to be held in permanent contact with the underside of the subfloor decking, shall encapsulate the obstruction, and a minimum of an R- 19 shall be installed below the obstruction.~~ Floor framing cavity insulation shall be installed to maintain permanent contact with underside of subfloor decking and shall not be overly compressed so as R-value is lost by components that are used to hold it in place If an obstruction (such as a duct or piping) is installed in the floor cavity option A or B is allowed Option A The insulation shall be held in permanent contact with the underside of the subfloor decking, shall fully encapsulate the obstruction, and a minimum of an R- 19 shall be installed below the obstruction. Option B Floor framing cavity insulation shall be permitted to be in contact with the topside of the exterior sheathing or continuous insulation installed on the bottom side of floor framing, and insulation shall extends from the bottom to the top of all perimeter floor framing members that is equal to or greater then the R-value reqirements of the exterior walls.
Crawl space walls	Exposed earth in unvented crawl spaces shall be covered with a Class I vapor retarder with overlapping joints sealed and edges sealed to the foundation walls and footings.	Where provided in lieu of floor insulation, insulation shall be permanently attached to the crawlspace walls and extend from the vapor barrier covering the dirt floor to the sill attached to the top of the foundation. Where the floor system between the house and the crawl space is insulated it must conform with the floor insulation requirement described above.
Shafts, penetrations	Duct shafts, utility penetrations, wiring penetrations, plumbing penetrations, gas line penetrations, and flue shafts or other similar penetrations through the building envelope shall be sealed.	Insulation shall not extend through draft-stopping or fire-stopping openings. Use caulking rated for the application
Narrow cavities	Cavities too small to insulate, shall be sealed with an air barrier material.	Batts in narrow cavities shall be cut to fit, or narrow cavities shall be filled by insulation that on installation readily conforms to the available cavity space.
Garage separation	Air sealing shall be provided between the garage and conditioned spaces.	
Recessed lighting	Recessed light fixtures installed in the building thermal envelope shall be air tight	Recessed light fixtures installed in the building thermal envelope shall be air tight,

COMPONENT	AIR BARRIER CRITERIA[a]	INSULATION INSTALLATION CRITERIA
	and sealed to the drywall.	IC rated.
Plumbing and wiring	~~All plumbing, ductwork, and wiring air barrier penetrations shall be sealed.~~ All penetration through the air barrier caused by running plumbing, ductwork, or wiring shall be sealed	Batt insulation shall be cut neatly to fit around obstructions (such as blocking or bridging), and split, installed, and/or fitted tightly around wiring, plumbing, ducting, and other services in the cavity, or insulation that on installation readily conforms to available space shall encapsulate any obstruction in the cavity.
Shower / tub on exterior wall	Exterior walls adjacent to shower stalls, shower pans, and tubs shall have an air barrier installed separating conditioned space and the exterior wall insulation. Tub and shower drain trap penetrations through the subfloor shall be sealed with an air barrier material.	Exterior walls adjacent to showers and tubs shall be insulated.
Electrical / fan / phone box on exterior walls/ceilings	Electrical, communication, or other boxes located in exterior walls, ceilings, or floors shall be air tight boxes or shall be made to be air tight using air barrier material's Bath fan housing adjacent to and or installed in unconditioned spaces shall be sealed to the drywall and made air tight.	Insulation completely fills voids between the box and exterior sheathing
HVAC register boots	HVAC supply or return registers/boots that penetrate the buildings thermal envelope shall be sealed to the subfloor or drywall.	
Fireplace	Exterior walls adjacent to fireplace enclosures shall have an air barrier installed encapsulating and separating interior conditioned space and exterior wall insulation. Fireplaces shall have tight fitting doors	Exterior walls adjacent to fireplaces shall be insulated.

a. In addition, inspection of log walls shall be in accordance with the provisions of ICC-400.

Commenter's Reason: Manufacturer instructions, best building practices, DOE's Building America program, Building Energy Code Programs, and other building educators all propose installing products and materials with best building practices and according to manufacturer instructions. However few go further than the code book to learn what best practices and manufactured instructions are. The intent of this new language is to clearly define air barrier and insulation requirements and installation practices that will lead to houses that can easily meet the air leakage standards of the energy code and ensure the performance of the stalled insulation materials.

The 2012 IECC also requires that insulation be installed correctly in order to comply with the air barrier requirements of the IECC. While it is important to install insulation correctly, this type of provision should not be linked to air sealing the house. This proposal provides two distinct sections to the table focused on either air sealing or insulation installation. It also provides a reference in the prescriptive requirements for insulation installation to the table.

Field experience shows that some trades continue to seal holes in the buildings enclosure with air permeable insulation, which is not best building practice does not meet manufacturers' intents for the use of their products.

When the 2009 IECC was released many code officials were introduced to the importance of air barriers and are still struggling to understand where and how an air barrier is integral to the building enclosure. This new language will better prepare trades, builders, and code officials with how and where air barriers should be installed. The quality of the installation and enforcement should increase due to greater clarity and specificity.

The air barrier and insulation table included in the 2009 and 2012 IECC do not require a minimum level of insulation for corners and headers. The new requirement specifies a minimum insulation value and also includes interior wall intersections that also reduce the possibility for full wall insulation in these areas of the building.

Field practice has found kneewalls that are not enclosed on the exterior (attic) vertical plane exhibit more air infiltration and provide the opportunity for insulation to fall away from kneewalls over time reducing the efficiency of the overall building.

Other field practices observed by raters include excessive compression of tabbed insulation batts when stapling the tabs to the side of the stud. This reduces insulation values and does not comply with manufacturer instructions. By adding this language to the table, insulation trades and others who install insulation will have a simplified description for installing batts and inset stapling.

This Public Comment corrects some of the concerns expressed by opponents of the proposal.

RE76-13

Final Action: AS AM AMPC____ D

RE79-13
Table R402.4.1.1 (IRC Table N1102.4.1.1)

Proposed Change as Submitted

Proponent: Brian Dean (Brian.Dean@icfi.com), Energy Efficient Codes Coalition; Garrett Stone, Brickfield Burchette Ritts & Stone, PC; Jeff Harris, Alliance to Save Energy; Harry Misuriello, American Council for an Energy-Efficient Economy; and Bill Prindle, Energy Efficient Codes Coalition

Revise as follows:

TABLE R402.4.1.1 (N1102.4.1.1)
AIR BARRIER AND INSULATION INSTALLATION INSPECTION

(Portions of Table not shown remain unchanged)

h. First value is cavity insulation, second is continuous insulation or insulated siding, so "13+5" means R-13 cavity insulation plus R-5 continuous insulation or insulated siding. ~~If structural sheathing covers 40 percent or less of the exterior, continuous insulation *R*-value shall be permitted to be reduced by no more than R-3 in the locations where structural sheathing is used – to maintain a consistent total sheathing thickness.~~

Reason: The purpose of this code change is to clarify and enhance compliance with and enforcement of the codes by organizing air barrier and insulation installation requirements into two separate checklists in the table. The proposal also updates and improves the language in the table to add clarity and to ensure that crucial elements of the thermal envelope are effectively sealed, installed and verified.

The proper installation of insulation and reasonable control of air leakage are both critical to achieving energy savings in homes. Although every building or dwelling unit is currently required to be tested for air leakage, a better-organized and more specific enumeration of key insulation and sealing requirements will lead to tighter, better-insulated, more energy efficient homes. The two columns are largely based on current insulation installation requirements and air barrier criteria in the 2012 IECC. We expect that as technology advances, and as building and inspection practices improve, this list will be updated. The reorganization of the requirements as presented above will facilitate that regular improvement in future code editions.

Cost Impact: The code change proposal will not increase the cost of construction.

Committee Action Hearing Results

Committee Action: Disapproved

Committee Reason: Proponent recommended disapproval given action on RE63-13.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Brian Dean, ICF International, representing the Energy Efficient Codes Coalition; Jeff Harris, Alliance to Save Energy; Harry Misuriello, American Council for an Energy-Efficient Economy (ACEEE); Bill Prindle, representing the Energy Efficient Codes Coalition; Garrett Stone, Brickfield, Burchette, Ritts & Stone, PC; Donald J. Vigneau, Northeast Energy Efficiency Partnerships Inc., request Approval as Submitted.

Commenter's Reason: We recommend approval of RE79 as submitted for the reasons stated in our original reason statement. While RE63 moves the language addressed by RE79 from a footnote to code text and we have submitted a public comment for approval as modified on that proposal, if RE63 is not approved as modified, we will be requesting that this code change be adopted to remove the exception.

RE79-13

Final Action: AS AM AMPC____ D

RE80-13
Table R402.4.1.1 (IRC Table N1102.4.1.1)

Proposed Change as Submitted

Proponent: Michael Schmeida, Divisional Manager-Sustainability and Government/Regulatory Affairs representing Tremco Commercial Sealants and Waterproofing, Beachwood, Ohio (mschmeida@tremcoinc.com)

Revise as follows:

TABLE R402.4.1.1 (N1102.4.1.1)
AIR BARRIER AND INSULATION INSTALLATION

Component	Criteria
Garage separation	Air sealing <u>and thermal separation</u> shall be provided between the garage and conditioned space <u>for all joints, service penetrations, and fenestrations</u>.

(Portions of Table not shown remain unchanged.)

Reason:
1. Sealing helps mitigate air movement into or out of the conditioned space, thereby reducing energy needs in mitigating uncontrolled air movement.
2. Requiring insulation insures continuity in the thermal envelope and eliminates conductive transfer of energy through un-insulated spaces.

Cost Impact: The impact would be $500 depending on geography for a 2000/sqft home, but the ROI would be 3-5 years depending on region, design, etc.

R402.4.1.1T #2-EC-SCHMEIDA

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: Rather than clarifying, the propose language provides unnecessary language to a provision that is presently understood.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Michael Schmeida, Divisional Manager-Sustainability and Government/Regulatory Affairs representing Tremco Commercial Sealants and Waterproofing, Beachwood, Ohio requests Approval as Modified by this Public Comment.

Replace the proposal as follows:

TABLE R402.4.1.1 (N1102.4.1.1)
AIR BARRIER AND INSULATION INSTALLATION

COMPONENT		CRITERIA
Garage separation	<u>Air sealing shall be provided between the garage and conditioned spaces.</u>	<u>Batt insulation cut neatly to fit around, or insulation that on installation readily conforms to available space, shall be installed around any shaft or penetration through the thermal envelope.</u>

		Batt insulation cut neatly to fit between door jambs and framing, or insulation that on installation readily conforms to available space, shall be installed between door jambs and framing.

Commenter's Reason: This modification does the following over the original submittal:

1. Makes the language more consistent with the rest of this section of the code, per testimony given in the public hearings.
2. Adapts the requested change to the format of RE85 as it was approved in the public hearings.

The addition of insulation ensures continuity in the thermal envelope, countering conductive thermal leaks around the fenestration not mitigated by sealing only.

RE80-13

Final Action: AS AM AMPC____ D

RE81-13
Table R402.4.1.1 (IRC N1102.4.1.1)

<u>Proposed Change as Submitted</u>

Proponent: Michael Schmeida, Divisional Manager-Sustainability and Government/Regulatory Affairs representing Tremco Commercial Sealants and Waterproofing, Beachwood, Ohio (mschmeida@tremcoinc.com)

Revise as follows:

TABLE R402.4.1.1 (N1102.4.1.1)
AIR BARRIER AND INSULATION INSTALLTION

COMPONENT	CRITERIA[a]
Air barrier and thermal barrier	A continuous air barrier shall be installed in the building envelope. Exterior thermal envelope contains a continuous air barrier. Breaks or joints in the air barrier shall be sealed. Air-permeable insulation shall not be used as a sealing material.
Ceiling/attic	The air barrier in any dropped ceiling/soffit shall be aligned with the insulation and any gaps in the air barrier sealed. Access openings, drop down stair or knee wall doors to unconditioned attic spaces shall be sealed.
Walls	Corners and headers shall be insulated and the junction of the foundation and sill plate shall be sealed. The junction of the top plate and top of exterior walls shall be sealed. Exterior thermal envelope insulation for framed walls shall be installed in substantial contact and continuous alignment with the air barrier. Knee walls shall be sealed.
Windows, skylights and doors	The space between window/door jambs and framing and skylights and framing shall be sealed <u>on both the interior and exterior with a middle insulating layer filling the gap between the fenestration and framing/opening.</u>
Rim joists	Rim joists shall be insulated and include the air barrier.
Floors (including above-garage and cantilevered floors)	Insulation shall be installed to maintain permanent contact with underside of subfloor decking. The air barrier shall be installed at any exposed edge of insulation.
Crawl space walls	Where provided in lieu of floor insulation, insulation shall be permanently attached to the crawlspace walls. Exposed earth in unvented crawl spaces shall be covered with a Class I vapor retarder with overlapping joints taped.
Shafts, penetrations	Duct shafts, utility penetrations, and flue shafts opening to exterior or unconditioned space shall be sealed.
Narrow cavities	Batts in narrow cavities shall be cut to fit, or narrow cavities shall be filled by insulation that on installation readily conforms to the available cavity space.
Garage separation	Air sealing shall be provided between the garage and conditioned spaces.
Recessed lighting	Recessed light fixtures installed in the building thermal envelope shall be air tight, IC rated, and sealed to the drywall.
Plumbing and wiring	Batt insulation shall be cut neatly to fit around wiring and plumbing in exterior walls, or insulation that on installation readily conforms to available space shall extend behind piping and wiring.

Shower/tub on exterior wall	Exterior walls adjacent to showers and tubs shall be insulated and the air barrier installed separating them from the showers and tubs.
Electrical/phone box on exterior walls	The air barrier shall be installed behind electrical or communication boxes or air sealed boxes shall be installed.
HVAC register boots	HVAC register boots that penetrate building thermal envelope shall be sealed to the subfloor or drywall.
Fireplace	An air barrier shall be installed on fireplace walls. Fireplaces shall have gasketed doors.

a. In addition, inspection of log walls shall be in accordance with the provisions of ICC-400.

Reason:

1. Installing a seal on both the interior and exterior side helps mitigate infiltration as well as exfiltration of air into or out of the wall assembly, thereby reducing energy needs in mitigating uncontrolled air movement.
2. Requiring insulation insures continuity in the thermal envelope and eliminates conductive transfer of energy through un-insulated spaces.

Cost Impact: The cost would be negligible.

R402.4.1.1T #3-EC-SCHMEIDA

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: The provision as written provides for a scenario where the sealing method as configured could cause moisture problems.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Michael Schmeida, Divisional Manager-Sustainability and Government/Regulatory Affairs representing Tremco Commercial Sealants and Waterproofing, Beachwood, Ohio requests Approval as Modified by this Public Comment.

Replace the proposal as follows:

TABLE R402.4.1.1 (N1102.4.1.1)
AIR BARRIER AND INSULATION INSTALLTION

COMPONENT		CRITERIA[a]
Windows, Skylights and Doors	The space between window/door jambs and framing and skylights and framing shall be sealed.	Batt insulation cut neatly to fit between window/door jambs and framing and skylights and framing, or insulation that on installation readily conforms to available space, shall be installed between window/door jambs and framing and skylights and framing.

a. In addition, inspection of log walls shall be in accordance with the provisions of ICC-400.

(Portions of Table not shown remain unchanged)

Commenter's Reason: This modification does the following over the original submittal:

1. Makes the language more consistent with the rest of this section of the code, per testimony given in the public hearings.
2. Adapts the requested change to the format of RE85 as it was approved in the public hearings.

The addition of insulation ensures continuity in the thermal envelope, countering conductive thermal leaks around the fenestration not mitigated by sealing only.

RE83-13
Table R402.4.1.1 (IRC Table N1102.4.1.1)

Proposed Change as Submitted

Proponent: Ellen Eggerton, representing Virginia Building and Code Officials Association

Revise as follows:

TABLE R402.4.1.1 (N1102.4.1.1)
AIR BARRIER AND INSULATION INSTALLATION

COMPONENT	CRITERIA[a]
Walls	Cavities within corners and headers shall be insulated by completely filling the cavity with a material having a thermal resistance of R3 per inch minimum. ~~and~~ The junction of the foundation and sill plate shall be sealed. The junction of the top plate and top of exterior walls shall be sealed. Exterior thermal envelope insulation for framed walls shall be installed in substantial contact and continuous alignment with the air barrier. Knee walls shall be sealed.

(Portions of Table not shown remain unchanged)

Reason: The current text says, "Corners and headers shall be insulated …" All headers and corners under all circumstances? Insulated to what level? This provision is a carryover of the 2009 IECC requirement. Varying answers to these questions have already lead to varying interpretations of the code requirements, uneven enforcement, and confusion in the regulated community. This proposal intends to allay some of that confusion by specifying that headers and corners must be insulated when there is an available cavity (e.g., a two-ply 2x header in a 2x4 wall leaves no cavity to fill) and by providing a practical definition of what *insulated* means in this context. Typical insulating materials like fiberglass and rigid foam can easily achieve R3 per inch.

Cost Impact: There will be a cost impact from this proposal to the extent that this requirement was not previously enforced due to ambiguity in the requirement. Regardless, the quantities of insulation being installed are small, but there may be many of these areas to insulate, depending on the size, design, and layout of the proposed residential building.

R402.4.1.1T-EC-EGGERTON

Committee Action Hearing Results

Committee Action: **Approved as Modified**

Modify the proposal as follows:

First sentence in "Criteria" column:

Cavities within corners and headers of frame walls shall be insulated by completely filling the cavity with a material having a thermal resistance of R3 per inch minimum.

Committee Reason: This a practical approach for an air barrier in corners and headers of frame walls. The modification is made to qualify where sealing is needed.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Don Surrena, CBO, representing the National Association of Home Builders, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

TABLE R402.4.1.1 (N1102.4.1.1)
AIR BARRIER AND INSULATION INSTALLATION

COMPONENT	CRITERIA[a]
Walls	Cavities within corners and headers shall be insulated by completely filling the cavity ~~with a material having a thermal resistance of R3 per inch minimum~~. The junction of the foundation and sill plate shall be sealed. The junction of the top plate and top of exterior walls shall be sealed. Exterior thermal envelope insulation for framed walls shall be installed in substantial contact and continuous alignment with the air barrier. Knee walls shall be sealed.

(Portions of Table not shown remain unchanged)

Commenter's Reason: While filling the cavity with insulation can provide an energy benefit; once a specific R-value per inch is required, there is a responsibility by the builder and inspector to verify this value. Who is to say that the installed density of a loose fill or partial batt insulation meets the requirement? Nearly all insulating materials will typically meet this requirement but this may add to the confusion rather than solve any problem.

The current language may create a situation where the builder uses "extra" wood as a nailer for siding or drywall (wood R-value approximately 1.25 per inch) and the interpretation is that it does not meet the requirements.

Changing the language to simply "filling the cavity" meets the intent without burdening the code official to verify the R-value requirement and potentially argue over necessary framing members within the wall.

RE83-13

Final Action: AS AM AMPC____ D

RE88-13
R402.4.1.2 (IRC N1102.4.1.2), R402.4.1.2.1 (NEW) (IRC N1102.4.1.2.1 (NEW))

Proposed Change as Submitted

Proponent: Michael D. Fischer, Kellen Company, representing the Center for the Polyurethanes Industry (mfischer@kellencompany.com)

Revise as follows:

R402.4.1.2 (N1102.4.1.2) Testing. The building or dwelling unit shall be tested by an *approved* agency and verified as having an air leakage rate of not exceeding ~~5~~ 4 air changes per hour in Climate Zones 1 and 2, and 3 air changes per hour in Climate Zones 3 through 8. Testing shall be conducted with a blower door at a pressure of 0.2 inches w.g. (50 Pascals). ~~Where required by the *code official*, testing shall be conducted by an *approved* third party.~~ A written report of the results of the test shall be signed by the testing agency ~~party conducting the test~~ and provided to the *code official*. Testing shall be performed at any time after creation and sealing of all penetrations of the *building thermal envelope*.

402.4.1.2.1 (N1102.4.1.2.1) The air leakage rate in Climate Zones 3 through 8 shall be permitted to be no greater than 4 air changes per hour where all heating and conditioning ducts, air handlers, and filter boxes are located within the *building thermal envelope.*

Reason: Building envelope tightness is a proven energy efficiency measure. With recent improvements in construction techniques and quality control, builders have demonstrated their ability to comply with air barrier requirements in the code as well as above-code programs. At the same time, the location of air handling ducts within the building thermal envelope has also become a more common and desirable construction technique- especially with new provisions for unvented attics in the IRC. This proposal offers a compromise that establishes a slight improvement in air barrier performance in the southern climate zones, as well as a trade-up in Climate Zones 3-8 that encourages the use of unvented attics.

Cost Impact: This proposal may result in an increased initial construction cost in some climate zones depending upon the method of construction, but is likely to provide a short break-even point on energy consumption and utility costs.

R402.4.1.2-EC-FISCHER

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: This is would be a weakening of the code stringency. In addition, 3rd party testing is not necessary.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Michael Fischer, Kellen Company, representing the Center for the Polyurethanes Industry, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R402.4.1.2 Testing. The building or dwelling unit shall be tested by an *approved* agency and verified as having an air leakage rate of not exceeding 5 ~~4~~ air changes per hour in Climate Zones 1 and 2, and 3 air changes per hour in Climate Zones 3 through 8. Testing shall be conducted with a blower door at a pressure of 0.2 inches w.g. (50 Pascals). A written report of the results of the test shall be signed by the testing agency and provided to the *code official*. Testing shall be performed at any time after creation and sealing of all penetrations of the *building thermal envelope*.

~~**402.4.1.2.1** The air leakage rate in Climate Zones 3 through 8 shall be permitted to be no greater than 4 air changes per hour where all heating and conditioning ducts, air handlers, and filter boxes are located within the *building thermal envelope.*~~

Commenter's Reason: This proposal originally contained two separate concepts: a requirement that blower door testing be performed by approved testing agencies and an ACH trade-off for buildings where the air movement system components are located within the thermal envelope. During the debate, there was a lack of consensus on the value of the trade-off. We are bringing this public comment forward without the trade-off, but preserving the concept that blower door testing be completed by an approved testing agency.

The current code language establishes the use of an approved agency as an exception rather than the rule. Since producers of other components of the building thermal envelope are required to use third party entities to demonstrate compliance with test requirements, and the same requirement for testing by an approved agency should apply for testing of the building air barrier. The control of air leakage is the last line of defense against the transmission of heat through the building envelope; it is critical that the same consideration for insulation and fenestration be applied to the air barrier testing.

RE88-13

Final Action: AS AM AMPC____ D

RE90-13
R402.4.1.2 (IRC N1102.4.1.2), Table R405.5.2(1) (IRC Table N1105.5.2(1))

Proposed Change as Submitted

Proponent: Don Surrena, CBO, representing National Association of Home Builders (NAHB) (dsurrena@nahb.org)

Revise as follows:

R402.4.1.2 (N1102.4.1.2) Testing. The building or dwelling unit shall be tested and verified as having an air leakage rate of not exceeding 5 air changes per hour in Climate Zones 1 and 2, and ~~3~~ 4 air changes per hour in Climate Zones 3 through 8. Testing shall be conducted with a blower door at a pressure of 0.2 inches w.g. (50 Pascals). Where required by the *code official*, testing shall be conducted by an *approved* third party. A written report of the results of the test shall be signed by the party conducting the test and provided to the *code official*. Testing shall be performed at any time after creation of all penetrations of the *building thermal envelope*.

Table R405.5.2(1) (N1105.5.2(1)
SPECIFICATIONS FOR THE STANDARD REFERENCE AND PROPOSED DESIGNS

BUILDING COMPONENT	STANDARD REFERENCE DESIGN	PROPOSED DESIGN
Air exchange rate	Air leakage rate of 5 air changes per hour in Climate Zones 1 and 2, and ~~3~~4 air changes per hour in Climate Zones 3 through 8 at a pressure of 0.2 inches w.g (50 Pa). The mechanical ventilation rate shall be in addition to the air leakage rate and the same as in the proposed design, but no greater than $0.01 \times CFA + 7.5 \times (N_{br} + 1)$ where: CFA = conditioned floor area Nbr = number of bedrooms Energy recovery shall not be assumed for mechanical ventilation.	For residences that are not tested, the same air leakage rate as the standard reference design. For tested residences, the measured air exchange rate[c]. The mechanical ventilation rated shall be in addition to the air leakage rate and shall be as proposed.

(Portions of table not shown remain unchanged)

Reason: Building tightness is an important part of an energy efficient and comfortable house; however, 3 air changes per hour at 50 Pascals is an extremely low target tightness especially for smaller homes. The ASHRAE Handbook of Fundamentals shows that less than 10% of new homes achieve 3 ACH or less. Four ACH is still an aggressive tightness level which will provide a tight, comfortable, energy efficient home for the consumer.

Cost Impact: The code change proposal will not increase the cost of construction.

R402.4.1.2-EC-SURRENA

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: This is a decrease in stringency relative to the 2012 IECC.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Tim Ryan, representing the International Association of Building Officials requests As Modified by this Public Comment.

Table R405.5.2(1) (N1105.5.2(1)
SPECIFICATIONS FOR THE STANDARD REFERENCE AND PROPOSED DESIGNS

BUILDING COMPONENT	STANDARD REFERENCE DESIGN	PROPOSED DESIGN
Air exchange rate	Air leakage rate of 5 air changes per hour ~~in Climate Zones 1 and 2, and 4 air changes per hour in Climate Zones 3 through 8~~ at a pressure of 0.2 inches w.g (50 Pa). The mechanical ventilation rate shall be in addition to the air leakage rate and the same as in the proposed design, but no greater than $0.01 \times CFA + 7.5 \times (N_{br} + 1)$ where: CFA = conditioned floor area Nbr = number of bedrooms Energy recovery shall not be assumed for mechanical ventilation.	For residences that are not tested, the same air leakage rate as the standard reference design. For tested residences, the measured air exchange rate[c]. The mechanical ventilation rated shall be in addition to the air leakage rate and shall be as proposed.

(Portions of table not shown remain unchanged)

Commenter's Reason: Building tightness is an important part of an energy efficient and comfortable house; however, 3 air changes per hour at 50 Pascals is an extremely low target tightness especially for smaller homes. Three air changes per hour not only is unusually tight, it also has the potential of causing indoor air quality problems if the ventilation systems are not installed or do not work properly. Five air changes per house is a reasonable air tightness rate that resembles a challenging but fair "minimum code" requirement.

This requirement has been changed to 5 ACH in nearly every jurisdiction that has adopted the 2012 IECC including: Illinois, Utah, local jurisdictions in Kansas, Missouri. In addition states that are in the adoption process of the 2012 IECC are all considering increasing the air tightness up to 5 ACH50.

RE90-13
Final Action: AS AM AMPC____ D

RE93-13
R402.4.1.3 (NEW) (IRC N1102.4.1.3 (NEW))

Proposed Change as Submitted

Proponent: Robby Schwarz, representing EnergyLogic, Inc. (robby@nrglogic.com)

Add new text as follows:

R402.4.1.3 (N1102.4.1.3) Connection to Garage. The building or dwelling unit shall be tested and verified as being separate from an attached garage. While the blower door is being utilized to test the building or dwelling unit's leakage rate, the connection between the dwelling unit and the garage shall also be tested. The pressure in the garage with reference to dwelling unit shall not be less than 45 Pascals relative to the dwelling unit when the dwelling unit pressure is at 50 Pascals relative to the outside.

Reason: Separation between the house(dwelling unit) and garage is specifically called out on the air barrier and insulation table R402.4.1.1 yet it is unclear what is meant by this and why it is called out separately from the rest of the thermal envelops sealing that separates conditioned space from unconditioned space. The rational is an extension of efficiency into safety to ensure that pollutants and contaminants form the garage will not enter the home. A visual or written reference to this makes no sense when a test is available to ensure that separation has occurred. Testing is the only way to ensure safety and in extension greater efficiency.

Cost Impact: The code change proposal will not increase the cost of construction.

R402.4.1.3 (NEW)-EC-SCHWARZ

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: This proposal was not supported by technical justification related to the energy efficiency impact. In addition, no cost justification was provided.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Robby Schwarz, EnergyLogic, Inc., requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R402.4.1.3 (N1102.4.1.3) Connection to Garage. The building or dwelling unit shall be tested and verified as being separate from an attached garage. While the blower door is being utilized to test the building or dwelling unit's leakage rate, the connection between the dwelling unit and the garage shall also be tested. ~~The pressure in the garage with reference to dwelling unit shall not be less than 45 Pascals relative to the dwelling unit when the dwelling unit pressure is at 50 Pascals relative to the outside.~~ The connection between the dwelling unit and the garage shall not be more than 10% of the total measured CFM@50 leakage of the dwelling unit.

Commenter's Reason: The link between efficiency and house tightness has been proven. The separation between the house (dwelling unit) and the garage is specifically called out in the air barrier and insulation table R402.4.1.1 largely due to the complexity of the framing and the difficulty and importance of sealing off the garage from the house. The code language, however, is unclear. Why is garage separation specifically called out separately from the rest of the thermal envelope and air barrier sealing that separates conditioned space from unconditioned space? In this location I believe the connection between life safety and energy efficiency is the reason to ensure that pollutants and contaminants from the garage will not enter the home and why specific consideration is given to separating the garage in the code. The problem is that a visual inspection cannot ensure separation and therefore cannot ensure efficiency or safety of the occupants. Testing is the only way to ensure safety and in extension greater efficiency.

RE93-13

Final Action: AS AM AMPC____ D

RE94-13
R402.4.3 (IRC N1102.4.3)

Proposed Change as Submitted

Proponent: Jeff Inks, representing the Window & Door Manufacturers Association.

Revise as follows:

R402.4.3 (N1102.4.3) Fenestration air leakage. Windows, skylights and sliding glass doors shall have an air infiltration rate of no more than 0.3 cfm per square foot (1.5 L/s/m2), and swinging doors no more than 0.5 cfm per square foot (2.6 L/s/m2), when tested according to NFRC 400 or AAMA/ WDMA/CSA 101/I.S.2/A440 by an accredited, independent laboratory and listed and labeled by the manufacturer.

> ~~**Exception:** Site-built windows, skylights and doors.~~

Reason: This proposal is primarily a clean-up. The exception for site-built fenestration was removed from the commercial requirements during the last code development cycle as there is no justification for allowing it. These assemblies are required to meet the air leakage provisions of C402.4.3 for IECC commercial construction. Likewise, site-built windows, skylights and doors, if used in IECC residential construction, should meet the requirements of Section R402.4.3 without exception.

Cost Impact: The code change proposal will not increase the cost of construction.

R402.4.3-EC-INKS

Committee Action Hearing Results

Committee Action: Disapproved

Committee Reason: The proposal was made with no cost justification. In addition this would remove flexibility for the builder from the code.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Jeff Inks, Window & Door Manufacturers Association requests Approval as Submitted.

Commenter's Reason: As was pointed out in the proposal, the exception for site-built fenestration was removed from the commercial requirements during the last code development cycle as there is no justification for allowing it.

By definition (see below) site-built fenestration is still comprised of factory fabricated components. These assemblies are different from "field fabricated" (also see below) which are not comprised of factory fabricated components. Because "site-built" components are factory fabricated for a specific use/assembly, specimen units can be assembled and tested by the manufacturer which is why these assemblies are required to meet the air leakage provisions of C402.4.3 for IECC commercial construction. Likewise, site-built windows, skylights and doors, if used in IECC residential construction, should meet the requirements of Section R402.4.3 without exception.

Removing this exception also does not remove any flexibility with respect to using these products. It simply requires for them to also meet the air leakage requirements which for the reasons stated above is reasonable.

Concerns regarding limits on flexibility can be addressed by making the exception applicable to field fabricated products.

"FENESTRATION PRODUCT, SITE-BUILT. A fenestration designed to be made up of field-glazed or field-assembled units using specific factory cut or otherwise factory formed framing and glazing units. Examples of site-built fenestration include storefront systems, curtain walls, and atrium roof systems. "

"FENESTRATION PRODUCT, FIELD-FABRICATED. A fenestration product whose frame is made at the construction site of standard dimensional lumber or other materials that were not previously cut, or otherwise formed with the specific intention of being used to fabricate a fenestration product or exterior door. Field fabricated does not include site-built fenestration. "

Public Comment 2:

Jeff Inks, Window & Door Manufacturers Association requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R402.4.3 Fenestration air leakage. Windows, skylights and sliding glass doors shall have an air infiltration rate of no more than 0.3 cfm per square foot (1.5 L/s/m2), and swinging doors no more than 0.5 cfm per square foot (2.6 L/s/m2), when tested according to NFRC 400 or AAMA/ WDMA/CSA 101/I.S.2/A440 by an accredited, independent laboratory and listed and labeled by the manufacturer.

Exception: Field-fabricated windows, skylights and doors.

IECC SECTION R202 (IRC N1101.9)
GENERAL DEFINITIONS

FENESTRATION PRODUCT, FIELD-FABRICATED. A fenestration product whose frame is made at the construction site of standard dimensional lumber or other materials that were not previously cut, or otherwise formed with the specific intention of being used to fabricate a fenestration product or exterior door. Field fabricated does not include site-built fenestration.

Commenter's Reason: This public comment addresses the committee's concern that deleting the air leakage exception for "site-built" fenestration would remove flexibility for the builder. This modification simply replaces "Site-built" with "Field-fabricated" and adds the "Field-fabricated" definition already established in the commercial provisions of the IECC.

For the reasons stated below, we do not believe an exception for "site-built" products as defined by the IECC is warranted. Approval of this proposal as modified by this public comments actually adds an exception that technically does not exist currently so it should improve the flexibility rather than restrict it.

Regarding removal of the exception for "site-built", as was pointed out in the original proposal, the exception for site-built fenestration was removed from the commercial requirements during the last code development cycle as there is no justification for allowing it.

By definition (see below) site-built fenestration is still comprised of factory fabricated components. These assemblies are different from "field fabricated" (as defined by the IECC and proposed for inclusion in the residential provisions) which are not comprised of factory fabricated components. Because "site-built" components are factory fabricated for a specific use/assembly, specimen units can be assembled and tested by the manufacturer which is why these assemblies are required to meet the air leakage provisions of C402.4.3 for IECC commercial construction. Likewise, site-built windows, skylights and doors, if used in IECC residential construction, should meet the requirements of Section R402.4.3 without exception.

Removing this exception also does not remove any flexibility with respect to using these products. It simply requires for them to also meet the air leakage requirements which for the reasons stated above is reasonable.

Concerns regarding limits on flexibility can be addressed by making the exception applicable to field fabricated products.

"FENESTRATION PRODUCT, SITE-BUILT. A fenestration designed to be made up of field-glazed or field-assembled units using specific factory cut or otherwise factory formed framing and glazing units. Examples of site-built fenestration include storefront systems, curtain walls, and atrium roof systems. "

"FENESTRATION PRODUCT, FIELD-FABRICATED. A fenestration product whose frame is made at the construction site of standard dimensional lumber or other materials that were not previously cut, or otherwise formed with the specific intention of being used to fabricate a fenestration product or exterior door. Field fabricated does not include site-built fenestration. "

RE94-13

Final Action: AS AM AMPC____ D

RE95-13
R402.5 (IRC N1102.5)

Proposed Change as Submitted

Proponent: Craig Conner, Building Quality, representing self (craig.conner@mac.com); Dr. Thomas D. Culp, Birch Point Consulting LLC, representing the Glazing Industry Code Committee (culp@birchpointconsulting.com)

Delete without substitution:

~~**R402.5 (N1102.5) Maximum fenestration U -factor and SHGC (Mandatory).** The area-weighted average maximum fenestration **U-**factor permitted using tradeoffs from Section R402.1.4 or R405 shall be 0.48 in Climate Zones 4 and 5 and 0.40 in Climate Zones 6 through 8 for vertical fenestration, and 0.75 in Climate Zones 4 through 8 for skylights. The area-weighted average maximum fenestration SHGC permitted using tradeoffs from Section R405 in Climate Zones 1 through 3 shall be 0.50.~~

Reason:
CONNER: The limits on U-factor and SHGC trade offs reduce flexibility without any compensating energy savings. A decrease in the energy efficiency of the windows through the performance calculation would have to be made up elsewhere leaving the resulting energy efficiency, so the energy result is neutral.

Given the stringency of the newer codes, this section mostly adds a bit of confusion to the code. The statement of a limit on trade offs is sometimes confused with the actual requirement itself (in Table R402.1). There is no need to bulk up the code with even small statements that seldom have any impact.

CULP: By definition, trade-offs are energy neutral, so these mandatory “hard limits” save no energy, but set artificial constraints that limit design flexibility and innovation. Practically speaking, the vast majority of “normal” windows already meet these criteria, so this section has little real impact, and only serves to (a) add confusion between these numbers and the real requirements in Table R402.1.1, and (b) cause compliance problems for unique or special applications.

For example, glass block used in a bathroom remodel:
… it has no label, so use the default U-factor and SHGC
… but the default values do not meet Table R402.1.1, so use a trade-off
… but the default values do not meet the hard limits in this section R402.5, so use area-weighted averaging
… but there is nothing else in the remodel to area-weight average.

So it becomes effectively illegal, even if there are other trade-offs that make the overall remodel even more energy efficient, and the only recourse is to seek a special allowance through the alternative methods provision.

This is just one example. What about special products used in tornado storm shelters that won’t meet the U-factor hard limit? What about vacuum glazing that meets the U-factor and greatly exceeds the required energy efficiency, but not the SHGC hard limit? Do we want to discourage vacuum glazing?

Granted, these are not common situations, but what have we accomplished by creating artificial barriers and extra headaches for code officials and builders? This section should be removed.

Cost Impact: The code change proposal will not increase the cost of construction.

R402.5-EC-CONNER-CULP

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: Maximums U-Factors and SHGC are needed to avoid issues with peak demand and moisture. This is an important “backstop” to assure minimum levels of envelope integrity. These minimums are used widely, and have been for several years.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Dr. Thomas D. Culp, Birch Point Consulting LLC, representing Glazing Industry Code Committee requests Approval as Submitted.

Commenter's Reason: We ask that you overturn the recommendation from the committee for disapproval, which was a split decision, and approve RE95 as-submitted. Much of the discussion at the code hearings has been about how to provide flexibility while upholding energy performance. Section R402.5 is completely counter to that goal and should be removed, as specified in this proposal. Even if you prove equivalent or better energy performance in the performance path, Section R402.5 adds an artificial barrier to the use of certain products and designs.

For the vast majority of "normal" windows this section is not a problem, so this section is not actually doing anything significant, yet it causes compliance problems for unique or special applications. Examples of how Section R402.5 creates compliance problems are given in the original reason statement. Some additional examples include commercial-type entrance doors in the lobby of an apartment building, or fire-rated curtain wall type entrance and stairways in a dormitory. These special applications will typically not meet the basic prescriptive criteria, and even if adjustments are made to the building design to show equivalent or better overall energy efficiency in the performance path, section R402.5 will still prevent them from being installed. The only recourse is to seek use of the alternative means and methods provision, which just creates more work for the code official and delay for the builder.

This section causes problems, does not save any energy, and should be removed. We ask that you vote "NO" on the initial motion for disapproval, and then to vote "YES" on a motion to approve RE95 as-submitted.

Public Comment 2:

Vickie Lovell, Intercode, Inc., representing International Window Film Association requests Approval as Submitted.

Commenter's Reason: Limits on fenestration U-factor and SHGC trade-offs do not promote flexibility and place needless and unfair restrictions on how code compliance can be achieved. It is an impediment to design innovation and opportunities for cutting edge technologies on building components, which is the opposite of promoting whole building energy performance.
More importantly, it causes confusion to designers, code officials and all other users of the code by overcomplicating it. It creates a subset of prescriptive requirements in the performance path which is inappropriate and is not consistent with the intent of the performance objectives of this section of the code.

RE95-13

Final Action: AS AM AMPC____ D

RE96-13
R402.5 (IRC N1102.5)

Proposed Change as Submitted

Proponent: Brian Dean, Energy Efficient Codes Coalition; Garrett Stone, Brickfield Burchette Ritts & Stone, PC; Jeff Harris, Alliance to Save Energy; Harry Misuriello, American Council for an Energy-Efficient Economy; and Bill Prindle, Energy Efficient Codes Coalition

Revise as follows:

R402.5 (N1102.5) Maximum fenestration *U*-factor and SHGC (Mandatory). The area-weighted average ~~maximum fenestration~~ *U*-factor ~~permitted~~ for vertical fenestration products when complying with this code ~~using trade offs from~~ under Section R402.1.4 or Section R405 shall not exceed the U-factor specified in Table R402.1.1 by more than 25% ~~be 0.48 in Climate Zones 4 and 5 and 0.40 in Climate Zones 6 through 8 for vertical fenestration, and 0.75 in Climate Zones 4 through 8 for skylights~~. The area-weighted average U-factor for skylights when complying with this code under Section R402.1.4 or Section R405 shall not exceed the U-factor specified in Table R402.1.1 by more than 25%. The area-weighted average ~~maximum fenestration~~ SHGC ~~permitted~~ for all fenestration products when complying with this code under ~~using trade-offs from~~ Section R405 shall not exceed the SHGC specified in Table R402.1.1 by more than 50%~~in Climate Zones 1 through 3 shall be 0.50~~.

Reason: The purpose of this code change is to modify the requirements and clarify the language related to the maximum U-factor and SHGC for fenestration when using trade-offs for code compliance. This revision improves the energy efficiency and usability of the energy code by ensuring that as prescriptive fenestration efficiency requirements change, the mandatory fenestration maximums (for trade-offs) will automatically adjust as well, specifically by setting the maximum weighted average U-factor at 25% above the prescriptive value and the SHGC at 50% above the prescriptive value. In addition, the revision improves and clarifies the language in the section.

For nearly a decade, the current version of the fenestration U-factor and SHGC maximums in Section R402.5 have provided an effective and critical backstop for fenestration efficiency trade-offs under the Total UA compliance path and the Simulated Performance Alternative. This section ensures that fenestration, which is a crucial element in the thermal envelope, particularly from the standpoint of comfort, as well as condensation, energy efficiency and HVAC sizing, will not be overly weakened by trade-offs.

Unfortunately, as prescriptive fenestration U-factors and SHGC requirements have improved substantially over the last few code change cycles, the fenestration maximums have remained unchanged. For example:

- In the 2006 IECC, the prescriptive SHGC requirement in climate zone 3 was 0.40 and the SHGC maximum in trade-offs was 0.50 (25% higher than the prescriptive value).
- In the 2009 IECC, the prescriptive SHGC requirement was improved to 0.30, but the SHGC maximum remained at 0.50 (67% higher).
- In the 2012 IECC, the prescriptive SHGC requirement was further improved to 0.25, but the SHGC maximum remained at 0.50 (100% higher).

The proposal sets the maximum area-weighted average U-factor 25% higher and the SHGC 50% higher than the prescriptive value, giving a reasonable (but not unlimited) amount of flexibility to the design professional. We chose 25% for U-factor and 50% for SHGC based on judgment after reviewing the resulting values, in recognition that prescriptive U-factors tend to be greater than prescriptive SHGC values, justifying a smaller percentage, and reflecting the need for more flexibility for SHGC due to passive solar concerns. The following table shows the effect of this new proposal on the maximum values for vertical windows:

Climate Zone	Prescriptive U-factor	Maximum U-factor Current	Maximum U-factor Proposed	Prescriptive SHGC	Maximum SHGC Current	Maximum SHGC Proposed
1	NR	NR	NR	0.25	0.50	0.38
2	0.40	NR	0.50	0.25	0.50	0.38
3	0.35	NR	0.44	0.25	0.50	0.38
4	0.35	0.48	0.44	0.40	NR	0.60
5	0.32	0.48	0.40	NR	NR	NR
6 - 8	0.32	0.40	0.40	NR	NR	NR

The proposal also applies a uniform backstop percentage over all climate zones, improving efficiency and simplifying compliance and enforcement in states that stretch across multiple climate zones. The new maximums also allow considerable flexibility for innovative designs such as passive solar, because individual or multiple windows may have significantly higher SHGC or U-factor values, as long as they achieve an area-weighted average value that is within a reasonable range of the prescriptive values.

Because the Total UA and Simulated Performance Alternative compliance options are typically software-based, the change to a percentage-based maximum should require no additional effort on the part of the builder or design professional. Over the long run, this proposal will simplify the code, improve energy efficiency, and add consistency because the maximum will automatically track any change to the fenestration U-factor or SHGC requirements.

The fenestration trade-off limits currently found in the residential chapter of the *IECC* are simple, mandatory measures that ensure all new buildings contain high-quality, cost-effective windows that save energy, provide reasonable comfort, resist condensation in colder climates and block unwanted solar gain in warmer climates. Without the protection of this backstop, fenestration values could be traded away to levels unacceptable in modern building practice. Given the improvements to window efficiency brought about by the 2012 *IECC* and our nation's high priority for energy efficiency, this proposal is a common-sense improvement to an effective code requirement.

- **Simple compliance.** The residential fenestration maximums are effective and easy to understand. These requirements have been successfully applied for the last several years. All states that have already adopted the 2006, 2009, and 2012 *IECC* have adopted these maximums to residential construction. They are also already seamlessly built into compliance software such as the Department of Energy's REScheck.
- **Flexible standard.** The area-weighted average approach embodied in the fenestration maximums allows considerable flexibility for the use of decorative glass, glass block, and other fenestration products, while maintaining a baseline performance for the building's overall glazing. In short, not all products are required to individually meet the maximum values; only the area-weighted average of all products in the building are required to meet the maximum values specified in this code provision.
- **Quality windows, energy savings and peak demand savings nationwide**. The fenestration maximums encourage the use of cost-effective energy-efficient windows nationwide. Because good windows reduce energy consumption both during peak cooling times in the summer months and during peak heating hours in the winter months, such windows help to reduce the strain on the electric grid and natural gas pipeline system and delay the need to build expensive peaking facilities. By reducing the trade-off of efficient windows for other measures, the maximums better capture the benefits of blocking solar gain and providing reasonable insulating value such as peak reduction, reduced cooling system sizes and year-round comfort. Consumers also enjoy the reduced costs that come with economies of scale and market transformation.
- **More comfortable buildings and less energy use.** Incremental changes in window efficiency can have a huge impact on occupant comfort because even the most efficient windows are, at best, still only the equivalent of about an R-3 wall in the winter. Moreover, unlike the opaque wall, even the best fenestration allows substantial summer solar heat gain into the conditioned space. Hot spots created by high solar gain in the summer and/or cold or drafty glass in the winter months can force an occupant to adjust the thermostat to compensate. A good window will provide reasonable insulating value, keeping occupants more comfortable during the coldest months. Similarly, windows with low SHGC will protect against hot spots and occupant discomfort, and will make it less likely that occupants will need to adjust the thermostat and use more energy.

For a more detailed discussion of the benefits of good fenestration, see the section on the benefits of efficient windows on the website of the Efficient Windows Collaborative (a Collaborative of the Alliance to Save Energy, the University of Minnesota, Center for Sustainable Building Research and Lawrence Berkeley National Laboratory, with support from the U.S. Department of Energy) -- http://www.efficientwindows.org/benefits.cfm.

The fenestration maximums have served an important role in ensuring residential energy efficiency for many years. We recommend that the proposed improvements to the fenestration maximums be adopted.

Cost Impact: The code change proposal will not increase the cost of construction.

R402.5-EC-DEAN-HARRIS-MISURIELLO-PRINDLE-STONE

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: The proponent did not demonstrate the technical merits of this proposal in a justifiable manner.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Jeff Inks, Window & Door Manufacturers Association requests Approval as Submitted.

Commenter's Reason: The variance between the prescriptive fenestration requirements and the trade-off cap limits need to remain consistent from edition to edition of the IECC in order to ensure the code is not inadvertently weakened as the proponents have pointed out.

Establishing the caps as a percentage of the respective prescriptive requirements is a much more sensible approach for ensuring the variance remains consistent than prescribing specific values because it alleviates the need for additional revisions to the cap values when prescriptive requirements are amended.

We also believe the technical merits of this approach are clear and have been clearly demonstrated by the proponent and in addition, that the basis for the proposed variance of 25% for U-factor and 50% for SHGC is sound.

Public Comment 2:

Brian Dean, ICF International, representing the Energy Efficient Codes Coalition; Jeff Harris, Alliance to Save Energy; Harry Misuriello, American Council for an Energy-Efficient Economy (ACEEE); Bill Prindle, representing the Energy Efficient Codes Coalition; Garrett Stone, Brickfield, Burchette, Ritts & Stone, PC; Donald J. Vigneau, Northeast Energy Efficiency Partnerships Inc., request Approval as Modified by this Public Comment.

Modify the proposal as follows:

R402.5 (N1102.5) Maximum fenestration *U*-factor and SHGC (Mandatory). The area-weighted average *U*-factor for vertical fenestration products when complying with this code under Section R402.1.4 or Section R405 shall not exceed 0.40 in climate zones 4 through 8 ~~the U-factor specified in Table R402.1.1 by more than 25%~~. The area-weighted average U-factor for skylights when complying with this code under Section R402.1.4 or Section R405 shall not exceed 0.65 in climate zones 4 through 8 ~~the U-factor specified in Table R402.1.1 by more than 25%~~. The area-weighted average SHGC for all fenestration products when complying with this code under Section R405 shall not exceed 0.40 in climate zones 1 through 3 ~~the SHGC specified in Table R402.1.1 by more than 50%~~.

Commenter's Reason: We recommend approval of RE96 as modified by this public comment. RE96 as modified will bring about a reasonable update to the fenestration maximums that have been in the IECC for many years.
The importance of the current fenestration maximums was recognized by the committee in recommending disapproval of RE95. The committee found: "Maximums U-Factors and SHGC are needed to avoid issues with peak demand and moisture. This is an important "backstop" to assure minimum levels of envelope integrity. These minimums are used widely, and have been for several years." The reason statement for the original RE96 also explains the benefits of the current requirements and the need to update in more detail.

Although we continue to believe that RE96 as submitted would provide long-term benefits by allowing the caps to automatically update whenever fenestration requirements are altered in the IECC, some concern was raised at the committee hearings about the use of a percentage instead of a fixed value. In order to provide additional clarity, we have modified the proposal to establish specific values for specific climate zones, and we have limited the reach of the proposal to only those climate zones covered by the fenestration maximums in the 2012 IECC. The U-factors selected as maximums reflect the prescriptive U-factors already established in milder climate zones (see Table R402.1.1). If a 0.40 U-factor is appropriate and cost effective for warm climate zone 2 in the current IECC, it is reasonable to set 0.40 as a trade-off limit or maximum in the much colder climates of zones 4 – 8. Similarly, if 0.40 SHGC is reasonable in the mixed climate zone 4, it is reasonable to set 0.40 SHGC as a maximum in the cooling-dominated climate zones 1 – 3. It should also be noted that these values are also reasonably consistent with those that would be produced by RE96, as submitted.

Regardless of whether ICC membership favors the original or the modified proposal, we believe that an update to the fenestration maximums is overdue. If the permanent fix provided by the original RE96 is not adopted, we recommend the modifications in this public comment to provide a one-time update to the fenestration maximums.

Public Comment 3:

R. Christopher Mathis, MC2 Mathis Consulting Company, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R402.5 (N1102.5) Maximum fenestration U-factor and SHGC (Mandatory). The area-weighted average ~~maximum fenestration~~ building component U-factor and SHGC permitted using tradeoffs from Section R402.1.4 or Section R405 shall not exceed the values in Table R402.5.1. ~~be 0.48 in Climate Zones 4 and 5 and 0.40 in Climate Zones 6 through 8 for vertical fenestration, and 0.75 in Climate Zones 4 through 8 for skylights. The area-weighted average maximum fenestration SHGC permitted using tradeoffs from Section R405 in Climate Zones 1 through 3 shall be 0.50.~~

TABLE 402.5.1
Maximum Building Component U-factors and Maximum Fenestration SHGC
When Complying Under Sections R402.1.4 or R405

Climate Zone	Fenestration U-Factor	Fenestration SHGC	Skylight U-Factor	Ceiling U-Factor	Frame Wall U-Factor	Mass Wall U-Factor	Floor U-Factor	Basement Wall U-Factor	Crawlspace Wall U-Factor
1	0.58	0.31	0.86	0.040	0.094	0.227	0.074	0.414	0.549
2	0.46	0.31	0.75	0.035	0.094	0.190	0.074	0.414	0.549
3	0.40	0.31	0.63	0.035	0.066	0.113	0.054	0.105	0.156
4 except Marine	0.40	0.50	0.63	0.030	0.066	0.113	0.054	0.068	0.075
5 and Marine 4	0.37	– -	0.63	0.030	0.066	0.094	0.038	0.058	0.063
6	0.37	– -	0.63	0.030	0.055	0.069	0.038	0.058	0.063
7 and 8	0.37	– -	0.63	0.030	0.055	0.066	0.032	0.058	0.063

Commenter's Reason: Building officials need some assurance that the trades allowed in 402.1.4 and 405 do not result in deficient building envelopes. This modification addresses this need by inserting a simple table defining the allowed limits on envelope trades. This table provides a "backstop" of protection, building upon the protective structure that already exists in R402.5. The proposal also protects against intentional or accidental "gaming" that can occur when seeking compliance via the UA tradeoff or performance path modeling approaches (Sections R402.1.4 and R405, respectively). This proposal provides a simple table of prescriptive envelope performance requirements in a code-familiar structure. It defines maximum allowed limits on envelope components when compliance is sought under R402.1.4 or R405. The maximum component values in the table are based on:

1. A 15% increase in U-factor (reductions in envelope efficiency) versus the 2012 IECC , and
2. A 25% increase in SHGC versus the 2012 IECC (as proposed in RE96).

Why is it important to insert these trading limitations?
The code focus is "***effective use of energy… over the useful life of the building***" (2012 IECC. Sections C101.3 and R101.3.) However, nowhere in this code is this critical code objective – "over the useful life of the building" – addressed.

RE96 (AMPC)-MATHIS
Envelope decisions often remain with the building for the life of the building. Numerous studies have investigated the "useful life" of various residential building materials, components and systems. Data from four such studies has been summarized below for building components relevant to Section 402.5.

Item	DOE Core Data Book[1]	NAHB Report[2]	NIBS Report[3]	ASHRAE Handbook HVAC Applications[4]
Envelope	(Years)	(Years)	(Years)	(Years)
Insulation	100	100	100	-
Windows	40	30	50	-
HVAC				
Furnace, Forced Air	14	17.5	18	18
Unit Heaters, Gas or Electric	15	17.5	13	13
Heat Pump	12	16	15	15
Air Conditioner	-	12.5	-	-
Central Air	11	15	15	15
Window Unit	9	10	10	10
Water Heater, Electric	13	11	14	-
Water Heater, Gas	11	10	12	-

1 U.S. Department of Energy. 2011
Buildings Energy Data Book. D&R International, Ltd. March 2012.
2 National Association of Home Builders. Study of Life Expectancy of Home Components. February 2007
3 U.S. Department of Housing and Urban Development. Residential Rehabilitation Inspection Guide. By the National Institute of Building Sciences. February 2000.
4 "ASHRAE Handbook Heating, Ventilating, and Air-Conditioning Applications", ASHRAE Inc., 2011.

As one can easily see, different building elements have dramatically different life expectancies, especially when considering the 100+ year life expectancy of the home.

Long-lasting building envelope decisions (insulation, windows, air sealing, etc.) define most of the heating and cooling loads of the building. Shorter-lived HVAC systems must then be sized and selected to meet those loads. Even shorter-lived hot water and lighting systems figure into the computer models and should also be weighed against the more durable envelope provisions.

For these reasons it is appropriate to have code requirements that ensure some basic levels of envelope component efficiency when using the tradeoff approaches in R402.1.4 and R405.

Currently, Section R402.5 is the only section providing protection against unreasonable UA or performance modeling trades. This proposal SIMPLIFIES that protection for the whole building envelope, not just the windows. Without such protection the code will continue to treat every building decision as though they have EQUAL life expectancies.

This table provides code officials a simple means to check the values proposed for code compliance under R402.1.4 and R405. These protections in the code are becoming ever more important as computer modeling and rating programs become more the norm for energy code compliance. IF these types of "trades" are to be allowed, they must be informed by our understanding of building product and component life expectancy, and have reasonable limits applied as appropriate. This proposal provides much-needed protection against dumb mathematical trades that MAY work in computer programs, but result in risks to the most basic goal of this code – **"effective use of energy… for the useful life of the building".**

Final Action: AS AM AMPC____ D

RE99-13

R403.1 (IRC N1103.1), R403.1.1 (IRC N1103.1.1), R403.1.2 (IRC N1103.1.2), R403.2.1 (IRC N1103.2.1), R403.2.2 (N1103.2.2), R403.2.3 (IRC N1103.2.3), R403.2.4 (NEW) (IRC N1103.2.4 (NEW)), R403.2.2.1 (IRC N1103.2.2.1), R403.2.6 (NEW), (IRC N1103.2.6 (NEW), Table R405.2(1) (IRC Table N1105.2(1))

Proposed Change as Submitted

Proponent: Brian Dean, Energy Efficient Codes Coalition; Garrett Stone, Brickfield Burchette Ritts & Stone, PC; Jeff Harris, Alliance to Save Energy; Harry Misuriello, American Council for an Energy-Efficient Economy; and Bill Prindle, Energy Efficient Codes Coalition.

Revise as follows:

R403.1 (N1103.1) Controls (Mandatory). ~~At least one thermostat shall be provided for each separate heating and cooling system.~~ Heating and cooling system controls shall comply with Sections R403.1.1 through R403.1.3.

R403.1.1 (N1103.1.1) Thermostat (Mandatory). Not less than one thermostat shall be provided for each separate heating and cooling system.

~~R403.1.1 (N1103.1.1)~~ R403.1.2 (N1103.1.2) Programmable thermostat (Mandatory). Where the primary heating system is a forced-air furnace, at least one thermostat per dwelling unit shall be capable of controlling the heating and cooling system on a daily schedule to maintain different temperature set points at different times of the day. This thermostat shall include the capability to set back or temporarily operate the system to maintain *zone* temperatures down to 55ºF (13ºC) or up to 85ºF (29ºC). The thermostat shall initially be programmed with a heating temperature set point not higher than 70ºF (21ºC) and a cooling temperature set point not lower than 78ºF (26ºC).

~~R403.1.2 (N1103.1.2)~~ R403.1.3 (N1103.1.3) Heat pump supplementary heat (Mandatory). Heat pumps having supplementary electric-resistance heat shall have controls that, except during defrost, prevent supplemental heat operation when the heat pump compressor can meet the heating load.

R403.2 (N1103.2) Ducts. Ducts and air handlers shall be sealed, tested for leakage and insulated in accordance with Sections R403.2.1 through R403.2.~~3~~6.

~~**R403.2.1 (N1103.2.1) Insulation (Prescriptive).** Supply ducts in attics shall be insulated to a minimum of R-8. All other ducts shall be insulated to a minimum of R-6.~~

> ~~**Exception:** Ducts or portions thereof located completely inside the *building thermal envelope*.~~

R403.2.1 (N1103.2.1) Building cavities (Mandatory). Building framing cavities shall not be used as ducts or plenums.

R403.2.2 (N1103.2.2) Sealing (Mandatory). Ducts, air handlers, and filter boxes shall be sealed. Joints and seams shall comply with either the *International Mechanical Code* or *International Residential Code*, as applicable.

Exceptions:

1. Air-impermeable spray foam products shall be permitted to be applied without additional joint seals.

2. Where a duct connection is made that is partially inaccessible, three screws or rivets shall be equally spaced on the exposed portion of the joint so as to prevent a hinge effect.

3. Continuously welded and locking-type longitudinal joints and seams in ducts operating at static pressures less than 2 inches of water column (500 Pa) pressure classification shall not require additional closure systems.

~~Duct tightness shall be verified by either of the following:~~

1. ~~Postconstruction test: Total leakage shall be less than or equal to 4 cfm (113.3 L/min) per 100 square feet (9.29 m^2) of conditioned floor area when tested at a pressure differential of 0.1 inches w.g. (25 Pa) across the entire system, including the manufacturer's air handler enclosure. All register boots shall be taped or otherwise sealed during the test.~~
2. ~~Rough-in test: Total leakage shall be less than or equal to 4 cfm (113.3 L/min) per 100 square feet (9.29 m^2) of conditioned floor area when tested at a pressure differential of 0.1 inches w.g. (25 Pa) across the system, including the manufacturer's air handler enclosure. All registers shall be taped or otherwise sealed during the test. If the air handler is not installed at the time of the test, total leakage shall be less than or equal to 3 cfm (85 L/min) per 100 square feet (9.29 m^2) of conditioned floor area.~~

   ~~Exception: The total leakage test is not required for ducts and air handlers located entirely within the building thermal envelope.~~

~~**R403.2.3 (N1103.2.3)Building cavities (Mandatory).** Building framing cavities shall not be used as ducts or plenums.~~

R403.2.3 (N1103.2.3) Duct testing (Mandatory). The ductwork in a building or dwelling unit shall be tested for air leakage. Testing shall be conducted at the rough-in stages or post-construction. Testing for duct leakage shall be at a pressure differential of 0.1 inches w.g. (25 Pa) across the entire system, including the manufacturer's air handler enclosure. All register boots shall be taped or otherwise sealed during the test. Testing shall be conducted by an *approved* third party. A written report of the results of the test shall be signed by the party conducting the test and shall be provided to the *code official*.

Exception: Ductwork air leakage testing shall not be required where all ducts and air handlers are located entirely within the *building thermal envelope*.

R403.2.4 (N1103.2.4) Duct leakage (Prescriptive). The total leakage of ducts, where measured in testing accordance with Section R403.2.3, shall meet one of the following requirements:

1. Rough-in test: Total leakage shall be less than or equal to 4 cfm (113.3 L/min) per 100 square feet (9.29 m^2) of conditioned floor area where the air handler is installed at the time of the test. Where the air handler is not installed at the time of the test, the total leakage shall be less than or equal to 3 cfm (85 L/min) per 100 square feet (9.29 m^2) of conditioned floor area.

2. Postconstruction test: Total leakage shall be less than or equal to 4 cfm (113.3 L/min) per 100 square feet (9.29 m^2) of conditioned floor area.

Exception:

~~R403.2.2.1 (N1103.2.2.1)~~ R403.2.5 (N1103.2.5) ~~Sealed~~ Air handler leakage (Mandatory). Air handlers shall have a manufacturer's designation for an air leakage of not more than 2 percent of the design air flow rate when tested in accordance with ASHRAE 193.

R403.2.6 (N1103.2.6) Insulation (Prescriptive). Supply ducts in attics shall be insulated to a *R-value* of not less than R-8. All other ducts shall be insulated to a *R-value* of not less than R-6.

Exception: Ducts or portions of ducts located completely inside the *building thermal envelope* shall not be required to be insulated.

TABLE R405.2(1) (N1105.2(1))
SPECIFICATIONS FOR THE STANDARD REFERENCE AND PROPOSED DESIGNS

BUILDING COMPONENT	STANDARD REFERENCE DESIGN	PROPOSED DESIGN
Thermal distribution systems	For ducted thermal distribution systems, the duct leakage rate shall be in accordance with Section R403.2.4 and the duct insulation shall be in accordance with Section R403.2.6. For nonducted thermal distribution systems, a distribution system efficiency, DSE, of 0.88 shall be applied to both the heating and cooling system.	Thermal distribution system efficiency shall be as tested or as specified in Table R405.5.2(2) if not tested. Duct insulation shall be as proposed.

(Portions of Table not shown remain unchanged)

Reason: The purpose of this code change is to make a number of improvements to the provisions of the code related to HVAC system controls and ducts. However, it should be noted that this proposal does not change or tighten required values for tested duct leakage, which were initially set in the 2009 *IECC* and tightened in the 2012 *IECC*. The proposed improvements include:

- Reorganize section R403.1 to clearly specify requirements for controls (no change proposed in substantive requirements for this section).
- Reorganize section R403.2 regarding duct sealing, testing and leakage requirements, including the following substantive changes:
  - Clarify that for required testing, such testing must be conducted by a code official-approved third party; and
  - Convert the duct leakage rate from a mandatory to prescriptive requirement (allowing duct leakage to be traded off under the performance path). Note that testing is still mandatory.
- Revise Table R405.5.2(1) to establish a baseline in the Standard Reference Home for duct leakage/distribution system efficiency. The baseline was incorrectly deleted in 2012.

This proposal maintains the efficiency provided by the improved duct leakage rate set in the 2012 *IECC*, and it improves the transparency and objectivity by requiring that testing be administered by a third party. This proposal also creates a practical solution for situations in which a completed duct system fails the leakage test, by allowing the duct performance shortfall to be offset by other improvements under section R405. This is an important consideration where the on-site testing requirement is already set at a tight level. As a result, this proposal adds flexibility for the builder and increased compliance at no additional energy cost. This proposal also reorganizes the subsections related to systems and ducts to add more clarity and simplicity to the code.

Cost Impact: The code change proposal will increase the cost of construction.

R403.1-EC-DEAN-HARRIS-MISURIELLO-PRINDLE-STONE.DOC

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: The proposal would require a third party testing agency which is overly restrictive for many communities.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Brian Dean, ICF International, representing the Energy Efficient Codes Coalition; Jeff Harris, Alliance to Save Energy; Harry Misuriello, American Council for an Energy-Efficient Economy (ACEEE); Bill Prindle, representing the Energy Efficient Codes Coalition; Garrett Stone, Brickfield, Burchette, Ritts & Stone, PC; Donald J. Vigneau, Northeast Energy Efficiency Partnerships Inc., request Approval as Modified by this Public Comment.

Modify the proposal as follows:

R403.2.3 (N1103.2.3) Duct testing (Mandatory). The ductwork in a building or dwelling unit shall be tested for air leakage. <u>The maximum total air leakage rate for ducts in any building or dwelling unit under any compliance path shall not exceed 8 cfm (226.5 L/min) per 100 square feet (9.29 m^2) of conditioned floor area.</u> Testing shall be conducted at the rough-in stages or post-construction. Testing for duct leakage shall be at a pressure differential of 0.1 inches w.g. (25 Pa) across the entire system, including the manufacturer's air handler enclosure. All register boots shall be taped or otherwise sealed during the test. <u>Where required by the code official,</u> ~~T~~testing shall be conducted by an *approved* third party. A written report of the results of the test shall be signed by the party conducting the test and shall be provided to the *code official*.

> **Exception:** Ductwork air leakage testing shall not be required where all ducts and air handlers are located entirely within the *building thermal envelope*.

R403.2.4 (N1103.2.4) Duct leakage (Prescriptive). The total leakage of ducts, where measured in testing accordance with Section R403.2.3, shall meet one of the following requirements:

1. Rough-in test: Total leakage shall be less than or equal to 4 cfm (113.3 L/min) per 100 square feet (9.29 m^2) of conditioned floor area where the air handler is installed at the time of the test. Where the air handler is not installed at the time of the test, the total leakage shall be less than or equal to 3 cfm (85 L/min) per 100 square feet (9.29 m^2) of conditioned floor area.
2. Postconstruction test: Total leakage shall be less than or equal to 4 cfm (113.3 L/min) per 100 square feet (9.29 m^2) of conditioned floor area.

> ~~**Exception:**~~

R403.2.5 (N1103.2.5) Air handler leakage (Mandatory). Air handlers shall have a manufacturer's designation for an air leakage of not more than 2 percent of the design air flow rate when tested in accordance with ASHRAE 193.

(Portions of proposal not shown remain unchanged)

Commenter's Reason: We recommend approval of RE99 as modified by this public comment. The reason statement for the original RE99 explains the purpose of the original proposed revisions. The proposed modifications in this public comment are intended to address two important issues: (1) the new language will permit the code official to determine whether independent testing is necessary and require it if deemed appropriate (this language is exactly the same as the language that currently applies to air leakage testing in section R402.4.1.2); and (2) the new language will set a mandatory maximum duct leakage of 8 cfm (226.5 L/min) per 100 square feet (9.29 m^2) of conditioned floor area (the level required by the 2009 IECC in section 403.2.2).

The value in allowing the code official to require independent duct testing is self-evident and the same as the value in requiring independent home air leakage testing as the code already does. As for the mandatory maximum, the current IECC sets the mandatory and prescriptive test requirements for duct leakage at the same leakage level – in most cases 4 cfm (226.5 L/min) per 100 square feet (9.29 m^2) of conditioned floor area. Because this value may be difficult to achieve in some cases, we do not object to permitting duct leakage to be traded off, to some degree, in the performance path for other reasonable energy efficiency improvements. However, there should be at least some limits on such trade-offs, particularly given other proposed changes to the performance path. As a result, we propose a mandatory maximum air leakage of 8 cfm be established – this will still leave reasonable room for more flexibility while ensuring some minimum level of performance.

RE99 -13

Final Action: AS AM AMPC____ D

RE106-13
R403.1.2 (IRC N1103.1.2)

Proposed Change as Submitted

Proponent: Eric Makela / Britt/Makela Group, Inc., representing Northwest Energy Codes Group (Eric@BrittMakela.com)

Revise as follows:

R403.1.2 (N1103.1.2) Heat pump supplementary heat (Mandatory). ~~Heat pumps having supplementary electric-resistance heat shall have controls that, except during defrost, prevent supplemental heat operation when the heat pump compressor can meet the heating load.~~ Unitary air cooled heat pumps shall include controls that minimize supplemental heat usage during start-up, set-up and defrost conditions. The controls shall anticipate need for heat and use compression heating as the first stage of heat. The controls shall indicate when supplemental heating is being used through visual means such as a light emitting diode indicator. Heat pumps equipped with supplementary heaters shall be installed with controls that prevent supplemental heater operation at outdoor temperatures greater than 40°F (4.4 °C). The auxiliary heat lock out control shall be set at 35°F (1.7°C)or less at final inspection.

Reason: The current language in the 2012 IECC requiring heat pump thermostats that is fairly general. The language requires a thermostat for heat pumps and includes language that outlines the general intent of the control but does not provide the level of detail needed to enforce the provision. The proposed language provides guidance on what to inspect for to determine of the supplemental heat is on. The proposed language also provides a temperature setpoint for when the supplemental heat is allowed to come on to satisfy the load (40°F). The existing language states that the control must prevent supplemental heat operation when the heat pump can meet the heating load but without a specific temperature threshold the provision is unenforceable. The proposed language is from the Washington State Residential Energy Code and has been field tested.

Cost Impact: The code change proposal will not increase the cost of construction.

R403.1.2-EC-MAKELA.DOC

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: This complicates the code needlessly. The existing language is straightforward and understandable.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Eric Makela, Britt/Makela Group, representing Northwest Energy Codes Group, requests Approval as Submitted.

Commenter's Reason: The current language in the 2012 IECC requiring heat pump thermostats that is fairly general. The language requires a thermostat for heat pumps and includes language that outlines the general intent of the control but does not provide the level of detail needed to enforce the provision. The proposed language provides guidance on what to inspect for to determine if the supplemental heat is on. The proposed language also provides a temperature setpoint for when the supplemental heat is allowed to come on to satisfy the load (≤ 40 °F). The existing language states that the control must prevent supplemental heat operation when the heat pump can meet the heating load but without a specific temperature threshold the provision is unenforceable. The proposed language is from the Washington State Residential Energy Code and has been field tested. Information on auxiliary heat lock out controls can be found at http://www.energy.wsu.edu/documents/AHT_Electric%20Heat%20Lock%20Out%20on%20Heat%20Pumps%20%282%29.pdf

RE106 -13

Final Action: AS AM AMPC____ D

RE107-13
R403.2.1 (IRC N1103.2.1)

Proposed Change as Submitted

Proponent: Shaunna Mozingo, City of Cherry Hills Village, representing Colorado Chapter of ICC, Inc. smozingo@coloradocode.net

Revise as follows:

R403.2.1 (N1103.2.1) Insulation (Prescriptive). Supply and return ducts in attics shall be insulated to a minimum of R-8. ~~All other ducts~~ Supply and return ducts in other portions of the building shall be insulated to a minimum of R-6.

Exception: Ducts or portions thereof located completely inside the building thermal envelope.

Reason: The requirement as written is commonly misinterpreted to say that all supply ducts in attics are insulated to R-8 and all other ducts in attics, including bathroom exhausts, returns, etc are insulated to R-6 when in fact, the intent was that the supply ducts in attics get R-8 and the supplies in other unconditioned spaces in the building, such as garages, ventilated crawl spaces, etc, get R-6. Also, the ducts should not be limited to supplies but should include return ducts as well. This intent is called out much more clearly in the commercial section of the code.

Cost Impact: The code change proposal will not increase the cost of construction.

R403.2.1-EC-MOZINGO.DOC

Committee Action Hearing Results

Committee Action: **Approved as Modified**

Modify the proposal as follows:

R403.2.1 (N1103.2.1) Insulation (Prescriptive).Supply and return ducts in attics shall be insulated to a minimum of R-8 where 3 inch diameter and greater and R-6 where less than 3 inch diameter. All other ducts supply and return ducts in other portions of the building shall be insulated to a minimum of R-6 where 3 inch diameter and greater and R-4.2 where less than 3 inch diameter.

Committee Reason: This proposed change reflects the original intent of the code that "all other ducts" was meant to mean supply and return ducts, not bathroom exhausts, etc. The modification is to reflect the fact that energy losses in smaller ducts are less.

Assembly Action: **As Submitted**

Individual Consideration Agenda

This code change proposal is on the agenda for individual consideration because the proposal received a successful assembly action of Approved as Submitted.

RE116-13
R403.2.2 (IRC N1103.2.2), Table R405.5.2(1) (IRC Table N1105.5.2(1))

Proposed Change as Submitted

Proponent: Don Surrena, CBO, National Association of Home Builders (NAHB) (dsurrena@nahb.org)

Revise as follows:

R403.2.2 (N1103.2.2) Sealing (Mandatory). Ducts, air handlers, and filter boxes shall be sealed. Joints and seams shall comply with either the *International Mechanical Code* or *International Residential Code*, as applicable.

Exceptions:

1. Air-impermeable spray foam products shall be permitted to be applied without additional joint seals.
2. Where a duct connection is made that is partially inaccessible, three screws or rivets shall be equally spaced on the exposed portion of the joint so as to prevent a hinge effect.
3. Continuously welded and locking-type longitudinal joints and seams in ducts operating at static pressures less than 2 inches of water column (500 Pa) pressure classification shall not require additional closure systems.

Duct tightness shall be verified by either of the following:

1. Postconstruction test: ~~Total~~ Leakage to the outside of a conditioned space or total leakage shall be less than or equal to 4 cfm (113.3 L/min) per 100 square feet (9.29 m^2) of conditioned floor area when tested at a pressure differential of 0.1 inches w.g. (25 Pa) across the entire system, including the manufacturer's air handler enclosure. All registers ~~boots~~ shall be taped or otherwise sealed during the test.
2. Rough-in test: Total leakage shall be less than or equal to 4 cfm (113.3 L/min) per 100 square feet (9.29 m^2) of conditioned floor area when tested at a pressure differential of 0.1 inches w.g. (25 Pa) across the system, including the manufacturer's air handler enclosure. All registers shall be taped or otherwise sealed during the test. If the air handler is not installed at the time of the test, total leakage shall be less than or equal to 3 cfm (85 L/min) per 100 square feet (9.29 m^2) of conditioned floor area.

Exception: The total leakage test is not required for ducts and air handlers located entirely within the building thermal envelope.

TABLE R405.5.2(1) (N1105.5.2(1))
SPECIFICATIONS FOR THE STANDARD REFERENCE AND PROPOSED DESIGNS

BUILDING COMPONENT	STANDARD REFERENCE DESIGN	PROPOSED DESIGN
Thermal distribution systems	<u>Untested distribution systems: DSE = 0.88</u> <u>Tested Ducts: Leakage rate to outside conditioned space as specified Section R403.2.2(1)</u> <u>Tested duct Location: Unconditioned attic</u> <u>Tested duct Insulation: in accordance with Section R403.2.1</u>	~~Thermal distribution system efficiency shall be as tested or as specified in Table R405.5.2(2) if not tested. Duct insulation shall be as proposed.~~ <u>Untested distribution systems: DSE from Table R405.5.2(2)</u> <u>Tested Ducts: Tested Leakage rate to outside conditioned space</u> <u>Duct Location: As proposed</u> <u>Duct Insulation: As proposed</u>

Reason: Currently there is no guidance in Table R405.5.2(1) on how to model ducts for the Standard Reference Design when performing a simulated energy performance calculation. Consequently, systems which perform better than the code minimum are not recognized in the performance analysis. Proposed changes provide clarity as to what distribution system efficiency should be applied to the Standard Reference Design and how the ducts should be modeled in the performance path.

The default distribution system efficiency (DSE) is set to 0.88 for untested systems in the standard reference design, which is the established default for ducts located in conditioned space. If ductless or hydronic systems are used, a recognized benefit will result in the performance model.

When a duct system is tested, the standard reference tightness is defined in section R403.2.2(1) (4cfm/100ft2 of CFA). Buildings with ducts tighter than the 4cfm/100ft2 will get credit for performing better than the minimum requirement. In addition, the manufacturers of the modeling software will have clear definition how to model the Standard Reference Designincluding duct placement and insulation level.

Changes in section R403.2.2 make it clear that postconstruction duct testing can be tested to either outside conditioned space or total duct leakage, as determined by the contractor.

Cost Impact: The code change proposal will not increase the cost of construction.

R403.2.2 #2-EC-SURRENA.DOC

Committee Action Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: This proposal is compatible with previous action on code change proposal no. RE112-13. This proposal also installs the information in Table 405.5.2(1) for tested ducts to relate to the change made in RE109-13.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Brian Dean, ICF International, representing the Energy Efficient Codes Coalition; Jeff Harris, Alliance to Save Energy; Harry Misuriello, American Council for an Energy-Efficient Economy

(ACEEE); Bill Prindle, representing the Energy Efficient Codes Coalition; Garrett Stone, Brickfield, Burchette, Ritts & Stone, PC; Donald J. Vigneau, Northeast Energy Efficiency Partnerships Inc., request Disapproval

Commenter's Reason: We recommend disapproval of RE116. RE116 should be disapproved because it weakens the current energy efficiency requirements of the IECC related to duct leakage. The IECC currently requires duct tightness to be verified either at rough-in or at post-construction, and in both cases, the test standard is the total leakage of the system. RE116 modifies the test to "leakage to the outside of a conditioned space," but at the same leakage level. This option will result in more total duct leakage than currently permitted, unless the ducts do not leak at all into the occupied conditioned space (a highly unlikely situation unless the ducts are not in conditioned space at all).

Duct systems should be designed (and tested) to verify that conditioned air actually reaches the intended spaces. Tighter duct systems (with low total leakage) will deliver conditioned air where it is supposed to go with minimal leakage to any unintended spaces – conditioned or not conditioned. A test that considers only "leakage to the outside of a conditioned space" could actually be a very inefficient system and result in far more energy usage to condition the space. For example, if an air handler is located inside conditioned space, and the first duct leading from the air handler leaks 20% of the conditioned air into the furnace room, the system may pass the "leakage to outdoors" test, but would certainly fail the "total leakage" test. Moreover, the conditioned air would not get to the intended space, resulting in far more heating and cooling energy being used to achieve the desired temperature and comfort.

RE116 creates an approach that would, in many cases, lead to significant energy losses as compared with the current IECC, and it should be disapproved.

RE116 -13

Final Action: AS AM AMPC____ D

RE119-13
R403.2.3 (IRC N1103.2.3)

<u>Proposed Change as Submitted</u>

Proponent: Dan Buuck, National Association of Home Builders (NAHB) (dbuuck@nahb.org)

Revise as follows:

R403.2.3 (N1103.2.3) Building cavities (Mandatory). Building framing cavities shall not be used as ducts ~~or plenums~~.

Reason: Right now we have a conflict between this section and the IMC and IRC, both of which allow plenums in stud cavities and joist spaces. There is also an apparent conflict within the IECC: It currently allows stud cavity and joist space plenums in residential occupancies more than three stories in height along with all other commercial buildings.

The general prohibition of plenums has also lost its effectiveness in regards to energy savings. When it was approved for the IECC, using stud spaces in exterior walls as plenums was still allowed. That it is now prohibited (see IRC M1601.1.1), so heat loss is not an issue.

During the Group A hearings a proposal to prohibit plenums in the IMC was not successful. The PMG CAC considered this conflict and decided not to support a proposal that would remove language in the IRC that provides guidance on the safe construction of plenums. This would have put the IRC in conflict with the IMC. States are also removing plenums from this section of the IECC as they adopt the 2012 version.

Cost Impact: The code change proposal will not increase the cost of construction.

R402.2.3-BUUCK.DOC

<u>Committee Action Hearing Results</u>

Committee Action: **Disapproved**

Committee Reason: The proponent recommended disapproval of this code change proposal.

Assembly Action: **None**

<u>Individual Consideration Agenda</u>

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Dan Buuck, National Association of Home Builders, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R403.2.3 (N1103.2.3) Building cavities (Mandatory). Building framing cavities shall not be used as ducts <u>or as a *plenum* for supply air. Studwall cavities in the outside walls of building envelope assemblies shall not be utilized as air *plenums*.</u>

Commenter's Reason: This public comment reinstates the long-standing practice of using stud and joist spaces as return air plenums. Additional language limiting their location and use was taken from Section M1601 Duct Construction.

Right now we have a conflict between this section and the IMC and IRC mechanical section, both of which allow plenums in stud cavities and joist spaces. There is also an apparent conflict within the IECC: Building cavity plenums are prohibited in one- and two-family homes, but are allowed in multi-family residential occupancies along with all other commercial buildings.

It is important to note that there is no requirement for return ducts/plenums. Returns simply provide an easier path for the air to get back to the air handler, thereby saving energy. So it is only logical to provide an economical solution for a non-required item. This change also allows the use of "jump ducts" which often use building cavities (and are actually *plenums*). Without this change jump ducts are technically not allowed.

The general prohibition of plenums in the energy section has also lost its effectiveness in regards to energy savings. When it was originally adopted in the IECC, using stud spaces in exterior walls as plenums was still allowed in the mechanical section. That it is now prohibited (see IRC M1601.1.1), so heat loss is not an issue. The last sentence of the modification is taken directly from that section.

During the Group A hearings a proposal to prohibit plenums in the IMC was not successful. The PMG CAC considered this conflict and decided not to support a proposal that would remove language in the IRC that provides guidance on the safe construction of plenums. This would have put the IRC in conflict with the IMC. States are also removing plenums from this section of the IECC as they adopt the 2012 version.

RE119 -13

Final Action: AS AM AMPC____ D

RE120-13
R403.2.3 (IRC N1103.2.3)

<u>Proposed Change as Submitted</u>

Proponent: Brenda A. Thompson, Clark County Building Department, Las Vegas NV, representing the ICC Sustainability, Energy & High Performance Code Action Committee (SEHPCAC)

Revise as follows:

R403.2.3 (N1103.2.3) Building cavities (Mandatory). Building framing cavities <u>in the *building thermal envelope*</u> shall not be used as ducts or plenums.

Reason: This proposal is submitted by the ICC Sustainability Energy and High Performance Code Action Committee (SEHPCAC). The SEHPCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portion thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the SEHPCAC has held 3 open meetings and over 30 workgroup calls which included members of the SEHPCAC as well as any interested party to discuss and debate proposed changes and public comments. Related documentation and reports are posted on the SEHPCAC website at: http://www.iccsafe.org/cs/SEHPCAC/Pages/default.aspx.

This proposal revises Section R403.2.3 to align with the requirements of Section M1601.1.1 of the IRC and Section 602.3 of the IMC, which prohibit building framing cavities in exterior walls to be used as ducts or plenums, but allow framing cavities in interior walls to be used as ducts or plenums. As currently configured these code sections conflict with one another and make enforcement confusing and difficult.

The current language in Section R403.2.2 of the IECC does not allow building cavities in interior walls or floors to be used as ducts. While this section would not prevent such interior walls or floors to be used as ducts or plenums, Section 602.3 of the IMC and Section M1601.1.1 prohibit their use as supply ducts. Therefore, these interior wall and floor building cavities would ultimately be permitted to be used only as return ducts.

Note that the IECC defines *building thermal envelope* as "The *basement walls, exterior walls*, floor, roof and any other building element that enclose *conditioned space* or provides a boundary between *conditioned space* and exempt or unconditioned space."

Also note that, while the *building thermal envelope* is an energy issue, ducts are a mechanical issue and are governed primarily by the IMC and the mechanical chapters of the IRC.

Cost Impact: The code change proposal will decrease the cost of construction.

R403.2.3-EC-THOMPSON-SEHPCAC.DOC

<u>Committee Action Hearing Results</u>

Committee Action: **Disapproved**

Committee Reason: There is no way to effectively test building cavities. Returns are especially problematic. A full return without leakage is necessary to protect the integrity of the combustion air zone.

Assembly Action: **None**

<u>Individual Consideration Agenda</u>

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Brenda Thompson, CBCO, Manager Building Inspections, Clark County Development Services, ICC Sustainability, Energy and High Performance Code Action Committee (SEHPCAC) Chair requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R403.2.3 (N1103.2.3) Building cavities (Mandatory). Building framing cavities ~~in~~ <u>which are part of the assemblies establishing</u> the *building thermal envelope* shall not be used as ducts or plenums.

Commenter's Reason: The Residential IECC Code Development committee disapproved this proposal and other similar proposals on the grounds that it is difficult to test such cavities when used as ducts and plenums. The proposal is modified to clarify that those cavities that are part of the assemblies that comprise the building thermal envelope would still be prohibited to be ducts and plenums, but those inside of the envelope – interior walls and interior floor/ceilings could be used. Those assemblies are not subject to the testing – the testing is for the thermal envelope.

This public comment is submitted by the ICC Sustainability Energy and High Performance Code Action Committee (SEHPCAC). The SEHPCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portion thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the SEHPCAC has held numerous open meetings and workgroup calls which included members of the SEHPCAC, as well as interested parties, to discuss and debate proposed changes and public comments.

Proposed Change as Submitted

Proponent: Edward R. Osann, Natural Resources Defense Council, on behalf of self. (eosann@nrdc.org)

Revise as follows:

R403.4 (N1103.4) Service hot water systems. Energy conservation measures for service hot water systems shall be in accordance with Sections R403.4.1, ~~and~~ R403.4.2 and R403.4.3.

R403.4.3 (N1103.4.3) Hot water pipe volume (Mandatory). In a service hot water distribution system, the volume in the piping between the end of a hot water fixture supply and the piping connection to a hot water source shall not exceed 0.5 gallon (1.9 liters). The hot water source shall be a recirculating system pipe, a heat-traced pipe or a water heater. The volume in the piping shall be calculated using the values in Table R403.4.3.

TABLE R403.4.3 (N1103.4.3)
INTERNAL VOLUME OF VARIOUS WATER DISTRIBUTION PIPING

	LIQUID OUNCES OF WATER PER FOOT LENGTH OF HOT WATER TUBING							
Nominal Size (Inches)	**Copper Type M**	**Copper Type L**	**Copper Type K**	**CPVC CTS SDR 11**	**CPVC SCH 40**	**PEX-AL-PEX ASTM F 1281**	**PE-AL-PE**	**PEX CTS SDR 9**
⅜	1.06	0.97	0.84	N/A	1.17	0.63	0.63	0.64
½	1.69	1.55	1.45	1.25	1.89	1.31	1.31	1.18
⅝	2.49	2.31	2.22	N/A	N/A	2.12	2.12	1.72
¾	3.43	3.22	2.90	2.67	3.38	3.39	3.39	2.35
1	5.81	5.49	5.17	4.43	5.53	5.56	5.56	3.91
1¼	8.70	8.36	8.09	6.61	9.66	8.49	8.49	5.81
1½	12.18	11.83	11.45	9.22	13.20	13.88	13.88	8.09
2	21.08	20.58	20.04	15.79	21.88	21.48	21.48	13.86

For SI: 1 inch = 25.4 mm, 1 liquid ounce = 0.0296 liters, 1.0 ounce = 0.00781 gallons,
0.5 gallon (1.9 liters) = 64.0 liquid ounces

Reason: Cold or tepid water in the initial draw from a hot water outlet is often unusable for its intended purpose, and is frequently purged, resulting in a waste of water, energy, and time for building occupants. Pipe insulation significantly reduces heat loss and helps to ensure that hot water gets to the shower sooner. However, a complementary strategy is to reduce the volume of water contained in the hot water distribution system in the first place.

This proposal, which is comparable to the criteria adopted by the US EPA WaterSense for New Homes specification in 2009, establishes a maximum volume of 0.5 gallons for water in a hot water supply line, based on internal volumes specific to the piping material. By allowing the volume limitation to be computed from runs from recirculation loops, this provision allows designers additional flexibility while effectively limiting the amount of water to be purged to ½ gallon per draw.

The proposal designates this provision as mandatory. The reason for this is that while the 2012 IECC performance approach allows credit for improving the efficiency of the hot water heat source, no credit is available for features of the hot water distribution system that might actually reduce the amount of hot water used, such as a limitation on hot water supply pipe volume Thus, even though this design criterion will save significant amounts of energy over the life of the building, its energy savings cannot be "scored" or accumulated within the performance framework of the code. If designated "prescriptive", it is likely to be ignored by builders using the performance path since it cannot contribute to compliance under the IECC performance approach. Thus, "mandatory" is the better approach at this time. If and when Section R405 is modified to ensure that the performance path will account for the energy attributes of the hot water distribution system, consideration can be given to removing the mandatory designation from this proposed section.

Cost Impact: This code change proposal is a design requirement that will not increase the cost of construction.

R403.4.2-EC-OSANN.DOC

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: This proposal would require that plumbing plans (water distribution system plumbing) be submitted for every project. Isn't there a simpler way? This would be too difficult for an inspector to check. This could also have the unintended consequence of making designers install additional water heaters.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Edward R. Osann, Natural Resources Defense Council, representing self; Harry Misuriello, American Council for an Energy-Efficient Economy; Brian Dean, representing the Energy Efficient Codes Coalition; Jeff Harris, Alliance to Save Energy; Bill Prindle, representing the Energy Efficient Codes Coalition; Garrett Stone, Brickfield, Burchette, Ritts & Stone, PC; Donald J. Vigneau, Northeast Energy Efficiency Partnerships Inc. request Approval as Modified by this Public Comment

Modify the proposal as follows:

R403.4 (N1103.4) Service hot water systems. Energy conservation measures for service hot water systems shall be in accordance with Sections R403.4.1, R403.4.2 and R403.4.3.

R403.4.3 (N1103.4.3) Hot water pipe volume (Mandatory). ~~In a service hot water distribution system, the volume in the piping between the end of a hot water fixture supply and the piping connection to a hot water source shall not exceed 0.5 gallon (1.9 liters).~~ The volume of water in a service hot water system between the termination of a supply pipe to individual fixtures indicated in Section R403.4.3.1 and the nearest source of hot water shall not exceed 128 ounces (3.8 liters). The hot water source shall be a recirculating system pipe, a heat-traced pipe or a water heater. The volume shall be the sum of the internal volumes of pipe, fittings, valves, meters and manifolds located between the heat source and the fixture supply pipe termination. The volume in the piping shall be calculated using the values in Table R403.4.3. Calculation of the internal volume of plumbing appurtenances and piping materials or dimensions not included in Table R403.4.3 shall be documented and *approved*.

R403.4.3.1 (IRC N1103.4.3.1) Scope. The volume limitation in Section P2904.1 shall apply to hot water supplied to all of the following fixtures:

1. lavatories
2. kitchen sinks
3. showers
4. tub-showers

TABLE R403.4.3 (N1103.4.3)
INTERNAL VOLUME OF VARIOUS WATER DISTRIBUTION PIPING

	LIQUID OUNCES OF WATER PER FOOT LENGTH OF HOT WATER TUBING

~~0.5~~ 1 gallon (~~1.9~~ 3.8 liters) = ~~64.0~~ 128 liquid ounces

Commenter's Reason: In response to the committee's concern that a simpler approach be found, the modification in this public comment simplifies and clarifies the original proposal in the following ways:

- Limits the applicability of the proposal to hot water piping serving three types of fixtures:
  - Showers and tub-shower combinations.
  - Kitchen sinks.
  - Lavatories.
- Increases the maximum volume permitted within a hot water supply pipe to any individual fixture to 1 gallon (128 ounces), up from ½ gallon in the original proposal.
- Conforms the table of internal volumes for various types and diameters of piping material to the values in Table E202.1 of the International Plumbing Code as approved for 2015.
- Clarifies that the permissible volume of water is to be calculated from the "nearest" source of hot water to an "individual" fixture.
- Adds a sentence to clarify the inclusion of the internal volume of valves, manifolds, and similar devices that may be located on hot water piping between the nearest heat source and the termination of the supply pipe at a fixture.
- Adds a sentence to allow calculation of the internal volume of plumbing appurtenances such as manifolds and pipe materials or dimensions that are not included in the table, with documentation satisfactory to the code official.

The initial purging of cooled-down hot water that is insufficiently hot for its intended purpose results in a waste of water, energy, and time for building occupants. Pipe insulation significantly reduces heat loss and helps to ensure that hot water gets to the user sooner. However, a complementary strategy is to reduce the volume of water contained in hot water piping in the first place.

A 2009 paper authored by Robert Hendron of the National Renewable Energy Laboratory and others[a] quantified the waste of hot water in initial draws waiting for water to reach 105ºF. Modeling the plumbing typical of a 3-bedroom, 2-bath, single-story home with a hot water distribution simulation tool found that an estimated 12 % of all hot water used on an annual basis is wasted. When viewed by fixture, the results are even more instructive:

- Showers – over 10 % wastage.
- Kitchen sinks – 18 % wastage.
- Lavatories – over 30 % wastage.

Purging at these fixtures is responsible for 95 % of the estimated total of nearly 3,000 gallons of hot water wastage annually. Of course, many new homes are built with more hot water outlets than this model's base case, and hot water distribution systems that are far less efficient. Nevertheless, this revision to RE122 will direct the attention of designers, installers, and code officials to the piping of fixtures that are responsible for most hot water waste.

The table in the proposal is simply a computational aid, to provide a handy, standardized reference for determining the volume of water per linear foot of pipe. The internal diameters of various types of piping material are different enough that including specific values for each type of pipe material is useful, helping designers find the desired combination of pipe length and permissible volume. Modifications to the table in this comment are simply to conform the Table to the values and materials already accepted for Table E202.1 in the IPC. Code officials we consulted viewed the table as helpful for inspection purposes as well.

The committee's final stated reason for disapproval, that this proposal *could* [emphasis added] make designers install multiple water heaters, is speculation. The proposal sets a maximum volume of water in hot water supply piping between a heat source and a shower, lavatory, or kitchen sink. This limit can be achieved with attention to water heater placement and piping layout at the design stage, and need not require multiple water heaters. The downsizing of pipe diameters and the substitution of piping materials with smaller internal diameters are additional strategies available to designers and installers. Reducing pipe length, reducing pipe diameter, and substituting composite piping material with smaller internal diameter each have the effect of reducing installation costs. And the designation of a recirculation system pipe as a heat source for purposes of calculating permissible hot water volume offers additional design flexibility for homes employing a recirculation system, an option often preferable to an additional water heater in a large home and likely to become more energy-efficient with the approval of RE125 as recommended by the committee.

Final Action: AS AM AMPC____ D

RE123-13
R202 (IRC N1101.9), R403.4 (IRC N1103.4), R403.4.1 (NEW) (IRC N1103.4.1 (NEW)), Chapter 5

Proposed Change as Submitted

Proponent: Meg Waltner, Natural Resources Defense Council (mwaltner@nrdc.org)

Revise as follows:

R403.4 (N1103.4) Service hot water systems. Energy conservation measures for service hot water systems shall be in accordance with Sections R403.4.1 ~~and R403.4.2~~, R403.4.2 and R403.4.3.

R403.4.1 (N1103.4.1) Water heating equipment (Prescriptive). This section shall apply only to buildings in climate zones 1 through 5. *Service water heating* equipment shall be of one or more of the types in the following list. Where replacement of existing *service water heating* equipment is required and the replacement equipment is of the same type as the existing, the replacement shall be have an efficiency that is the same or better than the existing equipment. Where existing equipment is replaced with another type of *service water heating* equipment, the equipment shall be of one or more of the types in the following list.

1. a *desuperheater water heater* listed and labeled to AHRI 470
2. a heat pump water heater a heat pump water heater with an energy factor, EF, of 2.0 or greater
3. a solar water heating system having a solar system heating fraction of 0.50 or greater
4. an instantaneous water heater
5. a fuel-gas fired storage water heater with energy factor, EF, of 0.67 or greater

Add new definition as follows:

IECC SECTION R202 (IRC N1101.9)
GENERAL DEFINITIONS

DESUPERHEATER WATER HEATER. A factory-made assembly of elements by which the flows of refrigerant vapor and water are maintained in a heat transfer relationship so that the refrigerant vapor is desuperheated and the water is heated.

Add new standard to Chapter 5 as follows:

AHRI

470-06 Performance Rating of Desuperheater/Water Heaters

Reason: As shown in the attached analysis prepared by the Department of Energy, there are cost effective ways to achieve significant energy savings in service water heating systems in climate zones 1-5 compared to standard-efficiency storage electric and fuel-fired heaters. The proposed change offers multiple options for compliance with the new requirement. Cost-effective measures should be included in the IECC as a measure of sound energy policy and to protect consumers from unnecessarily high future energy costs.

Water Heaters

Description

Residential envelopes have been getting tighter and better over the last few years. As a result, domestic water heating energy is emerging as a significant end-use from the efficiency stand-point. There are multiple ways of improving the efficiency of generating hot water in homes. DOE analyzed some of the more common methods – for homes with gas water heaters, water heaters with Energy factor (EF) greater than the federal minimum baseline and tankless water heaters are analyzed; for homes with electric water heaters, heat-pump water heaters are analyzed. Desuperheaters are analyzed for all cases.

The Life Cycle cost analysis uses the DOE Cost Effectiveness Methodology[1] for assessing cost effectiveness. This analysis has been carried out for the single family prototype, for 15 locations, one foundation type and one heating system except the heat pump water heater analysis which is carried out for homes with electric resistance and heat pump space heating. Table 1 indicates the location cost indices provided by Faithful and Gould (2011)[1] used to reflect local construction costs. Recent residential fuel prices specific to each location summarized in Table 2 are used for energy cost calculations. These have been obtained from the DOE Energy Information Administration.[2,3]

Table 1: Cost multipliers by State

Location	State	Climate Zone	Moisture Regime	multiplier

High efficiency gas storage water heaters

This concept looks at the energy savings potential of high efficiency storage water heater. The residential prototype is presently equipped with a 40 gallon hot water heater. Federal minimum efficiency requirements were revised in 2010 and compliance with the required standards for water heaters is required from April 2015. The new rule requires 40 gallon gas storage water heaters to have an EF of 0.615[2]. An EF of 0.67 is analyzed in this concept.

Table 2: Fuel Costs by State

Location	State	Climate Zone	Moisture Regime	Electricity-winter ($/kWh)	Electricity-summer ($/kWh)	Gas ($/thm)	Oil ($/MBtu)

Energy Cost Savings

Figure 1 below shows energy cost savings for each climate zone.

Cost Effectiveness

The cost for high efficiency water heaters were derived from the Technical Support document and Life Cycle Cost (LCC) spreadsheets for the Appliance Standards rule-making for water heaters[3][4]. These costs are blended for retrofits and new construction. To generate costs specific to new construction alone, the Crystal Ball (CB) analysis was re-run with the fractions set to 100% new construction and 0% retrofits.

The total installed cost for a 40 gallon gas storage water heater with EF 0.62 works out to $1609 while the total installed cost for a 40 gallon gas storage water heater with EF 0.67 works out to $1468. This unexpected drop in costs is due to lower venting costs associated with the high efficiency water heater. The baseline requires natural draft venting which has higher costs than the plastic power venting apparatus required by the high efficiency water heater.

It can be concluded that using a higher efficiency water heater not only saves energy during its life, but also costs less to install. This measure is thus, cost-effective.

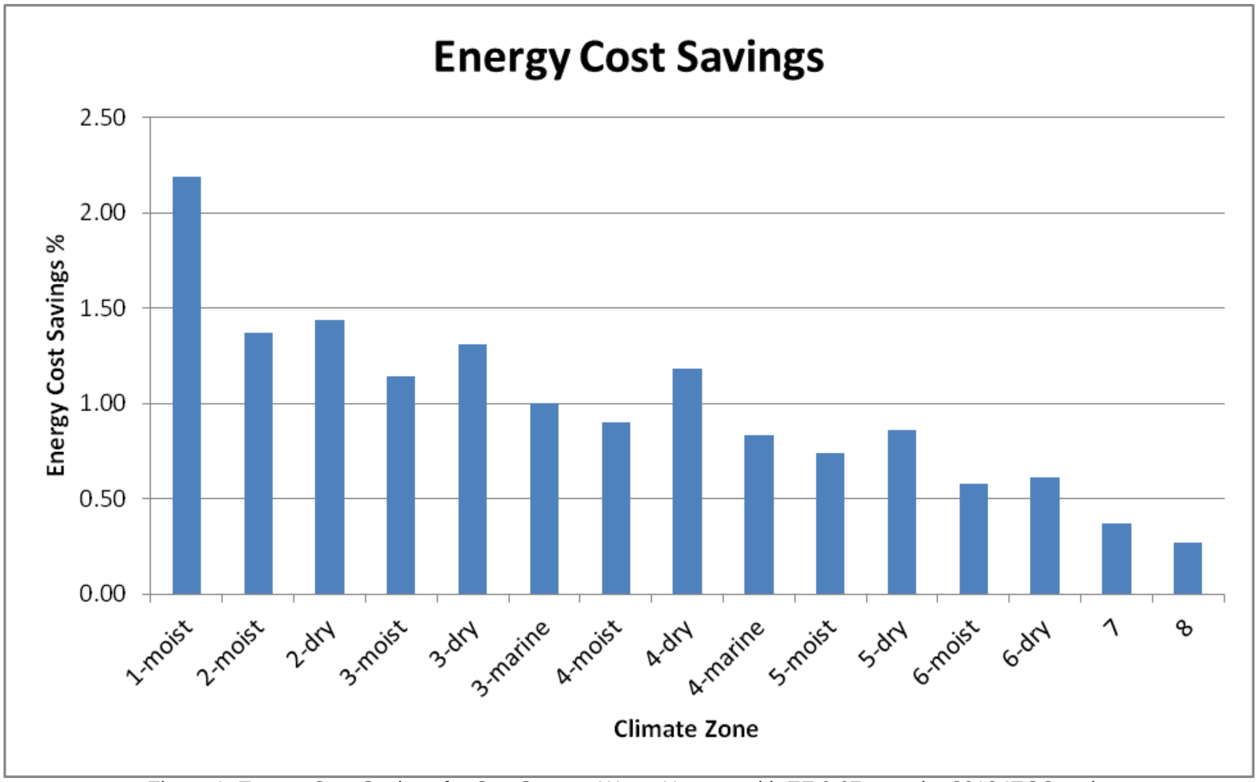

Figure 1: Energy Cost Savings for Gas Storage Water Heaters with EF 0.67 over the 2012 IECC code

[3] http://www1.eere.energy.gov/buildings/appliance_standards/residential/heating_products_fr_tsd.html

[4] http://www1.eere.energy.gov/buildings/appliance_standards/residential/heating_products_fr_spreadsheets.html

Tankless Water Heaters

The most common type of water heaters in residences are storage type. Stand-by losses are associated with storage tank water heaters because hot water draws are inconsistent in homes. This concept looks at tankless type of water heaters, which eliminate the stand-by losses almost entirely. Tankless water heaters have a small storage tank, usually 1 gallon, which has a small associated stand-by loss. Tankless water heaters with an Energy Factor (EF) of 0.82, which is the minimum EF for EnergyStar tankless water heaters[5], are analyzed in this concept.

There is some evidence that instantaneous water heaters don't perform at their rated efficiency when subjected to realistic hot water draw profiles, i.e., shorter draws that occur frequently during a typical day in residences. To account for this reduction in performance, the assumed EF of instantaneous water heaters is reduced to 92% of its value[6].

Energy Cost Savings

Figure 2 below shows energy cost savings for each climate zone.

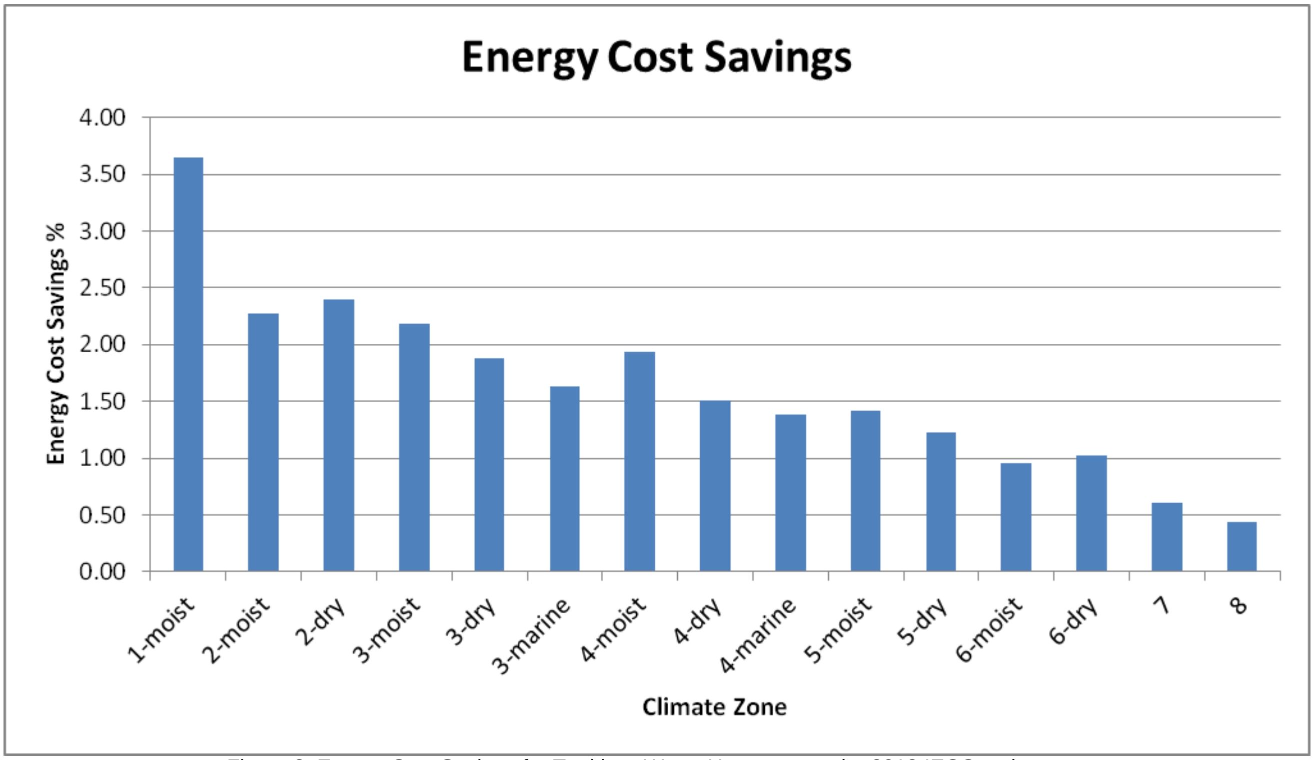

Figure 2: Energy Cost Savings for Tankless Water Heaters over the 2012 IECC code

Cost Effectiveness

The costs for gas fired instantaneous water heaters are derived from the Technical Support document and Life Cycle Cost (LCC) spreadsheets for the Appliance Standards rule-making for water heaters. These costs are blended for retrofits and new construction. To generate costs specific to new construction alone, the Crystal Ball (CB) analysis was re-run with the fractions set to 100% new construction and 0% retrofits.

The total installed cost for a 40 gallon gas storage water heater with EF 0.62 works out to $1609 while the total installed cost for a gas fired instantaneous water heater with EF 0.82 works out to $2376. Figure 3 below shows the Life Cycle Cost for this measure across all climate zones. Tankless water heaters turn out to be cost effective in the warmer climate zones but not so much as we move to the colder climate zones.

[5] EnergyStar website http://www.energystar.gov/index.cfm?c=water_heat.pr_crit_water_heaters
[6] RESNET reduction factor for the EF of instantaneous water heaters

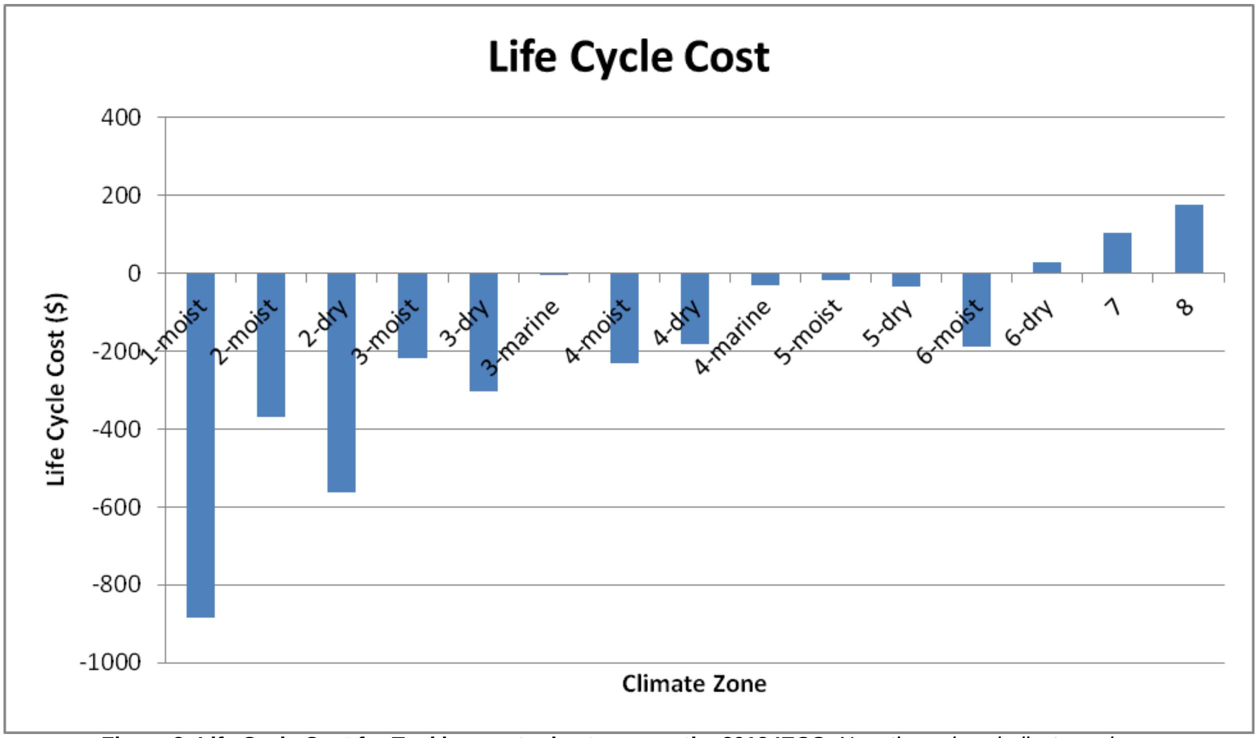

Figure 3: Life Cycle Cost for Tankless water heaters over the 2012 IECC. *Negative values indicate savings*.

Heat-Pump Water Heaters

Heat-Pump water heaters (HPWH) combine the elements of a heat-pump and a water heater. HPWHs extract heat from the surrounding space and use it to heat water. As a result, they provide the dual benefit of cooling a space while providing the required hot water. DOE considered a HPWH with EF 2.0 for this concept.

The HPWH is assumed to be located inside the conditioned living space. Water heaters are usually placed in unconditioned garages or in closets inside a conditioned space. In order to perform effectively, HPWHs require sufficient surrounding space for heat exchange which may not always be available within a conditioned space. Due to the nature of HPWHs, they perform much better within conditioned spaces in cooling dominated climates. HPWHs are simulated in all climate zones in this analysis.

Energy Cost Savings

Figure 4 below shows energy cost savings for each climate zone.

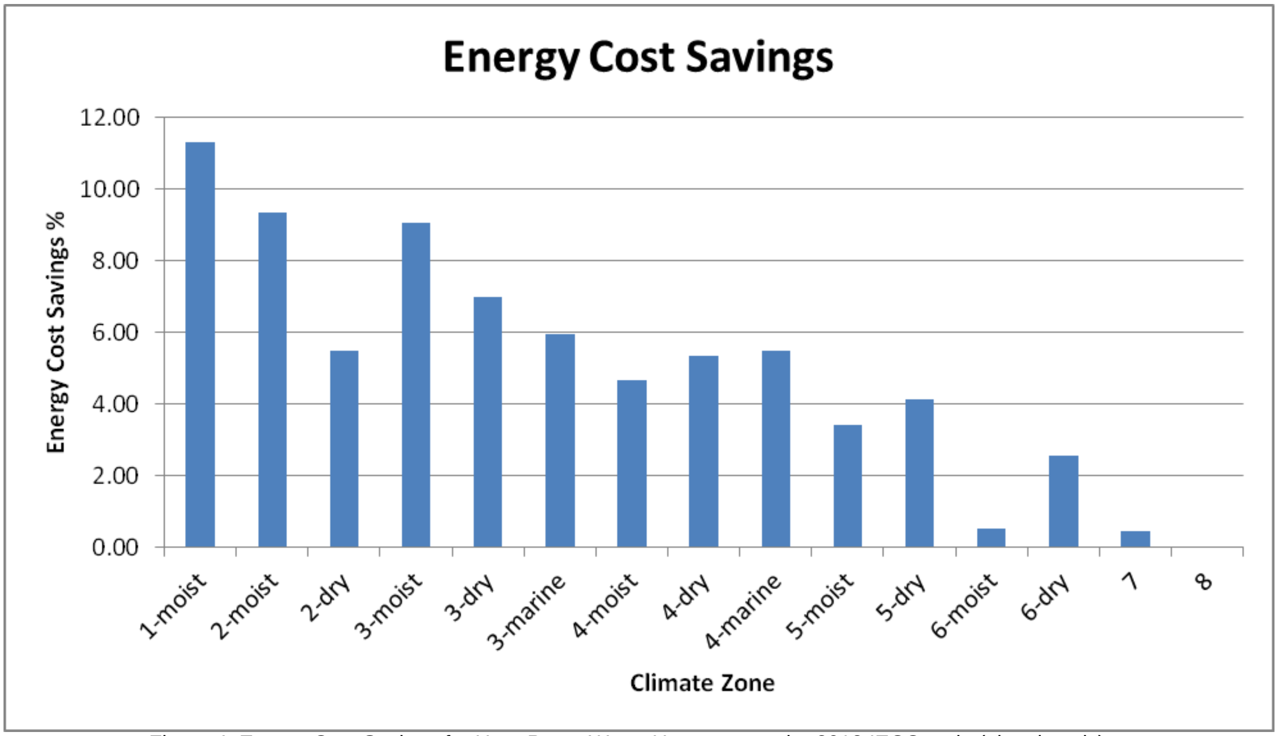

Figure 4: Energy Cost Savings for Heat-Pump Water Heaters over the 2012 IECC code (electric only)

Cost Effectiveness

The cost for high efficiency water heaters were derived from the Technical Support document and Life Cycle Cost (LCC) spreadsheets for the Appliance Standards rule-making for water heaters. These costs are blended for retrofits and new construction. To generate costs specific to new construction alone, the Crystal Ball (CB) analysis was re-run with the fractions set to 100% new construction and 0% retrofits.

According to this data, the installed cost of 40 gallon Electric Storage Water Heaters with EF 0.95 is $688 and that of an EF 2.35 Heat Pump Water Heater is $1697. State cost multipliers from table 2 are used to generate incremental costs by state. Figure 5 below shows the Life Cycle Cost Savings from this measure. According to our analysis, Heat-Pump water heaters in place of electric storage water heaters are cost effective in all zones.

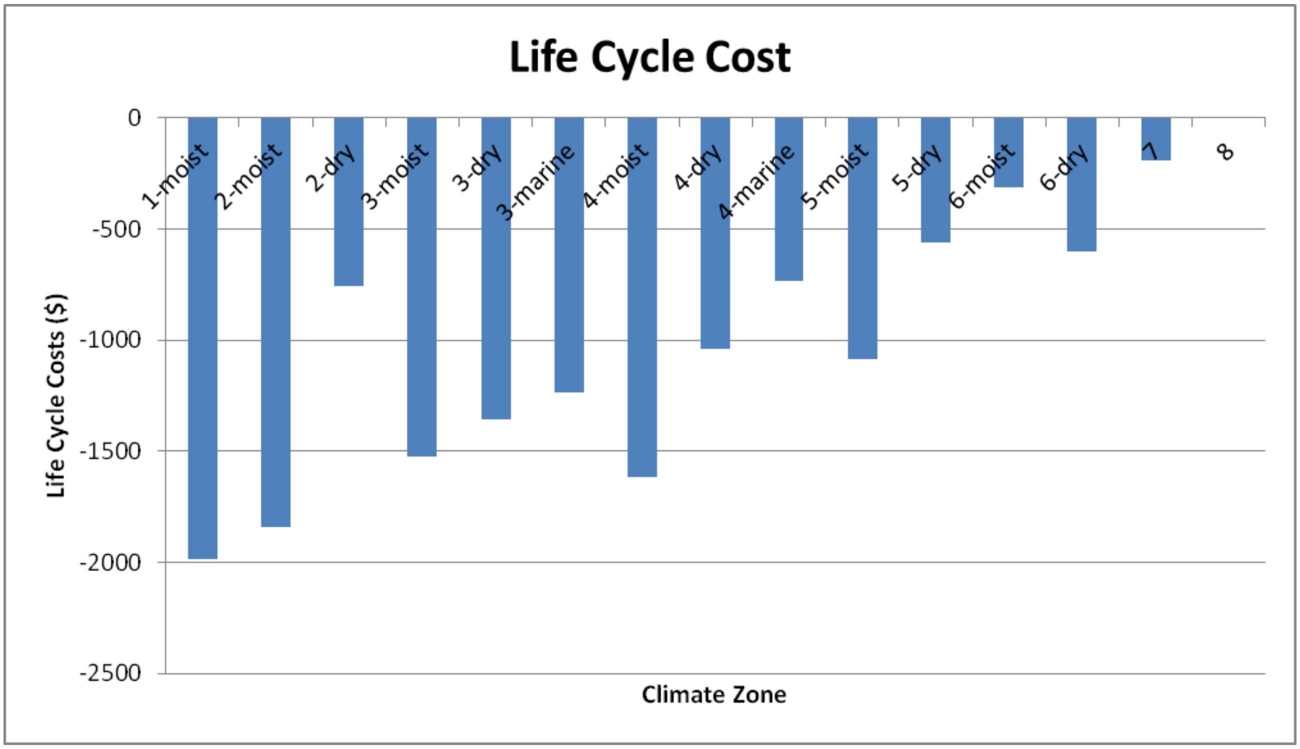

Figure 5: Life Cycle Cost for the concept over the 2012 IECC. *Negative values indicate savings*.

Desuperheaters

During summer operation, the heat removed from the refrigerant would normally be rejected to the atmosphere. Using this heat in the hot water system, therefore, results in significant energy savings because hot water heating is performed at a reduced energy input (greatly reduced in some cases). Heat supplied to the water during winter operation (in the heating season) is not "free" as in the cooling mode, because that heat would normally be used to satisfy space heating demands. However, energy savings are possible because the water heating takes place at an advantageous coefficient of performance (COP).

Energy Cost Savings

Figure 6 below shows energy cost savings for each climate zone. Desuperheaters are most effective for cooling dominated climate zones as it operates only when the air conditioner is running. Hence the expected the energy savings are much higher for CZ 1-3, with decreasing savings for the colder climate zones.

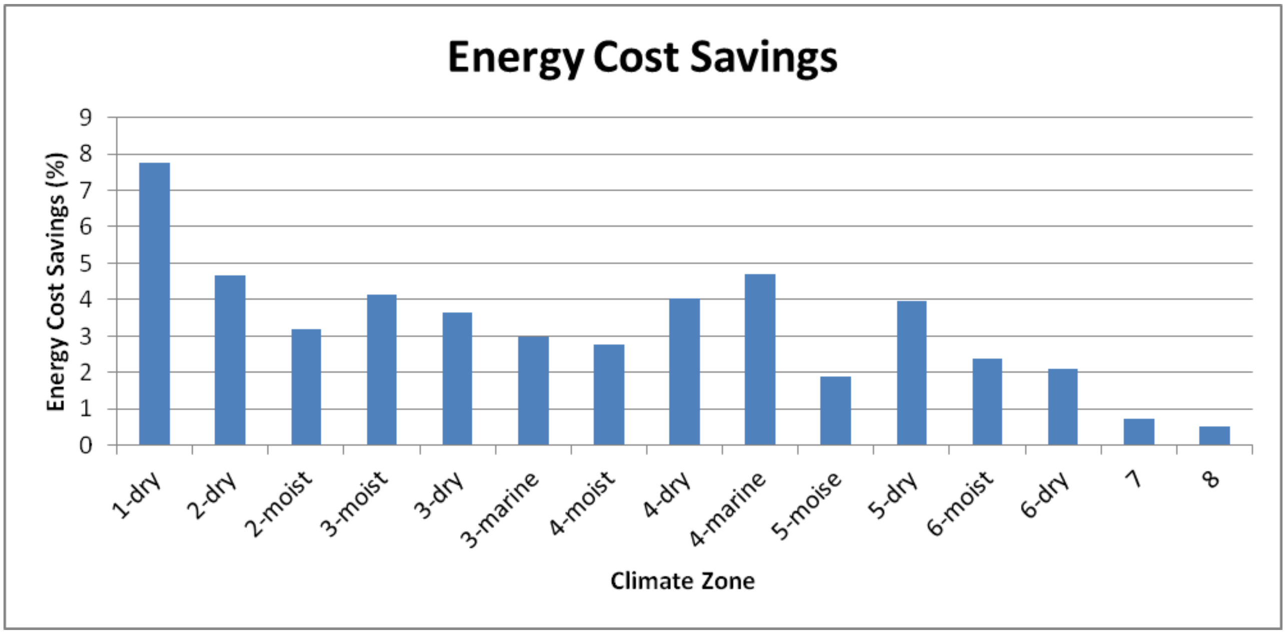

Figure 6: Energy Cost Savings over the 2012 IECC code for Desuperheaters

Cost Effectiveness

Data available online documents the cost of equipment at $500 with installation costs ranging from $500-$1000.[7] [8] An incremental cost of $1250 has been assumed for both equipment and installation.

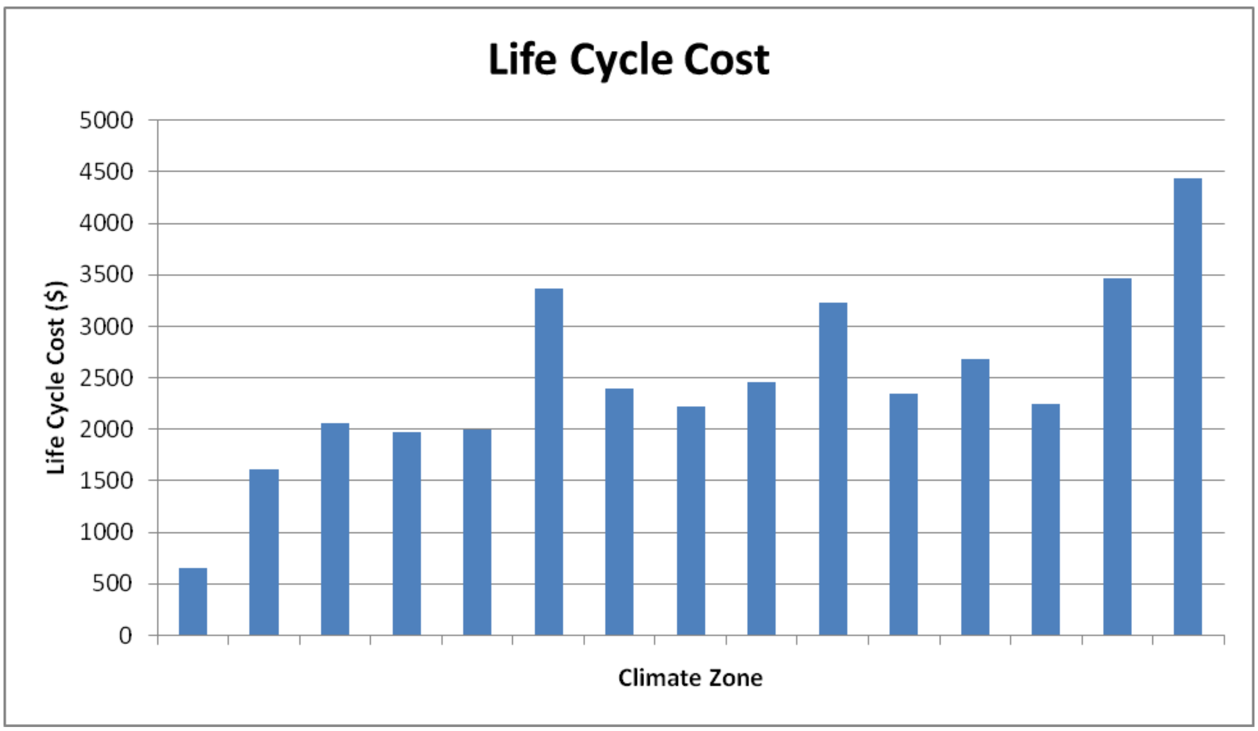

Figure 7: Life Cycle Costs over the 2012 IECC code for Desuperheaters

[7] http://bc3.pnnl.gov/wiki/index.php/Desuperheaters_(0004)
[8] NW Council Cots on Desuperheaters. August 2008, Regional Technical Forum.

Cost Impact: The code change proposal will increase the cost of construction.

Analysis: A review of the standards proposed for inclusion in the code, AHRI 470 with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 1 2013.

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: This code change would inappropriately limit products that can be used for service water heating. This would stifle innovation.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Meg Waltner, Natural Resources Defense Council (NRDC) representing the Natural Resources Defense Council (NRDC) (dgoldstein@nrdc.org) requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

R403.4.1 (N1103.4.1) Water heating equipment (Prescriptive). This section shall apply only to buildings in climate zones 1 through 5. ~~*Service water heating* equipment shall be of one or more of the types in the following list.~~ The entire hot water demand for a building shall be provided by one or more National Appliance Energy Conservation Act-compliant water heaters assisted by a *desuperheater water heater* listed and labeled to AHRI 470 or assisted by a solar water heating system having a solar system heating fraction of not less than 0.50 or greater.

Where ~~replacement of~~ any equipment portion of an existing *service water heating* ~~equipment~~ system is ~~required~~ replaced and the replacement equipment ~~is of the same type as the existing~~ utilizes the same fuel type as the replaced equipment, the replacement equipment shall ~~be~~ have an efficiency that is the same or ~~better~~ greater than the ~~existing~~ equipment replaced. Where any equipment portion of an existing ~~equipment is replaced with another type of~~ *service water heating* system is replaced with ~~the~~ equipment utilizing a different fuel type, the end result shall be that the entire hot water demand for the building shall be ~~of one or more of the types in the following list~~ provided by one or more National Appliance Energy Conservation Act-compliant water heaters assisted by a *desuperheater water heater* listed and labeled to AHRI 470 or assisted by a solar water heating system having a solar system heating fraction of not less than 0.50 or greater.

A hot water storage tank shall be provided for solar water heating systems except where the solar water heating system can utilize the storage tank of another type of water heater in the *service water heating* system.

> **Exception:** The requirement for National Appliance Energy Conservation Act-compliant water heaters assisted by a desuperheater water heater or assisted by a solar water heating system to shall not apply where the entire hot water demand for a building is provided by one or more of the following:
>
> ~~1. a *desuperheater water heater* listed and labeled to AHRI 470~~
> ~~2.~~ 1. ~~a heat pump water heater~~ a heat pump water heater with an energy factor, EF, of 2.0 or greater
> ~~3.~~ 2. a solar water heating system having a solar system heating fraction of ~~0.50~~ 1.0 ~~or greater~~
> ~~4.~~ 3. an instantaneous water heater
> ~~5.~~ 4. a fuel-gas fired storage water heater with energy factor, EF, of 0.67 or greater

Commenter's Reason: This modification revises the proposal to clearly state that the primary requirement is for the installation of any NAECA compliant water heater in combination with one of two measures that will enhance energy savings: a desuperheater water heater or a solar hot water heater. This will allow for and encourage innovation both by allowing for the installation of any water heater type and by encouraging the development and use of two technologies in combination with a water heater that increase energy savings. It also provides for exceptions to this primary option if other, higher efficiency, water heating options are installed.

As it is difficult to read through strike-out and underlined text, the resultant code text will be as follows:

R403.4.1 (N1103.4.1) Water heating equipment (Prescriptive). This section shall apply only to buildings in climate zones 1 through 5. The entire hot water demand for a building shall be provided by one or more National Appliance Energy Conservation Act-compliant water heaters assisted by a *desuperheater water heater* listed and labeled to AHRI 470 or assisted by a solar water heating system having a solar system heating fraction of not less than 0.50.

Where any equipment portion of an existing *service water heating* system is replaced and the replacement equipment utilizes the same fuel type as the existing equipment, the replacement equipment shall have an efficiency that is the same or greater than the equipment replaced. Where any equipment portion of an existing *service water heating* system is replaced with equipment utilizing a different fuel type, the end result shall be that the entire hot water demand for the building shall be provided by one or more National Appliance Energy Conservation Act-compliant water heaters assisted by a *desuperheater water heater* listed and labeled to AHRI 470 or assisted by a solar water heating system having a solar system heating fraction of not less than 0.50.

A hot water storage tank shall be provided for solar water heating systems except where the solar water heating system can utilize the storage tank of another type of water heater in the *service water heating* system.

Exception: National Appliance Energy Conservation Act-compliant water heaters shall not be required to be assisted by a desuperheater water heater or assisted by a solar water heating system where the entire hot water demand for a building is provided by one or more of the following:

1. a heat pump water heater with an energy factor, EF, of 2.0 or greater
2. a solar water heating system having a solar system heating fraction of 1.0
3. an instantaneous water heater
4. a fuel-gas fired storage water heater with energy factor, EF, of 0.67 or greater

Proposed Change as Submitted

Proponent: Gary Klein, Affiliated International Management, LLC Gary Klein (Gary@aim4sustainability.com)

THIS IS A 3 PART CODE CHANGE. PARTS I AND II WILL BE HEARD BY THE IECC RESIDENTIAL ENERGY CONSERVATION CODE DEVELOPMENT COMMITTEE AS 2 SEPARATE CODE CHANGES. PART III WILL BE HEARD BY THE IRC-PM COMMITTEE. SEE THE TENTATIVE HEARING ORDERS FOR THESE COMMITTEES.

PART II-IPC

Revise as follows:

[E] 607.2.1 ~~Hot~~ Heated water circulation and temperature maintenance systems ~~controls~~. For other than Group R2, R3 and R4 occupancies that are 3 stories or less in height above grade plane, automatic circulating hot water system pumps or heat trace shall be arranged to be conveniently turned off, automatically or manually, when the hot water system is not in operation. Heated water circulation and temperature maintenance systems for Group R2, R3 and R4 occupancies that are 3 stories or less in height above grade plane shall be in accordance with Section 607.2.1.1.

[E] 607.2.1.1 Group R2, R3 and R4 occupancies 3 stories or less. This section shall apply to Group R2, R3 and R4 occupancies that are 3 stories or less in height above grade plane. Heated water circulation systems shall be in accordance with Section 607.2.1.1.1. Heat trace temperature maintenance systems shall be in accordance with Section 607.2.1.1.2. *Access* to automatic controls, temperature sensors and pumps shall be provided. *Ready access* to manual controls shall be provided.

[E] 607.2.1.1.1 Circulation systems. Heated water circulation systems shall be provided with a circulation pump. The system return pipe shall be a dedicated return pipe or a cold water supply pipe. Gravity and thermo-syphon circulation systems shall be prohibited. Circulation system pump controls shall be demand activated. The controls shall start the pump upon sensing the presence of a user of a fixture or appliance, receiving a signal from the action of an action of a user of a fixture or appliance or sensing the flow of heated water to a fixture or appliance. The controls shall limit the water temperature increase in the return water piping to not more than 10ºF (5.6 ºC) greater than the initial temperature of the water in the return piping and shall limit the return water temperature to 102ºF (38.9ºC).

[E] 607.2.1.1.2 Heat trace systems. Electric heat trace systems shall comply with IEEE 515.1. Controls for such systems shall be able to automatically adjust the energy input to the heat tracing to maintain the desired water temperature in the piping in accordance with the times when heated water is used in the occupancy.

Add standards to Chapter 14 as follows:

The Institute of Electrical and Electronic Engineers, Inc.
3 Park Avenue

New York, NY 1016-5997

IEEE

515.1-2012 IEEE Standard for the Testing, Design, Installation, and Maintenance of Electrical Resistance Trace Heating for Commercial Applications

Reason: There are 2 primary reasons for this proposed change. 1) Correlate the language in the IECC, the IRC and the IPC; 2) Clarify the requirements for heated water circulation systems and for heat trace systems, if they are installed. The proposed changes do not require the use of circulation or heat trace.

The current code language is not the same in the IECC and the IPC. It should be. It should also be the same in the IRC since the heated water systems do not know what occupancy they are in.

The current language allows for continuously operating circulation pumps, which creates inefficiency in the hot water distribution system. It also does not address the use of heat trace in both codes and there is currently no requirement that the heat trace be suitable for the application. The consequence is that water heating energy consumption is increased.

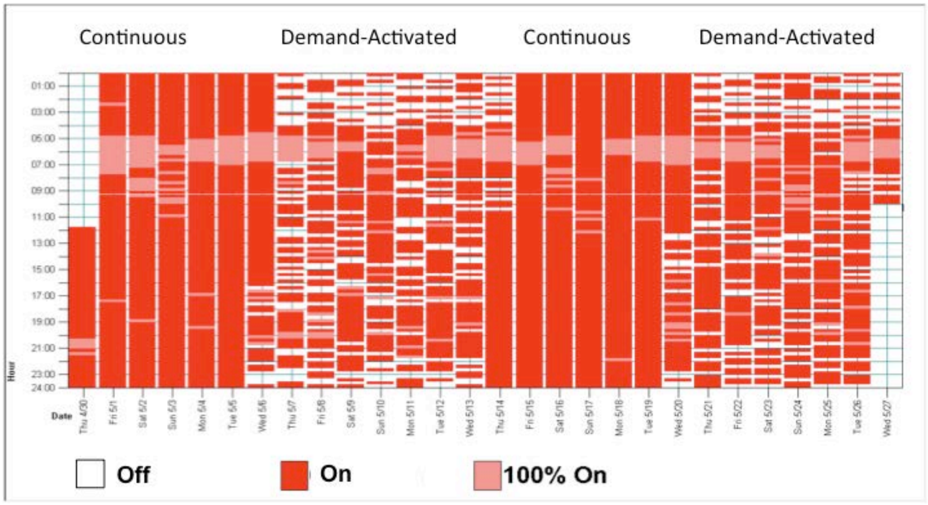
Figure 1 shows that demand activated circulation is significantly more energy efficient than any other type of heated water circulation system. The annual energy needed to keep the loop hot with water heated electrically or with natural gas are shown separately from the energy needed for the pump. The majority of the energy is lost in keeping the water in the loop at the desired temperature (all of it if there is a gravity loop). A small loop, 100 feet including the supply and the return was analyzed. The savings ranges from 87.5 percent when compared to a recirculation system that runs only 2-hours per day to 99 percent when compared to a recirculation system that runs only 24-hours per day. The operating costs and savings remain proportional as the length of the circulation loop and the flow rate of the pump increase.

Figure 1 Annual Energy Requirements for Demand Activated Circulation and Standard Recirculation

	Standard Recirculation						**Demand Activated Circulation**
	Daily Hours of Operation						
	24	12	8	6	4	2	0.25
Loop Heat Losses							
Natural Gas (therms)	292	146	97	73	49	24	3
Electric (kWh)	6,388	3,194	2,129	1,597	1,065	532	67
Pump Energy (kWh)	438	219	146	110	73	37	8

Figure 2 shows the differences in run-time at the water heater (or boiler) between a continuously pumped recirculation loop and one that has a demand activated pump control. Blank space (white) means the water heater was off. Red means some percent of run-time between zero and continuous. Pink means the water heater or boiler was running continuously. The test results come from studies done by Southern California Gas Company on a sample of more than 300 multi-family buildings with central water heaters and recirculation systems. Most systems tested were built before insulation was required on hot water recirculation loops. Savings ranged from 10-30 percent of the water heating energy use and 84 percent of the pump electricity use. The costs for installing the retrofit were paid back in just about one year. In new construction, the marginal costs would be recovered in just a few months

Figure 2 Run-time of Water Heater with Two Different Pump Controls



Why is demand-activated circulation such an efficient strategy? The 2012 IECC, IPC and IRC require that the hot water piping in automatic temperature maintenance systems in new buildings be insulated with pipe insulation. This means the water in the circulation loop will stay hot for a very long time – up to 45 minutes for ¾ inch nominal pipe up to 2 hours for 2-inch nominal pipe – even if the circulating pump is shut off. If this is the case, why run the pump when the water is still hot? Why run the pump when no one is in the building or when no one is demanding hot water? The only time it makes sense to run the pump is shortly before hot water is needed: hence the requirement that the pump be controlled on-demand.

The requirements for heat trace are partly to ensure that the systems can be operated in the most energy efficient manner consistent with providing heated water to the occupancy. The reference standards are included to ensure that installed systems are safe for the intended application. The energy consequences of using heat trace are very reasonable. Figure 3 presents the energy requirements for a heat trace system with the same hot water supply piping as the circulation systems shown in Figure 1. The energy requirements of keeping the trunk line hot – the same as keeping the supply portion of the loop hot in a circulating system – are 701 kWh per year, assuming 12 hours at high temp (115F) and 12 hours at economy temp (105F). This is equivalent to operating the loop about 3 hours per day, but with hot water available 24/7 in the supply trunk! This is a significant savings when water heating is done electrically or with a similarly expensive fuel. If the branches are also traced, we can deliver heated water even more quickly to the fixtures using only 1,682 kWh per year, which is the same energy as running the loop a little more than 6 hours a day.

Figure 3. Annual Energy Needed for Electric Heat Trace Systems

Heat Trace			
	(kWh per year)		
	Trunk	**Br**	**T-Br**
Supply Heat Losses			
High Temp	394	552	946
Economy Temp	307	429	736
Total Electricity	701	981	1,682

Cost impact: The proposal does not require either circulation or heat trace; however if either is selected, it clarifies the requirements for installation. Most recirculation systems today are installed with some form of control, usually a timer, a bandwidth thermostat (aquastat) or both. Some come with more sophisticated controls, such as programmable or are connected to an energy management system. In some cases, switching from these control strategies to demand activated controls will cost less. In other cases, the demand-activated controls will cost more.

Analysis: A review of the standards proposed for inclusion in the code, UL 515 and CSA 22.2 No 130-03 with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 1, 2013.

Committee Action Hearing Results

PART II – IPC

Committee Action: **Approved as Modified**

Modify the proposal as follows:

[E] 607.2.1.1.1 Circulation systems. Heated water circulation systems shall be provided with a circulation pump. The system return pipe shall be a dedicated return pipe or a cold water supply pipe. Gravity and thermo-syphon circulation systems shall be prohibited. ~~Circulation system pump controls shall be demand activated. The controls shall start the pump upon sensing the presence of a user of a fixture or appliance, receiving a signal from the action of an action of a user of a fixture or appliance or sensing the flow of heated water to a fixture or appliance. The controls shall limit the water temperature increase in the return water piping to not more than 10ºF (5.6 ºC) greater than the initial temperature of the water in the return piping and shall limit the return water temperature to 102ºF (38.9ºC).~~ Controls for circulating hot water system pumps shall start the pump based on the identification of a demand for hot water within the occupancy. The controls shall automatically turn off the pump when the water in the circulation loop is at the desired temperature and when there is no demand for hot water.

[E] 607.2.1.1.2 Heat trace systems. Electric heat trace systems shall comply with IEEE 515.1 or UL 515. Controls for such systems shall be able to automatically adjust the energy input to the heat tracing to maintain the desired water temperature in the piping in accordance with the times when heated water is used in the occupancy.

Add standard to Chapter 14 as follows:

UL

515-2011 Electrical Resistance Heat Tracing for Commercial and Industrial Applications including revisions through November 30, 2011

Committee Reason: The originally proposed control technology was too specific. The modified wording allows for different types of control technology. The UL 515 standard was added because most manufacturers are certifying heat trace products to the UL standard. The overall proposal was approved because the committee generally agreed that it costs too much to operate a circulation system all the time.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Gary Klein, Affiliated International Management, LLC, representing self, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

[E] 607.2.1 Heated water circulation and heat trace ~~temperature maintenance~~ systems. For ~~other than~~ Group R2, R3 and R4 occupancies that are 3 stories or less in height above grade plane, ~~automatic circulating hot water system pumps or heat trace shall be arranged to be conveniently turned off, automatically or manually, when the hot water system is not in operation.~~ heated water circulation and heat trace systems shall be installed in accordance with Section R403.4.1 of the *International Energy Conservation Code*. For other than Group R2, R3 and R4 occupancies that are 3 stories or less in height above grade plane, heated water circulation and heat trace ~~temperature maintenance~~ systems ~~for Group R2, R3 and R4 occupancies that are 3 stories or less in height above grade plane~~ shall be installed in accordance with ~~Section 607.2.1.1.~~ Section C404.5 of the *International Energy Conservation Code*. ~~circulating hot water systems shall be arranged to be provided with a manual switch having ready access, or an automatic switch, that can turn off the hot water circulating pump when the system is not in use. Heated water circulation and temperature maintenance systems for other than Group R2, R3 and R4 occupancies that are 3 stories or less in height above grade plane shall be in accordance with Section 607.2.1.1.~~

~~**[E] 607.2.1.1 For other than Group R2, R3 and R4 occupancies 3 stories or less**. This section shall apply to other than Group R2, R3 and R4 occupancies that are 3 stories or less in height above grade plane. Heated water circulation systems shall be in accordance with Section 607.2.1.1.1. Heat trace temperature maintenance systems shall be in accordance with Section 607.2.1.1.2. *Access* to automatic controls, temperature sensors and pumps shall be provided. *Ready access* to manual controls shall be provided.~~

~~**[E] 607.2.1.1.1 Circulation systems**. Heated water circulation systems shall be provided with a circulation pump. The system return pipe shall be a dedicated return pipe or a cold water supply pipe. Gravity and thermo-syphon circulation systems shall be prohibited. Controls for circulating hot water system pumps shall start the pump based on the identification of a demand for hot water within the occupancy. The controls shall automatically turn off the pump when the water in the circulation loop is at the desired temperature and when there is no demand for hot water.~~

~~**[E] 607.2.1.1.2 Heat trace systems.**~~ ~~Electric heat trace systems shall comply with IEEE 515.1 or UL 515. Controls for such systems shall be able to automatically adjust the energy input to the heat tracing to maintain the desired water temperature in the piping in accordance with the times when heated water is used in the occupancy.~~

~~**Add standard to Chapter 14 as follows:**~~

~~**IEEE**~~
~~515.1 2012 IEEE Standard for the Testing, Design, Installation, and Maintenance of Electrical Resistance Trace Heating for Commercial Applications~~

~~**UL**~~

~~515-2011~~ ~~Electrical Resistance Heat Tracing for Commercial and Industrial Applications including revisions through November 30, 2011~~

Commenter's Reason: The purpose of this proposal is to clarify the requirements for heated water circulation systems and for heat trace systems, <u>if they are installed</u>. The proposed changes do not require the use of circulation or heat trace.

The reason for this code change is to correlate the language in the IECC with that in the IPC. The floor modifications heard by the Committee were correct as far they went. However, on further review, parts of the original proposal that were not modified are complicated and undermine the intent of the modifications that were approved.

The requirements for efficient heated water circulation and electrical heat trace systems belong in the IECC. However, it is important for those implementing the IPC to know what is required of them when installing these systems. These systems affect the design and layout of the overall domestic piping supply, and need to carry a reference to avoid lapses in coordination with other requirements of the system controls.

In order to decrease the possibility of conflicting language appearing in the two documents, it makes sense to have the provisions in the IECC and the pointer in the IPC. This greatly simplifies the code language.

Supporting this modification will correlate the language in the IPC with that in the IECC.

I urge your support.

Proposed Change as Submitted

Proponent: Gary Klein, Affiliated International Management, LLC Gary Klein (Gary@aim4sustainability.com)

THIS IS A 3 PART CODE CHANGE. PARTS I AND II WILL BE HEARD BY THE IECC RESIDENTIAL ENERGY CONSERVATION CODE DEVELOPMENT COMMITTEE AS 2 SEPARATE CODE CHANGES. PART III WILL BE HEARD BY THE IRC-PM COMMITTEE. SEE THE TENTATIVE HEARING ORDERS FOR THESE COMMITTEES.

PART III-IRC

Add new text as follows:

SECTION P2905
HEATED WATER DISTRIBUTION SYSTEMS

P2905.1 Heated water systems. Heated water circulation and temperature maintenance systems shall be in accordance with Section N1103.4.1.

Reason: There are 2 primary reasons for this proposed change. 1) Correlate the language in the IECC, the IRC and the IPC; 2) Clarify the requirements for heated water circulation systems and for heat trace systems, if they are installed. The proposed changes do not require the use of circulation or heat trace.

The current code language is not the same in the IECC and the IPC. It should be. It should also be the same in the IRC since the heated water systems do not know what occupancy they are in.

The current language allows for continuously operating circulation pumps, which creates inefficiency in the hot water distribution system. It also does not address the use of heat trace in both codes and there is currently no requirement that the heat trace be suitable for the application. The consequence is that water heating energy consumption is increased.

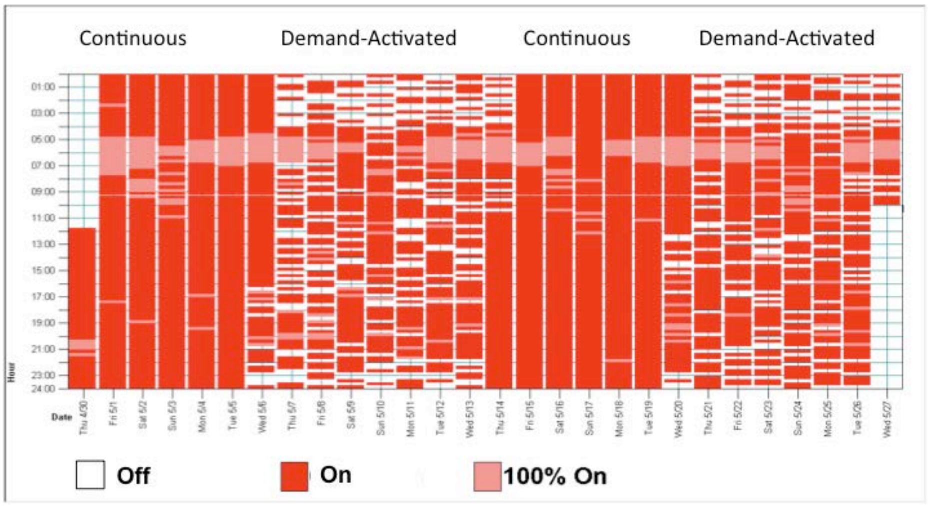
Figure 1 shows that demand activated circulation is significantly more energy efficient than any other type of heated water circulation system. The annual energy needed to keep the loop hot with water heated electrically or with natural gas are shown separately from the energy needed for the pump. The majority of the energy is lost in keeping the water in the loop at the desired temperature (all of it if there is a gravity loop). A small loop, 100 feet including the supply and the return was analyzed. The savings ranges from 87.5 percent when compared to a recirculation system that runs only 2-hours per day to 99 percent when compared to a recirculation system that runs only 24-hours per day. The operating costs and savings remain proportional as the length of the circulation loop and the flow rate of the pump increase.

Figure 1 Annual Energy Requirements for Demand Activated Circulation and Standard Recirculation

	Standard Recirculation						**Demand Activated Circulation**
	Daily Hours of Operation						
	24	12	8	6	4	2	0.25
Loop Heat Losses							
Natural Gas (therms)	292	146	97	73	49	24	3
Electric (kWh)	6,388	3,194	2,129	1,597	1,065	532	67
Pump Energy (kWh)	438	219	146	110	73	37	8

Figure 2 shows the differences in run-time at the water heater (or boiler) between a continuously pumped recirculation loop and one that has a demand activated pump control. Blank space (white) means the water heater was off. Red means some percent of run-time between zero and continuous. Pink means the water heater or boiler was running continuously. The test results come from studies done by Southern California Gas Company on a sample of more than 300 multi-family buildings with central water heaters and recirculation systems. Most systems tested were built before insulation was required on hot water recirculation loops. Savings ranged from 10-30 percent of the water heating energy use and 84 percent of the pump electricity use. The costs for installing the retrofit were paid back in just about one year. In new construction, the marginal costs would be recovered in just a few months

Figure 2 Run-time of Water Heater with Two Different Pump Controls



Why is demand-activated circulation such an efficient strategy? The 2012 IECC, IPC and IRC require that the hot water piping in automatic temperature maintenance systems in new buildings be insulated with pipe insulation. This means the water in the circulation loop will stay hot for a very long time – up to 45 minutes for ¾ inch nominal pipe up to 2 hours for 2-inch nominal pipe – even if the circulating pump is shut off. If this is the case, why run the pump when the water is still hot? Why run the pump when no one is in the building or when no one is demanding hot water? The only time it makes sense to run the pump is shortly before hot water is needed: hence the requirement that the pump be controlled on-demand.

The requirements for heat trace are partly to ensure that the systems can be operated in the most energy efficient manner consistent with providing heated water to the occupancy. The reference standards are included to ensure that installed systems are safe for the intended application. The energy consequences of using heat trace are very reasonable. Figure 3 presents the energy requirements for a heat trace system with the same hot water supply piping as the circulation systems shown in Figure 1. The energy requirements of keeping the trunk line hot – the same as keeping the supply portion of the loop hot in a circulating system – are 701 kWh per year, assuming 12 hours at high temp (115F) and 12 hours at economy temp (105F). This is equivalent to operating the loop about 3 hours per day, but with hot water available 24/7 in the supply trunk! This is a significant savings when water heating is done electrically or with a similarly expensive fuel. If the branches are also traced, we can deliver heated water even more quickly to the fixtures using only 1,682 kWh per year, which is the same energy as running the loop a little more than 6 hours a day.

Figure 3. Annual Energy Needed for Electric Heat Trace Systems

Heat Trace			
	(kWh per year)		
	Trunk	**Br**	**T-Br**
Supply Heat Losses			
High Temp	394	552	946
Economy Temp	307	429	736
Total Electricity	701	981	1,682

Cost impact: The proposal does not require either circulation or heat trace; however if either is selected, it clarifies the requirements for installation. Most recirculation systems today are installed with some form of control, usually a timer, a bandwidth thermostat (aquastat) or both. Some come with more sophisticated controls, such as programmable or are connected to an energy management system. In some cases, switching from these control strategies to demand activated controls will cost less. In other cases, the demand-activated controls will cost more.

Analysis: A review of the standards proposed for inclusion in the code, UL 515 and CSA 22.2 No 130-03 with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 1, 2013.

R403.4.1 #2-EC-KLEIN

Committee Action Hearing Results

For staff analysis of the content of IEEE 515.1-2012 relative to CP#28, Section 3.6, please visit:

PART III – IRC-Plumbing

Committee Action: **Disapproved**

Committee Reason: There is no need to have a pointer in the plumbing chapters to direct the reader to another chapter of the IRC. There could be no end to the amount of pointers we could put into the IRC.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Gary Klein, Affiliated International Management, LLC, representing self requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

P2905.1 Heated water <u>circulation systems and heat trace</u> systems. ~~Heated water circulation and temperature maintenance systems shall be in accordance with Section N1103.4.1.~~ <u>Circulation systems and heat trace systems, that are installed to bring heated water in close proximity to one or more fixtures, shall meet the requirements of Section N1103.4.1.</u>

Commenter's Reason: The Committee disapproved the code change because they felt there was no need for a pointer to another section in the IRC.

These systems affect the design and layout of the overall water distribution in a building. Designers and installers need to realize that temperature maintenance systems have requirements that are buried in the energy code chapters of the IRC. Plumbing-oriented users of the IRC have, in the past, simply focused on the plumbing chapters for their work. They rely on many pointers in the plumbing chapters to help remind them pick up plumbing-related items outside those chapters. For example, Sections P2602.2, P2603.2, P2801.3, P2801.7, P2903.8, P3001.2, and P3101.5. Let's help these readers understand how to design and install water temperature maintenance systems correctly the first time instead of embarrassing them at final inspection. This is just a simple pointer, not a code requirement.

The language of this "pointer section" is being reworded because during testimony at the hearing, I heard that some people thought this proposal *required* circulation systems and heat trace systems. No, that was not the intent and is not the intent of this reworded section. All this section is saying is where such systems are installed, do it in accordance with that section in the energy code chapter. The 2012 IRC *does not require* these systems. Perhaps another proposal in this cycle will be approved to require some limit as to how far away a fixture can be from the hot water source, I don't know at this point.

I urge your support of this comment.

THIS IS A 3 PART CODE CHANGE. PARTS I AND II WILL BE HEARD BY THE IECC RESIDENTIAL ENERGY CONSERVATION CODE DEVELOPMENT COMMITTEE AS 2 SEPARATE CODE CHANGES. PART III WILL BE HEARD BY THE IRC-PM COMMITTEE. SEE THE TENTATIVE HEARING ORDERS FOR THESE COMMITTEES.

PART I IECC-RESIDENTIAL PROVISIONS

Revise as follows:

R403.4.1 (IRC N1103.4.1) ~~Circulating~~ ~~hot~~ Heated water circulation and temperature maintenance systems (Mandatory)~~.~~ ~~Circulating hot water systems shall be provided with an automatic or readily *accessible* manual switch that can turn off the hot-water circulating pump when the system is not in use.~~ Heated water circulation systems shall be in accordance with Section R403.4.1.1. Heat trace temperature maintenance systems shall be in accordance with Section R403.4.1.2. Automatic controls, temperature sensors and pumps shall be *accessible*. Manual controls shall be *readily accessible*.

R403.4.1.1 (IRC N1103.4.1.1) Circulation systems. Heated water circulation systems shall be provided with a circulation pump. The system return pipe shall be a dedicated return pipe or a cold water supply pipe. Gravity and thermo-syphon circulation systems shall be prohibited. Circulation system pump controls shall be demand activated. The controls shall start the pump upon sensing the presence of a user of a fixture or appliance, receiving a signal from the action of an action of a user of a fixture or appliance or sensing the flow of heated water to a fixture or appliance. The controls shall limit the water temperature increase in the return water piping to not more than 10ºF (5.6 ºC) greater than the initial temperature of the water in the return piping and shall limit the return water temperature to 102ºF (38.9ºC).

R403.4.1.2 (IRC N1103.4.1.2) Heat trace systems. Electric heat trace systems shall comply with IEEE 515.1. Controls for such systems shall be able to automatically adjust the energy input to the heat tracing to maintain the desired water temperature in the piping in accordance with the times when heated water is used in the occupancy.

Add new standards to Chapter 5 (IRC Chapter 44) as follows:

The Institute of Electrical and Electronic Engineers, Inc.
3 Park Avenue
New York, NY 1016-5997

IEEE

515.1-2012 IEEE Standard for the Testing, Design, Installation, and Maintenance of Electrical Resistance Trace Heating for Commercial Applications

Reason: There are 2 primary reasons for this proposed change. 1) Correlate the language in the IECC, the IRC and the IPC; 2) Clarify the requirements for heated water circulation systems and for heat trace systems, if they are installed. The proposed changes do not require the use of circulation or heat trace.

The current code language is not the same in the IECC and the IPC. It should be. It should also be the same in the IRC since the heated water systems do not know what occupancy they are in.

The current language allows for continuously operating circulation pumps, which creates inefficiency in the hot water distribution system. It also does not address the use of heat trace in both codes and there is currently no requirement that the heat trace be suitable for the application. The consequence is that water heating energy consumption is increased.

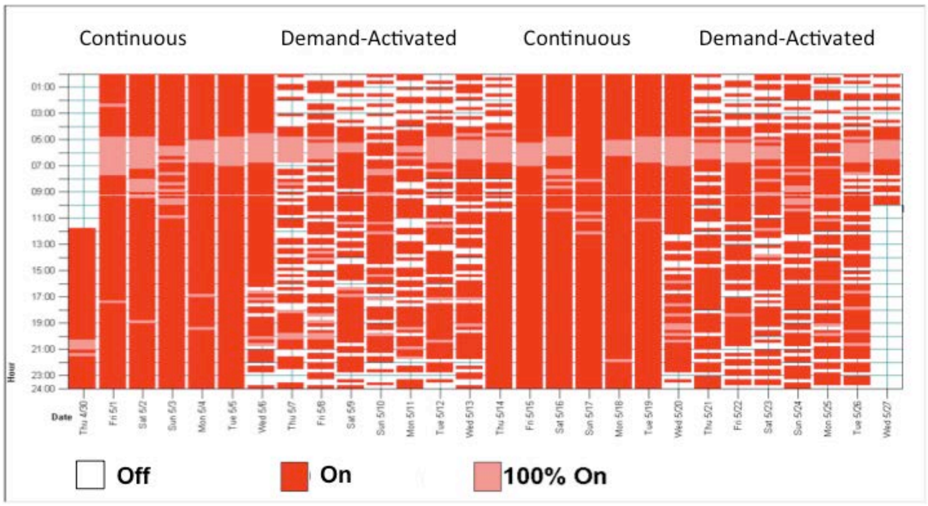
Figure 1 shows that demand activated circulation is significantly more energy efficient than any other type of heated water circulation system. The annual energy needed to keep the loop hot with water heated electrically or with natural gas are shown separately from the energy needed for the pump. The majority of the energy is lost in keeping the water in the loop at the desired temperature (all of it if there is a gravity loop). A small loop, 100 feet including the supply and the return was analyzed. The savings ranges from 87.5 percent when compared to a recirculation system that runs only 2-hours per day to 99 percent when compared to a recirculation system that runs only 24-hours per day. The operating costs and savings remain proportional as the length of the circulation loop and the flow rate of the pump increase.

Figure 1 Annual Energy Requirements for Demand Activated Circulation and Standard Recirculation

	Standard Recirculation						**Demand Activated Circulation**
	Daily Hours of Operation						
	24	12	8	6	4	2	0.25
Loop Heat Losses							
Natural Gas (therms)	292	146	97	73	49	24	3
Electric (kWh)	6,388	3,194	2,129	1,597	1,065	532	67
Pump Energy (kWh)	438	219	146	110	73	37	8

Figure 2 shows the differences in run-time at the water heater (or boiler) between a continuously pumped recirculation loop and one that has a demand activated pump control. Blank space (white) means the water heater was off. Red means some percent of run-time between zero and continuous. Pink means the water heater or boiler was running continuously. The test results come from studies done by Southern California Gas Company on a sample of more than 300 multi-family buildings with central water heaters and recirculation systems. Most systems tested were built before insulation was required on hot water recirculation loops. Savings ranged from 10-30 percent of the water heating energy use and 84 percent of the pump electricity use. The costs for installing the retrofit were paid back in just about one year. In new construction, the marginal costs would be recovered in just a few months

Figure 2 Run-time of Water Heater with Two Different Pump Controls



Why is demand-activated circulation such an efficient strategy? The 2012 IECC, IPC and IRC require that the hot water piping in automatic temperature maintenance systems in new buildings be insulated with pipe insulation. This means the water in the circulation loop will stay hot for a very long time – up to 45 minutes for ¾ inch nominal pipe up to 2 hours for 2-inch nominal pipe – even if the circulating pump is shut off. If this is the case, why run the pump when the water is still hot? Why run the pump when no one is in the building or when no one is demanding hot water? The only time it makes sense to run the pump is shortly before hot water is needed: hence the requirement that the pump be controlled on-demand.

The requirements for heat trace are partly to ensure that the systems can be operated in the most energy efficient manner consistent with providing heated water to the occupancy. The reference standards are included to ensure that installed systems are safe for the intended application. The energy consequences of using heat trace are very reasonable. Figure 3 presents the energy requirements for a heat trace system with the same hot water supply piping as the circulation systems shown in Figure 1. The energy requirements of keeping the trunk line hot – the same as keeping the supply portion of the loop hot in a circulating system – are 701 kWh per year, assuming 12 hours at high temp (115F) and 12 hours at economy temp (105F). This is equivalent to operating the loop about 3 hours per day, but with hot water available 24/7 in the supply trunk! This is a significant savings when water heating is done electrically or with a similarly expensive fuel. If the branches are also traced, we can deliver heated water even more quickly to the fixtures using only 1,682 kWh per year, which is the same energy as running the loop a little more than 6 hours a day.

Figure 3. Annual Energy Needed for Electric Heat Trace Systems

Heat Trace			
	(kWh per year)		
	Trunk	Br	T-Br
Supply Heat Losses			
High Temp	394	552	946
Economy Temp	307	429	736
Total Electricity	701	981	1,682

Cost impact: The proposal does not require either circulation or heat trace; however if either is selected, it clarifies the requirements for installation. Most recirculation systems today are installed with some form of control, usually a timer, a bandwidth thermostat (aquastat) or both. Some come with more sophisticated controls, such as programmable or are connected to an energy management system. In some cases, switching from these control strategies to demand activated controls will cost less. In other cases, the demand-activated controls will cost more.

Analysis: A review of the standards proposed for inclusion in the code, UL 515 and CSA 22.2 No 130-03 with regard to the

ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 1, 2013.

PART I – IECC – Residential

Committee Action: **Approved as Modified**

Modify the proposal as follows:

R403.4.1.1 (IRC N1103.4.1.1) Circulation systems. Heated water circulation systems shall be provided with a circulation pump. The system return pipe shall be a dedicated return pipe or a cold water supply pipe. Gravity and thermo-syphon circulation systems shall be prohibited. ~~Circulation system pump controls shall be demand activated. The controls shall start the pump upon sensing the presence of a user of a fixture or appliance, receiving a signal from the action of an action of a user of a fixture or appliance or sensing the flow of heated water to a fixture or appliance. The controls shall limit the water temperature increase in the return water piping to not more than 10ºF (5.6 ºC) greater than the initial temperature of the water in the return piping and shall limit the return water temperature to 102ºF (38.9ºC).~~ Controls for circulating hot water system pumps shall start the pump based on the identification of a demand for hot water within the occupancy. The controls shall automatically turn off the pump when the water in the circulation loop is at the desired temperature and when there is no demand for hot water.

R403.4.1.2 (IRC N1103.4.1.2) Heat trace systems. Electric heat trace systems shall comply with IEEE 515.1 or UL 515. Controls for such systems shall be able to automatically adjust the energy input to the heat tracing to maintain the desired water temperature in the piping in accordance with the times when heated water is used in the occupancy.

Add standard to Chapter 14 as follows:

UL

515-2011 Electrical Resistance Heat Tracing for Commercial and Industrial Applications including revisions through November 30, 2011

Committee Reason: The originally proposed control technology was too specific. The modified wording allows for different types of control technology. The UL 515 standard was added because most manufacturers are certifying heat trace products to the UL standard. The overall proposal was approved because the committee generally agreed that it costs too much to operate a circulation system all the time.

Assembly Action: **None**

RE126-13
R403.4.1 (IRC N1103.4.1)

Proposed Change as Submitted

Proponent: Eric Makela / Britt/Makela Group, Inc. representing Northwest Energy Codes Group (Eric@BrittMakela.com)

Revise as follows:

R403.4.1 (N1103.4.1) Circulating hot water systems (Mandatory). Circulating hot water systems shall be ~~provided with an automatic or readily *accessible* manual switch that can turn off the hot-water circulating pump when the system is not in use~~ <u>equipped with a control system that controls the recirculation pump operation based on measurement of hot water demand and hot water return temperature.</u>

Reason: The IECC has allowed the use of either manual or automatic controls for turning circulating pumps on and off for hot water recirculating systems. If manual controls are installed, the homeowner is responsible for turning the system on and off when needed. If not turned off, the pump will continue to circulate 120^{o} to 140 ^{o}F water through piping leading to pipe heat loss and also requiring the water heater to run longer to continue to bring the water up to temperature. Installing a time clock on the circulation pump is more dependable if set properly, but still can lead to losses in the piping and additional run time for the water heater with no benefit to the home owner if set to run when the occupants are not in the house. In addition to piping and water heating energy use, electricity to run the pump can also cost a few hundred dollars per year. Constant recirculation of hot water can also degrade piping. A study conducted by the California Energy Commission's Public Interest Energy Research demonstrated that hot water distribution systems lose significant amounts of energy. This is significant considering that water heating uses 31% of energy in a typical house.

Demand control is the best automatic control option and superior to both manual off and time clock controls. The design features will prevent the pump motor burning out due to an air pocket, which is a common failure. The demand controlled recirculation system matches the user's demand to the delivery of hot water. The user gets the hot water quickly when they want it. On demand pumps for water heating systems can potentially save $2 billion dollars a year in existing single family homes and $100 million in new construction. There is more potential for multi-family buildings. On demand systems prevent energy waste and mean less maintenance and repair costs over a standard recirculation system because the pump is only on when the occupant requires hot water.

This proposal will increase energy and water savings over a water heater circulation system with manual or automatic controls.

Cost Impact: The code change proposal will increase the cost of construction.

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: Disapproval requested by the proponent.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Eric Makela, Britt/Makela Group representing the Northwest Energy Codes Group requests Approval as Submitted.

Commenter's Reason: The IECC has allowed the use of either manual or automatic controls for turning circulating pumps on and off for hot water recirculating systems. If manual controls are installed, the homeowner is responsible for turning the system on an off when needed. If not turned off, the pump will continue to circulate 120^{o} to 140 ^{o}F water through piping leading to pipe heat loss and also requiring the water heater to run longer to continue to bring the water up to temperature. Installing a time clock on the circulation pump is more dependable if set properly, but still can lead to losses in the piping and additional run time for the water heater with no benefit to the home owner if set to run when the occupants are not in the house. In addition to piping and water heating energy use, electricity to run the pump can also cost a few hundred dollars per year. Constant recirculation of hot water can also degrade piping. A study conducted by the California Energy Commission's Public Interest Energy Research demonstrated that hot water distribution systems lose significant amounts of energy. This is significant considering that water heating uses 31% of energy in a typical house.

Demand control is the best automatic control option and superior to both manual off and time clock controls. The design features will prevent the pump motor burning out due to an air pocket, which is a common failure. The demand controlled recirculation system matches the user's demand to the delivery of hot water. The user gets the hot water quickly when they want it. On demand pumps for water heating systems can potentially save $2 billion dollars a year in existing single family homes and $100 million in new construction. There is more potential for multi-family buildings. On demand systems prevent energy waste and mean less maintenance and repair costs over a standard recirculation system because the pump is only on when the occupant requires hot water.

Approval of this proposal will increase energy and water savings as compared to a hot water circulation system with manual or automatic controls.

NOTE: PART II DID NOT RECEIVE A PUBLIC COMMENT AND IS ON THE CONSENT AGENDA, PART II IS REPRODUCED FOR INFORMATION PURPOSES FOLLOWING ALL OF PART III

Proposed Change as Submitted

THIS IS A 3 PART CODE CHANGE PROPOSAL. PARTS I AND II WILL BE HEARD BY THE IECC-RESIDENTIAL ENERGY CONSERVATION CODE DEVELOPMENT COMMITTEE AS TWO SEPARATE PROPOSALS. PART III WILL BE HEARD BY THE IRC-MP COMMITTEE. SEE THE TENTATIVE HEARING ORDERS FOR THESE COMMITTEES.

Proponent: Gary Klein, Affiliated International Management, LLC, representing self, (gary@aim4sustainability.com)

PART I – IECC-RESIDENTIAL PROVISIONS

Revise as follows:

R403.4.2 (IRC N1103.4.2) ~~Hot~~ Heated water pipe insulation (Prescriptive). Piping conveying water heated by a water heater shall be insulated. The insulation shall have a thermal resistance (*R-value*) of not less than R-3 or where tubular pipe insulation is used for insulating piping, the thermal conductivity, k, of such insulation shall be not greater than 0.28 Btu per inch/h●ft^2 ● F [0.40 W/(m●K)] for water temperatures less than or equal to 140°F (60°C) and not greater than 0.29 Btu per inch/h●ft^2 ● F [0.42 W/(m●K)] for water temperatures greater than 140°F (60°C) and less than or equal to 200°F (93.3°C). Tubular pipe insulation shall be installed in accordance with the insulation manufacturer's instructions. Pipe insulation shall be continuous except where the piping passes through a framing member. The minimum insulation thickness requirements of this section shall not supersede any greater insulation thickness requirements necessary for the protection of piping from freezing temperatures or the protection of personnel against external surface temperatures on the insulation. ~~Insulation for hot water pipe with a minimum thermal resistance (*R*-value) of R-3 shall be applied to the following:~~

1. ~~Piping larger than 3/4 inch (19 mm) nominal diameter.~~
2. ~~Piping serving more than one dwelling unit.~~
3. ~~Piping from the water heater to for kitchen outlets.~~
4. ~~Piping located outside the conditioned space.~~
5. ~~Piping from the water heater to a distribution manifold.~~
6. ~~Piping located under a floor slab.~~
7. ~~Buried in piping.~~
8. ~~Supply and return piping in recirculation systems other than demand recirculation systems.~~
9. ~~Piping with run lengths greater than the maximum run lengths for the nominal pipe diameter given in Table 403.4.2.~~

~~All remaining piping shall be insulated to at least R-3 or meet the run length requirements of Table 403.4.2.~~

~~TABLE R403.4.2 (N1103.4.2)~~
~~MAXIMUM RUN LENGTH (feet)~~[a]

~~Nominal Pipe Diameter of Largest Diameter Pipe in the Run (inch)~~	~~3/8~~	~~1/2~~	~~3/4~~	~~>3/4~~
~~Maximum Run Length~~	~~30~~	~~20~~	~~10~~	~~5~~

~~For SI: 1 inch=25.4 mm, 1 foot = 304.8 mm~~
~~a. Total length of all piping from the distribution manifold or the recirculation loop to a point of use.~~

Exceptions: Insulation shall not be required to be installed on the following:

1. Flexible connectors or reduced sized fixture supply tubing from the connection at the end of the fixture supply piping to a fixture fitting.
2. Valves, pumps and threaded unions in heated water piping.
3. Piping from shower and bath mixing valves to the water outlets.
4. Cold water piping that receives heated water as part of a water recirculation system that does not have a dedicated return pipe to the water heater.
5. Tubing from hot drinking-water heating units to the water outlet.
6. Piping at locations where a vertical support of the piping is installed.
7. Piping or tubing from a tankless water heater serving only one fixture.

TABLE R403.4.2 (N1103.4.2)
TUBULAR INSULATION WALL THICKNESS

NOMINAL PIPE OR TUBE DIAMETER (inches)	**MINIMUM INSULATION WALL THICKNESS (inches)**	
	≤140 °F WATER TEMPERATURE	**>140 °F to 200°F WATER TEMPERATURE**
≤3/8	3/8	3/8
> 3/8 to <3/4	1/2	1/2
> 3/4 to <1	3/4	1
≥1 to <1 1/2	1	1 1/2
≥1 ½ to <4	1 1/2	2
≥4 to <8	1 1/2	2
≥8	1 1/2	2

For SI: 1 inch = 25.4 mm; °C = [(°F – 32)]/1.8

Reason: PART I-IECC The current requirements as to where pipe insulation must be installed and the run length allowance where insulation *doesn't* have to be installed, are much too complex for most installers to comprehend. Think of trying to explain the current run length allowance to the typical person that ends up performing this type of work. It also requires too much thinking on the part the inspector when the inspector is facing a plumbing system that has some hot water piping insulated and some not. The insulation requirement needs to be simple – just insulate all of the hot water piping. The minor amount of savings by not insulating some lengths of hot water piping is overshadowed by confusion/time wasted in the field and the significant potential of not getting it correct (and failing an inspection).

The phrase "water heated by a water heater" was used instead of "hot water" because the IECC does not have a definition for hot water. Code users could refer to the definition found in the IRC and the IPC for hot water which says water of a temperature 110F or greater. However, an installer *could* try to justify not installing insulation on any piping with the claim that they intended to set the water heater temperature at 108F. This is not the intent of the existing language and by using the phrase "water heated by a water heater", this loophole will be closed.

The description of the required insulation is expanded. Where tubular pipe insulation is used, that material does not have an R value rating. The equivalent R value must be calculated. And while some submittal specification sheets show the equivalent R-value for each wall thickness, some do not. And how often does a submittal sheet show up on a jobsite? Tubular pipe insulation is specified in wall thickness and k value. The k value in this code section covers the most commonly used insulation materials for this application. To keep it simple – Table R403.4.2 is provided to show the required wall thicknesses that closely approximates a R value of R-3 for the two most common types of pipe insulation materials. This takes the calculations out of the picture to make it simple for installers and inspectors.

The option for insulating piping with materials that are R-value rated was left in this section because it is sometimes possible to "encapsulate" piping within wall or ceiling insulation without the need for installing tubular pipe insulation. Where piping is properly "nested" into fiberglass batts in walls or is covered with spray-in foam systems, the installation of tubular pipe insulation is a waste of time and money. This option needs to remain to allow these alternate cost savings methods to be used.

The last sentence "Pipe insulation shall be continuous along all piping." is intended to prohibit a common practice of just insulating piping up to where the piping enters and exits a structural member. For example, a pipe that runs vertically through the bottom plate of a wall or through a joist needs to be insulated continuously through those members in order for the insulated piping system to be effective in reducing energy loss.

The exceptions are added to this section to clarify where "piping insulation" is not required. Most items are common sense. Valves and pumps are difficult to insulate and the benefit of such effort is minimal. Let's keep is simple and easy.

PART II– IPC

The text that is struck out in IPC 607.5 is replaced with text that points the appropriate sections on the IECC that cover insulation.

Normally, the IPC only covers plumbing in commercial buildings. However, because the residential chapters in the IECC covers R2, R3 and R4 occupancy buildings that are 3 stories or less above grade plane in height *and* these occupancies are not covered by the plumbing chapter in the IRC, there needs to be a 'pointer section' in the IPC to alert the plumbing installer that there are piping insulation requirements in the residential provisions of the IECC that apply. Of primary concern are for allowing sufficient space around the piping (such as in wall cavities) and properly sizing holes through structural members to accommodate the insulation.

PART III – IRC

A new section is added in Chapter 29 of the IRC to alert the plumbing installer that the heated water piping installation must allow for insulating of the piping system. Of primary concern are for allowing sufficient space around the piping (such as in wall cavities) and properly sizing holes through structural members to accommodate the insulation.

Cost Impact: None.

R403.4.2-EC-KLEIN

Committee Action Hearing Results

PART I – IECC – Residential

Committee Action: Approved as Modified

Modify the proposal as follows:

R403.4.2 (IRC N1103.4.2) Heated water pipe insulation (Prescriptive). Piping conveying water heated by a water heater shall be insulated. The insulation shall have a thermal resistance (*R-value*) of not less than R-3 or where tubular pipe insulation is used for insulating piping, the thermal conductivity, k, of such insulation shall be ~~not greater than 0.28 Btu per inch/h•ft^2 • F [0.40 W/(m•K)] for water temperatures less than or equal to 140°F (60°C) and~~ not greater than ~~0.29~~ 0.31 Btu per inch/h•ft^2 • F [~~0.42~~ W/(m•K)] at ~~for water temperatures greater than 140°F (60°C) and less than or equal to~~ 200°F (93.3°C) and the minimum wall thickness shall be ½ inch (12.7 mm). Piping that is heat traced shall be insulated in accordance with the heat trace manufacturer's instructions. ~~Tubular~~ Pipe insulation shall be installed in accordance with the insulation manufacturer's instructions. Pipe insulation shall be continuous except where the piping passes through a framing member. The minimum insulation thickness requirements of this section shall not supersede any greater insulation thickness requirements necessary for the protection of piping from freezing temperatures or the protection of personnel against external surface temperatures on the insulation.

Exceptions: Insulation shall not be required to be installed on the following:

1. Flexible connectors or reduced sized fixture supply tubing from the connection at the end of the fixture supply piping to a fixture fitting.
2. Valves, pumps and threaded unions in heated water piping.
3. Piping from shower and bath mixing valves to the water outlets.
4. Cold water piping that receives heated water as part of a water recirculation system that does not have a dedicated return pipe to the water heater.
5. Tubing from hot drinking-water heating units to the water outlet.
6. Piping at locations where a vertical support of the piping is installed.
7. Piping or tubing from a tankless water heater serving only one fixture.

~~TABLE R403.4.2 (N1103.4.2)~~
~~TUBULAR INSULATION WALL THICKNESS~~

~~NOMINAL PIPE OR TUBE DIAMETER (inches)~~	**~~MINIMUM INSULATION WALL THICKNESS (inches)~~**	
	~~≤140 °F WATER TEMPERATURE~~	**~~>140 °F to 200°F WATER TEMPERATURE~~**
~~≤3/8~~	~~3/8~~	~~3/8~~
~~> 3/8 to <3/4~~	~~1/2~~	~~1/2~~
~~> 3/4 to <1~~	~~3/4~~	~~1~~
~~≥1 to <1 1/2~~	~~1~~	~~1 1/2~~
~~≥1 ½ to <4~~	~~1 1/2~~	~~2~~
~~≥4 to <8~~	~~1 1/2~~	~~2~~
~~≥8~~	~~1 1/2~~	~~2~~

~~For SI: 1 inch = 25.4 mm; °C = [(°F – 32)]/1.8~~

Committee Reason: The modifications were made to 1) simplify the requirements for insulating piping and 2) allow for the use of mineral fiber type insulation. The overall proposal was approved because the existing language was not clear as to what piping needed insulated.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Gary Klein, Affiliated International Management, LLC, representing self, requests Approval as Modified by the Code Committee as Published in the ROH.

Commenter's Reason: The Committee approved the modifications because they 1) simplified the requirements for insulating piping and 2) allowed for the use of mineral fiber type insulation. The overall proposal was approved because the existing language was not clear as to what piping needed insulated.

This section on insulating hot water piping is now much simpler to understand, implement and enforce: all hot water piping is to be insulated, with a few exceptions.

I urge your support of this code change.

For those who want a more detailed analysis, please continue reading:

Benefits of Pipe Insulation

In 2012, researchers at Lawrence Berkeley National Laboratory were able to analyze the hot water use data from 12 independent studies representing 159 single family households in climate zones covering much of the United States and some parts of Canada (see Figure 1). There were more than 22,900 days of data and 1,679,668 hot water draws, an average of more than 73 draws per day.

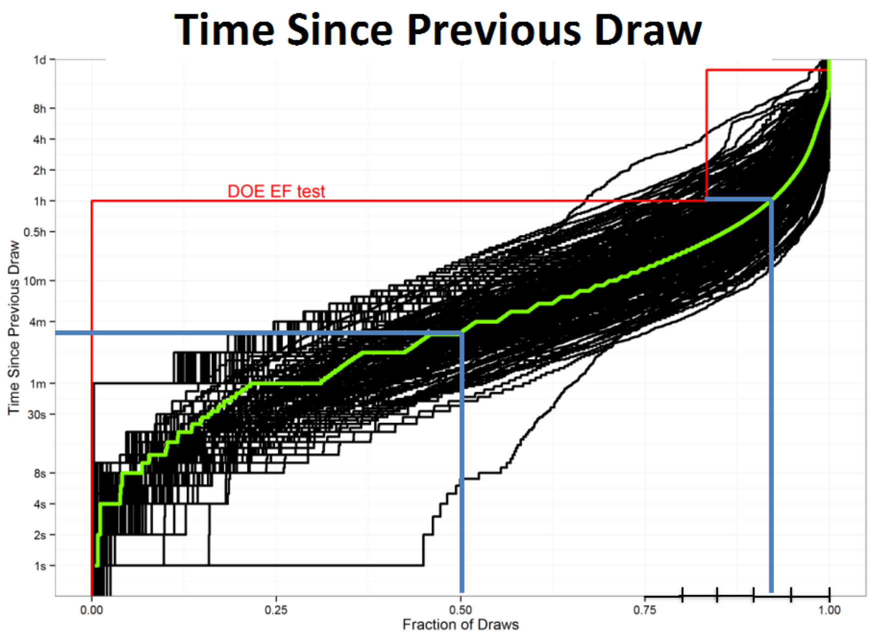
Figure 1. Location of Monitored Homes

Source: Jim Lutz and Moya Melody, Typical Hot Water Draw Patterns Based On Field Data, Lawrence Berkeley National Laboratory, November 2012.

Figure 2 shows this as the cumulative distribution of time from the previous draw. The green line is the mean of the data. The study found that almost 95 percent of all hot water events occurred within 60 minutes of each other. Hot water events are highly clustered as evidenced by 50% of all events occurring less than 3 minutes apart. This clustered hot water draw pattern matches what water utilities tell us about water use patterns which are dominated by morning peaks of 1-2 hours duration and evening secondary peaks of 3-5 hours duration during the work and school week and more spread-out use on the weekends, including lunch time and washing machine uses.

The clustering of hot water events is important relative to pipe insulation because the water in uninsulated ½ inch nominal pipe surrounded by room temperature air cools down from 120F to 105F in about 10 minutes; in ¾ inch nominal pipe it cools down in about 15 minutes. R-3 pipe insulation roughly doubles the cool down time to 20 minutes for ½ inch piping and roughly triples it to 45 minutes for ¾ inch piping. When the time between hot water events exceeds one hour, the water in the insulated pipes is likely to cool down back to ambient, minimizing the benefit of pipe insulation for spread out draws.

Figure 2. Time Since Previous Hot Water Event



Source: Jim Lutz and Moya Melody, Typical Hot Water Draw Patterns Based On Field Data, Lawrence Berkeley National Laboratory, November 2012.

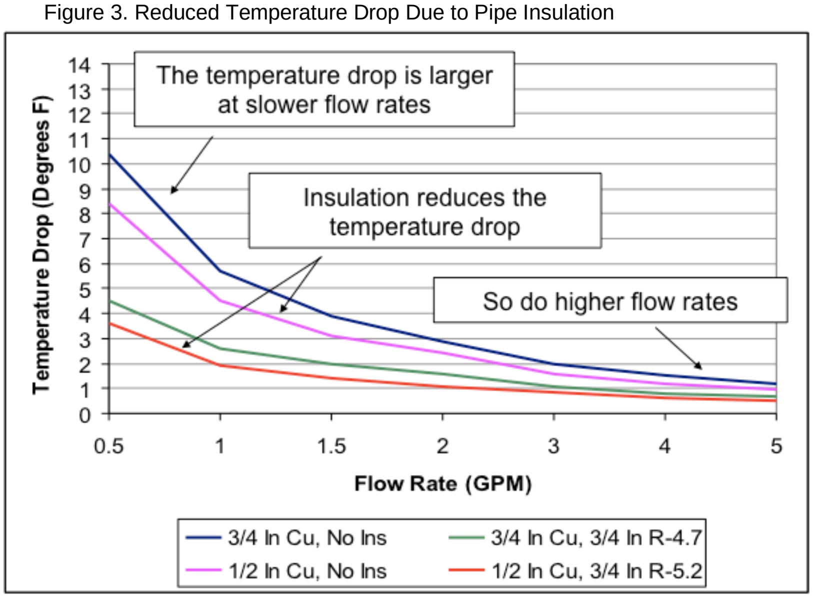
By delaying the cool-down time, insulation increases the number of “hot starts”-draws where the water in the pipe is hot enough for the next use-which reduces the amount of water that runs down the drain before hot water arrives at the fixtures. This reduces the time-to-tap for hot water to arrive, water waste and operating costs.

Another benefit of pipe insulation is that it reduces the temperature drop over a given distance of pipe to roughly half of what it would be at a given flow rate in uninsulated pipe. This can be seen in Figure 3. As an example, assuming a flow rate of 1 gpm in 100 feet of ¾ inch piping the temperature drop in uninsulated pipe would be about 5.5 F. Pipe insulation reduces this to about 2.75 F. This is important because reducing the temperature drop over the length of piping in the building means that would be possible to reduce the temperature at the water heater. Reducing the set-point temperature of a storage water heater by 1F will reduce the stand-by heat losses by at least 1 percent.

Both benefits are greater when the piping runs through harsher environments such as vented crawl spaces or attics in winter, unconditioned basements in cold climates and under slab foundations.

Floor plans and piping configurations that reduce the number of feet of piping also reduce the temperature drop, while at the same time reducing installation costs for both piping and pipe insulation.

Figure 3. Reduced Temperature Drop Due to Pipe Insulation



Estimated Insulation Costs

Pacific Northwest Laboratory provided an analysis that was used to support the DOE proposal on pipe insulation (Gary Klein, Affiliated International Management, LLC, *Cost Estimation for Materials and Installation of Hot Water Piping Insulation*, PNNL, June 2012). Excerpts from that analysis are used here.

The piping configuration used in the analysis was selected so that there is one trunk line for all hot water outlets; each outlet has its own relatively short branch from this trunk. To be conservative, the analysis assumed a relatively stretched out piping configuration for the 1-story 2400 ft^2 house; more feet, more cost. The 2-story 2400 ft^2 house has roughly half as many feet of pipe as the 1-story house; the piping configuration is much more compact. The 1-story 1200 ft^2 apartment piping configuration has the same "compactness" as the 2-story 2400 ft^2 house; the smaller number of feet are due to fewer fixture fittings. A 2-story 1200 ft^2 apartment could have an even more compact configuration and fewer feet of piping and associated insulation.

Figure 4 shows the estimated feet of pipe and for each configuration and the costs associated with each of three pricing assumptions. The cost estimates assume the use of R-3 (roughly ½ inch wall thickness, the same as the requirements in this code section) pipe insulation on all hot water piping. It would be possible to reduce costs by surrounding the piping in the attic with blown-in attic insulation.

The costs per foot for the low cost column were obtained by asking one of Northern California's largest residential new construction plumbing installers for price estimates. The costs per foot for the high cost column were obtained from three plumbers that work in the Orlando, Florida residential new construction market. Both of these costs are significantly lower than costs obtained from RS Means (more than $7 per foot) and are judged to be much more realistic of actual pipe installation costs in residential new construction. All of the costs assume the use of foam, not rubber or fiberglass pipe insulation. Foam is the least expensive and the one most commonly used when plumbers bid on installing pipe insulation.

Figure 4. Estimates of Feet of Pipe Insulation and Costs for Selected Floor Plans

	Estimates		
	Feet of Pipe Insulation	Installed Cost	
		Low	High
1-story 2400 sf	215	$ 236.50	$ 322.50
2-story 2400 sf	124	$ 136.40	$ 186.00
1-story 1200 sf	112	$ 123.20	$ 168.00

One important conclusion from this analysis is that it is possible to have a compact piping configuration in any size dwelling. The closer the hot water locations are to each other and to the water heater(s)that serve them, and the more directly the hot water piping is run from the water heater(s) to the fixture fittings, the fewer feet of pipe and therefore pipe insulation. The fewer feet, the less it costs to install.

Conversely, it is possible to install more feet of pipe and therefore pipe insulation than was assumed in this analysis. A more pipe-intensive hot water distribution method, such as a home-run manifold system could be chosen, or unnecessarily long trunks and branches could be installed in the system that was analyzed. More pipe means more pipe insulation. The more feet, the more it costs to install. It is unclear why this is beneficial to either the plumber or the builder, but unfortunately excessively long hot water distribution systems are often found in new construction.

Estimated Energy Savings

To estimate the energy savings it is reasonable to assume that the average length to the fixtures in the house is half the trunk length plus the length of the branch to the fixtures. The 1-story house has an average length of 67 feet; the 2-story house and the apartment have an average length of 31 feet. For simplicity we will use a range of 30-60 feet. The average volume in the 1-story house is about 1.5 gallons; the average volume in the 2-story house and the apartment is about 0.6 gallons.

The temperature drop without insulation over this distance ranges from 1.5-3.0 F. Insulation will reduce this to 0.75-1.5F. This analysis will assume insulation reduces the temperature drop by 1F.

Reducing the temperature drop by 1F reduces the stand-by heat losses by at least 1 percent. A typical gas storage water heater uses about 4,000,000 Btu per year for stand-by losses; an electric water heater uses about 1,000,000 Btu per year. This means the savings will be 40,000 Btu per year for natural gas and 10,000 Btu per year for electricity.

Based on the LBNL research findings, the typical house has about 73 hot water events each day. About 30 percent, or 21 of the draws are within 10 and 60 minutes apart (see Figure 2). Pipe insulation will eliminate most of the water and energy wasted while waiting for all of these hot water draws. When water is run down the drain waiting for hot water to arrive, new water enters the water heater to be heated. This means that it is necessary to account for the energy attached to this water by using the temperature difference between incoming cold-water temperatures and the water heater set point temperature. To be conservative, this analysis will assume that this temperature difference is only 50F, which is reflective of a warm climate.

Research sponsored by the California Energy Commission (reported by Hiller in ASHRAE) has shown that more water than is in the pipes comes out of the pipes before hot water arrives at the fixture fitting; for flow rates between 1 and 2 gpm, the additional waste ranges from 1.5 – 1.25 times the volume, respectively. Yes, the waste increases as the flow rate goes down. To be conservative, this analysis does not include this additional volume in the calculations.

Figure 5 converts volumetric waste into energy wasted. To find the range of potential savings we need to find the average volume that might be wasted per event (ranging from 0.6-1.5 gallons per event); follow that down until it intersects with the number of such events (21) and go over to the left to determine the number of Btus. Based on the assumptions in this analysis, the energy lost due to wasting water while waiting for the hot water to arrive ranges from 1,500,000 to 4,500,000 Btu per year.

The reduction in volumetric losses dominates the savings due to pipe insulation, so we will use those values to estimate the savings potential.

Assuming the typical household uses 60 gallons per day of hot water and the temperature is raised from 50 to 130F (a greater temperature rise than was assumed for the cool-down losses) it takes 14.6 million Btu a year to heat the water, not including the inefficiencies of the water heater. If the savings due to pipe insulation ranges from 1.5 to 4.5 million Btu per year, the percent savings ranges from 10.2 to 30.8 percent.

Figure 5 Converting Volume That Cools Down into Annual Energy

			Volume in Pipe That Cools Down							
		Gallons	0.0625	0.125	0.25	0.5	0.75	1	1.5	2
		Cups	1	2	4	8	12	16	24	32
Heat Loss										
Btu/Year	Btu/Day		Number of Times Per Day that Water in Pipe Cools Down							
500,000	1,370		53	26	13	7	4.4	3.3	2.2	1.6
1,000,000	2,740		105	53	26	13	9	7	4.4	3.3
1,500,000	4,110		158	79	39	20	13	10	7	5
2,000,000	5,479		210	105	53	26	18	13	9	7
2,500,000	6,849		263	132	66	33	22	16	11	8
3,000,000	8,219		316	158	79	39	26	20	13	10
3,500,000	9,589		368	184	92	46	31	23	15	12
4,000,000	10,959		421	210	105	53	35	26	18	13
4,500,000	12,329		474	237	118	59	39	30	20	15
5,000,000	13,699		526	263	132	66	44	33	22	16
5,500,000	15,068		579	289	145	72	48	36	24	18
6,000,000	16,438		631	316	158	79	53	39	26	20

This estimate is conservative for at least two reasons. First, the typical home has more stretched out piping than was assumed in the 2-story house and the 1-story apartment, so the volume of wasted water will be larger than estimated for the lower end of the range of volumetric losses. Second, the actual temperature difference between incoming cold water and the hot water set point is often less than 80F, so the energy needed to heat the water that has been wasted is likely to be smaller than estimated. Both of these factors will result in larger percentage savings.

In addition to the energy savings at the house, reducing water use saves energy by not having to treat and deliver cold water to the home and by not having to remove, treat and discharge the waste water. This energy savings generally does not occur at the home, unless one has a well. This is on the order of 5 kWh/1000 gallons for urban water and waste water systems combined; these energy savings were not included in this analysis.

Public Comment 2:

W. Ronald Burton of PTW Advisors, LLC representing Leading Builders of America requests Disapproval.

Commenter's Reason: The recommendation by the Residential IECC Code Development Committee for As Modified on code change proposal RE129-13 Part I should be overturned and the proposal disapproved. The proposal would require insulation on all hot water piping not currently required to be insulated regardless of its location in the structure. The proponent cites as a reason for making this change that the current requirements "are much too complex for most installers to comprehend" and further states that "it takes too much thinking on the part of the inspector…". We submit that the IECC already requires most hot water piping to be insulated including all piping to kitchen outlets and any distribution manifolds. Exceptions include specific piping from a distribution manifold to individual fixtures, but even that piping and any other piping runs must be no longer than the very limited lengths allowed in Table R403.4.2. We further submit that both plumbing contractors and plumbing inspectors are perfectly capable of dealing with complex plumbing systems – in fact they do it on a daily basis - and it is insulting to contend that the very clear requirements for insulating hot water piping in the residential section of the IECC are "too complex" and require "too much thinking". Finally, we submit that the cost of additional HW piping insulation required by this proposal is not justified by the minor savings in energy usage and this alone is ample reason for disapproval of this proposal.

NOTE: PART II DID NOT RECEIVE A PUBLIC COMMENT AND IS ON THE CONSENT AGENDA, PART II IS REPRODUCED FOR INFORMATION PURPOSES FOLLOWING ALL OF PART III

<u>Proposed Change as Submitted</u>

THIS IS A 3 PART CODE CHANGE PROPOSAL. PARTS I AND II WILL BE HEARD BY THE IECC-RESIDENTIAL ENERGY CONSERVATION CODE DEVELOPMENT COMMITTEE AS TWO SEPARATE PROPOSALS. PART III WILL BE HEARD BY THE IRC-MP COMMITTEE. SEE THE TENTATIVE HEARING ORDERS FOR THESE COMMITTEES.

Proponent: Gary Klein, Affiliated International Management, LLC, representing self, (gary@aim4sustainability.com)

PART III – IRC-P

Add new text as follows:

<u>SECTION P2905</u>
<u>HEATED WATER DISTRIBUTION SYSTEMS</u>

<u>P2905.1 Insulation of piping required.</u> <u>Piping conveying water heated by a water heater shall be insulated in accordance with Section N1103.4.2.</u>

Reason: PART I-IECC The current requirements as to where pipe insulation must be installed and the run length allowance where insulation *doesn't* have to be installed, are much too complex for most installers to comprehend. Think of trying to explain the current run length allowance to the typical person that ends up performing this type of work. It also requires too much thinking on the part the inspector when the inspector is facing a plumbing system that has some hot water piping insulated and some not. The insulation requirement needs to be simple – just insulate all of the hot water piping. The minor amount of savings by not insulating some lengths of hot water piping is overshadowed by confusion/time wasted in the field and the significant potential of not getting it correct (and failing an inspection).

The phrase "water heated by a water heater" was used instead of "hot water" because the IECC does not have a definition for hot water. Code users could refer to the definition found in the IRC and the IPC for hot water which says water of a temperature 110F or greater. However, an installer *could* try to justify <u>not</u> installing insulation on any piping with the claim that they intended to set the water heater temperature at 108F. This is not the intent of the existing language and by using the phrase "water heated by a water heater", this loophole will be closed.

The description of the required insulation is expanded. Where tubular pipe insulation is used, that material does not have an R value rating. The equivalent R value must be calculated. And while some submittal specification sheets show the equivalent R-value for each wall thickness, some do not. And how often does a submittal sheet show up on a jobsite? Tubular pipe insulation is specified in wall thickness and k value. The k value in this code section covers the most commonly used insulation materials for this application. To keep it simple – Table R403.4.2 is provided to show the required wall thicknesses that closely approximates a R value of R-3 for the two most common types of pipe insulation materials. This takes the calculations out of the picture to make it simple for installers and inspectors.

The option for insulating piping with materials that are R-value rated was left in this section because it is sometimes possible to "encapsulate" piping within wall or ceiling insulation without the need for installing tubular pipe insulation. Where piping is properly "nested" into fiberglass batts in walls or is covered with spray-in foam systems, the installation of tubular pipe insulation is a waste of time and money. This option needs to remain to allow these alternate cost savings methods to be used.

The last sentence "Pipe insulation shall be continuous along all piping." is intended to prohibit a common practice of just insulating piping up to where the piping enters and exits a structural member. For example, a pipe that runs vertically through the bottom plate of a wall or through a joist needs to be insulated continuously through those members in order for the insulated piping system to be effective in reducing energy loss.

The exceptions are added to this section to clarify where "piping insulation" is not required. Most items are common sense. Valves and pumps are difficult to insulate and the benefit of such effort is minimal. Let's keep is simple and easy.

PART II– IPC

The text that is struck out in IPC 607.5 is replaced with text that points the appropriate sections on the IECC that cover insulation.

Normally, the IPC only covers plumbing in commercial buildings. However, because the residential chapters in the IECC covers R2, R3 and R4 occupancy buildings that are 3 stories or less above grade plane in height *and* these occupancies are not covered by the plumbing chapter in the IRC, there needs to be a 'pointer section' in the IPC to alert the plumbing installer that there are piping insulation requirements in the residential provisions of the IECC that apply. Of primary concern are for allowing sufficient space around the piping (such as in wall cavities) and properly sizing holes through structural members to accommodate the insulation.

PART III – IRC

A new section is added in Chapter 29 of the IRC to alert the plumbing installer that the heated water piping installation must allow for insulating of the piping system. Of primary concern are for allowing sufficient space around the piping (such as in wall cavities) and properly sizing holes through structural members to accommodate the insulation.

Cost Impact: None.

R403.4.2-EC-KLEIN

Committee Action Hearing Results

PART III – IRC – Plumbing

Committee Action: **Disapproved**

Committee Reason: There is no need to have a pointer in the plumbing chapters to direct the reader to another chapter of the IRC. There could be no end to the amount of pointers we could put into the IRC.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Gary Klein, Affiliated International Management, LLC, representing self, requests Approval as Modified by this Public Comment

Modify the proposal as follows:

P2905.1 Clearance required for piping insulation ~~of piping required~~. The installation of piping conveying water heated by a water heater shall allow access for the installation of, and the clearances for, ~~be~~ ~~insulated in accordance with~~ piping insulation that is required by Section N1103.4.2.

Commenter's Reason: The Committee disapproved the code change because they felt there was no need of a pointer to another section in the IRC.

Heated water piping systems that are required to be insulated affects how the heated water piping system is designed and installed. Designers and installers need to realize the impact of installing heated water piping in certain locations because the proposed methods of insulating those systems might not allow adequate clearances or access. Plumbing-oriented users of the IRC have, in the past, simply focused on the plumbing chapters for their work. They rely on many pointers in the plumbing chapters to help remind them pick up plumbing-related items outside those chapters. For example, Sections P2602.2, P2603.2, P2801.3, P2801.7, P2903.8, P3001.2, and P3101.5. Let's help these readers understand that insulation might be required for some heated water pipes. If the piping installer is the installer of the insulation, then they will be informed as to where the insulation requirements are located in the IRC. If the piping installer is *not* that same as the insulation installer, it is imperative that the piping installer fully understand what pipes need insulated, what clearances are necessary to allow for the insulation to be installed, and what access to allow to that piping so the insulation installer can get in the location to perform the insulating work. This section will promote coordination between trades so the work is performed correctly the first time instead of embarrassing the trades people and the builder at final inspection.

This section does *not* require piping to be insulated. That is covered in the energy chapters. This section merely alerts the piping installer to allow room for the piping to be insulated, where insulation is necessary.

I urge your support of this comment.

RE129-13, Part III

Final Action: AS AM AMPC____ D

NOTE: PART II REPRODUCED FOR INFORMATION PURPOSES ONLY – SEE ABOVE

RE129-13, PART II-IPC

Revise as follows:

[E] 607.5 ~~Pipe~~ Insulation of piping. ~~Hot water piping in automatic temperature maintenance systems shall be insulated with not less than 1 inch (25 mm) of insulation having a conductivity not exceeding 0.27 Btu per inch/h • ft² • °F (1.53 W per 25 mm/m² • K). The first 8 feet (2438 mm) of hot water piping from a hot water-source that does not have heat traps shall be insulated with 0.5 inch (12.7 mm) of material having a conductivity not exceeding 0.27 Btu per inch/h • ft² • °F (1.53 W per 25 mm/m² • K).~~ For other than Group R2, R3 and R4 occupancies that are 3 stories or less in height above grade plane, piping to the inlet of a water heater and piping conveying water heated by a water heater shall be insulated in accordance with Sections C404.5 of the *International Energy Conservation Code*. For Group R2, R3 and R4 occupancies that are 3 stories or less in height above grade plane, piping to the inlet of a water heater and piping conveying water heated by a water heater shall be insulated in accordance with Section R403.4.2 of the *International Energy Conservation Code*.

Reason: PART I-IECC The current requirements as to where pipe insulation must be installed and the run length allowance where insulation *doesn't* have to be installed, are much too complex for most installers to comprehend. Think of trying to explain the current run length allowance to the typical person that ends up performing this type of work. RE130-13
R403.4.2 (IRC N1103.4.2)

Proposed Change as Submitted

Proponent: Edward R. Osann, Natural Resources Defense Council, on behalf of self (eosann@nrdc.org)

Revise as follows:

R403.4.2 (N1103.4.2) Hot water pipe insulation (Prescriptive). Insulation for hot water pipe with a minimum thermal resistance (*R*-value) of R-3 shall be applied to the following:

1. Piping larger than $^3/_4$ inch nominal diameter.
2. Piping serving more than one dwelling unit.
3. Piping from the water heater to kitchen outlets.
4. In occupancies with three or more bedrooms, piping from the water heater or recirculation system piping to the outlet for any shower or tub/shower combination.
~~4~~5. Piping located outside the conditioned space.
~~5~~6. Piping from the water heater to a distribution manifold.
~~6~~7. Piping located under a floor slab.
~~7~~8. Buried piping.
~~8~~9. Supply and return piping in recirculation systems other than demand recirculation systems.
~~9~~10. Piping with run lengths greater than the maximum run lengths for the nominal pipe diameter given in Table R403.4.2.

All remaining piping shall be insulated to at least R-3 or meet the run length requirements of Table R403.4.2.

Reason: Every adult in the United States has experienced the waiting time for water that is hot enough to step into the shower. Most do so on a regular basis, and often for a minute or more. While cold or tepid water in the initial draw from a hot water outlet serving a clothes washer, dishwasher, or lavatory sink may be usable for its intended purpose, cold or tepid water for showering is routinely purged, a waste of water, energy, and time. Pipe insulation significantly reduces heat loss and helps to ensure that hot water gets to the shower sooner. During showering, pipe insulation keeps the water hotter by reducing the temperature drop from the source of hot water to the shower outlet. This saves significant energy by making it possible to reduce the set point for the storage temperature at the hot water heater. Every 1°F reduction in hot water storage temperature reduces standby heat losses by almost 2%. During the cool-down phase, pipe insulation increases the time it takes for the temperature of the water to cool down, roughly doubling the cool-down time for ½ inch nominal pipe and tripling it for ¾ inch nominal pipe. This saves energy, water, and time for all those hot water events, including showers, that are clustered between 10 and 45 minutes apart, as when occupants are getting ready for work and school in the AM.

Cost Impact: This code change proposal will increase the cost of construction only to the extent that all or a portion of the pipe run to a shower would not already require insulation under the existing requirements of Section R403.4.2. For example, under the current language of this section, hot water pipe running in an unconditioned crawl space or attic is required to be insulated. Pipe running from a water heater to a distribution manifold is also required to be insulated, while up to 20 feet of ½ inch supply piping from a manifold to an end use such as a shower may be uninsulated. At an estimated cost of materials, labor, and profit of $1.10 to $1.50 per linear foot for installing foam insulation[1], the cost of insulating 20 feet of ½ inch supply piping would be $22 to $30.
Klein, Gary, "Cost Estimation for Materials and Installation of Hot Water Piping Insulation," prepared for Pacific Northwest National Laboratory, June 2012, accessible at <http://bc3.pnnl.gov/wiki/index.php/Downloads>.

During the cool-down phase, pipe insulation increases the time it takes for the temperature of the water to cool down, roughly doubling the cool-down time for ½ inch nominal pipe and tripling it for ¾ inch nominal pipe. This saves energy, water, and time for all those hot water events, including showers that are clustered between 10 and 45 minutes apart, as when occupants are getting ready for work and school in the morning.

RE130-13

Final Action: AS AM AMPC____ D

RE131-13
R403.4.2 (IRC N1103.4.2)

<u>Proposed Change as Submitted</u>

Proponent: Edward R. Osann, on behalf of Natural Resources Defense Council; Ryan Meres, on behalf of Institute for Market Transformation.(eosann@nrdc.org)

Revise as follows:

R403.4.2 (N1103.4.2) Hot water pipe insulation (~~Prescriptive~~ <u>Mandatory</u>). Insulation for hot water pipe with a minimum thermal resistance (*R*-value) of R-3 shall be applied to the following:

1. Piping larger than $^3/_4$ inch nominal diameter.
2. Piping serving more than one dwelling unit.
3. Piping from the water heater to kitchen outlets.
4. Piping located outside the conditioned space.
5. Piping from the water heater to a distribution manifold.
6. Piping located under a floor slab.
7. Buried piping.
8. Supply and return piping in recirculation systems other than demand recirculation systems.
9. Piping with run lengths greater than the maximum run lengths for the nominal pipe diameter given in Table R403.4.2.

All remaining piping shall be insulated to at least R-3 or meet the run length requirements of Table R403.4.2.

Reason: The 2012 edition of the IECC added this prescriptive section on hot water pipe insulation, containing a list of 9 factors or locations that require pipe to be insulated to R-3. However, because it is prescriptive and not mandatory, it is not required in any project that opts for the performance approach. Unfortunately, while the 2012 IECC performance approach allows credit for improving the efficiency of the hot water heat source, no credit is available for features of the hot water distribution system that might actually reduce the amount of hot water used, such as those listed in R403.4.2. (The HERS rating system is similarly drawn, offering no credit for hot water pipe insulation.) Thus, although hot water pipe insulation is known to save significant amounts of energy over the life of the building, the energy savings cannot be "scored" or accumulated within the performance framework of the code. Section R403.4.2 cannot contribute to compliance under the IECC performance approach, and is thus likely to be ignored. For these energy savings to be realized in all new residential buildings covered by the IECC, R403.4.2 should be mandatory instead of prescriptive. If and when Section R405 is modified to ensure that the performance path will account for the energy attributes of the hot water distribution system, consideration can be given to removing the mandatory designation from some or all portions of R403.4.2.

As was noted by the original proponents of Section R403.4.2, insulation of hot water piping reduces the waste of energy, water, and time during the delivery, use, and cool-down phases of a hot water event. During the delivery phase, when the piping runs in unconditioned spaces, in a slab, when it is buried or when the flow rate is very low (less than 1 gpm), pipe insulation significantly reduces the heat loss and helps to ensure that hot enough water gets to the outlets. During the cool-down phase, pipe insulation increases the time it takes for the temperature of the water to cool down, roughly doubling the cool-down time for ½ inch nominal pipe and tripling it for ¾ inch nominal pipe. This saves energy, water and time for all those hot water events that are clustered between 10 and 45 minutes apart, as when occupants are getting ready for work and school in the morning and during evening activities such as preparing and cleaning up from supper and getting ready for bed, as well as lunchtime when people are home during the day.

As hot water is being used, pipe insulation keeps the water hotter by reducing the temperature drop from the source of hot water to the outlet. This saves additional energy by making it possible to reduce the set point for storage temperature at the hot water heater. Every 1°F reduction in hot water storage temperature reduces standby heat losses by almost 2%.

Cost Impact: This code change proposal will not increase the cost of construction for builders following the prescriptive approach, i.e., the majority of all builders. For those following the performance path, pipe insulation will be an added cost. A recent estimate[1] of the cost of insulating hot water piping with R-3 foam insulation is $1.10 to $1.50 per linear foot, including labor, materials, and profit for the plumbing subcontractor. The cost of insulating all hot water piping in a 2400 ft^2 home was estimated by the same study to be $135 to $325, depending on building configuration. It should be noted that these estimates are based on insulation of ***all*** hot water piping in the home, which is more than is required by Section R403.4.2. Thus the actual impact on the cost of construction should be somewhat less than this range in most cases.

[1]Klein, Gary, "Cost Estimation for Materials and Installation of Hot Water Piping Insulation," prepared for Pacific Northwest National Laboratory, June 2012, accessible at <http://bc3.pnnl.gov/wiki/index.php/Downloads>.

R403.4.2-EC-OSANN.DOC

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: Proponent requested disapproval based upon action on RE129-13.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Brian Dean, ICF International, representing Energy Efficient Codes Coalition; Jeff Harris, Alliance to Save Energy; Harry Misuriello, American Council for an Energy-Efficient Economy (ACEEE); Bill Prindle, representing the Energy Efficient Codes Coalition; Garrett Stone, Brickfield, Burchette, Ritts & Stone, PC; Donald J. Vigneau, Northeast Energy Efficiency Partnerships Inc., request Approval as Submitted.

Commenter's Reason: We recommend approval of RE131 as submitted. Hot water pipe insulation requirements should be shown as "mandatory" since there is no mechanism to allow trade-offs under the performance path in Section R405. This approach will reduce confusion for buildings complying under the performance path as to what the insulation requirements are and will ensure that the energy saved from reasonable pipe insulation will be enjoyed by all residential buildings. If a reasonable method to include these requirements in the performance path for trade-offs is developed in the future, at that point the "mandatory" designation can be reconsidered.

RE131-13

R403.4.2 (IRC N1103.4.2), Table R403.4.2 (IRC Table N1103.4.2)

Proposed Change as Submitted

Proponent: Don Surrena, CBO, National Association of Home Builders (NAHB) (dsurrena@nahb.org)

Revise as follows:

R403.4.2 (N1103.4.2) Hot water pipe insulation (Prescriptive). Insulation for hot water pipe with a minimum thermal resistance (*R*-value) of R-3 shall be applied to the following:

1. Piping larger than 3/4 inch nominal diameter.
2. Piping serving more than one dwelling unit.
~~3. Piping from the water heater to kitchen outlets.~~
~~4~~3. Piping located outside the conditioned space.
~~5~~4. Piping from the water heater to a distribution manifold.
~~6~~5. Piping located under a floor slab.
~~7~~6. Buried piping.
~~8~~7. Supply and return piping in recirculation systems other than demand recirculation systems.
~~9. Piping with run lengths greater than the maximum run lengths for the nominal pipe diameter given in Table R403.4.2.~~

~~All remaining piping shall be insulated to at least R-3 or meet the run length requirements of Table R403.4.2.~~

~~TABLE R403.4.2 (N1103.4.2)~~
~~MAXIMUM RUN LENGTH (feet)[a]~~

~~Nominal Pipe Diameter of Largest Diameter Pipe in the Run (inch)~~	~~3/8~~	~~1/2~~	~~3/4~~	~~> 3/4~~
~~Maximum Run Length~~	~~30~~	~~20~~	~~10~~	~~5~~

Reason: Research has been performed by a two different sources that indicate insulating hot water piping in a residential home is not cost effective. The NAHB Research Center performed a study in 2010 that concluded, based on a low cost estimate that the simple payback for insulating hot water piping was in the 60 to 100 year range based on the piping material. Additionally, a 2009 study presented by the National Renewable Energy Lab at the ASME 3rd International Conference of Energy Sustainability estimated paybacks between 72 and 183 years for various insulation configurations.

First cost, as determined in the NAHB Research Center report varied between $500 and $1,200. The NREL report had a slightly smaller house with an estimated installation cost of $366.

The simulations demonstrate that the benefit of insulation is greatest when all of the hot water uses are spaced apart from 10 to 30 minutes; however, this is not typically how hot water is consumed in a home. The benefit of insulation is diminished with shorter and longer time between uses.

It was shown in the study that pipes located in colder locations such as an unconditioned crawl space, benefit more from pipe insulation than pipes located in more conditioned spaces. This is why the insulation requirement was not changed for hot water pipes outside conditioned space.

Plastic pipe was shown to have less loss than copper pipe and commensurately insulation is more beneficial on metal pipe than on plastic pipe. However, copper pipe is losing market share and currently is only being installed in 14% of new homes.

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: Proponent requested disapproval based upon action on RE129-13.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Craig Conner, Building Quality representing himself requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R403.4.2 (N1103.4.2) Hot water pipe insulation (Prescriptive). Insulation for hot water pipe with a minimum thermal resistance (*R*-value) of R-3 shall be applied to the following:

1. Piping ~~larger than~~ 3/4 inch <u>and larger in</u> nominal diameter.
2. Piping serving more than one dwelling unit.
3. Piping located outside the conditioned space.
4. Piping from the water heater to a distribution manifold.
5. Piping located under a floor slab.
6. Buried piping.
7. Supply and return piping in recirculation systems other than demand recirculation systems.

Commenter's Reason: This would not require pipe insulation on most pipes where the use of hot water is only occasional, but would retain the pipe insulation on the main lines (3/4 inch and larger) where the insulation is of more value because the flow of hot water is much more frequent. At least some portion of the pipe run to kitchens and bathrooms is likely to be 3/4 and larger and this is the piping that is most likely to have the highest number of uses because it is being shared by more plumbing fixtures. Specifying a requirement based on pipe size, rather than where the pipe leads to, is clearer and easier to inspect. This comment retains RE132's simplicity by eliminating the table based on pipe length.

RE132-13

Final Action: AS AM AMPC____ D

RE133-13
R403.4.2 (IRC N1103.4.2)

Proposed Change as Submitted

Proponent: Jeremiah Williams, U.S. Department of Energy (jeremiah.williams@ee.doe.gov)

Revise as follows:

R403.4.2 (N1103.4.2) Hot water pipe insulation (Prescriptive). Insulation for hot water pipe with a minimum thermal resistance (*R*-value) of R-3 shall be applied to the following:

1. ~~Piping larger than 3/4 inch nominal diameter.~~
~~2.~~ 1. Piping serving more than one dwelling unit.
~~3.~~ 2. Piping from the water heater to kitchen outlets.
~~4.~~ 3. Piping located outside the conditioned space.
~~5.~~ 4. Piping from the water heater to a distribution manifold.
~~6.~~ 5. Piping located under a floor slab.
~~7.~~ 6. Buried piping.
~~8.~~ 7. Supply and return piping in recirculation systems other than demand recirculation systems.
~~9.~~ 8. Piping with run lengths greater than the maximum run lengths for the nominal pipe diameter given in Table R403.4.2.

All remaining piping shall be insulated to at least R-3 or meet the run length requirements of Table R403.4.2.

Reason: Insulation requirements for ¾-in piping are currently inconsistent between the list in Section R403.4.2 and Table R403.4.2. Eliminating the list item eliminates the ambiguity.

Cost Impact: The code change proposal will not increase the cost of construction.

R403.4.2-EC-WILLIAMS.DOC

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: Proponent requested disapproval based upon action on RE129-13.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jeremiah Williams, U.S. Department of Energy requests Approval as Modified by this Public Comment

Modify the proposal as follows:

R403.4.2 Hot water pipe insulation (Prescriptive). Insulation for hot water pipe with a minimum thermal resistance (*R*-value) of R-3 shall be applied to the following:

1. Piping larger than 3/4 inch nominal diameter.
~~1~~ 2. Piping serving more than one dwelling unit.
~~2~~ 3. Piping from the water heater to kitchen outlets.

~~3~~ 4. Piping located outside the conditioned space.
~~4~~ 5. Piping from the water heater to a distribution manifold.
~~5~~ 6. Piping located under a floor slab.
~~6~~ 7. Buried piping.
~~7~~ 8. Supply and return piping in recirculation systems other than demand recirculation systems.
~~8~~ 9. Piping with run lengths greater than the maximum run lengths for the nominal pipe diameter given in Table R403.4.2.

All remaining piping shall be insulated to at least R-3 or meet the run length requirements of Table R403.4.2.

TABLE R403.4.2 Maximum Run Length (feet)[1]

Nominal Pipe Diameter of Largest Diameter Pipe in the Run (in.)	3/8	1/2	3/4	~~> 3/4~~
Maximum Run Length	30	20	10	~~5~~

Commenter's Reason: Insulation requirements for ¾-inch piping are currently inconsistent between the list in Section R403.4.2 and Table R403.4.2. This public comment eliminates the column in the table for pipe diameters of greater than ¾-inch, and therefore removes the ambiguity. This proposal was disapproved at the code action hearings only because DOE asked the committee for disapproval, since another proposal correcting the inconsistency was approved. DOE will withdraw this proposal if other proposals that fix this inconsistency are approved at the final action hearings.

DOE posted its draft proposals and public comments for the IECC on its Building Energy Codes website prior to submitting to the ICC. Interested parties were provided a 30 day public review in June 2013, for which notice was published in the *Federal Register* (Docket No. EERE-2012-BT-BC-0030) and announced via the DOE Building Energy Codes news email list. In response to stakeholder input, DOE revised its proposals and public comments, as appropriate, and submitted to the ICC.

For more information on DOE proposals and public comments, including how DOE participates in the ICC code development process, please visit: http://www.energycodes.gov/development.

R403.4.2 (NEW) (IRC N1103.4.2 (NEW)), IPC 202, IPC [E]607.2.1.1 (NEW), IRC P2905 (NEW), IRC P2905.1 (NEW)

Proposed Change as Submitted

THIS IS A 3 PART CODE CHANGE PROPOSAL. PARTS I AND II WILL BE HEARD BY THE IECC-RESIDENTIAL ENERGY CONSERVATION CODE DEVELOPMENT COMMITTEE AS 2 SEPARATE CODE CHANGES. PART III WILL BE HEARD BY THE IRC-PM COMMITTEE. SEE THE TENTATIVE HEARING ORDERS FOR THESE COMMITTEES.

Proponent: Gary Klein, Affiliated International Management, LLC, representing self, gary@aim4sustainability.com

PART I – IECC-RESIDENTIAL PROVISIONS

Add new text as follows:

R403.4.2 (IRC N1101.4.2) Demand recirculation systems. A water distribution system having one or more recirculation pumps that pump water from a heated water supply pipe back to the heated water source through a cold water supply pipe shall be a *demand recirculation water system.* Pumps shall have controls that comply with both of the following:

1. The control shall start the pump upon receiving a signal from the action of a user of a fixture or appliance, sensing the presence of a user of a fixture or sensing the flow of hot or tempered water to a fixture fitting or appliance.
2. The control shall limit the water temperature increase in the cold water piping to not more than 10ºF (5.6 ºC) greater than the initial temperature of the water in the piping and limits the temperature entering the cold water piping to 102ºF (38.9 ºC).

Reason: The purpose of this code change proposal is to clarify the requirements for installing circulation pumps in applications that use a cold water supply pipe to circulate the water back to the water heater. Demand recirculation water systems are significantly more energy efficient than other recirculation systems and are inherently safer when the cold water supply is used as the return.

Figure 1 shows that demand activated circulation is significantly more energy efficient than any other type of heated water circulation system. The annual energy needed to keep the loop hot with water heated electrically or with natural gas are shown separately from the energy needed for the pump. The majority of the energy is lost in keeping the water in the loop at the desired temperature (all of it if there is a gravity loop). A small loop, 100 feet including the supply and the return was analyzed. The savings ranges from 87.5 percent when compared to a recirculation system that runs only 2-hours per day to 99 percent when compared to a recirculation system that runs only 24-hours per day. The operating costs and savings remain proportional as the length of the circulation loop and the flow rate of the pump increase.

Figure 1 Annual Energy Requirements for Demand Activated Circulation and Standard Recirculation

	Standard Recirculation						Demand Activated Circulation
	Daily Hours of Operation						
	24	12	8	6	4	2	0.25
Loop Heat Losses							
Natural Gas (therms)	292	146	97	73	49	24	3
Electric (kWh)	6,388	3,194	2,129	1,597	1,065	532	67
Pump Energy (kWh)	438	219	146	110	73	37	8

The inherently better safety comes from the fact that the controls specified for demand recirculation water systems limit the flow of water from the hot water supply into the cold water supply to only minutes a day and because they limit the temperature of the water that is allowed to go into the cold water supply. There are five other control strategies for heated water recirculation systems (thermosyphon (gravity), continuous pumping, timer controlled, bandwidth temperature sensor (aquastat) controlled and a combination of timer and bandwidth temperature sensor (aquastat) controlled and none of them has the ability to meet these stringent requirements.

The requirements of this section should be identical in both the IECC and the IPC, since the language for the controls does not depend on occupancy

For more information and background on issues related to hot water distribution and for a more detailed analysis in support of this proposal please go to http://www.aim4sustainability.com Follow the link on the home page to Codes.

Cost impact: This proposal will not increase the cost of construction, as it does not require the use of demand recirculation water systems. In addition, the ability to use cold-water supply piping as a return pipe may reduce the cost of installing a circulation loop.

R403.4.2 (NEW) #1-EC-KLEIN

Committee Action Hearing Results

PART I – IECC – Residential

Committee Action: **Approved as Submitted**

Committee Reason: The proposal provides clarity on how demand recirculation systems that return water though a cold water pipe back to the source should operate.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment 1:

Gary Klein, Affiliated International Management, LLC, representing self, requests Approval as Submitted.

Commenter's Reason: The proposal provides clarity on how demand recirculation systems that return water though a cold water pipe back to the source should operate.

I agree with the Committee's reason and urge your support of this proposal.

Public Comment 2:

Greg Towsley, Grundfos representing self, requests As Modified by this Public Comment.

Modify the proposal as follows:

R403.4.2 (IRC N1101.4.2) Demand recirculation systems. A water distribution system having one or more recirculation pumps that pump water from a heated water supply pipe back to the heated water source through a cold water supply pipe shall be a demand recirculation water system. Pumps shall have controls that comply with both of the following:

1. The control shall start the pump upon receiving a signal from the action of a user of a fixture or appliance, sensing the presence of a user of a fixture<u>,</u> or sensing the flow of hot or tempered water to a fixture fitting or appliance.

2. The control shall limit the ~~water temperature increase in the cold water piping to not more than 10ºF (5.6 ºC) greater than the initial temperature of the water in the piping and limits the~~ temperature <u>of the water</u> entering the cold water piping ~~102ºF (38.9 ºC)~~ <u>104°F (40°C)</u>.

Commenter's Reason: The addition of the comma after fixture clarifies that there are three (3) options on how the pump will start. Eliminating the requirement of a temperature rise allows for innovation and reduces restriction of technology from only one design. Most thermostats available in the market are designed for 104°F, not 102°F.

RE136-13, Part II

Proposed Change as Submitted

THIS IS A 3 PART CODE CHANGE PROPOSAL. PARTS I AND II WILL BE HEARD BY THE IECC-RESIDENTIAL ENERGY CONSERVATION CODE DEVELOPMENT COMMITTEE AS 2 SEPARATE CODE CHANGES. PART III WILL BE HEARD BY THE IRC-PM COMMITTEE. SEE THE TENTATIVE HEARING ORDERS FOR THESE COMMITTEES.

Proponent: Gary Klein, Affiliated International Management, LLC, representing self, gary@aim4sustainability.com

PART II – IPC

Add new definition as follows:

DEMAND RECIRCULATION WATER SYSTEM. A water distribution system where one more pumps prime the service hot water piping with heated water upon demand for hot water.

Add new text as follows:

[E] 607.2.1.1 Demand recirculation controls. This section shall apply only to Group R2, R3 and R4 occupancies that are 3 stories or less in height above grade plane. A water distribution system having one or more recirculation pumps that pump water from a heated water supply pipe back to the heated water source through a cold water supply pipe shall be a *demand recirculation water system.* Pumps shall have controls that comply with both of the following:

1. The control shall start the pump upon receiving a signal from the action of a user of a fixture or appliance, sensing the presence of a user of a fixture or sensing the flow of hot or tempered water to a fixture fitting or appliance.

2. The control shall limit the water temperature increase in the cold water piping to not more than 10ºF (5.6 ºC) greater than the initial temperature of the water in the piping and limits the temperature entering the cold water piping to 102ºF (38.9 ºC).

Reason: The purpose of this code change proposal is to clarify the requirements for installing circulation pumps in applications that use a cold water supply pipe to circulate the water back to the water heater. Demand recirculation water systems are significantly more energy efficient than other recirculation systems and are inherently safer when the cold water supply is used as the return.

Figure 1 shows that demand activated circulation is significantly more energy efficient than any other type of heated water circulation system. The annual energy needed to keep the loop hot with water heated electrically or with natural gas are shown separately from the energy needed for the pump. The majority of the energy is lost in keeping the water in the loop at the desired temperature (all of it if there is a gravity loop). A small loop, 100 feet including the supply and the return was analyzed. The savings ranges from 87.5 percent when compared to a recirculation system that runs only 2-hours per day to 99 percent when compared to a recirculation system that runs only 24-hours per day. The operating costs and savings remain proportional as the length of the circulation loop and the flow rate of the pump increase.

Figure 1 Annual Energy Requirements for Demand Activated Circulation and Standard Recirculation

	Standard Recirculation						**Demand Activated Circulation**
	Daily Hours of Operation						
	24	12	8	6	4	2	0.25
Loop Heat Losses							
Natural Gas (therms)	292	146	97	73	49	24	3
Electric (kWh)	6,388	3,194	2,129	1,597	1,065	532	67

Pump Energy (kWh)	438	219	146	110	73	37	8

The inherently better safety comes from the fact that the controls specified for demand recirculation water systems limit the flow of water from the hot water supply into the cold water supply to only minutes a day and because they limit the temperature of the water that is allowed to go into the cold water supply. There are five other control strategies for heated water recirculation systems (thermosyphon (gravity), continuous pumping, timer controlled, bandwidth temperature sensor (aquastat) controlled and a combination of timer and bandwidth temperature sensor (aquastat) controlled and none of them has the ability to meet these stringent requirements.

The requirements of this section should be identical in both the IECC and the IPC, since the language for the controls does not depend on occupancy

For more information and background on issues related to hot water distribution and for a more detailed analysis in support of this proposal please go to http://www.aim4sustainability.com Follow the link on the home page to Codes.

Cost impact: This proposal will not increase the cost of construction, as it does not require the use of demand recirculation water systems. In addition, the ability to use cold-water supply piping as a return pipe may reduce the cost of installing a circulation loop.

R403.4.2 (NEW) #1-EC-KLEIN

Committee Action Hearing Results

PART III – IRC – Plumbing
Committee Action: **Disapproved**

Committee Reason: There is no need to have a pointer in the plumbing chapters to direct the reader to another chapter of the IRC. There could be no end to the amount of pointers we could put into the IRC.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Gary Klein, Affiliated International Management, LLC, representing self, requests Approval as Submitted.

Commenter's Reason: The Committee disapproved the code change because they felt there was no need of a pointer to another section in the IRC. This pointer section is only SUGGESTING A SIMPLIFICATION**-** Current design solutions customarily recirculate the hot water loop return directly back to the water heater with a dedicated return line. Allowing the cold water supply to be temporarily used as the return line reduces the costs of installing recirculation systems. This strategy was recognized by the Residential and Commercial Energy Committees, but only happens if the plumbing system design/installation is coordinated to achieve this result. There is therefore, a need for a pointer to the requirement.

I urge your support of this comment.

PART I-IECC RESIDENTIAL PROVISIONS

Add new text as follows:

R403.4.2 (IRC N1103.4.2) Efficient heated water supply piping. Heated water supply piping shall be in accordance with Section R403.4.2.1 or Section R403.4.2.2. The flow rate through ¼ inch piping shall not exceed 0.5 gpm (1.9 Lpm). The flow rate through 5/16 inch piping shall not exceed 1 gpm (3.8 Lpm). The flow rate through 3/8 inch piping shall not exceed 1.5 gpm (5.7 Lpm).

R403.4.2.1 (IRC N1103.4.2.1) Maximum allowable pipe length method. The maximum allowable piping length from the nearest source of heated water to the termination of the fixture supply pipe for *plumbing fixtures* and *plumbing appliances* shall be in accordance with the maximum piping length column~~s~~ in Table R403.4.2.1. Where the piping contains more than one size of pipe, the largest size of pipe within the piping shall be used for determining the maximum allowable length of the piping in Table R403.4.2.1.

TABLE R403.4.2.1 (IRC TABLE N1103.4.2.1)
PIPING VOLUME AND MAXIMUM PIPING LENGTHS

NOMINAL PIPE SIZE (inch)	VOLUME (liquid ounces per foot length)	MAXIMUM PIPING LENGTH (feet)	
		WATER FROM A WATER HEATER	WATER FROM A RECIRCULATION LOOP OR HEAT TRACED PIPE
1/4	0.33	50	50
5/16	0.5	50	48
3/8	0.75	50	32
1/2	1.5	43	16
5/8	2	32	12
3/4	3	21	8
7/8	4	16	6
1	5	13	5
1 ¼	8	8	3
1 ½	11	6	2
2 or larger	18	4	1

1 Gallon = 128 ounces. For SI: 1 inch=25.4 mm, 1 foot = 304.8 mm, 1 liquid ounce = 0.030 L

R403.4.2.2 (IRC N1103.4.2.2) Maximum allowable pipe volume method. The water volume in the piping shall be calculated in accordance with Section R404.4.2.2.1. The maximum volume from the nearest source of heated water to the termination of the fixture supply pipe for a *plumbing fixture* or *plumbing appliance* shall be 0.5 gallon (1.89 L) where the source of heated water is a water heater; and 0.19 gallon (0.7 L) where the source of heated water is a recirculating system or heat-traced piping.

R403.4.2.2.1 (IRC N1103.4.2.2.1) Water volume determination. The volume shall be the sum of the internal volumes of pipe, fittings, valves, meters and manifolds between the nearest source of heated water and the termination of the fixture supply pipe. The volume in the piping shall be determined from the volume column in Table R403.4.2.1. The volume contained within fixture shut off valves, within flexible water supply connectors to a fixture fitting and within a fixture fitting shall not be included in the water volume determination. Where heated water is supplied by a recirculating system or heat-traced piping, the volume shall include the portion of the fitting on the branch pipe that supplies water to the fixture.

Reason: This change speeds hot water to the user, saves energy and water, and potentially lowers construction costs. All these are accomplished by limiting the volume of water in the pipes.

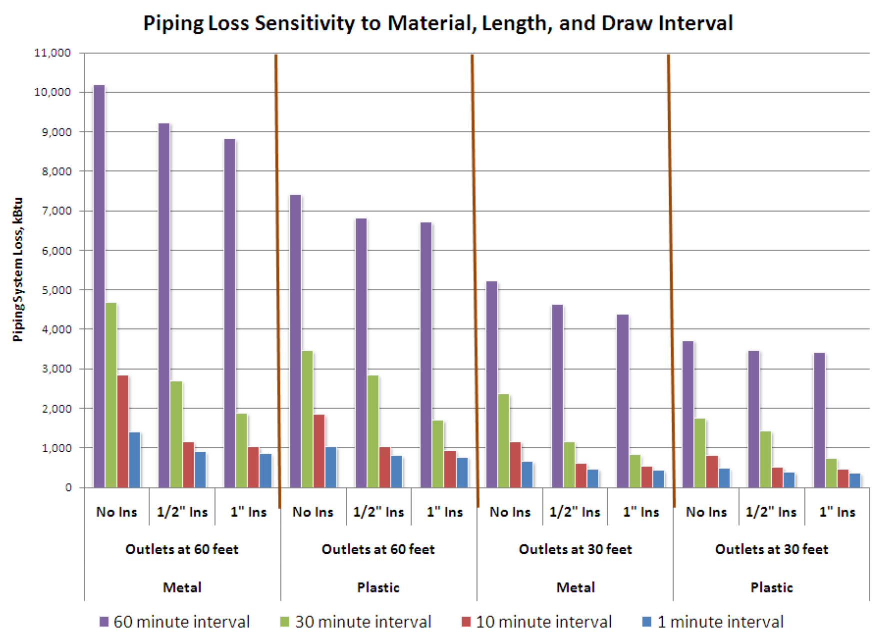
We have all have turned on the hot water and waited for it to get hot. While we wait water runs down the drain, wasting clean water. While we wait, our time is wasted. When we are done there is still hot water in the pipes, water which cools thereby wasting as much energy as it took to heat the water in the pipes. Pipes with larger volumes take longer to fill, waste more and are potentially more expensive to build.

This proposal remedies the problems above by reducing the water volume between the source of heated water and the use. The first method (Section R403.4.2.1) requires no calculation; it limits the water volume in the pipes by limiting the pipe length. The second option (Section R403.4.2.1) requires a calculation of volume in the pipes, but provides a table that translates the pipe length into a volume (columns 1 and 2); and provides quick options for different pipe assumptions in columns 3 and 4.

In simple form, cutting the volume in half: cuts the wait time in half, cuts the clean water wasted down the drain in half, cuts the energy loss while water goes through the pipes in half, and cuts the loss of energy from hot water left in the pipes after use in half.

A 2010 study done by the National Association of Home Builders Research Center shows the big impact of reducing hot water pipe volume. Figure 1, from that study, is below. The left half is for pipe 60 feet long. The right half is for pipe 30 feet long. Pick any case on the left and compare it to the same case on the right. Note there is always about a 50% reduction in piping energy lost in the 30-foot case. An example from the figure below, the energy loss of an uninsulated metal pipe 60 feet long drops from just over 10,000 kBtu to just over 5,000 kBtu for a pipe 30 feet long. Similarly uninsulated plastic pipe drops from about 7,300 kBtu to about 3,700 kBtu. The same pattern of reduction occurs when the piping is insulated.

Figure 1 Pipe Loss Comparison Using Parametric Analysis



Source: Domestic Hot Water System Piping Insulation: Analysis of Benefits and Costs, Figure 4, page 10 of 24, NAHB Research Center, December 2010.

Why is the maximum volume 0.5 gallon when the source of heated water is a water heater? So that following standard practice for plumbing engineers and meeting the minimum requirements in the energy code will be aligned. At present, they are not, with the result that hot water delivery times are greater than 30 seconds after the tap is opened; unacceptable performance according to the American Society of Plumbing Engineers.

Why is the maximum volume 0.19 gallon when the source of heated water is a circulation loop or heat-traced pipe? In exchange for the flexibility in the location of the water heater relative to the plumbing fixtures and plumbing appliances, the allowable volume that will be wasted has been reduced and the time-to-tap improved so that it will almost always fall into ASPE's range for Acceptable Performance.

The definition proposed is used in both the IRC and the IPC.

For more information and background on issues related to hot water distribution and for a more detailed analysis in support of this proposal please go to http://www.aim4sustainability.com Follow the link on the home page to Codes.

Cost impact: There are several ways to meet the requirements of this proposal, many of which cost less than current piping practices. I would recommend that builders and developers select one of the less expensive methods.

R403.4.2 #2 (NEW)-EC-KLEIN

Committee Action Hearing Results

PART I – IECC – Residential

Committee Action: Disapproved

Committee Reason: The proponents and opponents of RE122 are going to work together to bring that proposal, revised, forward in the public comment period. This proposal is disapproved in favor of the RE-122 being reworked and brought back at final action.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Gary Klein, Affiliated International Management, LLC, representing self, requests Approval as Modified by this Public Comment.

Modify the Proposal as follows:

R403.4.2.2 (IRC N1103.4.2.2) Maximum allowable pipe volume method. The water volume in the piping shall be calculated in accordance with Section R404.4.2.2.1. The maximum volume to the *plumbing fixtures* and *plumbing appliances* shall be 64 ounces (1.89 L) ~~where~~ from the source of heated water. Water heaters, circulating water systems and heat trace temperature maintenance systems shall be considered sources of heated water. ~~is a water heater; and 24 ounces (0.7 L) where the source of heated water is a recirculating system or heat-traced piping.~~

TABLE R403.4.2 (IRC TABLE N1103.4.2)
PIPING VOLUME AND MAXIMUM PIPING LENGTHS

NOMINAL PIPE SIZE (inch)	VOLUME (liquid ounces per foot length)	MAXIMUM PIPING LENGTH (feet)	
		~~WATER FROM A WATER HEATER~~	~~WATER FROM A RECIRCULATION LOOP OR HEAT TRACED PIPE~~
1/4	0.33	50	~~50~~
5/16	0.5	50	~~48~~
3/8	0.75	50	~~32~~
1/2	1.5	43	~~16~~
5/8	2	32	~~12~~
3/4	3	21	~~8~~
7/8	4	16	~~6~~
1	5	13	~~5~~
1 ¼	8	8	~~3~~
1 ½	11	6	~~2~~
2 or larger	18	4	~~1~~

1 Gallon = 128 ounces. For SI: 1 inch=25.4 mm, 1 foot = 304.8 mm, 1 liquid ounce = 0.030 L

Commenter's Reason: As agreed at the hearing, I have been working with the proponents of RE122 to revise that proposal for consideration at the FAH.

However, this proposal as originally submitted provides, what I believe is, a simpler, more inclusive method of achieving a similar result to what RE122 does. It is simpler because it provides one volume amount for all plumbing materials with the same nominal pipe diameter. This also makes it more inclusive when new piping materials are added to the code. It is also simpler because a maximum length for each nominal diameter has been provided for use by contractors and code officials; it will not always be necessary to calculate the volume. It will only be necessary to verify the nominal diameter and the length.

The purpose of the original proposal is to provide better hot water service to the occupants of our buildings. We have all experienced the problem of waiting for hot water to arrive at plumbing fixtures. Installing the hot water piping so that the delivery system is more efficient will stay with the building for 50-100 years. Similarly, the pain of an inefficient system will last just as long.

I have further simplified the original proposal based on feedback given by the IECC-CE Committee. There is now only one maximum length column. Now, the length (and the volume) from all sources of heated water to any plumbing fixture or appliance is the same.

I urge your support of either this public comment or support of RE122.

Public Comment 2:

Ryan Meres, Institute for Market Transformation, representing self, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R403.4.2 (IRC N1103.4.2) Efficient heated water supply piping. <u>From the nearest source of heated water to a plumbing fixture or plumbing appliance, the developed length of the piping shall not exceed 50 feet (15240 mm); or the piping length shall limit the time for heated water to arrive at its destination to not more than 30 seconds when the fixture or appliance is turned on to full hot, whichever is less. Water heaters, circulating water systems and heat trace temperature maintenance systems shall be considered sources of heated water.</u> ~~Heated water supply piping shall be in accordance with Section R403.4.2.1 or Section R403.4.2.2. The flow rate through ¼ inch piping shall not exceed 0.5 gpm (1.9 Lpm). The flow rate through 5/16 inch piping shall not exceed 1 gpm (3.8 Lpm). The flow rate through 3/8 inch piping shall not exceed 1.5 gpm (5.7 Lpm).~~

~~**R403.4.2.1 (IRC N1103.4.2.1) Maximum allowable pipe length method**. The maximum allowable piping length from the source of heated water to the termination of the fixture supply pipe shall be in accordance with the maximum piping length columns in Table R403.4.2. Where the piping contains more than one size of pipe, the largest size of pipe within the piping shall be used for determining the maximum allowable length of the piping in Table R403.4.2.~~

~~**R403.4.2.2 (IRC N1103.4.2.2) Maximum allowable pipe volume method**. The water volume in the piping shall be calculated in accordance with Section R404.4.2.2.1. The maximum volume to the *plumbing fixtures* and *plumbing appliances* shall be 64 ounces (1.89 L) where~~ ~~<u>from</u>~~ ~~the source of heated water.is a water heater; and 24 ounces (0.7 L) where the source of heated water is a recirculating system or heat-traced piping.~~

~~**R403.4.2.2.1 (IRC N1103.4.2.2.1) Water volume determination**. The volume shall be the sum of the internal volumes of pipe, fittings, valves, meters and manifolds between the source of heated water and the termination of the fixture supply pipe. The volume in the piping shall be determined from the volume column in Table R403.4.2. The volume contained within fixture shut off valves, within flexible water supply connectors to a fixture fitting and within a fixture fitting shall not be included in the water volume determination. Where heated water is supplied by a recirculating system or heat-traced piping, the volume shall include the portion of the fitting on the branch pipe that supplies water to the fixture.~~

~~**TABLE R403.4.2 ((IRC TABLE N1103.4.2)**~~
~~**PIPING VOLUME AND MAXIMUM PIPING LENGTHS**~~

Add new definition:

<u>**WATER HEATER.** Any heating appliance or equipment that heats potable water and supplies such water to the potable hot water distribution system.</u>

Commenter's Reason: As agreed at the hearing, we have been working with the proponents of RE122 to revise that proposal for consideration at the FAH.

At this time, hot water distribution systems in residential buildings are not required to limit the length between the source of hot water and the plumbing fixtures and plumbing appliances. In contrast, commercial buildings are required to limit the length to 50 feet of developed length in accordance with provisions in the IPC.

However, meeting the maximum length provision does not ensure that hot water will arrive at fixtures in a timely manner. It also wastes energy. It also means that plumbing engineers cannot meet their standards of practice.

The purpose of this proposal is to provide better, more energy efficient, hot water service to the occupants of our buildings. We have all experienced the problem of waiting for hot water to arrive at plumbing fixtures. Installing the hot water piping so that the delivery system is more efficient will stay with the building for 50-100 years. Similarly, the pain of an inefficient system will last just as long.

This proposal brings the length limitation from the IPC into the IECC. Since most of the buildings in the occupancies governed by IECC-RE generally have a smaller footprint that those that use IECC-CE, it should be easier for them to bring the uses within 50 feet of the sources of hot water. The proposal adds the provision that the hot water supply shall deliver hot water within 30 seconds after the plumbing fixture has been turned on. This provision is in line with the marginal performance standards of practice for plumbing engineers (See the orange row in Figure 1).

Figure 1. ASPE Time-to-Tap Performance Criteria

Source: Domestic Water Heating Design Manual – 2nd Edition, ASPE, 2003, page 234

Most plumbing fixtures and plumbing appliances in residential occupancies operate from 1 – 2.5 gpm. Figure 2 shows that the volume in the piping will be a maximum of 64 ounces for plumbing fixtures with these flow rates. When flow rates are lower, the volume needs to be smaller.

Figure 2 Comparing Pipe Volume, Plumbing Fixture Flow Rate and the Time-to-Tap

Volume in the Pipe (ounces)	Minimum Time-to-Tap (seconds) at Selected Flow Rates					
	0.25 gpm	0.5 gpm	1 gpm	1.5 gpm	2 gpm	2.5 gpm
2	4	1.9	0.9	0.6	0.5	0.4
4	8	4	1.9	1.3	0.9	0.8
8	15	8	4	2.5	1.9	1.5
16	30	15	8	5	4	3
24	45	23	11	8	6	5
32	60	30	15	10	8	6
64	120	60	30	20	15	12
128	240	120	60	40	30	24

	Acceptable Performance	1 – 10 seconds
	Marginal Performance	11 – 30 seconds
	Unacceptable Performance	31+ seconds

The changes in this comment simplify the proposal by reducing the perceived complexity of having a table and also by making the requirements the same for all sources of hot water.

We urge your support.

Proposed Change as Submitted

THIS IS A 2 PART CODE CHANGE PROPOSAL. PART I WILL BE HEARD BY THE IECC-RESIDENTIAL ENERGY CONSERVATION CODE DEVELOPMENT COMMITTEE. PART II WILL BE HEARD BY THE IRC-PM COMMITTEE. SEE THE TENTATIVE HEARING ORDERS FOR THESE COMMITTEES.

Proponent: Gary Klein, Affiliated International Management, LLC, representing self, (gary@aim4sustainability.com)

PART II IRC-P

Add new text as follows:

SECTION P2905
HEATED WATER DISTRIBUTION SYSTEMS

P2905.1 Heated water supply piping. Heated water supply piping shall be in accordance with Section N1103.4.2.

Reason: This change speeds hot water to the user, saves energy and water, and potentially lowers construction costs. All these are accomplished by limiting the volume of water in the pipes.

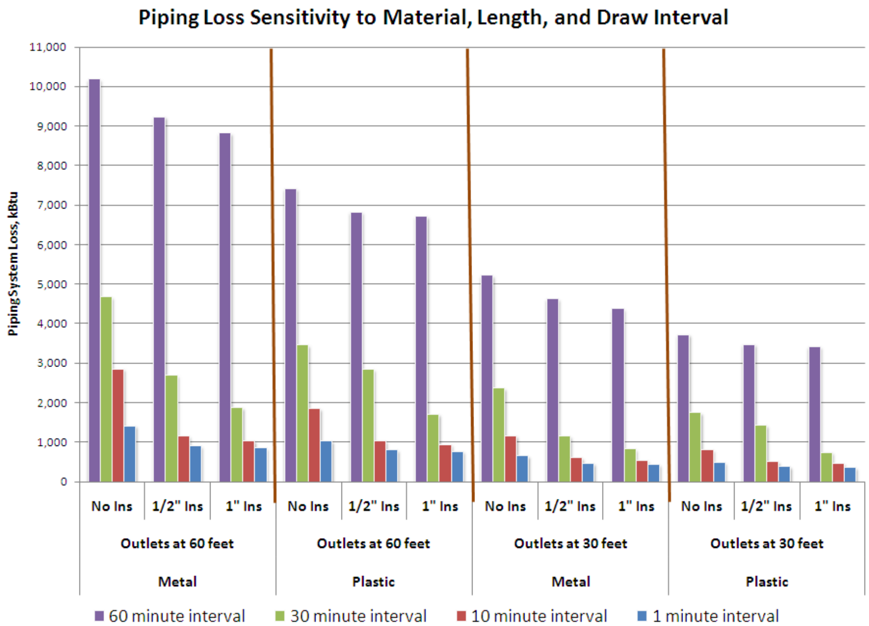
We have all have turned on the hot water and waited for it to get hot. While we wait water runs down the drain, wasting clean water. While we wait, our time is wasted. When we are done there is still hot water in the pipes, water which cools thereby wasting as much energy as it took to heat the water in the pipes. Pipes with larger volumes take longer to fill, waste more and are potentially more expensive to build.

This proposal remedies the problems above by reducing the water volume between the source of heated water and the use. The first method (Section R403.4.2.1) requires no calculation; it limits the water volume in the pipes by limiting the pipe length. The second option (Section R403.4.2.1) requires a calculation of volume in the pipes, but provides a table that translates the pipe length into a volume (columns 1 and 2); and provides quick options for different pipe assumptions in columns 3 and 4.

In simple form, cutting the volume in half: cuts the wait time in half, cuts the clean water wasted down the drain in half, cuts the energy loss while water goes through the pipes in half, and cuts the loss of energy from hot water left in the pipes after use in half.

A 2010 study done by the National Association of Home Builders Research Center shows the big impact of reducing hot water pipe volume. Figure 1, from that study, is below. The left half is for pipe 60 feet long. The right half is for pipe 30 feet long. Pick any case on the left and compare it to the same case on the right. Note there is always about a 50% reduction in piping energy lost in the 30-foot case. An example from the figure below, the energy loss of an uninsulated metal pipe 60 feet long drops from just over 10,000 kBtu to just over 5,000 kBtu for a pipe 30 feet long. Similarly uninsulated plastic pipe drops from about 7,300 kBtu to about 3,700 kBtu. The same pattern of reduction occurs when the piping is insulated.

Figure 1 Pipe Loss Comparison Using Parametric Analysis



Source: Domestic Hot Water System Piping Insulation: Analysis of Benefits and Costs, Figure 4, page 10 of 24, NAHB Research Center, December 2010.

Why is the maximum volume 0.5 gallon when the source of heated water is a water heater? So that following standard practice for plumbing engineers and meeting the minimum requirements in the energy code will be aligned. At present, they are not, with the result that hot water delivery times are greater than 30 seconds after the tap is opened; unacceptable performance according to the American Society of Plumbing Engineers.

Why is the maximum volume 0.19 gallon when the source of heated water is a circulation loop or heat-traced pipe? In exchange for the flexibility in the location of the water heater relative to the plumbing fixtures and plumbing appliances, the allowable volume that will be wasted has been reduced and the time-to-tap improved so that it will almost always fall into ASPE's range for Acceptable Performance.

The definition proposed is used in both the IRC and the IPC.

PART I – IECC RESIDENTIAL PROVISIONS

Add new text as follows:

R403.4.2 (N1103.4.2) Efficient heated water supply piping. Heated water supply piping shall be in accordance with Section R403.4.2.1 or Section R403.4.2.2. The flow rate through ¼ inch piping shall not exceed 0.5 gpm (1.9 Lpm). The flow rate through 5/16 inch piping shall not exceed 1 gpm (3.8 Lpm). The flow rate through 3/8 inch piping shall not exceed 1.5 gpm (5.7 Lpm).

R403.4.2.1 (N1103.4.2.1) Maximum allowable pipe length method. The maximum piping length from the nearest source of heated water to the termination of the fixture supply pipe for a public lavatory faucet shall be in accordance with the maximum piping length column~~s~~ in Table R403.4.2. Where the piping contains more than one size of pipe, the largest size of pipe within the piping shall be used for determining the maximum allowable length of the piping in Table R403.4.2.1.

TABLE R403.4.2.1 (N1103.4.2.1)
PIPING VOLUME AND MAXIMUM PIPING LENGTHS

NOMINAL PIPE SIZE (inch)	VOLUME (liquid ounces per foot length)	MAXIMUM PIPING LENGTH (feet)
		LAVATORY FAUCETS—PUBLIC
1/4	0.33	6
5/16	0.5	4
3/8	0.75	3
1/2	1.5	2
5/8	2	1
3/4	3	0.5
7/8	4	0.5
1	5	0.5
1 ¼	8	0.5
1 ½	11	0.5
2 or larger	18	0.5

For SI: 1 inch=25.4 mm, 1 foot = 304.8 mm, 1 liquid ounce = 0.030 L

R403.4.2.2 (N1103.4.2.2) Maximum allowable pipe volume method. The maximum piping volume from the nearest source of heated water to the termination of the fixture supply pipe for a public lavatory faucet shall be 2 ounces (0.06 L). The water volume in the piping shall be calculated in accordance with Section R404.4.2.2.1.

R403.4.2.2.1 (N1103.4.2.2.1) Water volume determination. The volume shall be the sum of the internal volumes of pipe, fittings, valves, meters and manifolds between the nearest source of heated water and the termination of the fixture supply pipe. The volume in the piping shall be determined from the volume column in Table R403.4.2.1. The volume contained within fixture shut off valves, within flexible water supply connectors to a fixture fitting and within a fixture fitting shall not be included in the water volume determination. Where heated water is supplied by a recirculating system or heat-traced piping, the volume shall include the portion of the fitting on the branch pipe that supplies water to the fixture.

Reason: The problem of heated water taking an excessively long time to arrive at lavatory faucets in public restrooms is well known. The length of time the faucets are used during each hand washing event is very short, often around 5 seconds. Federal law requires low flow rate or small, metered volumes for the faucets in these applications. Health codes expect heated water for washing hands in these applications. The dilemma is that the volume of not-hot water in the piping from the source of hot water to the faucets is much too large for the heated water to arrive in a timely fashion; even at the 50-foot limit currently required in the 2012 IPC. Supporting this proposal will correlate the IECC with Federal law and local health codes by providing heated water for hand washing in a timely matter.

The delivery of hot water to public lavatory faucets needs to be considered separately because of potential health issues. The events are short and the flow rates are low. Table 1 shows the time-to-tap performance based on the requirements in the proposal. The 0.25 and 0.5 gpm columns are typical of the flow rates for public lavatory faucets. The volume in the pipe was chosen so that heated water would arrive in the first part of the hot water event so that every person who uses the public lavatory will have the benefits of hot water.

Table 1 Time-to-Tap Performance when the Volume in the Piping from the Source to the Use is 2 ounces

Volume in the Pipe (ounces)	Minimum Time-to-Tap (seconds) at Selected Flow Rates					
	0.25 gpm	0.5 gpm	1 gpm	1.5 gpm	2 gpm	2.5 gpm
2	3.8	1.9	0.9	0.6	0.5	0.4

The energy savings comes from not losing the heat from the water as it tries to arrive at the faucets.

For more information and background on issues related to hot water distribution please read the 4-part series at: http://www.allianceforwaterefficiency.org/Residential_Hot_Water_Distribution_System_Introduction.aspx

Cost impact: There are several ways to meet the requirements of this proposal, some of which cost less than current heated water system practices. I would recommend that builders and developers select one of the less expensive methods.

R403.4.2 #3 (New)-EC-KLEIN

Committee Action Hearing Results

PART I – IECC – Residential

Committee Action: **Disapproved**

Committee Reason: This is a similar proposal to RE137. Point of use water heaters could be used to solve the problem that this proposal is trying to solve.

Assembly Action: **Approved as Submitted**

Individual Consideration Agenda

This code change proposal is on the agenda for individual consideration because the proposal received a successful assembly action of Approved as Submitted and public comments were received.

Public Comment 1:

Gary Klein, Affiliated International Management, LLC, representing self,requests Approval as Submitted.

Commenter's Reason: The Committee disapproved this proposal saying that point of use water heaters could be used to solve the problem that this proposal is trying to solve.

The committee was correct. Point-of-use water heaters are <u>one</u> of the possible solutions to the problem we have all encountered: not getting hot or tempered water to wash our hands in public restrooms. This proposal requires that, regardless of the method used to heat the water – including point-of-use water heaters – the volume between the source of hot water and the public lavatory faucets must be small. This is to ensure that heated water is actually delivered to the faucets for every user.

We urge your support of the Assembly Action and approve this code change.

Public Comment 2:

Ryan Meres, Institute for Market Transformation, representing self, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R403.4.2 (IRC N1103.4.2) Efficient heated water supply piping. <u>From the nearest source of heated water to a public lavatory faucet, the time for heated water to arrive at its destination shall not exceed 5 seconds when the faucet is turned on to full hot or for hands-free faucets, with the mixing valve set to the specified outlet temperature. Water heaters, circulating water systems and heat trace temperature maintenance systems shall be considered sources of heated water.</u> ~~Heated water supply piping shall be in accordance with Section R403.4.2.1 or Section R403.4.2.2. The flow rate through ¼ inch piping shall not exceed 0.5 gpm (1.9 Lpm). The flow rate through 5/16 inch piping shall not exceed 1 gpm (3.8 Lpm). The flow rate through 3/8 inch piping shall not exceed 1.5 gpm (5.7 Lpm).~~

~~**R403.4.2.1 (IRC N1103.4.2.1) Maximum allowable pipe length method**. The maximum allowable piping length from the source of hot or tempered water to the termination of the fixture supply pipe shall be in accordance with the maximum piping length columns in Table R403.4.2. Where the piping contains more than one size of pipe, the largest size of pipe within the piping shall be used for determining the maximum allowable length of the piping in Table R403.4.2.~~

~~**R403.4.2.2 (IRC N1103.4.2.2) Maximum allowable pipe volume method**. The water volume in the piping shall be calculated in accordance with Section R404.4.2.2.1. The maximum volume of water in the piping from the source of heated water to public lavatory faucets, metering or non-metering, shall be 2 ounces (0.06 L).~~

~~**R403.4.2.2.1 (IRC N1103.4.2.2.1) Water volume determination**. The volume shall be the sum of the internal volumes of pipe, fittings, valves, meters and manifolds between the source of heated water and the termination of the fixture supply pipe. The volume in the piping shall be determined from the volume column in Table R403.4.2. The volume contained within fixture shut off valves, within flexible water supply connectors to a fixture fitting and within a fixture fitting shall not be included in the water volume determination. Where heated water is supplied by a recirculating system or heat-traced piping, the volume shall include the portion of the fitting on the branch pipe that supplies water to the fixture.~~

~~**TABLE R403.4.2 ((IRC TABLE N1103.4.2)**~~
~~**PIPING VOLUME AND MAXIMUM PIPING LENGTHS**~~

Add new definition:

WATER HEATER. Any heating appliance or equipment that heats potable water and supplies such water to the potable hot water distribution system.

Commenter's Reason: The Committee disapproved this proposal saying that point of use water heaters could be used to solve the problem that this proposal is trying to solve.

This proposal focuses on the delivery of heated water to <u>public lavatory faucets</u> a problem all of us are familiar with.
The committee was correct. Point-of-use water heaters are <u>one</u> of the possible solutions to the problem we have all encountered: not getting hot or tempered water to wash our hands in public restrooms.

Current plumbing practice results in a significant waste of energy, without actually providing the intended or code required (health) service. The energy waste occurs when the water in the branches and fixture supplies cools down between the intermittent uses that occur in public bathrooms. The solution is to limit the volume between the source of heated water and the faucets or the time-to-tap for hot water to arrive after the faucet is turned on.

The purpose of this proposal is to provide better, more energy efficient, hot water service to the occupants of our buildings. Installing the hot water piping so that the delivery is more efficient will stay with the building for 50-100 years. Similarly the pain of an inefficient system will last just as long.

This comment simplifies the original proposal by saying that the hot water supply piping shall deliver hot water within 5 seconds after the public lavatory faucet has been turned on. This time limit is important because the actual amount of time a public lavatory faucet is used is generally less than 10 seconds. It only makes sense to have a code that delivers hot water in the first portion of the short event. This revised code section is now in line with the acceptable performance standards of practice for plumbing engineers (See the green row in Figure 1).

Figure 1. ASPE Time-to-Tap Performance Criteria

Source: Domestic Water Heating Design Manual – 2nd Edition, ASPE, 2003, page 234

Public lavatory faucets are a special case in the code as their flow rate is generally 0.5 gpm or less. However, since most public lavatory faucets are hands-free, the hot water portion of the mix is closer to 0.25 gpm. Figure 2 shows that the volume in the piping needs to be small for the heated water to arrive quickly at the faucets.

Figure 2 Comparing Pipe Volume, Plumbing Fixture Flow Rate and the Time-to-Tap

Volume in the Pipe (ounces)	Minimum Time-to-Tap (seconds) at Selected Flow Rates					
	0.25 gpm	0.5 gpm	1 gpm	1.5 gpm	2 gpm	2.5 gpm
2	4	1.9	0.9	0.6	0.5	0.4
4	8	4	1.9	1.3	0.9	0.8
8	15	8	4	2.5	1.9	1.5
16	30	15	8	5	4	3
24	45	23	11	8	6	5
32	60	30	15	10	8	6
64	120	60	30	20	15	12
128	240	120	60	40	30	24

	Acceptable Performance	1 – 10 seconds
	Marginal Performance	11 – 30 seconds
	Unacceptable Performance	31+ seconds

The changes in this comment simplify the proposal by reducing the complexity of having a table.

We urge your support.

Proposed Change as Submitted

THIS IS A 2 PART CODE CHANGE. PART I WILL BE HEARD BY THE IECC RESIDENTIAL ENERGY CONSERVATION CODE DEVELOPMENT COMMITTEE. PART II WILL BE HEARD BY THE IRC-PM COMMITTEE. SEE THE TENTATIVE HEARING ORDERS FOR THESE COMMITTEES.

Proponent: Gary Klein, Affiliated International Management, LLC, representing self, (gary@aim4sustainability.com)

PART II-IRC-P

Add new text as follows:

SECTION P2905
HEATED WATER DISTRIBUTION SYSTEMS

P2905.1 Heated water supply piping. Heated water supply piping shall be in accordance with Section N1103.4.2.

Reason: The problem of heated water taking an excessively long time to arrive at lavatory faucets in public restrooms is well known. The length of time the faucets are used during each hand washing event is very short, often around 5 seconds. Federal law requires low flow rate or small, metered volumes for the faucets in these applications. Health codes expect heated water for washing hands in these applications. The dilemma is that the volume of not-hot water in the piping from the source of hot water to the faucets is much too large for the heated water to arrive in a timely fashion; even at the 50-foot limit currently required in the 2012 IPC. Supporting this proposal will correlate the IECC with Federal law and local health codes by providing heated water for hand washing in a timely matter.

The delivery of hot water to public lavatory faucets needs to be considered separately because of potential health issues. The events are short and the flow rates are low. Table 1 shows the time-to-tap performance based on the requirements in the proposal. The 0.25 and 0.5 gpm columns are typical of the flow rates for public lavatory faucets. The volume in the pipe was chosen so that heated water would arrive in the first part of the hot water event so that every person who uses the public lavatory will have the benefits of hot water.

Table 1 Time-to-Tap Performance when the Volume in the Piping from the Source to the Use is 2 ounces

Volume in the Pipe (ounces)	~~Minimum~~ Time-to-Tap (seconds) at Selected Flow Rates					
	0.25 gpm	0.5 gpm	1 gpm	1.5 gpm	2 gpm	2.5 gpm
2	3.8	1.9	0.9	0.6	0.5	0.4

The energy savings comes from not losing the heat from the water as it tries to arrive at the faucets.

For more information and background on issues related to hot water distribution please read the 4-part series at: http://www.allianceforwaterefficiency.org/Residential_Hot_Water_Distribution_System_Introduction.aspx

Cost impact: There are several ways to meet the requirements of this proposal, some of which cost less than current heated water system practices. I would recommend that builders and developers select one of the less expensive methods.

R403.4.2 #3 (NEW)-EC-KLEIN

Committee Action Hearing Results

PART II – IRC – Plumbing

Committee Action: **Disapproved**

Committee Reason: There is no need to have a pointer in the plumbing chapters to direct the reader to another chapter of the IRC. There could be no end to the amount of pointers we could put into the IRC.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Gary Klein, Affiliated International Management, LLC, representing self, requests Approval as Submitted.

Commenter's Reason: The Committee disapproved the code change because they felt there was no need of a pointer to another section in the IRC.

I am asking you to approve the proposal as originally submitted because I am concerned that if this doesn't pass, are the plumbers, builders and code officials in your jurisdiction going to realize that something in the energy code section of the IRC is going to affect their work?

I urge your support of this comment.

RE138-13, Part II

Final Action: AS AM AMPC____ D

RE143-13
R403.6 (IRC N1103.6)

Proposed Change as Submitted

Proponent: Philip Debes, Dan Deen, Steve Frazer, Lloyd Larkin, Allan Tyson, Jim Walker, all of P and N Distribution, Inc. representing themselves. Clifton Payne of DNV KEMA (Det Norske Veritas and Keuring Elektrotechnische Materialen Arnhem) Energy and Sustainability, representing Energy Design Systems, Philip Jeffers, Energy Design Systems, Inc, representing self, Scott Miller, Knauf Insulation representing self

Revise as follows:

R403.6 (N1103.6) Equipment Sizing (Mandatory). Heating and cooling equipment shall be sized in accordance with ~~ACCA Manual S based on building loads calculated in accordance with ACCA Manual J or other *approved* heating and cooling calculation methodologies.~~ standard engineering heat loss and heat gain formulas coupled with appropriate weather data, home construction materials and other considerations normally used in the HVAC industry.

Reasons:

[DEBES, DEEN, FRAZER, LARKIN, TYSON, WALKER] ACCA Manual J and ACCA Manual S are trademarks. Code officials mistakenly believe ACCA is the certifying agent for IECC code compliance. ACCA charges royalties for ACCA approved software and resells software directly to contractors. ACCA is an HVAC software competitor, not a certifying authority.

[PAYNE] ACCA Manual J and ACCA Manual S are trademarks. ACCA is not the certifying agent for IECC code compliance, as ACCA Code officials appear to mistakenly believe. ACCA charges royalties for ACCA approved software and resells software directly to contractors. ACCA is an HVAC software competitor, not a certifying authority. By referencing ACCA in R403.6, the IECC would be selecting and endorsing one product from the marketplace over overs, not simply providing a standard that should be used to size HVAC equipment. This would create an unlevel playing field by providing ACCA with a competitive advantage.

[JEFFERS]
1. ACCA Manual J and ACCA Manual S are trademarks. ACCA and ACCA's software partners are using the IECC code to intimidate contractors. See attachment 1: ACCA "Contractors Beware", See attachment 2: Bob Volin, ACCA Code Committee Member, Photo Shopping his Letterhead onto the Code's Section R403.6 and convincing contractors into buying "ACCA Approved Software" and trying to force software developers into royalty payments totaling millions of dollars. ACCA is restraining trade, eliminating competition, and inhibiting development of more accurate software and procedures. Building Inspectors mistakenly interpret "in accordance with" to mean "approved by". ACCA uses this fact to create a de-facto IECC software certification process, making millions in fees, royalties, and reselling the software ACCA "approves". ACCA is a software competitor and Section R403.6 creates unfair competition.

2. For existing houses ACCA's Manual J procedure has no relationship to any sound engineering practice. None of the inputs such as a home's leakage rate, duct loss/gain, or any other value are known, and these inputs can have wide tolerances. Contractors use inputs that give them the answers they want. This is called confirmation Bias. An ACCA load calculation on an existing house is no different from guessing the size. The fact that contractors work ACCA's procedure backwards is widely known in the HVAC industry. ACCA load calculations average 140% of operating loads and can contribute to comfort, health, safety issues, and dramatically overstate energy usage.

> "they simply change some of the inputs to make the procedure spit out answer they're comfortable with and no one questions their answers." - Hank Rutkowski P.E. Author ACCA Manual J.

3. There is no evidence what so ever that "proper sizing" saves energy.

Media Contact: Melissa Broadus, 703-575-4477 melissa.broadus@acca.org

Contractors: Beware of Inappropriate Load Calculation Software

Manual J ® is the ANSI-approved national standard for determining residential load calculations for HVACR systems, and is required by many building codes and regulations. It is produced by the Air Conditioning Contractors of America (ACCA), the nation's largest association of indoor environmental systems professionals.

Given the complexities of modern construction, contractors and design professionals are encouraged to use software for accurate system design. However, not all load calculation software is created equal.

ACCA is reminding contractors that only those software programs that have been approved and licensed by ACCA as "Powered by Manual J ®" can be considered in compliance with codes and regulations requiring the use of Manual J ®.

As of today, the only software programs that meet the requirements for Manual J ® load calculations are:

- **RHVAC Residential Load Calculation from Elite Software**
- **Right – J from Wrightsoft**
- **AccuLoads from ADTEK Software Company**
- **Florida Solar Energy Center's EnergyGauge**

Any other software program, online service or mobile application cannot be considered to be compliant with the Manual J ® standard and should not be used where Manual J ® is required. Use of non-authorized software may pose a liability for the contractor that installs the system.

For more information on Manual J ®, the ACCA system design process, and load calculation software, visit https://www.acca.org/industry/system-design.

Software providers interested in applying for validation and licensing of their product should contact Glenn Hourahan at glenn.hourahan@acca.org.

Manual J ® is a registered federal trademark of the Air Conditioning Contractors of America.

The Air Conditioning Contractors of America (ACCA) is a non-profit association serving more than 60,000 professionals and 4,000 businesses in the HVACR community, who work together to promote professional contracting, energy efficiency, and healthy, comfortable indoor environments for all Americans. For more information, visit www.acca.org.

Air Conditioning Contractors of America 2800 Shirlington Road, Suite 300 | Arlington, VA 22206 | 703-575-4477 | www.acca.org

Air Design Concepts, Inc.

Contractors: Beware of Inappropriate Load Calculation Software

Contractor Alert!

By now most you know as of March 15th 2012 load calculation will be required on

ALL AC CHANGE OUTS.

101.4.7.1.2 Replacement equipment sizing **(mandatory)**. An A/C contractor or licensed Florida PE shall submit a nationally recognized method based sizing calculation to the code official at the time of permit application for total replacement of the condensing and evaporator components of HVAC systems in accordance with Florida law and the provisions of Section **403.6.1**or Section **503.2.1**.as applicable.

403.6 Heating and cooling equipment (Mandatory).

403.6.1 Equipment sizing. Heating and cooling equipment shall be sized in accordance with ACCA Manual S based on the equipment loads calculated in accordance with **Manual J or other approved heating and cooling calculation methodologies,** based on building loads for the directional orientation of the building. The manufacturer and model number of the outdoor and indoor units (if split system) shall be submitted along with the sensible and total cooling capacities at the design conditions described in Section 302.1. This Code does not allow designer safety factors, provisions for future expansion or other factors which affect equipment sizing.

Approved methodologies by Florida code

- ACCA Manual J
- ASHRAE
- Florida PE

Manual J ® is the ANSI-approved national standard for estimating residential heating and cooling loads for HVACR systems. It is the reference cited in both national model building codes. Authorities having jurisdiction (AHJ) may approve alternative methods of load calculation, however, most AHJs recognized Manual J8 due to its long history and wide acceptance in the HVAC industry. Manual J is produced by the Air Conditioning Contractors of America (ACCA), the nation's largest association of indoor environmental systems professionals.

Given the complexities of modeling modern construction, HVAC contractors and other design professionals are encouraged to use software for accurate system design. However, not all load calculation software is created equal. ACCA is reminding contractors that only those software programs that have been approved and licensed by ACCA as "Powered by Manual J ®" can be considered compliant with the procedure referenced in the model codes.

As of today, the only software programs that meet the requirements for Manual J ® load calculations are:

- **RHVAC Residential Load Calculation from Elite Software**
- **Right – J from Wrightsoft**
- **AccuLoads from ADTEK Software Company**
- **Florida Solar Energy Center's EnergyGauge**

Any other software program, online service or mobile application, or stating they are based upon, cannot be considered to be compliant with the Manual J ® standard and should not be used where Manual J ® is required. Use of non-authorized software may pose a liability for the contractor that represents that they have complied with the Manual J® procedures.

[MILLER] ACCA Manual J and ACCA Manual S are trademarks. Code officials mistakenly believe ACCA is the certifying agent for IECC code compliance. ACCA charges royalties for ACCA approved software and resells software directly to contractors. ACCA is an HVAC software competitor, not a certifying authority.

ACCA Manual S and Manual J are trademarks of ACCA. According to ACCA, all software must be approved by ACCA or it does not comply with the intent of the IECC R-code and there are significant fees associated with the ACCA approval process. From the following link demonstrates that ACCA believes it has authority to appraise and charge a fee to other software developers for all software used in the IECC 2012 load calculation process:

https://www.acca.org/archives/news-and-media/news-room/press-releases/5524

The contents of the above link are as follows and the highlighted portion should be considered problematic from a trade restriction standpoint. It can be proven that this position has cost manufacturers significant sales because the manufacturer's software (while correct) has not been approved by and fees paid to ACCA.

Contractors: Beware of Inappropriate Load Calculation Software

For more information on Manual J ®, the ACCA system design process, and load calculation software, visit https://www.acca.org/industry/system-design.

Cost Impact: The code change proposal will not increase the cost of construction.

R403.6-EC-DEBES.DOC

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee believes that the ACCA Standards continue to be accepted and useful references for equipment sizing. The references do not preclude the code user from using other software.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Richard Grace, Fairfax County, representing Virginia Plumbing and Mechanical Inspectors Association and Virginia Building and Code Officials Association requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R403.6 (N1103.6) Equipment Sizing (Mandatory). Heating and cooling equipment shall be sized in accordance with ACCA Manual S <u>or other approved sizing methodologies</u> <u>based on building loads calculated in accordance with ACCA Manual J or other approved heating and cooling calculation methodologies.</u> ~~standard engineering heat loss and heat gain formulas coupled with appropriate weather data, home construction materials and other considerations normally used in the HVAC industry.~~

Commenter's Reason: The current language permits ONLY the use of ACCA Manual S to size residential heating and cooling equipment. There are other sizing methodologies, such as ASHRAE's Handbook series, that are quite acceptable and approvable for use in sizing residential HVAC equipment.

RE143-13

Final Action: AS AM AMPC____ D

RE144-13
R403.6 (IRC N1103.6)

Proposed Change as Submitted

Proponent: Richard Grace, Virginia Plumbing and Mechanical Inspectors Association and Virginia Building and Code Officials Association (Richard.Grace@fairfaxcounty.gov)

Revise as follows:

R403.6 (N1103.6) Equipment and appliance Sizing (Mandatory). Heating and cooling equipment and appliances shall be sized in accordance with ACCA Manual S based on building loads calculated in accordance with ACCA Manual J or other approved heating and cooling calculation methodologies.

Exception: Heating and cooling equipment and appliances shall not be limited to the capacities determined in accordance with Manual S where any of the following conditions apply:

1. The specified equipment or appliance utilizes multi-stage technology or variable refrigerant flow technology and the loads calculated in accordance with Manual J fall within the range of the manufacturer's published capacities for that equipment or appliance.
2. The specified equipment or appliance manufacturer's published capacities cannot satisfy both the total and sensible heat gains calculated in accordance with Manual J and the manufacturer's next larger standard size unit is specified.
3. The specified equipment or appliance is the smallest capacity unit available from the specified manufacturer.

Reason:

Item 1 - Current technology is widely available that incorporates multi-stage or VRF systems for increased efficiency. Some of these appliances have such a wide span of functionality that they extend beyond the allowable requirements outlined in Manual S. However, this technology allows the appliance to operate between minimum and maximum capacities, based on loads imposed, thus eliminating the problems associated with single-stage, oversized appliances. Additionally, the appliance will operate efficiently during times where outdoor air temperatures exceed those used to calculate the loads in Manual J.

Item 2 - Often times, the appliance manufacturer's published total and sensible capacities are at odds with the requirements of Manual S. There are many cases where the total capacity of the appliance will fall within the parameters of Manual S in relation to the calculated total gain, however the sensible capacity of the appliance may fall short of the calculated sensible gain, thus unable to provide efficient sensible cooling for the space. When the manufacturer's next standard size larger is chosen to meet the sensible gain, the total capacity of the appliance may then exceed the requirements of Manual S. Choosing the larger appliance will enable a more efficient and effective system.

Item 3 - The current code language does not have provisions for sizing appliances for minimal dwelling unit or dwelling addition loads, other than forcing owners and contractors to change appliances to less desirable systems. For example; a 2 story townhouse, in climate zone 4, with 600 square feet per floor wants to utilize a two-zone system, or a separate heat pump system for each floor. A 1.5 ton unit per floor would exceed the requirements of Manual S, however a 1.5 ton unit could be the smallest available appliance made by the desired manufacturer. Current language would require a complete design change, such as utilizing a single appliance to serve the entire dwelling rather than the more desirable two-zone system, or requiring a system that utilizes electric baseboard heating and window-mounted air conditioning units. This is absurd, and an unfair to an owner that desires to reduce energy costs.

Cost Impact: None

R403.6-EC-GRACE.DOC

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: The proponent requested disapproval. The proponent intends to submit public comments to ACCA Manual S, rather than pursue code change in the IECC. The request for disapproval would allow the proponent to pursue this later in the public comment phase if need be.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Richard Grace, Fairfax County, representing Virginia Plumbing and Mechanical Inspectors Association and Virginia Building and Code Officials Association requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R403.6 (N1103.6) Equipment and appliance Sizing (Mandatory). Heating and cooling equipment and appliances shall be sized in accordance with ACCA Manual S <u>or other approved sizing methodologies</u> based on building loads calculated in accordance with ACCA Manual J or other approved heating and cooling calculation methodologies.

> **Exception:** Heating and cooling equipment and appliance~~s~~ <u>sizing</u> shall not be limited to the capacities determined in accordance with Manual S <u>or other approved sizing methodologies</u> where any of the following conditions apply:
>
> 1. The specified equipment or appliance utilizes multi-stage technology or variable refrigerant flow technology and the loads calculated in accordance with ~~Manual J~~ <u>the approved heating and cooling methodology</u> fall within the range of the manufacturer's published capacities for that equipment or appliance.
> 2. The specified equipment or appliance manufacturer's published capacities cannot satisfy both the total and sensible heat gains calculated in accordance with ~~Manual J~~ <u>the approved heating and cooling methodology</u> and the ~~manufacturer's~~ next larger standard size unit is specified.
> 3. ~~The specified equipment or appliance is the lowest capacity unit available from the specified manufacturer.~~

Commenter's Reason: After listening to the discussions presented during the Committee Action Hearings, we have incorporated those concerns within this modification. The first being the addition of "other approved sizing methodologies". ACCA's Manual S is not the ***only*** approved, appropriate sizing methodology available to size residential HVAC equipment. The current language would not permit other sizing methodologies such as ASHRAE's Handbook series. The second modification was to reword the language to provide clarity to the text. The third modification was to remove the third exception based on concerns voiced during testimony about the broad aspects that such an exception would permit.

The following is from the original reason statement:

Item 1 - Current technology is widely available that incorporates multi-stage or VRF systems for increased efficiency. Some of these appliances have such a wide span of functionality that they extend beyond the allowable requirements outlined in Manual S. However, this technology allows the appliance to operate between minimum and maximum capacities, based on loads imposed, thus eliminating the problems associated with single-stage, oversized appliances. Additionally, the appliance will operate efficiently during times where outdoor air temperatures exceed those used to calculate the loads in Manual J.

Item 2 - Often times, the appliance manufacturer's published total and sensible capacities are at odds with the requirements of Manual S. There are many cases where the total capacity of the appliance will fall within the parameters of Manual S in relation to the calculated total gain, however the sensible capacity of the appliance may fall short of the calculated sensible gain, thus unable to provide efficient sensible cooling for the space. When the manufacturer's next standard size larger is chosen to meet the sensible gain, the total capacity of the appliance may then exceed the requirements of Manual S. Choosing the larger appliance will enable a more efficient and effective system.

Public Comment 2:

Luis Romeo Escobar, Air Conditioning Contractors of America requests Disapproval.

Commenter's Reason: The proposed exceptions to ACCA Manual S should be disapproved for the following reasons:

1. Variable refrigerant flow (VRF) technology is addressed in the revised Manual S. The committee that led the revision effort included representatives of VRF manufacturers. The new Manual S over size limits have been vetted by these committee members and is based on the available OEM expanded performance data. ACCA is following ICC procedures to ensure that the updated Manual S is the one referenced in the 2015 IRC and IECC.
2. Exceptions #2 and #3 are not based on sound technical grounds, but instead are contrived to benefit sales of a particular product class. This is specifically against the entire intent of Manual S and exactly what the industry needs to get away from.
3. The cost impact of this proposed change is not "none" as indicated by the proponents. Larger-than-necessary equipment will generally have higher initial costs (longer pay-back), higher energy costs due to constant cycling on-and-off of the equipment, shortened equipment lifespan (again, due to the wear-and-tear of constant cycling), and will have higher

maintenance costs if the proponents' example of two oversized units for one house is the case (homeowners are generally charged based on the number of units being serviced).

4. In the reasoning for item 3 the proponents state that a homeowner will see reduced energy costs by installing two oversized units as opposed to one properly sized unit – this patently absurd and unsubstantiated. The proponents, unfortunately not unlike many design practitioners, seem to think that installing two units is the only way to properly zone a home, which is not the case.
5. The main reason why the industry has a standard to avoid oversizing is in order to ensure that there is proper humidity control in the home. Severely oversized equipment does not stay on long enough for the coil to reach a low enough temperature for adequate moisture removal. This can result in the presence of mold and mildew, not to mention lead to an uncomfortable interior ambience (the dry-bulb temperature will be low, but the humidity high so it will feel clammy to the occupant). Clearly, this proposal would in no way makes a home safer, but instead puts the occupants in greater risk of developing serious health issues from the presence of moisture.
6. Manual S is not a suggestion, as the proponents erroneously purport. It is an industry developed, ANSI recognized standard that sets clear oversize limits that must be adhered to. While the old Manual S did have permissive language that may not have been adequately addressed by the directions on the inside cover, great care has been taken to ensure that the normative sections of the new Manual S are written in mandatory, enforceable language that is acceptable for the i-codes. It will undergo a second ANSI public review, during which anyone (proponents included) may submit a comment to correct any deficiencies.
7. Any exceptions to Manual S should be based on industry research, and not on personal anecdote. To date, no credible research has been produced that supports the claim that hugely oversized HVAC equipment is desirable or leads to a safer, more sustainable, more affordable, or more resilient home.
8. For situations in which the OEM expanded performance data is not available, the new Manual S provides a path for compliance in which the manufacturer certifies that the equipment meets the home's physical requirements.
9. Manual S already has procedures that allow for regional differences (the comparison of heating degree days to cooling degree days for qualification of different heat pump sizing limits).
10. One common problem that is used as justification for gross oversizing is that the specified OEM doesn't offer equipment with small enough capacity for the load requirements. Unfortunately, this will continue to be that case as long as the Manual S requirements are not enforced. This proposal is effectively asks code officials to compensate for a lack of OEM product offerings, which is not the purpose of the building codes (in fact, it will serve as a catch 22 that will prolong the same problem).

RE144-13

Final Action: AS AM AMPC____ D

RE145-13
R403.9.3 (NEW) (IRC N1103.9.3.1 (NEW))

Proposed Change as Submitted

Proponent: Edward R. Osann, Natural Resources Defense Council, on behalf of self (eosann@nrdc.org)

Add new text as follows:

R403.9.3.1 (N1103.9.3.1) Mechanical retraction mechanism. Vapor retardant pool covers having a dry weight of 40 lbs (18.1 kg) or more for heated pools associated with one- or two-family homes shall be provided with a mechanical retraction mechanism. The mechanism shall be designed for the cover material, the cover weight and the dimensions of the cover.

Reason: Pool covers serve to retain heat in heated pool systems and reduce water loss due to evaporation – but only when used. Swimming pools at single-family residences are frequently not professionally managed or maintained, and such pools are most likely to go for several consecutive days without use. These characteristics support the use and value of a pool cover. However, the frequent deployment and retraction of a large pool cover by an individual swimmer in a single-family setting is problematic, contributing to widespread disuse of this valuable energy- and water-saving feature.

This proposal would require a pool cover to come with a means for mechanical retraction if it weighs 40 pounds or more. While the most common type of floating cover material is relatively light (0.1 lb per ft^2), the weight of a cover for a moderately sized back yard pool (18' X 36') can surpass 60 lbs. and be unwieldy for an individual to handle. The proposal is not specific as to the means or design of the device for mechanical retraction, and does *not* require a permanently affixed automatic retraction system. A hand operated device of suitable size would meet the requirements of this proposal.

Cost Impact: Hand operated mechanical equipment for the retraction of pool covers are marketed at around $200, and are available from several manufacturers. At least 5 manufacturers provide automatic pool cover equipment.

R403.9.3.1 (NEW)-EC-OSANN.DOC

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: This proposed requirement is not an energy code issue.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Edward R. Osann, Natural Resources Defense Council representing self, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R403.9.3.1 Mechanical retraction mechanism required. Vapor retardant pool covers having a dry weight of 40 lbs (18.1 kg) or more for heated in-ground pools associated with one- or two-family homes shall be provided with a mechanical retraction mechanism. The mechanism shall be designed for the cover material, the cover weight and the dimensions of the cover.

Reason: The committee raised concern over the suitability and availability of retraction equipment for above-ground pools. In response, the modification in this comment would limit the requirement to covers provided for in-ground pools.

RE145-13
Final Action: AS AM AMPC____ D

RE146-13
R403.10 (New) (IRC N1103.10 (New))

Proposed Change as Submitted

Proponent: Steve Rosenstock, Edison Electric Institute, representing Edison Electric Institute (srosenstock@eei.org(

Add new text as follows:

R403.10 (N1103.10) Fireplace systems (Mandatory). Fuel gas fired fireplace systems shall not have continuously burning pilot lights.

Reason: This language is consistent with the language on continuously burning pilot lights for pool heaters and gas lighting systems in the IECC. As of April 2012, under a 2009 US Department of Energy rulemaking, residential gas cooking equipment is not allowed to have continuously burning pilot lights.

According to the Hearth, Patio, and Barbecue Association, between 573,000 and 1,017,000 gas fireplace / hearth systems were shipped to North America every year between 2008 and 2011 (about 67 to 70% of total hearth shipments. See http://www.hpba.org/index.php?id=238 for more details). Many of these units are shipped to new homes with continuously burning pilot lights, ranging from 800 to 1,200 Btu's per hour. For a fireplace that has a pilot light using 1,000 Btu/hr, and is in "standby" mode for about 8000 hours per year (assuming that the fireplace is used 5 hours per day for 150 days of the year), the pilot light uses 8 million Btu's, or 80 therms. At a national average cost of $1.06 per therm, the cost to a typical consumer is nearly $85 per year.

With propane systems, 8 million Btu's is equivalent to 87.59 gallons. At a national average cost of $2.56 per gallon (*Federal Register* page 24940 April 26, 2012, Representative Average Unit Costs of Energy), the cost to a propane consumer is slightly more than $224 per year.

As a reference point, according to the 2010 AGA *Gas Facts 2008*, a typical gas range uses about 52 therms (5.1 Mcf) per year, and a typical clothes dryer uses about 50 therms (49 Mcf) per year (Table 10-1, page 78). In fact, according to the AGA publication, in the Pacific region of the US, residential natural gas fireplaces use more energy (28.3 Mcf) than a typical residential natural gas water heater (22.1 Mcf) and gas range (5.1 Mcf) combined.

Significant energy savings are available with current technology. With advanced controls (electronic spark ignition, for example), the standby energy losses are eliminated, and the average US consumer saves nearly $85 to $224 per year, based on the examples shown.

Cost Impact: The code change proposal will not increase the cost of construction. Electronic ignitions are widely available.

R403.10-EC-ROSENSTOCK.DOC

Committee Action Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: Continuously burning pilot lights use a significant amount of energy. Disallowing them will represent energy savings. This action is consistent with previous year's actions on gas pilot lights for pool heaters and gas lighting systems.

Assembly Action: **Disapproved**

Individual Consideration Agenda

This code change proposal is on the agenda for individual consideration because the proposal received a successful assembly action of Disapproved and because public comments were submitted.

Public Comment 1:

Don Denton, representing Don Denton, Consulting Engineer requests Disapproval.

Commenter's Reason: Proposed code change RE146-13 should be disapproved, because unvented gas heating products would be eliminated by its adoption. It is improper for three key reasons:

First, **a code change should not eliminate a safety requirement of an ANSI national product standard and the United States Consumer Product Safety Commission (CPSC).** The ANSI national product standard requires unvented gas heating products to have a precisely made standing pilot as a safety device to shut-off the unit in case of oxygen reduction in the room air. It has been mandated by the CPSC for the past 34 years.

Second, **no code change related to energy conservation should eliminate the most energy efficient gas appliance that exists**. Besides, the standing pilot's energy isn't wasted, as it adds needed heat to the room.

Third, **consumers should not be denied the choice to buy unvented gas heating products.** The proponent's claim that the code change would not increase the cost of construction is wrong. Unvented gas heating products provide not only energy savings, but acquisition and installation savings as well.

Public Comment 2:

Mark Krebs, Laclede Gas Co., representing self requests Disapproval.

Commenter's Reason: Fuel gas-fired fireplaces are short-term use decorative hearth products that serve a unique, value-added function for the users. Unlike pool heaters, fireplaces are not unattended, automatically controlled appliances. Unlike continuously operating gas lights, fireplaces do not operate throughout the year, nor do they operate unattended overnight. One of the unique, value-added functions of a fuel gas fired fireplace systems is the pilot light ignition function. It is a reliable approach that can be used without electricity service.

Consumers making the choice of purchasing a fireplace with pilot light ignition understand the value added and limited operating cost impact of this unique feature. Since the pilot light can be manually shut off and re-opened repeatedly by the user, it is a uniquely useful function that can be included with the product at minimum annual energy cost. Such useful and unique features should not be prohibited in a minimum energy code.

Public Comment 3:

Patrick A. McLaughlin, McLaughlin & Associates, representing The Air-Conditioning, Heating and Refrigeration Institute, requests Disapproval.

Commenter's Reason: The Air-Conditioning, Heating and Refrigeration Institute request disapproval of RE146. Requiring that fireplace systems not have a continuously burning pilot light will violate NAECA for some appliances and the pilot light is a component of the oxygen depletion safety system in others. These safety and preemption issues override the minor energy efficiency gains.

Public Comment 4:

James Ranfone, American Gas Association, representing self, requests Disapproval.

Commenter's Reason: This comment is in support of the floor action taken during the hearings to disapprove the proposal. The proposal proponent provided misleading information to justify a ban of widely available consumer product. The proponent stated that "*according to the Hearth, Patio, and Barbecue Association that between 573,000 and 1,017,000 gas fireplace / hearth systems were shipped to North America every year between 2008 and 2011 (about 67 to 70% of total hearth shipments. See http://www.hpba.org/index.php?id=238 for more details)*." They failed to note that a significant portion of those shipments are classified as heaters (both vented and unvented) and therefore subject to federal efficiency regulations. The ban would violate federal preemption of these products. It would also ban unvented fireplace heaters that have a standing pilot to operate the oxygen depletion system (ODS).

Based on misleading shipments they calculated a significant energy/cost savings to the consumer. They failed to note that many homeowners extinguish the pilot lights on decorative appliances for a significant portion of the year. At a minimum the proponent should have reduced their stated savings to account for a certain percentage of such homeowners. Therefore, the proponent overstated potential energy and cost savings to the consumer.

In addition, the proponent falsely claimed the code change would not increase the cost of construction. A non-pilot light appliance would most likely be a more expensive appliance and some would require adding electrical service to the gas-fired fireplace, both of which would result in an increase in construction costs.

The intent of EEI's initiative to seek a code ban based on energy savings is questionable, since the likely appliance substitute would be electric decorative fireplaces and electric resistance- type room heater. Such electric appliances would potentially use more energy and be more costly for the consumer to operate. In section R405.3 of the IRC, the performance-based compliance path has a 3.16 energy source multiplier factor for electric and a 1.1 factor for natural gas. The U.S. DOE 2013 representative unit residential cost figures are $35.46 per million Btu for electricity and $10.87 per million Btu for natural gas, substantiating the 3.16 multiplier.

For all these reasons AGA supports disapproval of this proposal.

Public Comment 5:

Thomas Stroud, Hearth, Patio and Barbecue Association, representing self, requests Disapproval.

Commenter's Reason:

1. Energy savings claims are not supportable. Energy savings claims presented are not supportable. We can walk you through the calculations, but even using a "worst case" evaluation, energy loss is less than the equivalent of a 100W light bulb per unit, and in a "most likely" set of parameters, the energy loss is less than the equivalent of a 50W light bulb. Weighing all factors and risks, it is clear that the potential savings, if there are indeed any, is not justified or even prudent.

    a. Vent free products - all of the pilot heat goes to the conditioned space and therefore, effectively contributes to heating the conditioned space thus, reducing the amount of primary heat required, so there is NO net loss of energy.
    b. Direct vent products - fireplace efficiencies are approximately 65%, so conservatively, 60% of the pilot heat goes to the conditioned space in those applications, leaving 40% as a "loss."
    c. B-vent products - some of the heat would go to the conditioned space, but for this discussion, we'll consider it all lost.
    d. ALL products pilot heat cannot be considered "lost" while the main burner is on, so we can deduct run time from the equation, as well as time when the pilot is turned off.
    e. Even if vent free is only 10% of the installed population of concern, another 15% is B-vent and the remaining 75% is direct vent, a direct calculation using 1,000Btu/h as a normalized typical pilot rate tells us the energy "loss" is:
        i. 100% of 15% B-vents, or 0.15*1000=150Btu/h
        ii. 0% of 10% vent-free units, or 0*1000=0Btu/h
        iii. 40% of 75% direct vent units, or 0.3*1000=300Btu/h
        iv. Which totals a loss usage of 150+0+300Btu/h = **450Btu/h** for every unit that has a continuous pilot on a normalized "typical" basis.
    f. Additionally:

        a. We can safely assume the units will be operated a total of 10 "burn days" per year as an average, so 10/365=0.027, or 2.7%.
        b. Subtracting 2.7% from 450Btu/h leaves us with 0.973*450Btu/h=**438Btu/h**, which applies to EVERY normalized "typical" unit with a continuous pilot.
        c. If we assume conservatively, that 50% of people turn their pilots off during the "off-season", and we agree the "off-season" is 50% of the year, then we can say that 0.5*0.5=25% of the year, a normalized "typical" pilot is turned off.
        d. 25% of 450Btu/h for the normalized "typical" unit is 0.25*450Btu/h=**113Btu/h.**
    g. So the final loss usage for the normalized "typical" continuous pilot is 438Btu/h-113Btu/h=***325Btu/h***. At 3.412Btu/Wh, this translates to a continuous burning 325/3.412=95W light bulb.
    h. And this does not even consider the energy "loss" from whatever other ignition means will be used in place of the continuous pilot!
2. Recognition of Products
    a. It is essential that if the ban on continuously burning pilot lights goes forward, there must be a definition of "continuously burning pilot". The importance of this is so that it is clear what types of pilots are allowed. The definition in ANSI Z21.20 is;
        i. Continuous. An ignition source which, once placed in operation, is intended to remain ignited or energized continuously until manually interrupted.
    b. It is likewise essential that there is a clear understanding among the code inspection community of what is and is not allowed. As you know, there are flame-type pilots that are not "continuous", which would be acceptable.
    c. Proven pilot systems are the primary type among hearth products, vs. the systems that directly sense main flame employed in the other products we've heard about (pool heaters and gas lights).
3. Elimination of products built to ANSI safety standards
    a. The ban on continuously burning pilot lights will eliminate products from the marketplace that have no loss at all from their continuously burning pilot. As noted above, since the unvented gas products do not vent to the exterior, all heat derived from the pilot stays within the dwelling.
4. Safety
    a. Many manufacturers stand behind their claims that, particularly in cold climates, their products will function better with a standing pilot. As well as the fact that any loss of energy from the pilot might likewise be a loss when cold air enters a non-piloted system and the resulting cold glass surface of the glass fireplace front requires additional heat from the dwelling. There has been no research to prove or disprove this claim.

Nonetheless they stand behind many years of functioning well with a continuously burning pilot and stand behind their claims that their users largely follow their use instructions to turn the pilots off in the summer months.

   b. Finally, as you are aware, there have been safety concerns raised related to different types of ignition systems. Regardless of your position related to what those are, I think you'd agree that these types of products must be as safe as we can make them; that your consideration must be at the system level, and must include consideration of application and environments where differences in parameters and combinations of conditions can bring about different responses in these products. So, if you consider that certain types of systems occur more frequently in certain climates and locations, and if you realize it's that way because decision makers with optimum safety being in their best interest drove them to it, then eliminating one of their options drives them to something else; some OTHER system than what they know to be successful and safe. Would such a change cause problems that can be directly assigned to having eliminated an option that has performed so flawlessly for so long?

5. Finally, the statement that there would be no increase in construction cost is incorrect. Most products operating on standing pilots currently will need to go through a Research & Development stage to switch piloting systems, as well as the fact that many of the non-standing pilot units will now have to have power run to them, adding to the cost.

Public Comment 6:

Bruce Swiecicki, National Propane Gas Association, representing self, requests Disapproval.

Commenter's Reason: The banishment of standing pilot lights in fuel gas fireplace systems would have a negative effect on the safety of the general public for the following reasons:

1. The oxygen depletion system (ODS) is a safety device that is used to monitor the oxygen level in a room or space where an unvented fireplace system is installed. The ODS has an exemplary safety record of being used in 22 million units over the past 32 years. The ODS shuts the appliance off automatically if the oxygen level in the room drops to a level of 18%, which correlates with the amount of carbon monoxide in the space. The ODS requires a standing pilot light to function and therefore the acceptance of RE146-13 would prohibit the use of this important safety device.
2. Invariably, winter in the United States brings with it power outages and significant hardships, due to ice and snow damaging power lines. Often times people are left with no alternatives to heat their families and their homes and they turn to burning fuels indoors in appliances that are not listed or safe to use inside of buildings. It is very important that appliances that have been tested and listed for use indoors and that can function safely during power outages continue to be permitted by the code. Many of these appliances, including the fireplaces that RE146-13 is addressing, are ignited by standing pilot lights.
3.

We request the ICC membership to disapprove RE146-13.

RE150-13
R202 (NEW) (IRC N1101.9 (NEW)), R404.1 (IRC N1104.1)

Proposed Change as Submitted

Proponent: Don Surrena, CBO, National Association of Home Builders (NAHB) (dsurrena@nahb.org)

Revise as follows:

R404.1 (N1104.1) Lighting equipment (Mandatory). ~~A minimum of seventy-five percent of the~~ Lamps in permanently installed lighting fixtures shall be high efficacy lamps ~~or a minimum of seventy-five percent of the permanently installed lighting fixtures shall contain only high efficacy lamps~~.

Exceptions:

1. Lamps in low-voltage lighting.
2. Lamps controlled by a dimmer or an *automatic control device*.
3. Lamps of 10 watts or less.
4. Lamps contained in appliances

Add new definition as follows:

AUTOMATIC CONTROL DEVICE. A device or system capable of automatically turning lighting loads off without manual intervention. Automatic control devices often include a feature for turning lights on manually.

Reason: Builder installed lighting represents roughly 7% of residential electricity use. This proposal has the potential to reduce household energy use by over 1%.
By requiring lamps (rather than fixtures) to be high efficacy, leaves open the ability for innovative new lighting technologies which can be used in a standard lighting base.
Durability of fixture ballasts is also a concern. Ballast repairs are not generally done by a consumer and will typically require an electrician replace the fixture at a significant cost increase to the consumer.
The new language is simpler, more enforceable and more stringent. It makes the code require 100% high efficacy lighting with an allowance for standard efficacy when special lighting controls are used.
Exceptions still maintain the stringency, but provide reasonable allowances for small lighting loads.

Cost Impact: The code change proposal will not increase the cost of construction.

R404.1-EC-SURRENA.DOC

Committee Action Hearing Results

Committee Action: **Approved as Modified**

Modify the proposal as follows:

AUTOMATIC CONTROL DEVICE. A device or system capable of automatically turning ~~lighting~~ loads off without manual intervention. The device or system may include a manual feature but is not required. ~~Automatic control devices often include a feature for turning lights on manually.~~

Committee Reason: The proposal provides needed flexibility in the code for meeting energy efficiency goals. The modification is made to recognize that an automatic control device could apply to equipment other than lighting.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Deborah Frankhouser, Four Point Lighting Design, representing International Association of Lighting Designers, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

R404.1 (N1104.1) Lighting equipment (Mandatory). Lamps in permanently installed lighting fixtures shall be high efficacy lamps.

Exceptions:

1. Lamps in low-voltage lighting.
2. ~~Lamps~~ Not more than 50% of lamps in permanently installed fixtures shall be allowed to be non-high efficacy where such fixtures are controlled by a dimmer switch or automatic control device.
3. Lamps of 10 watts or less.
4. Lamps contained in appliances.

(*Portions of proposal not shown remain unchanged.)*

Commenter's Reason: The proposal as approved by the committee, would allow 100% of lighting to be low efficacy if it was on a dimmer of automatic control device; from an energy efficiency standpoint, this is a step backwards.

The modification above strikes a good balance between those who want the flexibility of using some preferred low efficacy sources (using dimming or automatic shutoff to increase energy efficiency), while maintaining current industry energy efficiency expectations. This modification also maintains the simplicity of the proposal. Exception 2 is optional- for those who do not want to count lamps, they can meet the high efficacy requirement without doing any percentage calculation; only those who want to use exception number 2 would be required to demonstrate that the low efficacy lamps did not exceed 50% of the total lamps.

Public Comment 2:

Hope Medina, City of Cherry Hills Village, CO, representing self, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

R404.1 (N1104.1) Lighting equipment (Mandatory). A minimum of seventy-five percent of the Lamps in permanently installed lighting fixtures shall be high efficacy lamps or a minimum of seventy-five percent of the permanently installed lighting fixtures shall contain only high efficacy lamps.

Exceptions:

1. Lamps in low-voltage lighting.
~~2. Lamps controlled by a dimmer or a~~An *automatic control device*.
~~3.~~2 Lamps of 10 watts or less.
4.3 Lamps contained in appliances

(*Portions of proposal not shown remain unchanged.)*

Commenter's Reason: I am in favor of what the proponent is attempting to do with the code change, but I feel that dimmer switches will be used as a loophole to the code requirement. Using a dimmer switch as an exception to the requirement may increase the use of incandescent bulbs.

I have reviewed plans and inspected homes where an excessive amount of permanent fixtures are wired to a dimmer switch in every room. This change would have increased energy usage in these homes that are from both track builders and custom home builders.

Public Comment 3:

Donald Vigneau, AIA, representing Northeast Energy Efficiency Partnerships Inc., requests Disapproval.

Commenter's Reason: The proposed definition for *automatic control device* is flawed; would apply to loads other than electrical lighting; and would allow systems with no manual switch control to turn lighting on or off without any means for intervention. This was not corrected by the modification language approved.

The added Exception would allow for any and all non-efficient bulbs using these automatic controls without limitation and eliminate any claimed savings in increasing the percentage of high-efficiency lamps.

The change would not decrease the work level of code officials in determining compliance, as every switching arrangement would have to be inspected to determine if it met these provisions and could not be overridden or defeated. There is no difficulty (as suggested in the original reason statement) of obtaining high-efficiency lamps that are able to utilize standard Edison bases, whether CFL or LED. The ability to circumvent the 75 percent high-efficiency lamp/fixture standard with the use of dimmers, many of which that would actually increase the connected load, reduces the lighting efficiency below what is currently required in the existing code.

The proposal is flawed and should be disapproved.

RE150-13

Final Action: AS AM AMPC____ D

RE153-13
R405.2 (IRC N1105.2)

<u>Proposed Change as Submitted</u>

Proponent: Craig Conner, Building Quality, representing self (craig.conner@mac.com)

Revise as follows:

R405.2 (N1105.2) Mandatory requirements. Compliance with this section requires that the mandatory provisions identified in Section 401.2 be met. ~~All supply and return ducts not completely inside the building thermal envelope shall be insulated to a minimum of R-6.~~

Reason: Duct insulation is labeled both "prescriptive" in Section R403.2.1 and "mandatory" in R405.2. It can't be both.

Cost Impact: The code change proposal will not increase the cost of construction.

R405.2-EC-CONNER.DOC

<u>Committee Action Hearing Results</u>

Committee Action: **Disapproved**

Committee Reason: The proponent did not supply any technical justification for this lessening of requirements.

Assembly Action: **None**

<u>Individual Consideration Agenda</u>

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Craig Conner, Building Quality, representing self, requests Approval as Submitted.

Commenter's Reason: The committee thought this was a reduction in requirements; however the struck sentence has lower requirements than the retained sentence. The confusion is clear, but the proposed resolution does not seem to be a reduction in requirements.

The retained section is:
"R403.2.1 Insulation (Prescriptive). Supply ducts in attics shall be insulated to a minimum of R-8. All other ducts shall be insulated to a minimum of R-6."

The struck sentence is:
"All supply and return ducts not completely inside the building thermal envelope shall be insulated to a minimum of R-6."

Public Comment 2:

Jay Crandell, P.E., representing the Foam Sheathing Committee of the American Chemistry Council requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R405.2 (N1105.2) Mandatory requirements <u>and other limitations</u>. Compliance with this section requires that the mandatory provisions identified in Section 401.2 be met. All supply and return ducts not completely inside the building thermal envelope shall be insulated to a minimum of R-6<u>. U-factors for opaque building thermal envelop components included in Table R402.1.3 shall not be increased by more than 15 percent in the proposed design on an area-weighted average basis for each component.</u>

Commenter's Reason: While the committee noted that there was no technical justification given for deleting a technical requirement, the proposal makes an important point: The duct insulation requirement is not a mandatory requirement in the context of Chapter 4. But, in the context of Section R405.2, it is a limitation on the performance path. Basically, the code is saying that one cannot simply have an entirely "energy neutral" approach to the performance path because this can have negative impacts on the performance of certain systems and potential unintended consequences. Therefore, this public comment recognizes that Section R405.2 is actually addressing both mandatory requirements and other limitations that apply to the performance path. The title of the section is changed accordingly to clarify its purpose and the limit regarding ductwork is maintained as in the existing code (first underlined sentence).

In addition, this proposal in effect is dealing with the appropriateness of having limitations on the performance path that are not otherwise captured in mandatory statements. It is also clear from the committee's reason for disapproval that such limitations (or the absence thereof) should have a technical rationale. Thus, it is appropriate to consider limitations as this is the fundamental subject of the proposal.

Ductwork is actually part of the building envelop per se when in unconditioned spaces. Conditioned air from the interior of the building is subject to heat loss when being transported through ducts just as heat loss occurs through ceilings, walls, and other building envelope assemblies or components. When using the performance path on a purely "energy neutral" basis without limitation or discretion, unintended consequences can occur that are not adequately prevented by a purely "energy neutral" approach to performance (without technically sound limitations). Technically sound limitations bring to bear performance considerations that go beyond a view of just keeping the energy balance in an overall sense, but potentially harming performance in the details.

For the same reason it is important to limit the performance approach with respect to ducts in unconditioned space, it is also important to limit the performance approach in regard to its potential to degrade the performance of the building thermal envelope. Over-reaching reductions in building envelope thermal efficiency, like ductwork, can have unintended consequences. Some of these consequences that justify reasonable limitations on the performance path include:

1. An imbalance or over-reliance on one means of conserving energy which has a shorter service life, can result in a much less robust means of achieving energy efficiency. Therefore service life should be taken into consideration when establishing appropriate limitations on tradeoffs.
2. The potential for unlimited reductions in thermal envelope efficiency can result in poorer performance in ways that are not accounted for in the performance path. For example, when significantly reducing the building envelope insulation, interior surfaces are subject to larger temperature gradients dramatically affecting occupant comfort. This often results in changing of the set-point temperature further degrading the energy performance of the building. Also, in the case of power outages or equipment failure, it is more difficult to maintain tolerable living conditions.

Finally, it is important to recognize that other sections of the code also impose reasonable limitations on the performance path. For example, Section R402.5 imposes a limitation on the amount of increase in the overall U-factor for fenestration. Without such limits on the performance path, unintended consequences will occur that have other than "energy neutral" performance implications (e.g., excessive condensation on windows in colder climates and occupant discomfort leading to corrective actions such as increasing energy consumption by altering the set-point temperature). Such precedents for limitations on performance or simulation methods go beyond the energy code. For example, a 15% limit on reduction of wind loads is imposed on wind tunnel simulations unless worst-case scenarios are considered that demonstrate the reductions are "safe". Therefore, a similar approach is taken in this public comment to ensure a robust and balanced use of the performance path while avoiding the potential for "weak links" in the overall building system.

RE153-13

Final Action: AS AM AMPC____ D

RE154-13
R405.2 (IRC N1105.2), R405.2.1 (NEW) (IRC N1105.2.1 (NEW))

Proposed Change as Submitted

Proponent: Robby Schwarz, EnergyLogic Inc., representing EnergyLogic, Inc. (robby@nrglogic.com)

Revise as follows:

R405.2 (N1105.2) Mandatory requirements. Compliance with this section requires that the mandatory provisions identified in Section R401.2 be met. All supply and return ducts not completely inside the *building thermal envelope* shall be insulated to a minimum of ~~R-6~~ R-8. Ductwork, that is either partially or completely within the thermal layer of the wall system of the *building thermal envelope,* shall have insulation of a *R-value* of not less than R-10 on the side of the duct that is away from the conditioned space. Where the duct is in a wall cavity and the R-10 insulation does not completely fill the cavity, the remaining cavity space shall be filled with insulation to the extent that the requirement for insulating the exterior wall of the building is met or the cavity space is completely filled, whichever is less. Ductwork, that is either partially or completely within the thermal layer of a floor system of the *building thermal envelope,* shall have insulation of a *R-value* of not less than R-19 on the side of the duct that is away from the conditioned space. Floor cavity insulation shall be installed in accordance with Section R402.2.7. Where the duct is in a floor cavity and the R-19 insulation does not completely fill the cavity, the remaining cavity space shall be filled with insulation to the extent that the requirement for insulating the floor system of the building is met or the cavity space is completely filled, whichever is less.

R405.2.1 (N1105.2.1) In process inspection requirement. Inspections of the code-required energy specifications documented in the simulated performance code-compliance reports shall be verified to demonstrate that the as-built conditions meet or exceed the specified parameters used for the code-compliance reports. The entity or persons who performed the analysis shall perform the inspections or where *approved*, other *approved* entities or persons shall perform the inspection.

Reason: Field inspection, in order to create an accurate computer generated energy analysis, should be required for following reasons:

1. For production building, a plan is often mastered and that one plan may be built over 100 times. To ensure that each house meets the performance analysis, each home must be inspected.
2. Computer generated energy analyses utilize worst case configuration of the proposed design and requires evaluations and inputs that must be confirmed in the specific home that is built to ultimately determine if the actually built home meets the intent of the energy code. Examples of this are worst case air leakage and duct leakage numbers but also orientation, window square footage, number of bedrooms and foundation type.
3. The reality is that houses built from a set of plans change. The actual built home may generally reflect the homes plans but window square footage, orientation, and even insulation and mechanical equipment are often different from what was proposed. The inspection process ensures that the energy analysis is addressed and site specific which ultimately ensures that the home that received its permit from the proposed design's energy analysis has carried out what they have proposed, which is to meet the intent of the code, even if each component of the home is not exactly the same as what was on the set of plans.

Cost Impact: On a national basis there could be a cost impact as most jurisdiction's would allow third party inspections and not do the energy analysis themselves. However, this is one of many code compliance pathways the builder may choose and it is important that the builder realize that when this option is chosen that they in essence are locking themselves into a code compliance path that requires energy analysis and inspection. In Colorado, many builders utilize this path and are seeing value due to increased quality assurance, consistency across jurisdictional boundaries in a home rule state, and measured quantification of compliance.

R405.2-EC-SCHWARZ.DOC

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: Items of this detail do not belong in the performance side of the code. This seems to be a shotgun approach to dealing with insulation ductwork on the performance side.

Assembly Action: None

<u>Individual Consideration Agenda</u>

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Robby Schwarz, EnergyLogic Inc., representing EnergyLogic, Inc., requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R405.2 (N1105.2) Mandatory requirements. Compliance with this section requires that the mandatory provisions identified in Section R401.2 be met. All supply and return ducts not completely inside the *building thermal envelope* shall be insulated to a minimum of ~~R-6~~ <u>R-8.</u> ~~Ductwork, that is either partially or completely within the thermal layer of the wall system of the *building thermal envelope,* shall have insulation of a *R-value* of not less than R-10 on the side of the duct that is away from the conditioned space. Where the duct is in a wall cavity and the R-10 insulation does not completely fill the cavity, the remaining cavity space shall be filled with insulation to the extent that the requirement for insulating the exterior wall of the building is met or the cavity space is completely filled, whichever is less. Ductwork, that is either partially or completely within the thermal layer of a floor system of the *building thermal envelope,* shall have insulation of a *R-value* of not less than R-19 on the side of the duct that is away from the conditioned space. Floor cavity insulation shall be installed in accordance with Section R402.2.7. Where the duct is in a floor cavity and the R-19 insulation does not completely fill the cavity, the remaining cavity space shall be filled with insulation to the extent that the requirement for insulating the floor system of the building is met or the cavity space is completely filled, whichever is less.~~

R405.2.1 (N1105.2.1) In process inspection requirement.
Inspections of the code-required energy specifications documented in the simulated performance code-compliance reports shall be <u>field</u> verified <u>and documented.</u> ~~to demonstrate that the as-built conditions meet or exceed the specified parameters used for the code-compliance reports. The entity or persons who performed the analysis shall~~ <u>be permitted to</u> ~~perform the inspections or where *approved*, other *approved* entities or persons shall perform the inspection.~~ <u>Inspections shall be performed by the code official or approved third party.</u>

Commenter's Reason: I agree with the committee that I was trying to do too much with this code change. I therefore pared down the proposal to its most important aspect mandatory inspection.

Field inspection, in order to create an accurate computer generated energy analysis, should be required for following reasons:

1. For production building, a plan is often mastered and that one plan may be built repeatedly from the master. To ensure that each house meets the performance analysis, each home must be inspected.
2. Computer generated energy analyses utilize worst case configuration of the proposed design and requires evaluations and inputs that must be confirmed in the specific home that is built to ultimately determine if the actual built home meets the intent of the energy code. Examples of this are worst case air leakage and duct leakage numbers but also orientation, window square footage, number of bedrooms and foundation type.
3. The reality is that houses built from a set of plans change. The actual built home may generally reflect the home's plans but window square footage, orientation, and even insulation and mechanical equipment are often different from what was proposed. The inspection process ensures that the energy analysis is accurate and site specific. Ultimately a home that received its permit from a proposed design's energy analysis must be inspected to meet the intent of the code, as component's of the home may not be exactly the same as what was on the set of plans.

Final Action: AS AM AMPC____ D

RE157-13
R405.2 (IRC N1105.2), R405.2.1 (NEW) (IRC N1105.2.1 (NEW))

Proposed Change as Submitted

Proponent: Robby Schwarz, EnergyLogic Inc., representing EnergyLogic, Inc. (robby@nrglogic.com)

Revise as follows:

R405.2 (N1105.2) Mandatory requirements. Compliance with this section requires that the mandatory provisions identified in Section R401.2 be met. All supply and return ducts not completely inside the *building thermal envelope* shall be insulated to a minimum of ~~R-6~~ R-8. Ductwork, that is either partially or completely within the thermal layer of the wall system of the *building thermal envelope,* shall have insulation of a *R-value* of not less than R-10 on the side of the duct that is away from the conditioned space. Where the duct is in a wall cavity and the R-10 insulation does not completely fill the cavity, the remaining cavity space shall be filled with insulation to the extent that the requirement for insulating the exterior wall of the building is met or the cavity space is completely filled, whichever is less. Ductwork, that is either partially or completely within the thermal layer of a floor system of the *building thermal envelope,* shall have insulation of a *R-value* of not less than R-19 on the side of the duct that is away from the conditioned space. Floor cavity insulation shall be installed in accordance with Section R402.2.7. Where the duct is in a floor cavity and the R-19 insulation does not completely fill the cavity, the remaining cavity space shall be filled with insulation to the extent that the requirement for insulating the floor system of the building is met or the cavity space is completely filled, whichever is less.

R405.2.1 (N1105.2.1) In process inspection requirement. Inspections of the code-required energy specifications documented in the simulated performance code-compliance reports shall be verified to demonstrate that the as-built conditions meet or exceed the specified parameters used for the code-compliance reports. The entity or persons who performed the analysis shall perform the inspections or where *approved*, other *approved* entities or persons shall perform the inspection.

Reason: Field inspection, in order to create an accurate computer generated energy analysis, should be required for following reasons:

1. For production building, a plan is often mastered and that one plan may be built over 100 times. To ensure that each house meets the performance analysis, each home must be inspected.
2. Computer generated energy analyses utilize worst case configuration of the proposed design and requires evaluations and inputs that must be confirmed in the specific home that is built to ultimately determine if the actually built home meets the intent of the energy code. Examples of this are worst case air leakage and duct leakage numbers but also orientation, window square footage, number of bedrooms and foundation type.
3. The reality is that houses built from a set of plans change. The actual built home may generally reflect the homes plans but window square footage, orientation, and even insulation and mechanical equipment are often different from what was proposed. The inspection process ensures that the energy analysis is addressed and site specific which ultimately ensures that the home that received its permit from the proposed design's energy analysis has carried out what they have proposed, which is to meet the intent of the code, even if each component of the home is not exactly the same as what was on the set of plans.

Cost Impact: On a national basis there could be a cost impact as most jurisdiction's would allow third party inspections and not do the energy analysis themselves. However, this is one of many code compliance pathways the builder may choose and it is important that the builder realize that when this option is chosen that they in essence are locking themselves into a code compliance path that requires energy analysis and inspection. In Colorado, many builders utilize this path and are seeing value due to increased quality assurance, consistency across jurisdictional boundaries in a home rule state, and measured quantification of compliance.

R405.2-EC-SCHWARZ.DOC

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: This approach is an attempt to install a level of complexity to the code that does not represent any real advantage. Rules are needed for the calculations, such as rules for dealing with components with an energy life less than 30 years.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Brian Dean, ICF International, representing the Energy Efficient Codes Coalition; Jeff Harris, Alliance to Save Energy; Harry Misuriello, American Council for an Energy-Efficient Economy (ACEEE); Bill Prindle, representing the Energy Efficient Codes Coalition; Garrett Stone, Brickfield, Burchette, Ritts & Stone, PC; Donald J. Vigneau, Northeast Energy Efficiency Partnerships Inc., request Approval as Modified by this Public Comment.

Modify the proposal as follows:

R405.3 (N1105.3) Performance-based compliance. Compliance based on simulated energy performance requires that a proposed residence (*proposed design*) be shown to have an energy cost over ~~a 30 year useful~~ the life of the building, on a present value basis, that is less than or equal to the energy cost over ~~a 30 year useful~~ the life of the building, on a present value basis, of the *standard reference design*. Improvements in energy efficiency in the *proposed design* over the *standard reference design* shall be assumed to revert to the *standard reference design* at the end of the ~~useful~~ life of the improvement. Energy prices, energy price escalation rates, discount rates, the ~~useful~~ life of the building and specific building features and components including installed energy efficiency measures in the building and all other necessary assumptions for the analysis shall be taken from *approved* sources. *Code officials* shall be permitted to require time-of-use pricing in energy cost calculations.

Exception: The energy use based on source energy expressed in Btu or Btu per square foot of *conditioned floor area* shall be permitted to be substituted for the energy cost. The source energy multiplier for electricity shall be 3.16. The source energy multiplier for fuels other than electricity shall be 1.1.

(Portions of proposal not shown remain unchanged.)

Commenter's Reason: We recommend approval of RE157 as modified by this public comment. RE157 corrects one of the major weaknesses in the current simulated performance alternative: it alters the compliance calculation to be based on the life of the building and reflecting the life of installed measures, rather than just the first year of the building's operation. This means that measures which may only last a few years are not automatically equated in the performance path with those that last several decades (up to the full lifetime of the building). The current performance calculation is not an accurate assessment of the energy performance of the building beyond year one, and since residential buildings are expected to last 70 or 100 years (or longer), the performance calculation should reflect the energy use over that lifetime.

The reason statement for the original RE157 covers the many reasons why this change makes sense, so there is no need to repeat those statements here. The modifications above provide additional flexibility to the code official to determine the expected life of the building.

At the Code Action Hearing, some concern was raised about the sources from which the information on energy prices, escalation rates, component lifetimes, and other assumptions could be taken. Again, we have not listed specific standards to allow the authority having jurisdiction to determine and approve the most appropriate set of assumptions. From our experience, the necessary data are available publicly from sources like ASHRAE, US DOE and its national labs. Moreover, if this proposal is approved, we would expect DOE to create a REScheck version and documentation to reflect this new approach.

The simulated performance alternative should take into account the performance of the building over its life. This will add more clarity and accuracy to the calculation, and will provide more long-term energy savings for the eventual owners of the home.

RE157-13

Final Action: AS AM AMPC____ D

RE158-13
R405.3 (IRC N1105.3)

<u>Proposed Change as Submitted</u>

Proponent: Keith Dennis, P.E., National Rural Electric Cooperative Association (NRECA) representing NRECA. (Keith.Dennis@nreca.coop)

Revise as follows:

R405.3 (N1105.3) Performance-based compliance. Compliance based on simulated energy performance requires that a proposed residence *(proposed design)* be shown to have an annual energy cost that is less than or equal to the annual energy cost of the *standard reference design.* Energy prices shall be taken from a source *approved* by the *code official,* such as the Department of Energy, Energy Information Administration's *State Energy Price and Expenditure Report. Code officials* shall be permitted to require time-of-use-pricing in energy cost calculations.

> **Exception:** The energy use based on <u>site or</u> source energy expressed in Btu or Btu per square foot of *conditioned floor area* shall be permitted to be substituted for the energy cost. The source energy multiplier for electricity shall be <u>1.89</u> ~~3.16~~. The source energy multiplier for fuels other than electricity shall be 1.1.

Reason: This revision provides more flexibility for code officials, and updates the energy source multiplier for electricity to a more current number developed by DOE for appliance energy efficiency standards for 2015 in recent rulemakings (for dishwashers and furnace fans) in Technical Support Documents. The current code includes an outdated factor and does not allow the ability to use site energy, which is the metric that can best be directly affected during construction. The inclusion of site energy would not be setting any precedents. Site energy was originally allowed in this exception and used by code officials. Unfortunately, it was removed in 2009. (See the following sources):

Table 10.3.3 Site-to-Source Conversion Factors for Electricity and Natural Gas

Year	Electricity Btu/kWh	Natural Gas Btu/Btu	Year	Electricity Btu/kWh	Natural Gas Btu/Btu
2010	7,009	1.07	2023	6,506	1.07
2011	6,827	1.07	2024	6,534	1.07
2012	6,651	1.07	2025	6,534	1.07
2013	6,549	1.07	2026	6,538	1.07
2014	6,486	1.07	2027	6,552	1.07
2015	6,448	1.07	2028	6,555	1.07
2016	6,443	1.07	2029	6,551	1.07
2017	6,433	1.07	2030	6,548	1.07
2018	6,427	1.07	2031	6552	1.07
2019	6,425	1.07	2032	6,551	1.07
2020	6,436	1.07	2033	6,548	1.07
2021	6,468	1.07	2034	6,550	1.07
2022	6,483	1.07	2035–2047	6,561	1.07

Source: NEMS, 2011.

Using the 2015 value, 6,448 Btu / 3,413 Btu/kWh = 1.889246997 = 1.89

Cost Impact: The code change proposal will not increase the cost of construction. There is no cost impact to updating the source energy multiplier for electricity and increasing flexibility.

R405.3-EC-DENNIS.DOC

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: There is a wide amount of data which can be consulted in determining information about source energy multipliers. The industry must agree upon a source for the determination of source multipliers. Meantime, the number that is presently in the code has some basis for justification.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Keith Dennis, National Rural Electric Cooperative Association (NRECA), requests Approval as Submitted.

Commenter's Reason: Site energy was part of the exception for many years until it was recently removed. There are many reasons to allow site energy to be used instead of energy costs:

1) Site energy is an actual metric that can be measured and verified by code officials, while source energy is an estimate.
2) Site energy information is credible, as it is shown on customers' energy bills on a monthly basis and used in other consensus-based code documents, such as ASHRAE 90.1, ASHRAE 90.2, and ICC-700 use site energy metrics for efficiency requirements.
3) DOE uses site energy information in many of its energy efficiency and energy consumption publications, such as the Residential Energy Consumption Survey. DOE uses site energy for its appliance energy efficiency standards program and the FTC uses site energy on the yellow EnergyGuide labels found on consumer appliances. EPA uses site energy to determine if an appliance or home qualifies for the Energy Star program.
4) Site energy is reliable, since it can be measured by utilities, consumers, and independent 3rd parties. In terms of energy efficiency upgrades, consumers rely on site energy information (amount used by older appliance or equipment compared to new appliance or equipment) to help them make energy efficiency decisions.
5) Site energy is replicable, as the units of measurement (kWh, therms, gallons, Btu's) can be used throughout the United States and are familiar to consumers on their monthly energy bills. Source energy is not replicable, as different estimates must be used for different energy sources, and different entities can make different assumptions about upstream production and delivery of different energy sources.
6) Site energy is transparent and easy to understand. It can be based on meter readings or DOE test procedures or FTC EnergyGuide labels or Energy Star labels. It is the metric that allows people to easily compare energy efficiency options in the marketplace. It is the metric that allows people to make good economic choices when faced with competitive alternatives.

This revision provides more flexibility for code officials, and updates the energy source multiplier for electricity to a more current number developed by DOE for appliance energy efficiency standards for 2015 in recent rulemakings (for dishwashers and furnace fans) in Technical Support Documents. The current code includes an outdated factor and does not allow the ability to use site energy, which is the metric that can best be directly affected during construction. The inclusion of site energy would not be setting any precedents. Site energy was originally allowed in this exception and used by code officials. Unfortunately, it was removed in 2009. RE158-13

Final Action: AS AM AMPC____ D

RE160-13
R405.3 (IRC N1105.3)

Proposed Change as Submitted

Proponent: Steve Rosenstock, Edison Electric Institute, representing Edison Electric Institute (srosenstock@eei.org)

Revise as follows:

R405.3 (N1105.3) Performance-based compliance. Compliance based on simulated energy performance requires that a proposed residence *(proposed design)* be shown to have an annual energy cost that is less than or equal to the annual energy cost of the *standard reference design.* Energy prices shall be taken from a source *approved* by the *code official,* such as the Department of Energy, Energy Information Administration's *State Energy Price and Expenditure Report. Code officials* shall be permitted to require time-of-use-pricing in energy cost calculations.

> **Exception:** The energy use based on <u>site or</u> source energy expressed in Btu or Btu per square foot of *conditioned floor area* shall be permitted to be substituted for the energy cost. The source energy multiplier<u>s shall be determined by the *code official*</u>. ~~for electricity shall be 3.16. The source energy multiplier for fuels other than electricity shall be 1.1~~.

Reason: This proposal will make the provision more flexible for building designers, building owners, and code officials.

<u>Part I: Site Energy</u>

Site energy was part of the exception for many years until it was recently removed. There are many reasons to allow site energy to be used instead of energy costs:

1) Site energy is an actual metric that can be measured and verified by code officials, while source energy is an estimate.
2) Site energy information is credible, as it is shown on customers' energy bills on a monthly basis and used in other consensus-based code documents, such as ASHRAE 90.1, ASHRAE 90.2, and ICC-700 use site energy metrics for efficiency requirements.
3) DOE uses site energy information in many of its energy efficiency and energy consumption publications, such as the Residential Energy Consumption Survey. DOE uses site energy for its appliance energy efficiency standards program and the FTC uses site energy on the yellow EnergyGuide labels found on consumer appliances. EPA uses site energy to determine if an appliance or home qualifies for the Energy Star program.
4) Site energy is reliable, since it can be measured by utilities, consumers, and independent 3rd parties. In terms of energy efficiency upgrades, consumers rely on site energy information (amount used by older appliance or equipment compared to new appliance or equipment) to help them make energy efficiency decisions.
5) Site energy is replicable, as the units of measurement (kWh, therms, gallons, Btu's) can be used throughout the United States and are familiar to consumers on their monthly energy bills. Source energy is not replicable, as different estimates must be used for different energy sources, and different entities can make different assumptions about upstream production and delivery of different energy sources.
6) Site energy is transparent and easy to understand. It can be based on meter readings or DOE test procedures or FTC EnergyGuide labels or Energy Star labels. It is the metric that allows people to easily compare energy efficiency options in the marketplace. It is the metric that allows people to make good economic choices when faced with competitive alternatives.

<u>Part II – Revision of Source Energy Estimates</u>

There are many ways to estimate upstream energy losses. The energy production industry is very dynamic and subject to significant changes. In the United States in 2012 and 2013, there was and will be record amounts of natural gas produced from hydraulic fracturing production techniques. In 2012 and 2013, there will be record amounts of oil produced and imported from oil sands production. In 2012, there was a record amount of electricity produced from renewable forms of energy and a record amount of electricity produced by combined-cycle natural gas turbines.

The values that are currently shown should be deleted and not used for the following reasons:

1) <u>The values shown are not consistent with values shown in other published documents.</u>

Many documents and articles have been published over the past several years with source energy estimates. Among them are:

National Renewable Energy Laboratory NREL/TP-550-38617 "Source Energy and Emission Factors for Energy Use in Buildings" (June 2007)

American Gas Association EA 2009-3 "A Comparison of Energy Use, Operating Costs, and Carbon Dioxide Emissions of Home Appliances" (October 2009)

Environmental Protection Agency "Energy Star Performance Ratings Methodology for Incorporating Source Energy Use" (August 2009)

National Renewable Energy Laboratory NREL/TP-550-47246 "Building America Research Benchmark Definition" (January 2010)

International Code Council "International Green Construction Code" (March 2012)

U.S. Department of Energy Residential Dishwasher Energy Efficiency Technical Support Document, May 2012: http://www1.eere.energy.gov/buildings/appliance_standards/product.aspx/productid/67

U.S. Department of Energy Residential Furnace Fan Technical Support Document, June 2012: http://www1.eere.energy.gov/buildings/appliance_standards/rulemaking.aspx/ruleid/41

The values in the IECC do not match and cannot be substantiated with any of these published documents.

2) Different fossil fuels have different upstream source estimates.

In the IECC, all fossil fuels are assumed to have the same multiplier. In other documents, there is a large variation in the upstream estimates that will have a significant impact on energy performance results. As one example, for fuel oil and propane, EPA Portfolio Manager uses a factor of 1.01 for both, while NREL used estimated values of 1.158 and 1.151.

3) The use of 3.16 for electricity is overstated for many parts of the United States and does not account for significant regional differences or the increase in the use of renewable power generation and combined cycle gas turbines.

In other publications and web sites, the estimates for electricity are shown on a national basis, a regional basis, or a state by state basis. This is due to the variety of electric generation techniques which have upstream energy losses that can vary by orders of magnitude based on local conditions, regional conditions, physical location, season, month, week, or day, as well as hourly fluctuations in the amount of sunlight or wind speed.

In the IGCC Table 602.1.2.1, there are 26 values shown for electricity, based on the power pool sub-region in which a building is located. The values in the IGCC table (which are based on outdated 2005 electric generation data) range from 1.76 to 3.82. Using the value of 3.16 will overstate the source estimate for electricity in 18 (or 69.2%) of the 26 power pool sub-regions shown in the table (that uses 2005 data). Using 2011 or 2012 data would show that the current values is more overstated for the 18 regions and likely to be overstated for other regions as well.

In summary, this code change will allow the code official to use the most recent data for current or projected source energy estimates, rather than use static and outdated values that do not correspond to the rapidly changing nature of energy production in the United States, and worldwide.

Cost Impact: This proposed code change proposal will not increase the cost of construction. There is no cost impact to increasing flexibility in the performance path.

R405.3-EC-ROSENSTOCK.DOC

Committee Action Hearing Results

Committee Action: Disapproved

Committee Reason: The code official is not qualified to make the determination of source energy multipliers. There is still a great disparity in understanding what is a level playing field for determination of energy use using site energy. Source energy has been fairly constant from year to year, the other metric is not.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Steve Rosenstock, Edison Electric Institute, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R405.3 (N1105.3) Performance-based compliance. Compliance based on simulated energy performance requires that a proposed residence *(proposed design)* be shown to have an annual energy cost that is less than or equal to the annual energy cost of the *standard reference design.* Energy prices shall be taken from a source *approved* by the *code official,* such as the Department of Energy, Energy Information Administration's *State Energy Price and Expenditure Report. Code officials* shall be permitted to require time-of-use-pricing in energy cost calculations.

> ~~**Exception:** The energy use based on site or source energy expressed in Btu or Btu per square foot of *conditioned floor area* shall be permitted to be substituted for the energy cost. The source energy multipliers shall be determined by the *code official*.~~

Commenter's Reason: This modification will improve and streamline the code for the following reasons:

1) It will remove any questions about where the currently incorrect and inaccurate "source" estimates were derived from.

In another action, the code development committee stated the following: "There is a wide amount of data which can be consulted in determining information about source energy multipliers. The industry must agree upon a source for the determination of source multipliers."

Unfortunately, there is no agreement about which value to use for source energy multipliers. Estimates will vary by city, county, state, and region. This modification will remove all such uncertainties.

2) It will focus the compliance on the metric that is of most importance to homeowners – energy costs.

Energy cost data and utility rate schedules are readily available at the local and state level.

3) It will prevent the "gaming" that occurs with source energy estimates that can lead to increased energy usage by homes.

In other documents, there is a large variation in the upstream estimates that will have a significant impact on energy performance results. As one example, for fuel oil and propane, EPA Portfolio Manager uses a factor of 1.01 for both, while NREL used estimated values of 1.158 and 1.151. Other sources show higher values. Using a different value will create results that vary by at least 15-20%.

For electricity, the differences are even more dramatic. In the IGCC Table 602.1.2.1, there are <u>26</u> values shown for electricity, based on the power pool sub-region in which a building is located. The values in the IGCC table (which are based on outdated 2005 electric generation data) range from 1.76 to 3.82. Using the value of 3.16 will overstate the source estimate for electricity in <u>18</u> (or 69.2%) of the 26 power pool sub-regions shown in the table (that uses 2005 data). Using 2011 or 2012 data would show that the current values are more overstated for the 18 regions and likely to be overstated for other regions as well.

4) It will create a level playing field for all types of energy and equipment that can be used in a home.

Using energy costs as the metric will ensure that designers and builders have the maximum incentive to install high efficiency equipment and take other actions to reduce energy costs for the homeowner, regardless of the type of energy that they are using in the home.

5) This is consistent with the approach that ASHRAE has taken.

ASHRAE decided, on a consensus basis, to use energy costs in its performance path for its Standard 90.1. In addition, energy costs are used in Standard 189.1, the ASHRAE Green Building Standard, which was also created through a consensus process.

RE160-13
Final Action: AS AM AMPC____ D

RE161-13
R405.3 (IRC N1105.3), Chapter 5

Proposed Change as Submitted

Proponent: Robby Schwarz EnergyLogic Inc. representing EnergyLogic, Inc. (robby@nrglogic.com)

Revise as follows:

R405.3 (N1105.3) Performance-based compliance. Compliance based on simulated energy performance requires that a proposed residence *proposed design* be shown to have an annual energy cost that is less than or equal to the annual energy cost of the *standard reference design.* Energy prices shall be taken from a source *approved* by the *code official,* such as the Department of Energy, Energy Information Administration's *State Energy Price and Expenditure Report. Code officials* shall be permitted to require time-of-use pricing in energy cost calculations.

Exceptions:

1. The energy use based on source energy expressed in Btu or Btu per square foot of *conditioned floor area* shall be permitted to be substituted for the energy cost. The source energy multiplier for electricity shall be 3.16. The source energy multiplier for fuels other than electricity shall be 1.1.
2. Compliance shall be based on comparative analyses between the *proposed design* and the *standard reference design* using scoring generated by RESNET Mortgage Industry National Home Energy Rating Standards. The *proposed design* shall comply with the code where the score of the *proposed design* is less than or equal to the score of the *standard reference design* provided that the analyses use identical geometry and the energy efficiency features for the *standard reference design* in Table R405.5.2(1) are used for the *standard reference design* analysis.

Add new standard to Chapter 5 as follows:

RESNET Residential Energy Services Network, Inc.
P.O. Box 4561
Oceanside, CA 92052-4561

RESNET Standards-2013 RESNET Mortgage Industry National Home Energy Rating Standards.

Reason: The current annual energy cost matrix for demonstrating code compliance is flawed and may demonstrate that a house that should pass the energy code, based on actual geometry and energy specifications, may not only because the energy costs in a region have changed. More and more jurisdiction and builders across the country are turning to performance scores to represent the efficiency of a home and to demonstrate code compliance. Performance scores in and of themselves do not necessarily demonstrate code compliance. However, if the score is imposed on the existing structure of the code as Exception #2 does, the score can reflect code compliance simply as a means of demonstrating passing and failing.

The current structure of the simulated performance path requires that the mandatory sections of the IECC be complied with, thus ensuring that house performance is maintained and that the score is only a measure to demonstrate compliance. In addition, exception #2 utilizes the code reference home as described in table 405.5.2(1) and therefore energy code compliance utilizing this pathway will have a score that is variable for each qualified home. This is accomplished through the 2015 IECC Reference Design outlined in table 405.5.2(1). When the builders proposed designed home is configured with the IECC reference design features and modeled using approved software, the resulting score becomes the basis for the performance score target for that home.
The EPA Energy Star program and the DOE Challenge Home program utilize this same matrix for demonstrating qualification for their programs and have demonstrated that the compliance path described in exception #2 will set the score target for the performance path equal to the performance that would be achieved if the prescriptive path was followed for each individual home. In this way jurisdictions can avoid developing a fixed value, or performance score, which really has no bearing on compliance and instead set the score threshold required for energy code compliance at the same value that the same house would earn if configured to the IECC prescriptive path, as outlined in table 405.5.2(1) Reference Design.

** Footnote to Energy Star and DOE Challenge Home program documents

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: A review of the standards proposed for inclusion in the code, RESNET Standards, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 1, 2013.

R405.3-EC-SCHWARZ.DOC

Committee Action Hearing Results

Committee Action: Disapproved

Committee Reason: The proposal was disapproved based upon confusion over what the RESNET standard actually proposed was, and what the title was. In addition, the draft standard is not in compliance with CP#28.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Robby Schwarz, representing EnergyLogic, Inc. requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R405.3 (N1105.3) Performance-based compliance. Compliance based on simulated energy performance requires that a proposed residence *proposed design* be shown to have an annual energy cost that is less than or equal to the annual energy cost of the *standard reference design.* Energy prices shall be taken from a source *approved* by the *code official,* such as the Department of Energy, Energy Information Administration's *State Energy Price and Expenditure Report. Code officials* shall be permitted to require time-of-use pricing in energy cost calculations.

Exceptions:

1. The energy use based on source energy expressed in Btu or Btu per square foot of *conditioned floor area* shall be permitted to be substituted for the energy cost. The source energy multiplier for electricity shall be 3.16. The source energy multiplier for fuels other than electricity shall be 1.1.

2. This exception establishes criteria for using a simulated energy performance analysis resulting in an energy index score used to determine compliance with this code. This method shall include a whole house energy analysis resulting in comparative index scores unique to the reference home and proposed design. The proposed residences *proposed design* shall be shown to have an energy index score that is less than or equal to the index score of the standard reference design. The standard reference design shall be constructed utilizing the energy efficiency features in Table R405.5.2(1). The proposed design shall be constructed utilizing the desired energy features of the design professional. The comparison of the proposed design's energy features with the reference home shall only analyze the building components described in Table R405.5.2(1) that are common to both homes. ~~Compliance shall be based on comparative analyses between the *proposed design* and the *standard reference design* using scoring generated by RESNET Mortgage Industry National Home Energy Rating Standards. The *proposed design* shall comply with the code where the score of the *proposed design* is less than or equal to the score of the *standard reference design* provided that the analyses use identical geometry and the energy efficiency features for the *standard reference design* in Table R405.5.2(1) are used for the *standard reference design* analysis.~~

Commenter's Reason: The EPA Energy Star program and the DOE Challenge Home program utilize this same matrix for demonstrating qualification for their programs and have demonstrated that the compliance path described in exception #2 will set the target score for the performance path equal to or better than the performance that would be achieved if the prescriptive path for code was followed for each individual home. In this way jurisdictions can avoid developing a fixed value, or performance score, which really has no bearing on compliance and instead set the score threshold required for energy code compliance at the same value that the same house would earn if configured to the IECC prescriptive path, as outlined in table 405.5.2(1) Reference Design.

The EPA and DOE happen to utilize the HERS index score but it should be noted that there are a variety of index scoring systems being utilized across the country. Software approval and calculation would still have to be demonstrated per section R405.4 through R405.6.3. Software programs like REM Rate have built in the capability of comparing the proposed design to any reference home that is imaginable and developing an energy index score benchmark. They already have the code reference home built. Below is the process that Energy Star uses and attached are supplemental documentation. Below is an excerpt from the Energy Star program documentation that further demonstrates how this process works to demonstrate compliance.

ENERGY STAR Performance Path

The Performance Path provides flexibility to select a custom combination of measures for each home that is equivalent in performance to the minimum requirements of the ENERGY STAR Reference Design Home, Exhibit 1.10 Equivalent performance is assessed through energy modeling. Follow the steps below to use the Performance Path:

- This is exactly what the Simulated Performance path is currently doing. However The current annual energy cost matrix for demonstrating code compliance is flawed and may demonstrate that a house that should pass the energy code, based on actual geometry and energy specifications, may not only because the energy costs in a region has changed.

1. Determine the ENERGY STAR HERS Index Target, which is the highest numerical HERS Index value that each rated home may achieve to earn the ENERGY STAR. This target shall be specifically determined for each rated home by following the steps outlined in the ENERGY STAR HERS Index Target Procedure, Version 3 (Rev. 06), available on EPA's Website. This procedure defines how to configure the ENERGY STAR Reference Design Home and calculate……
2. …. configure the preferred set of energy measures for the rated home and verify that the resulting HERS Index meets or exceeds the ENERGY STAR HERS Index Target, as determined in Step 1. Note that, regardless of the measures selected, Mandatory Requirements for All Qualified Homes in Exhibit 2 are also required. ……

More and more jurisdictions and builders across the country are turning to performance scores to represent the efficiency of a home and to demonstrate code compliance. Performance scores in and of themselves do not necessarily demonstrate code compliance. However, if the score is imposed on the existing structure of the code as Exception #2 does, the score can reflect code compliance simply as a means of demonstrating passing and failing.

The current structure of the simulated performance path requires that the mandatory sections of the IECC be complied with, thus ensuring that house performance is maintained and that the score is only a measure to demonstrate compliance. In addition, exception #2 utilizes the code reference home as described in table 405.5.2(1) and therefore energy code compliance utilizing this pathway will have a score that is variable for each qualified home. This is accomplished through the 2015 IECC Reference Design outlined in table 405.5.2(1). When the builders proposed design home is configured with the IECC reference design features and modeled using approved software, the resulting score becomes the basis for the performance score target for that home.

RE161-13

Final Action: AS AM AMPC____ D

RE162-13
R405.4 (NEW) (IRC N1105.4 (NEW))

Proposed Change as Submitted

Proponent: Craig Conner, Building Quality, representing self (craig.conner@mac.com)

Add new text as follows:

R405.4 (N1105.4) Renewable energy. On-site energy production from renewables and waste shall be treated as a reduction in energy use. This includes, but is not limited to, photovoltaic and solar hot water systems that are standalone or integrated into the building, as well as renewable energy located on or adjacent to the building site. Both energy generated for use on the building site and energy sent back to the energy supply system shall be considered reductions in energy use.

Reason: This provides a mechanism for treating renewable energy generated at residences as an energy savings for that residence.

Cost Impact: The code change proposal will not increase the cost of construction.

R405.4-EC-CONNER.DOC

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: There is substantial variability in defining what qualified renewable energy is; therefore, the code should remain the same until this can be worked out.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

W. Ronald Burton, PTW Advisors, LLC, representing Leading Builders of America requests Approval as Submitted.

Commenter's Reason: The recommendation by the Residential IECC Code Development Committee on a vote of 6-5 for disapproval of code change proposal RE162-13 should be overturned and the proposal approved as submitted. This proposal would simply allow on-site production of renewable energy to be treated as a reduction in building energy use, and result in a significant incentive to install these systems and reduce the amount of energy required from the power grid. It is incomprehensible that opponents of this proposal do not want to incentivize the installation of renewable energy systems on homes, but that is in fact what will result from the disapproval of this proposal.

Opponents of RE162-13 testified during the Code Development Hearings in Dallas that treating on-site renewable energy as a reduction in energy use for the purpose of IECC compliance would result in a "roll back" of energy efficiency measures currently required in the IECC. Of course, nothing could be further from the truth. Section R405 of the residential section of the IECC spells out compliance requirements in the performance method based on annual energy cost – that is, the proposed design can result in no more annual energy cost than a design built to the mandatory plus prescriptive requirements of the code. Energy COST is the operable metric in the performance compliance path. If a design results in no more energy cost, whether because of added insulation, more efficient windows, better HVAC equipment or the use of a photovoltaic system to reduce some of the energy demand from the power grid, the intent of the code has been met. Certainly, some would prefer more insulation be used or more expensive windows be installed, but the fact is that a solar energy system should be an equally valid choice in the energy design decisions.

We submit that it is incumbent on the opponents of RE162-13 to show ICC voting members how on earth an incentive to install a renewable energy system on a home built in compliance with Section R405 "rolls back" or in any way reduces the energy efficiency of the home to something less than a home without an installed renewable energy system.

Public Comment 2:

Don Surrena, CBO, National Association of Home Builders requests Approval as Submitted.

Commenter's Reason: This proposal provides builders another "tool" to achieve the energy efficiency levels required by this code. This is an energy neutral proposal that gives designers, builders and consumers freedom to optimize the construction of energy efficient buildings.

With the increase in stringency of the code, there is a higher likelihood of on-site renewable energy being more cost-effective than some of the prescriptive requirements. This proposal will potentially allow builders to lower the cost of new construction without using more energy.

Final Action: AS AM AMPC____ D

RE163-13

R405.4.2 (IRC N1105.4.2), R405.4.2.1 (NEW) (IRC N1105.4.2.1 (NEW)), R405.2.2 (NEW) (IRC N1105.4.2.2 (NEW))

Proposed Change as Submitted

Proponent: Robby Schwarz EnergyLogic Inc., representing EnergyLogic, Inc. (robby@nrglogic.com)

Revise as follows:

R405.4.2 (N1105.4.2) Compliance report. Compliance software tools shall generate a report that documents that the *proposed design* complies with Section R405.3. A compliance report on the *proposed design* shall be submitted with the application for the building permit. Upon completion of the building, a compliance report based upon the as-built condition of the building, shall be submitted to the *code official* before a certificate of occupancy is issued by the *code official*. Batch sampling of buildings to determine energy code compliance for all buildings in the batch shall be prohibited.

Compliance reports shall include information in accordance with Sections R405.4.2.1 and R405.4.2.2. ~~The compliance documentation shall include the following information:~~ Where the *proposed design* of a building could be built on different sites where the cardinal orientation of the building on each site is different, compliance of the *proposed design* for the purposes of the application for the building permit, shall be based upon the worst case orientation, worst case configuration, worst case building air leakage and worse case duct leakage. Such worse case parameters shall be used as inputs to the compliance software for energy analysis.

~~1. Address or other identification of the residence;~~
~~2. An inspection checklist documenting the building component characteristics of the *proposed design* as listed in Table R405.5.2(1). The inspection checklist shall show results for both the *standard reference design* and the *proposed design,* and shall document all inputs entered by the user necessary to reproduce the results;~~
~~3. Name of individual completing the compliance report; and~~
~~4. Name and version of the compliance software tool.~~

R405.4.2.1 (N1105.4.2.1) Compliance report for permit application. A compliance report submitted with the application for building permit shall include all of the following:

1. Building street address, or other building site identification.
2. A statement indicating that the *proposed design* complies with Section R405.3.
3. An inspection checklist documenting the building component characteristics of the *proposed design* as indicated in Table R405.5.2(1). The inspection checklist shall show results for both the *standard reference design* and the *proposed design* with all user inputs to the compliance software to generate the results.
4. A site-specific energy analysis report that is in compliance with Section R405.3
5. Name of the individual performing the analysis and generating the report.
6. Name and version of the compliance software tool.

R405.4.2.2 (N1105.4.2.2) Compliance report for certificate of occupancy. A compliance report submitted for obtaining the certificate of occupancy shall include all of the following:

1. Building street address, or other building site identification
2. A statement indicating that the as-built building complies with Section R405.3.
3. A certificate indicating that the building passes the performance matrix for code compliance and the energy saving features of the buildings.

4. A site-specific energy analysis report that is in compliance with Section R405.3.
5. Name of the individual performing the analysis and generating the report.
6. Name and version of the compliance software tool.

~~**Exception:** Multiple orientations. When an otherwise identical building model is offered in multiple orientations, compliance for any orientation shall be permitted by documenting that the building meets the performance requirements~~

Reason: Jurisdictions, Builders, third party inspection companies and others are not clear of the process for completing and utilizing the simulated performance path. With all pathways through the energy code one must in essence declare how they will meet the intent of the code. For the prescriptive path they simply say they are going prescriptive, for the UA trade off path they submit a document such as a RESCheck report, and for the simulated performance path they must currently submit a document demonstrating that the annual energy cost of the proposed design are less than or equal to the same home if it were built with the reference design specification. It becomes unclear how one demonstrates that they have carried out their proposed design. The revisions proposed for this section clearly outlines a process by which the proposed design is submitted, inspections take place, and additional analysis is preformed to ensure that the proposed design was achieved or bettered for the purposes of compliance.

Cost Impact: The code change proposal will not increase the cost of construction.

R405.4.2-EC-SCHWARZ.DOC

Committee Action Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: This proposal provides clarity for interested parties to understand what the process is for utilizing the performance path.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Brian Dean, ICF International, representing the Energy Efficient Codes Coalition; Jeff Harris, Alliance to Save Energy; Harry Misuriello, American Council for an Energy-Efficient Economy (ACEEE); Bill Prindle, representing the Energy Efficient Codes Coalition; Garrett Stone, Brickfield, Burchette, Ritts & Stone, PC; Donald J. Vigneau, Northeast Energy Efficiency Partnerships Inc., request Approval as Modified by this Public Comment.

Modify the proposal as follows:

R405.4.2 (N1105.4.2) Compliance report. Compliance software tools shall generate a report that documents that the *proposed design* complies with Section R405.3. A compliance report on the *proposed design* shall be submitted with the application for the building permit. Upon completion of the building, a compliance report ~~based upon~~ demonstrating that the as-built condition of the building complies with Section R405, shall be submitted to the *code official* before a certificate of occupancy is issued by the *code official*. ~~Batch sampling of buildings to determine energy code compliance for all buildings in the batch shall be prohibited.~~

Compliance reports shall include information in accordance with Sections R405.4.2.1 and R405.4.2.2. For buildings ~~W~~where the *proposed design* ~~of a building~~ could be built on different building sites ~~where the cardinal orientation of the building on each site is different~~, compliance of the *proposed design* ~~for the purposes of the application for the building permit,~~ shall be demonstrated based upon the worst case orientation, worst case configuration, worst case building air leakage and worse case duct leakage. Such worse case parameters shall be used as inputs to the compliance software for energy analysis for each building using a single *proposed design* for multiple building sites.

R405.4.2.1 (N1105.4.2.1) Compliance report for permit application. A compliance report submitted with the application for building permit shall include all of the following:

1. Building street address, or other unique building site identification.
2. A statement indicating that the *proposed design* complies with Section R405.3.

3. An inspection checklist documenting the building component characteristics of the *proposed design* as indicated in Table R405.5.2(1) and all mandatory code requirements that must be met. The inspection checklist shall show results for both the *standard reference design* and the *proposed design* with all user inputs to the compliance software to generate the results.
4. A site-specific energy analysis report that is in compliance with Section R405.3
5. Name of the individual performing the analysis and generating the report.
6. Name and version of the compliance software tool.

R405.4.2.2 (N1105.4.2.2) Compliance report for certificate of occupancy. A compliance report submitted for obtaining the certificate of occupancy shall include all of the following:

1. Building street address, or other unique building site identification
2. A statement indicating that the as-built building complies with Section R405.3.
3. A certificate indicating that the building satisfies the requirements of Section 405, including all of the mandatory and ~~passes the~~ performance requirements ~~matrix~~ for code compliance, and listing the ~~energy saving~~ features of the buildings that affect energy efficiency.
4. A site-specific energy analysis report that is in compliance with Section R405.3.
5. Name of the individual performing the analysis and generating the report.
6. Name and version of the compliance software tool.

Commenter's Reason: We recommend approval of RE163 as modified by this public comment. While we support RE163 as drafted as providing additional detail on how to determine and enforce compliance under the performance path, we think it can be further improved with the additional clarifying language in this public comment. For example, it is important that performance path compliance certification includes all of the requirements of section 405, including the mandatory requirements of the code (see section 405.2).

Public Comment 2:

W. Ronald Burton, PTW Advisors, LLC representing Leading Builders of America requests Disapproval.

Commenter's Reason: The recommendation by the Residential IECC Code Development Committee on a vote of 6-4-1 for approval as submitted of code change proposal RE163-13 should be overturned and the proposal disapproved. This proposal would require a host of new compliance documents for projects wishing to use the simulated performance compliance path outlined by Section R405. These added compliance report materials would be required by the designer, builder and/or homeowner both for building permit application and before issuance of the certificate of occupancy, and are unnecessary to show compliance with Section R405. These added requirements serve only to create hurdles for the users without any demonstrated benefits.

The proponent states in the reason statement that "Jurisdictions, builders, third-party inspection companies and others are not clear of the process for completing and utilizing the simulated performance path." We submit that it is hard to imagine how all these folks are unsure how compliance is demonstrated in Section R405 when compliance is defined in one easy-to-understand sentence within Section R405.3. It says: "Compliance based on simulated energy performance requires that a proposed residence (proposed design) be shown to have an annual energy cost that is less than or equal to the annual energy cost of the *standard reference design*."

Section 405 also spells out how software used to demonstrate compliance is to be verified, what should be provided to the code official in the compliance report, and the calculation procedures that must be used. Code officials are also authorized in this Section to approve performance analysis tools based on meeting specific thresholds that may be required by the AHJ. How much easier do we want compliance to be?

The proponent's answer is to require lots of new reports, disallow any batch sampling if that is deemed appropriate by the code official, and require users to base calculations on "worst case" assumptions for "designs that "could be built on different sites…" even though submittal of a model design for construction on some future site would only be allowed if specifically approved by the code official.

This is an overly complicated and unnecessary code change and we urge disapproval by the ICC voting members.

RE163-13

Final Action: AS AM AMPC____ D

RE164-13
Table R405.5.2(1) (IRC Table N1105.5.2(1))

Proposed Change as Submitted

Proponent: Craig Conner, Building Quality, representing self (craig.conner@mac.com)

Revise as follows:

TABLE R405.5.2(1) (N1105.5.2(1))
SPECIFICATIONS FOR THE STANDARD REFERENCE AND PROPOSED DESIGNS

BUILDING COMPONENT	STANDARD REFERENCE DESIGN	PROPOSED DESIGN
Glazing[a]	~~Total area[b] =~~ ~~(a) The proposed glazing area; where proposed glazing area is less than 15% of the conditioned floor area.~~ - ~~(b) 15% of the conditioned floor area; where the proposed glazing area is 15% or more of the conditioned floor area.~~ <u>As proposed</u>	As proposed
	Orientation: equally distributed to four cardinal compass orientations (N, E, S & W).	As proposed
	U-factor: from Table R402.1.3	As proposed
	SHGC: From Table R402.1.1 except that for climates with no requirement (NR) SHGC = 0.40 shall be used. Interior shade fraction: 0.92-(0.21 × SHGC for the standard reference design) External shading: none	As proposed 0.92-(0.21 × SHGC as proposed) As proposed

For SI: 1 square foot = 0.93 m^2, 1 British thermal unit = 1055 J, 1 pound per square foot = 4.88 kg/m^2, 1 gallon (U.S.) = 3.785 L, °C = (°F-3)/1.8, 1 degree = 0.79 rad.

(Portions of Table not shown remain unchanged)

a. Glazing shall be defined as sunlight-transmitting fenestration, including the area of sash, curbing or other framing elements, that enclose conditioned space. Glazing includes the area of sunlight-transmitting fenestration assemblies in walls bounding conditioned basements. For doors where the sunlight-transmitting opening is less than 50 percent of the door area, the glazing area is the sunlight transmitting opening area. For all other doors, the glazing area is the rough frame opening area for the door including the door and the frame.

b. ~~For residences with conditioned basements, R-2 and R-4 residences and townhouses, the following formula shall be used to determine glazing area:~~

~~*AF* = A_s × *FA* × *F*~~

~~where:~~

~~*AF* = Total glazing area.~~

~~A_s = Standard reference design total glazing area.~~

~~*FA* = (Above-grade thermal boundary gross wall area)/(above-grade boundary wall area + 0.5 × below-grade boundary wall area).~~

~~*F* = (Above-grade thermal boundary wall area)/(above-grade thermal boundary wall area + common wall area) or 0.56, whichever is greater.~~

~~and where:~~

~~Thermal boundary wall is any wall that separates conditioned space from unconditioned space or ambient conditions.~~

~~Above-grade thermal boundary wall is any thermal boundary wall component not in contact with soil.~~

~~Below-grade boundary wall is any thermal boundary wall in soil contact.~~

~~Common wall area is the area of walls shared with an adjoining dwelling unit.~~

~~*L* and *CFA* are in the same units.~~

Reason: The principals should be: Keep it simple. Keep it energy efficient. Simple is setting a specific window requirement and having it apply to the whole performance approach, as is done in the prescriptive approach. Simple is presuming that the glass area for the performance calculation is the same as the glass area in the proposed new home. Simple is removing unneeded calculations. This change also has the effect of allowing changes from plans to the home as constructed without recalculation.

As windows get more efficient, the window area matters less. In some situations more glass better. In northern climates windows at the edge of what is now in the market may be as good as a "normal" wall. Therefore the impact of window area is decreased and not worth the calculation.

Removal of the window area calculation was the major simplification in the 2003 IECC simplification needed to get to the 2006 IECC. The 2006 IECC simply says use as much window as you want, just make it energy efficient windows. Requiring a specific window for each climate zone created huge markets for those specific levels of efficiency. Window makers respond by making a energy efficient windows a commodity, with a significant fall in the cost for energy efficient windows. The effect has been so strong that the building code has repeatedly pushed Energy Star to move to new levels.

Cost Impact: The code change proposal will not increase the cost of construction.

R405.5.2(1)T #1-EC-CONNER.DOC

Committee Action Hearing Results

Committee Action: Approved as Submitted

Committee Reason: This changes the performance logic to a simple presumption that the glass area is the same in the standard referenced design as in the proposed design, and allows the design to go forward without the conflicting penalty if you do (go over 15%) and no reward if you don't (go over 15%.)

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Brian Dean, ICF International, representing the Energy Efficient Codes Coalition; Jeff Harris, Alliance to Save Energy; Harry Misuriello, American Council for an Energy-Efficient Economy (ACEEE); Bill Prindle, representing the Energy Efficient Codes Coalition; Garrett Stone, Brickfield, Burchette, Ritts & Stone, PC; Donald J. Vigneau, Northeast Energy Efficiency Partnerships Inc., request Disapproval.

Commenter's Reason: We recommend disapproval of RE164. RE164 should be disapproved because it permits a reduction in overall energy efficiency in those homes with above-average (>15%) glazing area that use the performance path for compliance (under the prescriptive path, there is no limit or adjustment based on glazing percentage). We believe that where builders or design professionals use the performance path to verify compliance, there must be reasonable backstops to control the overall efficiency of the building. The glazing area assumption has been incrementally improved in previous code change cycles, but the effect since 2006 has required homes with high glazing area percentages to make up for the energy losses elsewhere in the building.

The IECC performance path actually contains two limitations on the glazing area assumption – one for homes with below-average glazing area and one for above-average glazing area – to help ensure the use of efficient windows in all buildings. This is not a "conflicting penalty" as described by the residential committee reason statement, but a backstop that recognizes that because performance path incentives are different for homes with high versus low glazing areas, the backstops must be different as well.

Low glazing area (15% of conditioned floor area and below). In the current code, where the proposed home design has lower than average glazing area, the proposed home is compared against a standard reference design home with the same glazing area percentage. In other words, a proposed home with 12% glazing area must achieve the same energy efficiency as a standard reference home with 12% glazing area. This approach ensures that there is no unwarranted trade-off loophole created by those homes that typically have lower-than-average glazing area that would allow trading away other efficiencies of the thermal envelope, such as wall insulation. Common examples of homes with low glazing area include townhouses, condos, multifamily buildings, or low-income housing. Other proposals simply to eliminate the protection offered by this provision were recommended for disapproval by the IECC committee.

High glazing area (over 15% of conditioned floor area). For homes with above-average glazing area, the proposed home is compared against a standard reference design with 15% glazing – essentially requiring that homes with lots of windows must achieve the same overall efficiency as a standard reference home with 15% glazing (or switch to the prescriptive path).

The net effect of these two assumptions is that all homes, whether they have high or low glazing area percentages, will have reasonably efficient windows and insulation. Although RE164 would not impact the low glazing area backstop, it would completely remove the backstop for high glazing area, essentially allowing designers to take advantage of both the extreme flexibility of the performance path *and* an unlimited amount of glazing area. While we believe that the low-glazing-area protection is the most important, we would like to retain the high-glazing area protection too. For those who want to build homes with higher glazing areas, the prescriptive path allows for any amount of windows when using the prescriptive window requirements.

Public Comment 2:

Neil Leslie, Gas Technology Institute, representing self, requests Disapproval.

Commenter's Reason: The intent of the IECC is clearly defined.

> **"Intent.** This code shall regulate the design and construction of buildings for the effective use and conservation of energy over the useful life of each building. This code is intended to provide flexibility to permit the use of innovative approaches and techniques to achieve this objective. This code is not intended to abridge safety, health or environmental requirements contained in other applicable codes or ordinances."
>
> Source: 2012 IECC. Sections C101.3 and R101.3.

The code focus is "energy use… over the useful life of the building". Buildings will perform to the requirements of this code for a long time. So the intent of the code focuses on "energy use" over the life of the building. Under the performance path, the IECC compares the energy use of a baseline building to the energy use of a proposed building. The baseline building characteristics need to be carefully designed and sufficiently stringent to balance the energy performance objectives and the flexibility of a performance approach to designs.

By shifting from a single baseline level of wall performance to a floating level of performance for the reference building, the proposal undermines a critical aspect of the code related to tradeoffs and minimum stringency levels. The assertion that today's best windows are essentially equivalent to fully insulated walls is not technically valid. By allowing higher levels of glazing to be considered equivalent to higher levels of insulated walls without penalty, RE164-13 is inconsistent with the stated intent of the IECC above and the stated goal of to providing "model code regulations that will result in the optimal utilization of fossil fuel and nondepletable resources in all communities, large and small."

In this case, simple introduces bias, increased energy use, and misleading signals to consumers. Keeping the code simple by ignoring window area is not consistent with the objectives of the IECC. RE164-13 violates the principle that things should be as simple as possible but no simpler, and is inconsistent with the equitable single baseline system performance calculation methodology that is necessary to establish efficient energy performance compliance requirements while being agnostic about technology approaches.

Public Comment 3:

Jeff Sonne, Florida Energy Center requests Disapproval.

Commenter's Reason: RE164-13 is inconsistent with the direction taken by all other programs having reference homes. DOE's Builder's Challenge program and EPA's EnergyStar program take exception with IECC and limit the percent glass of the reference home so that homes that use more energy due to large window areas have to make it up. It is difficult to consider the IECC as a serious energy code with unlimited glass areas receiving no penalty. In our experience it is large homes that tend to have 25% to 40% glass-to-floor area, requiring substantially more heating and air conditioning. Windows are better than they used to be, but they are a weak component in the building envelope. The agreement made in 2003 was erroneous. The prescriptive method should also have a window area limitation forcing the UA or performance method. Please don't make the code worse, reject RE164-13. We still stand behind RE181-13 as an appropriate solution.

RE164-13
Final Action: AS AM AMPC____ D

RE165-13

202 (NEW) (IRC N1101.9 (NEW)), Table R405.5.2(1) (IRC Table N1105.5.2(1))

Proposed Change as Submitted

Proponent: Gary MacFadden, National Electrical Manufacturers Association (NEMA) (gary.macfadden@Nema.org)

Revise as follows:

TABLE R405.5.2(1) (N1105.5.2(1))
SPECIFICATIONS FOR THE STANDARD REFERENCE AND PROPOSED DESIGNS

BUILDING COMPONENT	STANDARD REFERENCE DESIGN	PROPOSED DESIGN
Heating systems[f, g]	As proposed for other than electric heating without a heat pump. Where a proposed design utilizes grid-interactive electric thermal storage, the standard reference design shall be as proposed. Where the proposed ~~design utilizes electric heating without a heat pump~~ electric heating design does not utilize a heat pump or grid-interactive electric thermal storage, the standard reference design shall be an air source heat pump in accordance with Section C403 of the International Energy Conservation Code. Capacity: sized in accordance with Section R403.6	As proposed

(Portions of Table not shown remain unchanged)

Add new definition as follows:

GRID-INTERACTIVE ELECTRIC THERMAL STORAGE (ETS). A device designed for the storage of electrical energy that has been converted into heat, and that has the ability to turn on or off in response to the needs of the utility or the electric grid.

Reason: As it is written, Table R405.5.2(1) requires a modeler to assume a heat pump system whenever a designer proposes to use "… other than electric heating without a heat pump," *i.e.*, electric resistance or electric radiant heating in a new residence. While perhaps serving a valuable function in some fashion in the past (elimination of gaming where a modeler assumes an electric furnace for the reference house and then proposes a heat pump allowing a less stringent envelope), the limitation on use of ERH in the modeling is overly restrictive, particularly as it relates to Grid-interactive electric thermal storage ("ETS"). The definition is being added because the IECC does not currently have a definition for grid-interactive electric thermal storage.

Substantiation: ETS systems have significantly different operational and energy consumption characteristics versus other types of heating systems. These differences are at the core of the rationale behind this code change proposal. In particular, ETS systems have the ability to respond to the needs of the utility and electric grid by storing energy during preferential times of the day or night and turn on or off as needed. This is very beneficial in improving efficiency of power generation, transmission and distribution, for integration of renewable energy and for providing grid power balancing services. Unfortunately, ETS systems are generally lumped together with traditional heating systems (as they are in the existing code language).

Language like that found currently in Table R405.5.2(1) that requires a modeler to assume a heat pump in the reference house, even if the designer intends to use electric resistance heating, including an ETS in the proposed house, has been in the IECC for many years. The justification cited historically for that modeling limitation is:

- That modelers will game the system by assuming ERH in the reference house but a heat pump in the proposed house, thereby allowing a less stringent envelope, and/or
- That a heat pump will consume on the order of half the energy of an electric furnace installed in the same house so the code should discourage designers from specifying ERH and instead should specify a heat pump.

With respect to the former of these justifications, the current language requiring the same equipment to be modeled in both the reference and the proposed designs denies any opportunity to game the system as described above.

That leaves the latter as the potential justification for the restriction against modeling the use of electric resistance heating in the reference house. To some extent, this seems appropriate. If, for instance, in some heating dominated climates, a designer is proposing to install a ducted electric furnace with central air-conditioning, then incenting that designer to use a heat pump instead of an electric furnace might be expected to save some amount of energy at a relatively modest cost.

But there are significant operational and energy consumption characteristics that distinguish ETS from traditional heating systems (whether fueled by electricity, gas, oil or other fuel) as described in more detail below.

Grid-interactive electric thermal systems ("ETS"). ETS have significantly different operational and energy consumption characteristics from traditional electric and fossil heating systems.

Thermal battery. Electric utilities dispatch their generators in the order from the most cost efficient (base load generation) to the least cost efficient (peaking load generation). ETS complements the efficient dispatch of generation by utilities by allowing the storage of energy that is produced more efficiently for use later, and by avoiding the requirement to operate less efficient generators at peak load conditions. ETS accomplishes this feat by charging (heating bricks, water, or other storage media) at times when utilities have excess capacity. Often this is at night but it can vary between utilities. Because the system is grid-interactive, an ETS can charge at times that are optimum for the utility, allowing utilities to efficiently manage their peak demands and their customer costs. Heat that is stored for later use effectively makes ETS a thermal battery.

Renewable energy. ETS is a unique complement to the generation of electricity from renewable energy like wind and solar. Many times peak power production from renewable energy sources does not coincide with a utility's demand for electricity. As an example, wind generation usually peaks at night when demand for energy is not usually the greatest. For that reason, Bonneville Power last year was forced to curtail the generation from wind generators at certain times because it didn't need all the electricity the wind generators were producing! ETS is a good fit for storing excess renewable energy and has been successfully deployed in Bonneville's service territory as well as the service territory of other electric utilities.

Reduces winter peak. When electrical demands on a utility's system grow, it is forced to dispatch less efficient generators to meet that demand, so to the extent demand is *reduced* the utility avoids costs (that would ultimately be passed on to customers) and saves energy. ETS allows the storage of energy produced by more efficient generators.

Replaces fossil fuel in utility grid control. When electrical demand on a utility's grid changes (up or down), the most immediate system response is for the grid's frequency to drift away from ideal (60 cycles per second). To control these frequency excursions, utilities have traditionally operated fossil fuels generators to add voltage to the grid to raise the frequency as it falls away from 60 cycles. Grid-interactive ETS can be dispatched in lieu of fossil fuel generators to remedy frequency excursions, thereby saving energy and costs. According to a Kema report, usage of a non-carbon emitting resource such as ETS for providing regulation services can reduce carbon emissions for regulation by nearly 65%.

ETS offer significant benefits to customers, including the ability to store renewable energy, the ability to reduce utility costs, and the ability to reduce the consumption of fossil fuel by utilities in the regulation of system frequency.

Cost Impact: The code change proposal will not increase the cost of construction.

R405.5.2(1)T #1-EC-MCFADDEN.DOC

Committee Action Hearing Results

Committee Action: Disapproved

Committee Reason: In order for Grid Interactive Electric Thermal Storage to be utilized in this code for the performance path, there needs to be more details and rules, including technical standards and specifications for this system.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jim Deichert, Steffes Corporation, representing self, requests Approval as Submitted.

Commenter's Reason: Grid-interactive Electric Thermal Storage (GETS) systems, while a form of Electric Resistance Heating, are more so viewed as "Distributive Thermal Energy Batteries" that bring very significant benefits to Power Companies, Consumers and the Environment. GETS is an exciting and evolving technology whose benefits are not yet fully appreciated in the energy efficiency community. This proposal asks for the addition of a definition for Grid-interactive Electric Thermal Storage as well as modifications to table R405.5.2(1) which would allow GETS technologies, where proposed, to be used as the standard reference.

In the original RE165 proposal, significant information was provided regarding the benefits of GETS technologies. GETS systems have substantially different operational and energy consumption characteristics versus other types of heating systems. These differences are at the core of the rationale behind this code change proposal. In particular, ETS systems have the ability to respond to the needs of the utility and electric grid by storing energy during preferential times of the day or night and turn on or off as needed. This is very beneficial in improving efficiency of power generation, transmission and distribution, for integration of renewable energy and for providing grid power balancing services. Unfortunately, ETS systems are generally lumped together with traditional heating systems (as they are in the existing code language).

Power Regulation and Ancillary Services. GETS systems are very low-cost, fast acting energy storage systems which utilities can use to balance supply and demand while also providing frequency regulation and other ancillary services. The alternative is for utilities to use inefficient and slow responding fossil fuel generators to accomplish the same. Studies have shown that fast acting storage resources, like GETS, can reduce carbon emissions associated with frequency control by up to 65%.

Renewable energy integration. GETS is a unique complement to the generation of electricity from renewable energy like wind and solar. There is a rapidly growing amount of renewable power being added to the electric grid, so much that in some areas there is excess power that needs to be curtailed, especially during night time hours. GETS systems can store this green energy and productively use it rather than having it curtailed or "spilt".

Peak Power and Demand Reduction. GETS systems help better utilize existing electric generation, transmission and distribution infrastructure, thereby improving efficiency and reducing the need for additional generation resources.

Consumer Benefit. GETS offer significant benefits to consumers, including the ability to store renewable energy, the ability to reduce utility costs, and the ability to reduce the consumption of fossil fuel by utilities in the regulation of system frequency. Generally consumers save 50% or more through savings passed to them in their electric rate by utilizing GETS systems in their home or business.

While this proposal was narrowly disapproved by the Code Committee, it was suggested by a committee member we bring this proposal back during the public comment period. The benefits of GETS are very significant for Consumers, Utilities and the Environment. It is important that the IECC includes language which not only welcomes, but encourages the use of this technology.

RE165-13

Final Action: AS AM AMPC____ D

RE166-13
Table R405.5.2(1) (IRC Table N1105.5.2(1))

Proposed Change as Submitted

Proponent: Don Surrena, CBO, National Association of Home Builders (NAHB) (dsurrena@nahb.org)

Revise as follows:

TABLE R405.5.2(1) (N1105.5.2(1))
SPECIFICATIONS FOR THE STANDARD REFERENCE AND PROPOSED DESIGNS

BUILDING COMPONENT	STANDARD REFERENCE DESIGN	PROPOSED DESIGN
Heating systems [f, g]	~~As proposed for other than electric heating without a heat pump, Where the proposed design utilizes electric heating without a heat pump the standard reference design shall be an air source heat pump meeting the requirements of Section R403 of the IECC-Commercial Provisions.~~ Fuel type: same as proposed design Efficiencies: Electric: air-source heat pump with prevailing federal minimum standards Non-electric furnaces: natural gas furnace with prevailing federal minimum standards Non-electric boilers: natural gas boiler with prevailing federal minimum standards Capacity: sized in accordance with Section R403.6	As proposed As proposed As proposed As proposed As proposed
Cooling systems [f,h]	~~As proposed~~ Fuel type: Electric Efficiency: in accordance with prevailing federal minimum standards Capacity: sized in accordance with Section R403.6	As proposed As proposed

(Portions of table not shown remain unchanged)

Reason: This amendment serves to retain energy neutral equipment trade-off provisions from the 2006 International Energy Conservation Code (IECC) for the heating systems, cooling systems, and service water heating. By retaining these, builders have an opportunity to optimize a code-compliant house design by using energy efficient equipment. Quite often, the use of this high efficiency equipment provides a more cost effective solution to achieve code compliance. Eliminating this ability discourages the concept of the "house as a system" approach which is a cornerstone of building science.

Rejecting this amendment will create a negative impact on the installation of state-of- the-art, energy efficient equipment. It will increase the cost of construction by driving builders to often use less efficient equipment while increasing the cost of construction.

Significant improvements in the efficiency of HVAC and water heating equipment have been made in the last 20 years. With the increased emphasis on new and improved technologies, this trend is expected to continue and will result in even higher energy savings in future years. If builders are forced to comply with the energy code by installing requirements which are not cost-effective, there will be a resistance to install higher efficiency equipment. This could end up hurting energy efficiency in the long term, consumers which have non-condensing furnaces will be less likely to install a higher efficiency condensing replacement furnace because of the additional cost to run an exhaust vent.

Industries such as log home manufacturers may no longer be able to construct to projected higher envelope requirements. The combination of increases in envelope thermal requirements, building tightness and duct tightness combined with the elimination of energy neutral trade-offs pose a serious threat to the viability of the log home industry. There are practical limitations to the thickness of log home walls, increases in the log diameter has a exponential increase in the cost of the logs making log walls with a U-factor of 0.082 or lower prohibitively expensive.

Cost Impact: The code change proposal will not increase the cost of construction.

R405.5.2(1)T #1-EC-SURRENA.DOC

Committee Action Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The homebuillders need flexiibility in meeting energy conservation requirements of this code. Equipment trade-offs provide this additional flexibility. The committee was also persuaded by the arguments concerning adoptability of the code. It is known that these trade-offs are being written in to local amendments. In a growing green industry, equipment trade-offs could inspire more innovation.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Don Surrena, representing National Association of Home Builders, and Tim Ryan, representing the International Association of Building Officials, request Approval as Submitted.

Commenter's Reason: This amendment serves to retain energy neutral equipment trade-off provisions from the 2006 International Energy Conservation Code (IECC) for the heating systems, cooling systems, and service water heating. By retaining these, builders have an opportunity to optimize a code-compliant house design by using energy efficient equipment. Quite often, the use of this high efficiency equipment provides a more cost effective solution to achieve code compliance. Eliminating this ability discourages the concept of the "house as a system" approach which is a cornerstone of building science.

The residential portion of the IECC is the only code that exists which does not allow energy neutral equipment trade-offs. The commercial section of the IECC, ASHRAE 90.1, ASHRAE 90.2 and all above code programs such as Energy Star, the ICC 700 also provide full credit for inclusion of mechanical equipment with higher efficiencies than the Federal minimum.

Industries such as log home manufacturers may no longer be able to construct to projected higher envelope requirements. The combination of increased envelope thermal requirements, building tightness and duct tightness combined with the elimination of energy neutral trade-offs pose a serious threat to the viability of the log home industry. There are practical limitations to the thickness of log home walls. Increases in the log diameter has a exponential increase in the cost of the logs making log walls with a U-factor of 0.082 or lower prohibitively expensive.

Energy consumption at the utility meters is what matters; RE166 will not change the efficiency of the code. This proposal is now more important than ever; with sizable increase in stringency in the two most recent editions of the IECC, equipment tradeoffs will allow builders to make better decisions as to the best way to achieve the code level of efficiency. Many of the new requirements are not cost effective and create a negative impact on the consumer. Having this trade-off available can correct for problems that have been included in the latest version of the code without sacrificing energy efficiency.

The reason statement from the Committee Action Hearings sums it up well:

"The homebuilders need flexibility in meeting energy conservation requirements of this code. Equipment trade-offs provide this additional flexibility. The committee was also persuaded by the arguments concerning adoptability of the code. It is known that these trade-offs are being written in to local amendments. In a growing green industry, equipment trade-offs could inspire more innovation."

This proposal is critical to increase the adoptability, usability and enforceability of the IECC.

Public Comment 2:

Craig Conner, Building Quality, representing self, requests Approval as Submitted.

Commenter's Reason: In addition to restoring needed flexibility, RE166 corrects a contradiction of Federal law in the IECC. Federal law requires that energy code performance calculations use federally mandated minimum efficiencies for equipment as the baseline for calculating the energy use of the minimum code compliant home. The IECC's Standard Reference Design, which is the IECC's baseline for performance calculations, therefore is required to use the Federal minimum equipment efficiency. Specifically, the Standard Reference Design requirement for "*heating systems*", "*cooling systems*" and "*service water heating*" in the IECC's Table R405.5.2(1) to be "*as proposed*" violates Federal law. RE166 changes the Standard Reference Design equipment efficiency from "as proposed" to "federal minimum standards" and thereby makes the IECC consistent with Federal law and therefore more adoptable by states local jurisdictions.

The specific Federal law is Section 6297(f)(3)(D) of the Energy Policy & Conservation Act (EPCA) as amended by the National Appliance Energy Conservation Act (NAECA). This requires Federal minimum efficiency standards be used in energy code performance calculations for "covered products". Residential furnaces, air conditioners, heat pumps and water heaters are "covered products". Section 6297(f)(3)(D) allows "baseline building designs", such as the IECC's "Standard Reference Design", for performance calculations <u>only</u> if the baseline is the Federal minimum equipment efficiency standards. NAECA expressly preempts state and/or local building codes for new construction from using the 2012 IECC's "as proposed" in baseline energy-code performance calculations. This provision requires that a code with an energy performance calculation for a residential furnace, air conditioner, heat pump, or water heater use the Federal minimum equipment efficiency standard as its baseline. Specifically the Federal law states that for building designs that contain a "covered product" that "the baseline building designs are based on the efficiency level for such covered product which meets but does not exceed .. " the Federal energy conservation standard. In plain language "meets but does not exceed" is the same as saying "equals". When adopted by a jurisdiction the IECC's Table R405.5.2(1) would seem to violate Federal law by having a baseline equipment efficiency that is "as proposed".

RE166 will resolve the conflict with Federal law by setting the Standard Reference Design equipment efficiency to be the "federal minimum standards" as it was in the 2006 IECC.

NAECA is codified into the U.S. Code in title 42, chapter 77, subchapter III. The Federal law can be viewed on the web at:
http://www.gpo.gov/fdsys/pkg/USCODE-2011-title42/pdf/USCODE-2011-title42-chap77-subchapIII.pdf
The relevant section is on page 5849, left column, in section "(D)". Fair warming- It is in legal language.

Public Comment 3:

Vickie Lovell, Intercode, Inc., representing self, requests Approval as Submitted.

Commenter's Reason: Restoring the equipment trade-off from the 2006 IRC promotes flexibility and undoes a needless restriction on how code compliance can be achieved. Without this provision, the code is an impediment to design innovation, and a disincentive for opportunities of cutting-edge equipment technologies and related mechanical components. That is the opposite of promoting whole house energy performance.

Public Comment 4

Jay Crandell, P.E., ARES Consulting, representing the Foam Sheathing Committee of the American Chemistry Council, requests Approval as Modified by this Public Comment

Modify the proposal as follows:

TABLE R405.5.2(1) (N1105.5.2(1))
SPECIFICATION FOR THE STANDARD REFERENCE AND PROPOSED DESIGNS

BUILDING COMPONENT	STANDARD REFERENCE DESIGN	PROPOSED DESIGN[a]

a. The proposed design shall use U-factors for the opaque building thermal envelope building components that are no more than 15% greater than those included in Table R402.1.3 as determined on an area-weighted average basis for each component .

(Remainder of table contents unchanged; re-label existing footnotes accordingly)

Commenter's Reason: It is important to promote reasonable flexibility in achieving energy efficiency.

RE166 does not set a reasonable baseline for equipment efficiency or reasonable flexibility. Some of the federal minimums for equipment efficiency are changing but others are not, leaving minimums at unreasonably low levels that have long been out paced by the market. Until the federal minimums are in line with commonly used equipment efficiencies in the market place they should not be allowed as a baseline in the code.

When using the performance path on a purely "energy neutral" basis without limitation or discretion, unintended consequences can occur that are not adequately prevented by a purely "energy neutral" approach to performance (without technically sound limitations). The potential for over-reaching reductions in building envelope thermal efficiency that are enabled by RE166-13 can have unintended consequences. Some of these consequences that justify reasonable limitations on trading off the opaque thermal envelope in the performance path include:

1. An imbalance or over-reliance on one means of conserving energy which has a shorter service life, can result in a much less robust means of achieving energy efficiency. Therefore service life should be taken into consideration when establishing appropriate limitations on tradeoffs.
2. The potential for unlimited reductions in thermal envelope efficiency can result in poorer performance in ways that are not accounted for in the performance path. For example, when significantly reducing the building envelope insulation, interior surfaces are subject to larger temperature gradients dramatically affecting occupant comfort. This often results in changing of the set-point temperature further degrading the energy performance of the building. Also, in the case of power outages or equipment failure, it is more difficult to maintain tolerable living conditions.

Finally, it is important to recognize that other sections of the code also impose reasonable limitations on the performance path to address unintended consequences that are not accounted for in a purely "energy neutral" view of the performance path. For example, Section R402.5 imposes a limitation on the U-factors for fenestration. Without such limits on the performance path, unintended consequences will occur that have other than "energy neutral" performance implications (e.g., excessive condensation on windows in colder climates and occupant discomfort leading to corrective actions such as increasing energy consumption by altering the set-point temperature). Similarly, Section R405.2 contains a limitation on minimum duct insulation in unconditioned spaces. Such precedents for limitations on performance simulation methods go beyond the energy code. For example, a 15% limit on reduction of wind loads is imposed on wind tunnel simulations unless worst-case scenarios are considered that demonstrate the reductions are "safe". Therefore, a similar approach is taken in this public comment.

It is important to recognize that this public comment provides guidance that ensures energy efficiency is implemented in a distributed fashion such that unintended consequences are avoided and trade-offs do not result in an imbalanced overall building energy efficiency design.

Public Comment 5

Neil Leslie, Gas Technology Institute, representing self, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

Table R405.5.2(1)
SPECIFICATION FOR THE STANDARD REFERENCE AND PROPOSED DESIGNS

BUILDING COMPONENT	STANDARD REFERENCE DESIGN	PROPOSED DESIGN
Heating systems[f~~, g~~]	Fuel type: ~~same as proposed design~~ Electric Efficienc~~ies~~y: ~~Electric:~~ air-source heat pump with prevailing federal minimum standards ~~Non-electric furnaces: natural gas furnace with prevailing federal minimum standards~~ ~~Non-electric boilers: natural gas boiler with prevailing federal minimum standards~~	
Cooling systems[~~f, h~~g]		
Service water heating[~~f, g,h,i~~]	Fuel type: ~~same as proposed design~~ Electric	

~~f. For a proposed design with multiple heating, cooling or water heating systems using different fuel types, the applicable standard reference design system capacities and fuel types shall be weighted in accordance with their respective loads as calculated by accepted engineering practice for each equipment and fuel type present.~~
f~~g~~. For a proposed design without a proposed heating system, a heating system with the prevailing federal minimum efficiency shall be assumed for both the standard reference design and proposed design.
g~~h~~. For a proposed design home without a proposed cooling system, an electric air conditioner with the prevailing federal minimum efficiency shall be assumed for both the standard reference design and the proposed design.
~~i. For a proposed design with a nonstorage-type water heater, a 40-gallon storage-type water heater with the prevailing federal minimum energy factor for the same fuel as the predominant heating fuel type shall be assumed. For the case of a proposed design without a proposed water heater, a 40-gallon storage-type water heater with the prevailing federal minimum efficiency for the same fuel as the predominant heating fuel type shall be assumed for both the proposed design and standard reference design.~~

Commenter's Reason: The IECC has already chosen the right metrics for energy performance in Section R405.3:

1. Energy cost budget (for adopting authorities mainly concerned about the homeowner's economic objectives), or
2. Source energy budget (for adopting authorities mainly concerned about the homeowner's energy consumption impacts on primary energy consumption).

However, for these to be implemented in a fair and equitable manner, one critical additional step is needed: A single baseline building energy budget. This amendment provides the critical single baseline budget methodology to implement this code correctly and equitably. It is only by implementing the correct metrics correctly - i.e. through the single baseline methodology – that the IECC can avoid adverse effects and unintended consequences on users of the code.

This amendment corrects the flawed multiple baseline systems tradeoff methodology in RE166-13. It establishes an all electric building as the starting point for all energy use comparisons under R405.3. Without these changes, it is not possible for the multiple baseline systems methodology in RE166-13 to be "energy neutral".

Any multiple baseline systems methodology is inherently biased against fuel choices. You must have a single baseline. Multiple baseline systems are also biased against any technology options that might have lower energy cost and higher source energy efficiency. This is especially true for water heating but also applies to space heating in northern climates.

As currently written, RE166-13 establishes the reference design building energy cost budget or source energy budget AFTER fuel choices are made. Therefore it is energy biased because it treats different energy forms as if they are equal when they are not, thereby always favoring one fuel choice over another inappropriately.

The multiple baseline system methodology in RE166-13 is inconsistent with the stated intent of the IECC to provide *"model code regulations that will result in the optimal utilization of fossil fuel and nondepletable resources in all communities, large and small."* The current provisions treat various technology options as equivalent to each other even though there are demonstrable and meaningful differences in energy cost and source energy use among the fuel choice and technology options, especially for electric resistance and natural gas options. This results in suboptimal utilization of fossil fuels because significantly more coal and natural gas are burned in power plants to provide electricity for inefficient qualifying electric technologies than would be consumed by burning natural gas directly in the home using the more source energy efficient and lower energy cost gas technology.

As currently written, RE166-13 inserts a dangerous "fuel bias" in the code that this amendment fully corrects by changing to fuel blind, single baseline compliance provisions.

The revised tables and text completely decouple the proposed building design choices from the standard reference design building's energy cost or source energy performance requirement. The reference energy and technology choices in the revised section were selected to provide a practical and effective requirement to meet the intent of the standard while still offering appropriate incentives for the best available technologies based on their energy cost or source energy benefits. By shifting to electric technologies for all baseline systems, this amendment allows determination of an equitable energy cost or source energy budget at a reasonable level of performance using compliant electric technology options.

The most useful comparison illustrating the inherent flaw in the RE166-13 methodology is a minimally compliant electric storage water heater compared to a minimally compliant gas storage water heater. Homes using NAECA minimum efficiency electric resistance storage water heating qualify equally as a NAECA minimum gas storage water heater, even though both the annual energy costs and primary energy consumption are much higher for the resistance water heater than for the gas water heater (typically twice as high). Based on a typical home in the midwest, annual energy use for an NAECA minimum electric resistance water heater is 3,920 kWH, while a NAECA minimum gas water heater uses 205 therms. Using average Missouri energy rates available from EIA of $0.098 per kWh and $1.05 per therm, the electric water heater annual cost of operation is $384, while the natural gas water heater costs only $215 per year, a 79% increase in the energy cost budget for the electric water heater. Using the respective source energy conversion factors of 3.16 and 1.1 in the IECC, the source energy consumption of the electric water heater is 42.3 MBtu while the source energy consumption for the gas water heater is only 22.6 MBtu, an 87% increase in the source energy budget for the electric water heater. RE166-13 considers them equal for compliance purposes because it uses a separate, biased reference home for determining compliance for electric water heating systems. The lower energy cost and source energy represent benefits to consumers and society, yet they are not rewarded in the RE166-13 methodology. It is this "best efforts" harmful bias that the proposed shift to a single baseline system methodology fully corrects.

There is another development in 2013 that corroborates this amendment and a shift to an equitable single baseline methodology for consistency. ASHRAE Standard 90.1-2013 (a deemed-to-comply option in IECC-2014) will include for the first time a new single baseline system methodology in the performance path for all new commercial buildings. This methodology is identical to the single baseline mechanical system methodology proposed in RE179. The 90.1 single baseline tables are more sophisticated than those in RE179 to accommodate the wide variety of building types and regional building practices in the commercial sector. By including the proposed methodology in the residential provisions of the 2014 IECC, the residential and commercial provisions will be internally consistent.

Public Comment 6:

Brian Dean, ICF International, representing the Energy Efficient Codes Coalition; Jeff Harris, Alliance to Save Energy; Harry Misuriello, American Council for an Energy-Efficient Economy (ACEEE); Bill Prindle, representing the Energy Efficient Codes Coalition; Garrett Stone, Brickfield, Burchette, Ritts & Stone, PC; Donald J. Vigneau, Northeast Energy Efficiency Partnerships Inc., request Disapproval

Commenter's Reason: We recommend disapproval of RE166. In RE166, NAHB proposes to reintroduce an enormous loophole into the IECC residential energy provisions by re-creating the opportunity to trade-off the efficiency of other elements of the building for heating, cooling, and water heating equipment that is better than the least efficient equipment permitted to be sold under federal law. The net result would be that the same, fairly efficient equipment now typically installed in new homes due to technology advances, market conditions, and consumer preferences would result in zero energy savings – because the energy savings from efficient equipment would disappear through the a leakier thermal envelope and other efficiency downgrades allowed by the proposed trade-offs. **Reinstating the equipment trade-off loophole would be the single biggest step backward in energy efficiency proposed by any proponent in this cycle and should be rejected.**

Here is a summary of some of the many major problems with this NAHB proposal:

- The proposed trade-off would allow a massive reduction in the more permanent features of the building that affect energy efficiency (such as insulation, windows, building tightness and duct tightness) if reasonably efficient heating, cooling and hot water equipment is installed. Exchanging a weaker permanent envelope for much shorter-life equipment, which is likely to be installed anyway, is not reasonable. For example, a water heater with less than a 10 year life should not be used to reduce the amount of insulation or to trade-off for a leaky building – creating problems that will last for the life of the home.
- **Depending on the efficiency of the equipment installed and the climate zone, allowing equipment trade-offs could amount to up to 20% (or more) potential reduction from the requirements of the current code nationwide in any home where the equipment is above the federal minimum standard.** Such a trade-off could be used to wipe out most of the specific efficiency improvements included in the 2009 and 2012 IECC.
- The proponent does not offer good reasons for the IECC to reverse course and retreat on the issue of equipment trade-offs. Equipment trade-offs were removed from the IECC two code cycles ago; no trade-offs are permitted by the 2009 or 2012 IECC. Nothing significant has changed to justify going backward. In both of the previous code cycles, a majority of the IECC development committee and an overwhelming majority of the ICC's governmental members voted to remove these trade-offs and then later, to keep them out of the IECC. Earlier this year, on a close 6 to 5 vote, the IECC residential energy committee, with 4 NAHB representatives out of 11 voters, recommended this NAHB proposal for approval.
- The federal government has reviewed and approved for state and local adoption both the 2009 IECC and 2012 IECC, finding that the removal of the trade-offs improved the energy efficiency of the code. Since these equipment trade-offs are not allowed by the 2009 IECC, state or local adoption of the 2015 IECC with this added provision would appear to violate commitments made by the states, as a condition of receiving federal funding, to adopt the 2009 IECC and achieve 90% compliance.
- Reinstating the trade-off will not help encourage code adoption, as some claim. **Equipment trade-off provisions have been removed from the current code adopted in 2/3 of the states and numerous localities. As a result, numerous homes have been built nationwide without any discernible problems from elimination of the trade-off. Reinstating this trade-off would only serve to move all of these codes sharply backward.** While the committee's reason suggests that trade-offs are being

adopted locally on a widespread basis, no one has offered any evidence to substantiate that claim; the fact that 2/3 of states have adopted the 2009 or 2012 IECC without such trade-offs show that this claim has no basis in reality. In fact, we expect that reinstating the trade-offs would have the opposite effect -- many of the energy code supporters who currently support energy code updates would likely become strong opponents of adoption of a weakened 2015 IECC with such a trade-off.

- On a technical basis, equipment trade-offs are fundamentally a problem because, unlike other features (such as the building envelope), state and local codes are prohibited by federal law from setting a reasonable performance baseline for such equipment. Because the federal government has sole authority to set standards for such mechanical equipment, it is appropriate that the IECC leave this issue to the federal government. Reintroducing trade-offs would move the IECC back into this area of primary federal jurisdiction:

o For the code to establish a standard or baseline for federally-regulated equipment, it can only use federal minimum standards.

o Federal minimum standards for each type of equipment have been set at different times, under different circumstances, and under a different process than model or state codes, and subject to various regulatory, legal and political constraints – including long lead times to introduce a new level and a requirement that the same level of efficiency apply to equipment in new construction and to replacement equipment for existing homes, where it is often more difficult and costly to accommodate the latest technology.

o These federal minimum standards do not represent reasonable code baselines for efficient equipment comparable to baselines set in the code for other parts of the building.

o Federal minimum standards establish the minimum level at which equipment can be purchased for any purpose nationwide and are far too inefficient as compared with current building practice, creating a major compliance loophole that allows builders to reduce efficiency in other parts of the building.

o We are aware of no other baseline building feature in the energy code that can be traded-off that is set at the minimum level allowed to be sold under federal law.

o Allowing equipment trade-offs based on federal minimums introduces a significant fuel bias, currently in favor of natural gas, because the gap between the federal minimum standard and the typical efficiency level determined by the market is currently much wider for gas equipment than electric equipment. This is well illustrated by the fact that in 2015 gas furnaces will have an artificially low 80 AFUE standard nationwide as compared to the more rigorous 8.2 HSPF standard for electric heat pumps. As a result, homebuilders with an equipment trade-off can find far more trade-off potential by choosing gas equipment. Even the federal government has recognized that 80 AFUE for gas furnaces is far too low and has unsuccessfully attempted to increase it.

- While supporters of this proposal attempt to justify it in the name of "flexibility," this is just a euphemism for "loophole." It is a loophole because the typical equipment being sold and installed is already far more efficient than the minimum standard. **For example, if RE166 were approved, a builder could capitalize on the 90+ AFUE furnace they are likely already installing, and increase heating energy consumption by 10% to 15% (and energy costs paid by the homebuyer) by applying trade-offs to reduce thermal efficiency of the envelope.** We estimate the total impact on code-covered energy uses from a trade-off for a 90+ AFUE furnace to range from 6% to 9% lost energy cost savings nationwide, depending on the choice between 90 AFUE and 96 AFUE, and up to 14% lost savings in the coldest climate zones.
- As discussed in more detail below, a majority of gas furnaces sold in the US are 90+ AFUE. In states with colder climates, where the trade-off created by the efficient furnace is much greater, the number is far higher. On top of the furnace trade-off, the builder can also install a better hot water heater (with a relatively short operating life) for another, possibly even larger trade-off that further weakens the building envelope.
- The proponent also argues that trade-offs are necessary to avoid discouraging efficient equipment. Yet there is no evidence that builders need the trade-off to encourage better equipment. High-efficiency equipment continues to improve and penetrate the market even though trade-offs are currently not allowed in most states. Moreover, in many jurisdictions, the builder or homebuyer qualifies for utility incentives for such equipment. Utility incentives for equipment in new homes are likely to go away if trade-offs are reinstituted, since utilities typically are not permitted by their regulators to subsidize free ridership. Elimination of utility incentives will undercut, instead of support, the installation of efficient equipment.
- Similarly, the argument that equipment trade-offs are "energy neutral" touts a false equivalence by focusing on energy use on Day One and ignoring the use of energy over time. Replacing more permanent features with less permanent features is not energy neutral over time. Moreover, such an argument ignores the fact already noted above that the code is required to use minimum federal standards and cannot set reasonable levels of efficiency.
- Use of more efficient equipment in lieu of other energy efficiency measures also creates numerous other problems. For example, trading off envelope features for equipment also results in:
    - o Less comfortable homes due to weaker building envelopes and the likelihood to use more energy by adjusting the thermostat to compensate;
    - o Homes that are less resilient in the face of emergencies like hurricanes and snowstorms, where power or gas supply is no longer available and the homeowner is reliant on the building thermal envelope, not the equipment, to provide a habitable environment (the weaker the envelope, the greater the risk to the health and safety of the occupant); and
    - o Higher equipment loads and peak demands, with added first-cost for more heating or cooling capacity and negative impacts on utility generation, transmission and distribution systems.
- Reinstituting equipment trade-offs will create a bias for the performance path and lead to a migration away from compliance through the simple prescriptive path; greater utilization of the much more complex performance path will substantially complicate code compliance and enforcement.

Many of these issues are discussed in more detail below. We call on the Governmental Members to vote to retain a reasonable energy code by rejecting NAHB's efforts to take the code back to 2006.

1. Equipment trade-offs will create a huge energy efficiency loss for the nation and are not "energy neutral."

Although states can set performance baseline requirements for efficiency for most building components, certain types of mechanical equipment, including heating, cooling, and water heating equipment, are subject to a rigid set of requirements under Federal law. If any state incorporates equipment into a performance equation, it is mandated under federal law to base any trade-off on federal minimum efficiencies, which are well below the typical efficiency of equipment installed in many cases. (This law was designed to preclude states from indirectly requiring the use of more efficient equipment than the federal minimum standard requires.) Using gas furnaces as an example, even if builders routinely install condensing natural gas furnaces with 90+% efficiency, the state is prohibited under federal law from requiring 90+% efficient furnaces or anything more efficient than the federal minimum – generally an 80% efficient gas furnace. This creates an enormous (greater than 10%) loophole between the baseline amount of heating energy used and the actual amount used by the equipment, allowing a substantial degrading of the efficiency of other measures when using the performance path.

When the IECC permitted an equipment trade-off in the past (pre-2009 IECC), this federal preemption of state equipment requirements created a trade-off gap that was routinely exploited to reduce the efficiency of other elements of the building. According to an analysis produced by ICF International modeling the effects of this proposal, the impact on building energy efficiency if this trade-off were permitted again would be substantial. In the following table, 5 different trade-off packages illustrate the magnitude of the resulting trade-off loophole that will reduce the long-term energy efficiency of the building.

	2015 Federal Minimum Equipment Efficiency	Readily Available Equipment Efficiency	National Average Increase in Energy Use
Example 1 - Natural Gas (90 AFUE Only)			
Natural Gas Furnace	80 AFUE	90 AFUE	6%
Air Conditioner	13 SEER/14 SEER	13 SEER/14 SEER	0%
Water Heater	0.59 Gas DHW	0.59 Gas DHW	0%
		National Average	6%
		Climate Zone Averages	0-9%

	2015 Federal Minimum Equipment Efficiency	Readily Available Equipment Efficiency	National Average Increase in Energy Use
Example 2 - Natural Gas (Moderate Efficiency Equipment)			
Natural Gas Furnace	80 AFUE	92 AFUE	7%
Air Conditioner	13 SEER/14 SEER	16 SEER	2%
Water Heater	0.59 Gas DHW	0.67 Gas DHW	3%
		National Average	12%
		Climate Zone Averages	9-13%

	2015 Federal Minimum Equipment Efficiency	Readily Available Equipment Efficiency	National Average Increase in Energy Use
Example 3 - Natural Gas (High Efficiency Equipment)			
Natural Gas Furnace	80 AFUE	96 AFUE	9%
Air Conditioner	13 SEER/14 SEER	19 SEER	4%
Water Heater	0.59 Gas DHW	0.80 Gas DHW	9%
		National Average	22%
		Climate Zone Averages	18-30%

	2015 Federal Minimum Equipment Efficiency	Readily Available Equipment Efficiency	National Average Increase in Energy Use

Example 4 - Electric (Moderate Efficiency Equipment)			
Heat Pump	8.2 HSPF	8.5 HSPF	1%
Air Conditioner	14 SEER	16 SEER	2%
Water Heater	0.92 Elec DHW	0.95 Elec DHW	2%
		National Average	5%
		Climate Zone Averages	3-10%

	2015 Federal Minimum Equipment Efficiency	Readily Available Equipment Efficiency	National Average Increase in Energy Use
Example 5 - Electric (High Efficiency Equipment)			
Heat Pump	8.2 HSPF	9.2 HSPF	3%
Air Conditioner	14 SEER	19 SEER	4%
Water Heater	0.92 Elec DHW	1.15 Elec DHW	13%
		National Average	21%
		Climate Zone Averages	13-29%

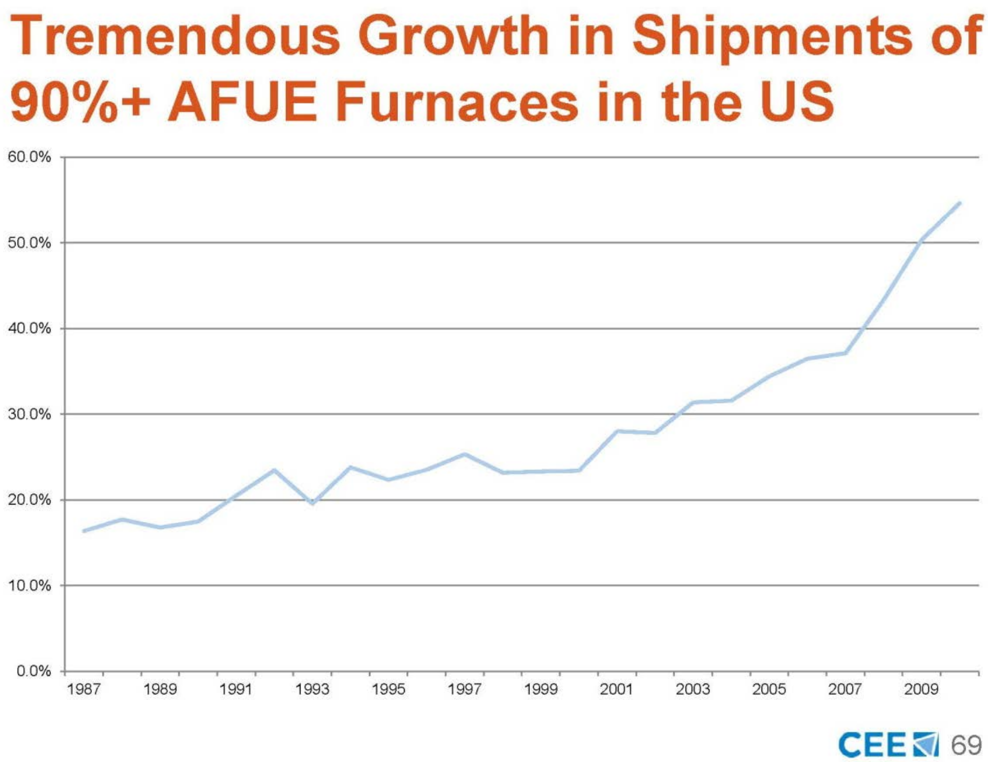
The national average percentage numbers in the tables indicate the amount of energy savings at risk if a builder uses readily available mechanical equipment as a means of “trading off” elements of the thermal building envelope such as insulation or windows. Thus, if RE166 is successful, and equipment trade-offs are included in the IECC for heating, cooling, and water heating equipment available to be installed in homes in 2015, new homes would be built to a substantially less efficient standard.

As an example, in Climate Zone 3, further analysis conducted by ICF International shows that homes that use high efficiency heating, cooling and water heating equipment can trade-off **ALL** of the following measures: wall insulation from R-20 to R-11, infiltration from 3 ACH50 to 7 ACH50, window U-factor from 0.35 to 0.75, window SHGC from 0.25 to 0.50, and duct leakage from 4 CFM/100 SF to 10 CFM/100 SF. Even if the high-efficiency equipment were not being installed in any case, the proposed trade-off, claimed to be energy cost neutral in the first year, would result in larger equipment sizes (63% larger furnace and 80% larger air conditioner), higher peak demand (22% increase) and significant comfort reduction due to having a leakier home, with leakier ducts and more extreme temperature at the exterior surfaces of the home. The larger equipment sizes will increase the cost of future equipment purchases, the higher peak demand will continue to stress the electric grid and the comfort reduction will cause higher energy bills, occupant turnover and lower property values.

To restore the equipment trade-offs in the IECC amounts to an unnecessary and costly giveaway and a massive backslide in energy efficiency.

2. **Energy efficient equipment will be installed even without a trade-off, so this provision represents an enormous loophole for builders and results in increased energy use, less comfort, and higher operating costs for all subsequent owners of the home.**

As can be seen in the chart below from the Consortium for Energy Efficiency (CEE) with data from AHRI, there has been a steady growth in the number of 90%+ AFUE furnaces across the entire US. In addition to this long term trend, recent data from US EPA show that in 2011, 55% of the furnaces shipped in the US were 90%+ AFUE ENERGY STAR furnaces. At the local level, in more northern heating climates where the 90+ furnace will create the greatest trade-off opportunity, the number is obviously much higher. For example, the Energy Center of Wisconsin shows that 90% of all furnaces in Wisconsin are 90%+ AFUE as of the 4th quarter of 2011. The potential for abuse of the furnace trade-off alone is staggering.



Source: AHRI

3. **Short-term "flexibility" should not come at the expense of permanent energy efficiency.**

Despite the widespread adoption of the IECC with no equipment trade-offs for the last four years and the major problems with such trade-offs, some still argue that an equipment trade-off adds necessary "flexibility," and that without these trade-offs, codes will not be adopted and buildings will not be constructed with efficient equipment. This argument ignores three important realities: (1) efficient buildings should have both an efficient thermal envelope AND efficient equipment; (2) efficient equipment, because of consumer demand, utility incentives, and market maturity, is already widely used even without code trade-offs; and (3) about two-thirds of the states have already adopted the IECC without any such trade-offs.

Allowing direct trade-offs for building mechanical equipment, typically with much shorter life spans than the structure itself, ignores the long-term value of the permanent thermal envelope. Well-insulated homes provide a cost savings stream for homeowners for a much longer period than HVAC equipment, which will have to be replaced several times over the lifetime of the home. While the IECC performance path analysis and other similar measures calculate the energy use or energy cost over a one year period, this is only a limited snapshot of the home's lifetime. A true analysis of the impact on the eventual homeowner must consider the impact of various measures over the life of the home.

A good illustration of the long-term energy impact of equipment trade-offs is to assume two homes: the first built to the 2012 IECC with minimum federal equipment, and the second built using equipment trade-offs to reduce the thermal envelope of the IECC. It should be noted that this illustration only addresses the long-term impact and not the free-rider issue -- that many homes will have upgraded equipment already. In the first year, the two homes may use the same amount of energy (assuming the equipment performs per spec). However, as heating, cooling, and/or water heating equipment is replaced every 5 to 20 years, it is reasonable to expect that improved efficiencies will result in the equipment in both homes becoming the same over time – through a combination of updated federal standards and ongoing technology improvements and market forces – or at least that the less efficient equipment in the first home will improve more rapidly than the more efficient equipment in the second home (it is also possible that the home with the more efficient equipment will replace that equipment with less efficient units). As this transition happens, **the 2012 IECC house will always outperform the trade-off house, because it will benefit both from the stronger thermal envelope *and* more efficient equipment** once replacement occurs. In addition, the home relying upon more efficient equipment will also need to size the equipment larger, will generate higher peak loads and the homeowner will have a home that will not respond as well during emergencies where electricity or gas is unavailable.

4. **The ICC should continue to stand behind its decisions over the past two code cycles to eliminate and keep equipment trade-offs out of the residential energy code.**

To restore equipment trade-offs in the 2015 IECC would not only be a significant setback in energy efficiency for states adopting that code, but such a reversal of position would also undercut the credibility of the IECC. Despite efforts of some stakeholders at the state level, the vast majority of states do not currently allow trade-offs of equipment efficiency for thermal envelope efficiency. The states have followed the lead set by both the 2009 and 2012 versions of the IECC – that such trade-offs are unnecessary and no longer appropriate. Currently, at least 33 states have adopted either the 2009 or 2012 IECC without any equipment trade-offs (in other states, where the code is adopted by local government, in many cases the new codes have also been adopted without trade-offs).

Congress also endorsed the 2009 IECC by reference in federal law -- the 2009 American Recovery and Reinvestment Act (ARRA) – setting the 2009 IECC as the starting point for state code adoption and implementation. All fifty states committed to adopt a residential code that meets or exceeds the 2009 IECC (which does not contain an equipment trade-off) under ARRA, and received over $5 billion in DOE State Energy Program grants in return. Adoption of equipment trade-offs would be inconsistent with this law and these commitments.

The U.S. Department of Energy explained some of the benefits of eliminating the equipment trade-off in its analysis of the 2009 IECC, when it found that the 2009 IECC version was an improvement over the 2006 version and found that the elimination of the trade-offs would likely result in energy savings in the home:

> Because building envelopes have substantially longer lives than HVAC and/or water heating equipment, energy savings from envelope improvements may persist for many more years than comparable equipment improvements. Also, because high-efficiency equipment is already the predominant choice in many markets, disallowing envelope/equipment tradeoffs is likely to result in improved overall efficiency in many situations.

See 75 Fed. Reg. 54131, 54138 (Sept 3, 2010).

A well-insulated thermal building envelope will yield substantial cost-savings benefits to a homeowner for the lifetime of the home, and the IECC should not trade away these long-term benefits for short-term savings associated with HVAC trade-offs. Such an amendment could roll back the energy code requirements currently enforced in most states, and could negatively impact the nation's energy conservation efforts for generations to come. We urge disapproval of RE166 and all other similar equipment trade-off proposals.

RE166-13

Final Action: AS AM AMPC____ D

RE169-13
Table R405.5.2(1) (IRC Table N1105.5.2(1))

Proposed Change as Submitted

Proponent: Gary MacFadden, National Electrical Manufacturers Association (NEMA) (gary.macfadden@Nema.org)

Revise as follows:

TABLE R405.5.2(1) (N1105.5.2(1))
SPECIFICATIONS FOR THE STANDARD REFERENCE AND PROPOSED DESIGNS

BUILDING COMPONENT	STANDARD REFERENCE DESIGN	PROPOSED DESIGN
Heating systems[f, g]	As proposed for other than electric heating without a heat pump. Where the proposed design utilizes ducted electric heating without a heat pump, the standard reference design shall be an air source heat pump meeting the requirements of Section R403 of the IECC—Commercial Provisions. Where the proposed design is for an electric heating system that does not use a duct system, the standard reference design shall be as proposed. Capacity: sized in accordance with Section R403.6	As proposed

(Portions of table not shown remain unchanged)

Reason: As it is written, Table R405.5.2(1) requires a modeler to assume a heat pump system whenever a designer proposes to use "… other than electric heating without a heat pump," *i.e.*, electric resistance or electric radiant heating (collectively "ERH") in a new residence. While perhaps serving a valuable function in some fashion (elimination of gaming where a modeler assumes an electric furnace for the reference house and then proposes a heat pump allowing a less stringent envelope), the limitation on use of ERH in the modeling is overly restrictive. ERH is available in many different applications and the performance characteristics of non-ducted ERH are very different from the performance characteristics of ducted heating systems, whether fueled by electricity, gas, or any other fuel. In addition to no duct energy losses, non-ducted ERH also enjoys significant energy savings from zoning. This proposal attempts to preserve the benefit of eliminating gaming while still recognizing the energy savings potential of non-ducted ERH.

Substantiation: ERH is available in a number of different configurations, including electric furnace, baseboard, radiant and PTAC. For purposes of this proposal, however, only non-ducted ERH is being considered. The operational and energy consumption characteristics of ducted vs. non-ducted ERH are significant and are at the core of the rationale behind this code change proposal. Unfortunately, ducted and non-ducted ERH systems are often grouped together (as they are in the existing code language).

Language like that found currently in Table R405.5.2(1) that requires a modeler to assume a heat pump in the reference house, even if the designer intends to use electric baseboard heating in the proposed house, has been in the IECC for many years. The justification cited historically for that modeling limitation is:

- That modelers will game the system by assuming ERH in the reference house but a heat pump in the proposed house, thereby allowing a less stringent envelope, and/or
- That a heat pump will consume on the order of half the energy of an electric furnace installed in the same house so the code should discourage designers from specifying ERH and instead should specify a heat pump.

With respect to the former of these justifications, the current language requiring the same equipment to be modeled in both the reference and the proposed designs denies any opportunity to game the system as described above.

That leaves the latter as the sole justification for the modeling restriction against using electric resistance heating as the equipment assumption in the reference house. To some extent, this seems appropriate. If, for instance, in a heating dominated climate, a designer is proposing to install a ducted electric furnace with central air-conditioning, then incenting that designer to use a heat pump instead would probably be expected to save significant amounts of energy at a relatively modest cost.

But there are significant operational and energy consumption characteristics that distinguish ***ducted from non-ducted*** ERH as described in more detail below.

Ducted vs. non-ducted heating systems. Non-ducted ERH has significantly different operational and energy consumption characteristics from ducted heating systems.

Fan Power. Numerous studies over the last decade have identified furnace fan energy usage as more significant than before believed. As a result, the U.S. Department of Energy has initiated a rulemaking to establish a test procedure for determining furnace fan energy. Likewise, the Environmental Protection Agency now has an Energy Star rating for efficient furnace fans. Of course, non-ducted ERH like baseboard or radiant doesn't use a fan. On this basis, a reasonable person could conclude that, all other things being held constant, a non-ducted ERH system (without a fan) would consume less energy than a ducted electric furnace with a fan.

Duct loss and fan induced infiltration. Energy losses through ductwork are recognized as significant and come from two distinct sources; air lost through ductwork to the outside and induced infiltration/exfiltration caused by duct pressurization. Air lost to the outside is self-explanatory and is, in fact, already recognized by the 2012 IECC (and earlier versions) in Table R405.5.2(2) where distribution system efficiency is discounted under certain common conditions. In addition, there is growing recognition that ductwork design can have a significant impact on infiltration/exfiltration. On this basis, a reasonable person could conclude that, all other things being held constant, a non-ducted ERH system would consume less energy than a ducted electric furnace.

Zoning. Ducted, central heating, whether it be a ducted heat pump, electric furnace, gas furnace or other, is designed to serve large areas, most often an entire house. Non-ducted ERH, on the other hand, generally divides a house up into numerous independently controlled zones. The energy efficiency benefits of zoning are well documented as it allows users to heat only those areas that are occupied resulting in significant savings. On this basis, a reasonable person could conclude that, all other things being held constant, a zoned, non-ducted ERH system would consume less energy than a ducted electric furnace.

Additional considerations. Few people would argue that, at the margin, a zoned, non-ducted ERH would be expected to consume fewer btu's over the course of a winter than a ducted electric furnace. In addition to these operational differences, however, (no fan energy, no duct losses, benefits of zoning), there are other reasons why ERH should be treated differently from ducted heating systems as noted below.

Cooling. There are still a non-trivial amount of new homes built in the United States every year without central cooling. According to the EIA, over 800,000 new homes were built between 2000 and 2009 without air-conditioning. A recent study in the Pacific Northwest revealed a relationship between increased use of cooling energy in homes that use heat pumps vis-à-vis electric furnaces. While there are a number of potential explanations, at least one explanation is that people using ERH consciously decline to install air conditioning. Thus, incenting the use of heat pumps over ERH may have the unintended result of increasing summer cooling energy.

Cooling dominated climate. In cooling dominated climates, with relatively few heating degree days (DOE Climate Zones 1 & 2), driving a builder to use a heat pump which would save relatively little – if any – heating energy due to the warm climate would result in fewer dollars for that builder to spend on other things like more attic insulation or higher SEER air-conditioning – something that would actually result in energy savings.

Non-ducted ERH has significantly different operating characteristics than ducted heating systems.

With respect to the assumption that a heat pump system will consume less than half the btus's of an electric resistance heating system because the heat pump has a COP of 2 or better, this assumption may be valid for a comparison between a ducted heat pump and a ducted electric resistance furnace, but it not accurate for non-ducted, zoned ERH (*See* Note 1 below)

In a study conducted by the National Association of Home Builders Research Center for the U.S. Department of Energy, an occupied house in the Washington, D.C. area was monitored for performance over a winter. The house contained three distinct heating systems; central electric heat pump, electric radiant heat, and electric baseboard heat. After the data was weather normalized, it revealed that, under actual homeowner controlled conditions, the electric radiant system used 33% percent less energy than the heat pump system and 52% less than the electric baseboard system. Thus, the heat pump only saved about 36% the energy consumed by the electric baseboard system.

Heat pumps are a great option when a person wants a central, ducted hearing and cooling system but they having different operating characteristics from a non-ducted ERH system.

Note 1. Recent field data from a large survey of homes suggests that the actual (vs. theoretical) relationship may not be as well understood as previously believed. *See* study at http://www.nwcouncil.org/energy/rtf/meetings/2009/04/Draft%202008%20NEEM%20Study_040608.pdf (p. 21) where observed heat pump energy savings were far short of expectations and the report said

> "For the heat pump cases, however, the apparent similarity between electric resistance and heat pump systems suggest minimal savings for the more efficient heat pump option. Some form of behavioral ―takeback‖, poor heat pump installations or increased summer cooling load for heat pumps vis-à-vis resistance houses seem the likeliest explanations. Given that a number of the zone 1 sites (e.g.: Medford, Oregon; Yakima, Washington; and The Dalles, Oregon), have cooling climates, the latter seems plausible. A possible alternate contributing explanation is that these heat pump units do not in fact achieve an average COP of as much as 2 under actual operating conditions. Field notes from heat pump cases in the Oregon sample (a high percentage of heat pumps) mentioned occupants who complained about a lack of comfort to their heating contractor and were told by their heating contractors to switch the heat pumps to run in electric resistance heating mode."

Cost Impact: The code change proposal will not increase the cost of construction.

R405.5.2(1)T #2-EC-MCFADDEN.DOC

Committee Action Hearing Results

Committee Action: Disapproved

Committee Reason: This proposal would have the effect of possibly doubling the heating use of the house by allowing the energy budget to be higher.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Gary MacFadden, The National Electrical Manufacturers Association, representing NEMA, requests Approval as Submitted.

Commenter's Reason: Table 405.5.2(1) establishes criteria for calculating energy budgets for persons that would like to use the IECC's performance path to demonstrate code compliance. As part of that process the Table sets out minimum requirements for the modeling of equipment. For all equipment except electric resistance heating, the space heating equipment that is modeled in the reference house must be identical to equipment modeled in the proposed house.

With electric resistance heating, however, the Table requires the modeling of a heat pump for all homes using electricity to heat – even if the owner plans to use zoned electric resistance heat for space heating.

In our original support of RE169 we provided voluminous documentation of the many differences between *non-ducted* electric resistance heating (like zoned baseboard and radiant panels) and the operation of a heat pump.

Without repeating those citations, we would like to summarize as follows:

1. Electric baseboard has no duct losses,
2. Electric baseboard consumes no fan energy,
3. Electric baseboard causes no fan induced home infiltration or exfiltration,
4. Electric baseboard complements the growing production of electricity from renewable sources like wind and solar,
5. Unlike central heating systems, electric baseboard enjoys room-by-room zoning allowing efficient operation.

Electric baseboard heating is not the best choice in all applications --- but it is the right choice in many instances. For example, over 1,000,000 homes have been built over the last 10 years that do not use air conditioning!! Incenting people that don't want air conditioning to use a heat pump is not a good policy given growing concerns over summer peak power demands. In another example, the Founder of the Passive House Institute chose to heat her new house with electric baseboard.

This proposal would simply match modeling of electric baseboard heating to those circumstances where a person elects not to use ducted central heating *and* they don't want air conditioning.

RE169-13

Final Action: AS AM AMPC____ D

RE170-13
Table R405.5.2(1) (IRC Table N1103.5.2(1))

Proposed Change as Submitted

Proponent: Don Surrena, CBO, National Association of Home Builders (NAHB) (dsurrena@nahb.org), and Mark Halverson, APA-The Engineered Wood Association & Loren Ross, The American Wood Council. (help@apawood.org).

Note: *RE177 was listed in the code change monograph separately with Mark Halverson as the proponent. Since RE177 was a duplicate of RE170, RE177 was withdrawn, and Mark Halverson is listed as a co-proponent on this code change proposal.*

Revise as follows:

TABLE R405.5.2(1) (N1103.5.2(1))
SPECIFICATIONS FOR THE STANDARD REFERENCE AND PROPOSED DESIGNS

BUILDING COMPONENT	STANDARD REFERENCE DESIGN	PROPOSED DESIGN
Glazing[a]	Total area[b] =	As proposed
	~~(a) The proposed glazing area; where proposed glazing area is less than 15% of the conditioned floor area.~~	
	~~(b)~~ 15% of the conditioned floor area~~; where the proposed glazing area is 15% or more of the conditioned floor area.~~	As proposed
	Orientation: equally distributed to four cardinal compass orientations (N, E, S, & W)	As proposed
	U-factor: from Table R402.1.3	As proposed
	SHGC: From Table R402.1.1 except that for climates with no requirement (NR) SHGC = 0.40 shall be used.	0.92-(0.21 × SHGC as proposed)
	Interior shade fraction: 0.92-(0.21 × SHGC for the standard reference design)	As proposed
	External shading: none	

(Portions of table not shown remain unchanged)

Reason: (Surrena) Walls generally perform better thermally than windows. Currently in the code there is no incentive in the performance path for the building designer to optimize the window area in order to save energy and provide daylighting, egress and views that makes for a safe and comfortable house. These modifications will provide the building designer the ability to reduce window area and get credit for the energy saved. As this section is currently written, the house is penalized for having more than 15% window area yet receives no credit toward code compliance when the window area is reduced below 15%. This change rectifies this disparity and makes the performance path a more representative of actual energy use.

(Halversen) The greatest thermal break in our wall systems is glazing. While glazing areas greater than 15% of the floor area are penalized for reduced energy efficiency, glazing areas less than 15% are not recognized for increasing energy efficiency. Homes with a lower percentage of windows and doors generally perform better than the code minimum (15%); therefore, these homes should get credit for the additional energy efficiency. This will enhance the readability of the code while making it easier to understand, more equitable, and provide flexibility to builders and architects.

Every avenue must be explored when elevating energy code efficiency to the next level, and this offers an efficiency increase that has not yet been recognized in the code.

We ask the support of the committee for this proposal.

Cost Impact: The code change proposal will not increase the cost of construction.

R405.5.2(1)T #2-EC-SURRENA.DOC

Committee Action Hearing Results

Committee Action: Disapproved

Committee Reason: This proposal would penalize small dwellings where the percentage of openings must necessarily be larger than 15%, and they cannot take advantage of the tradeoff. This also has the effect of increasing the energy budget by lowering the amount of loss in the standard referenced design. RE164-13 is the better approach for this issue.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Don Surrena, National Association of Home Builders, and Tim Ryan, representing the International Association of Building Officials, request Approval as Submitted.

Commenter's Reason: Building walls generally perform much better thermally than windows. This code change proposal will provide the building designer the option to reduce window area and get the appropriate energy credits for the amount of energy saved. As this section is currently written, the home designer is penalized for having more than 15% window area, but receives no energy credits toward code compliance when the window area is reduced below 15%. This code change proposal fixes this disparity and makes the performance path ~~a~~ more representative of actual energy use.

Public Comment 2:

Paul Coats and Mark Halverson, representing APA-The Engineered Wood Association/American Wood Council request Approval as Submitted.

Commenter's Reason: Assuming that the energy code is being developed to save energy, it seems obvious that decreasing the area of windows (which are typically only an R3 or less) in a wall system and increasing the opaque wall areas (R13, R20 and R20+5) should be recognized as an energy-saving measure in the code. Regardless of the climate zone, window and door areas do not have the thermal resistance of opaque walls. It is even difficult to advocate the advantages of passive heat gains during the colder weather months given the fact that SHGC values have no minimum limitations in any of the climate zones. The International Energy Conservation Code must recognize that buildings with fewer windows save energy and incentivize the use of fewer windows.

The committee commented during the hearings that they feared that the builders would somehow "game the system" by using the energy credit for less windows to off-set energy efficiency in other areas of the structure. However, the trading-off of the energy efficiencies of the building components and systems is the basis of performance paths. To hinder the builders' and designers' abilities to meet energy efficiency in any way that they choose creates inequities in the code that lead to preferential treatment of some products and systems and limitations to market access for other products and systems.

The committee's reason statement endorsed the approach of RE 164-13 which removes all area restrictions for windows and doors in the performance path. This position, along with denying energy savings from reduced window area, indicates that the committee thinks that the area of windows is not related to energy savings. Apparently, the committee accepted the proponent's reason statement in RE 164-13 to "keep it simple and keep it energy efficient." Simplicity is good, but the impact on energy efficiency is not acceptable. The proponent of RE164-13 claimed that "as windows get more efficient, the window area matters less" and that windows in the market in colder climates "may be as good as a 'normal' wall". In reality, the thermal performance of code-conforming windows is not comparable to opaque walls. In the 2006 IECC windows ranged in U-factors from U-1.2 to U-0.35 and in the 2012 code windows ranged from U-NR to U-0.32. In contrast, U-factors for walls range from 0.082 to 0.048. In the 2012 IECC, walls are typically 6 times more energy efficient than windows. The least insulated walls (Climate Zone 1) are 4 times more efficient than the windows required in the coldest climate zone (Climate Zone 8). There is no indication that window U-factors will approach the U-factors of opaque walls in the near term. It is absurd to remove the weakest link in heat resistance from consideration in the performance path.

While continuous insulation advocates continue to be concerned about the "thermal break" of wood wall framing materials, the even greater thermal break of windows and doors will now be unrestricted in area. The thermal resistances through the wood framing path in an opaque wall are calculated as R6.8 for 2x4 walls and R9.3 for 2x6 walls, while window values hover around an R3 level or less. It would appear that the code is moving in a direction that is neither product neutral nor encouraging energy efficiency.

We urge the body's support of this code change proposal that is product neutral and saves energy.

RE170-13

Final Action: AS AM AMPC____ D

RE171-13
Table R405.5.2(1) (IRC Table N1105.5.2(1))

Proposed Change as Submitted

Proponent: Jeremiah Williams / U.S. Department of Energy (jeremiah.williams@ee.doe.gov)

Revise as follows:

TABLE R405.5.2(1) (N1105.5.2(1))
SPECIFICATIONS FOR THE STANDARD REFERENCE AND PROPOSED DESIGNS

BUILDING COMPONENT	STANDARD REFERENCE DESIGN	PROPOSED DESIGN
Glazing[a]	Total area (exclusive of glazing of thermally isolated sunrooms)[b] = (a) The proposed glazing area; where proposed glazing area is less than 15% of the conditioned floor area. (b) 15% of the conditioned floor area; where the proposed glazing area is 15% or more of the conditioned floor area. Orientation: equally distributed to four cardinal compass orientations (N, E, S & W). *U*-factor: from Table R402.1.3 SHGC: From Table R402.1.1 except that for climates with no requirement (NR) SHGC = 0.40 shall be used. Interior shade fraction: 0.92-(0.21 × SHGC for the standard reference design) External shading: none	As proposed As proposed As proposed As proposed 0.92-(0.21 × SHGC as proposed) As proposed
Thermally isolated sunrooms	~~None~~ Geometry and orientation: same as proposed Opaque ceiling and wall insulation: in accordance with Section R402.2.12 Opaque wall solar absorptance = 0.75 Opaque wall emittance = 0.90 Fenestration U-factor: in accordance with Section R402.3.5	As proposed As proposed As proposed As proposed As proposed

(Portions of table not shown remain unchanged)

Reason: In the current code, there is no connection between the performance path and the prescriptive requirements for thermally isolated sunrooms. Including thermally isolated sunrooms in the standard reference design, if present in the proposed design, ensures a proper comparison against the code's associated prescriptive requirements and minimizes confusion about the applicability of the sunroom specifications for homes complying via the performance path.

Cost Impact: The code change proposal will not increase the cost of construction.

R405.5.2(1) #3-EC-WILLIAMS.DOC

Committee Action Hearing Results

Committee Action: Disapproved

Committee Reason: This proposed change would represent a significant increase in the energy budget for the standard referenced design.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jeremiah Williams, U.S. Department of Energy requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

TABLE R405.5.2(1) (N1105.5.2(1))
SPECIFICATIONS FOR THE STANDARD REFERENCE AND PROPOSED DESIGNS

Glazing[a]	Total area (exclusive of glazing of thermally isolated sunrooms)[b] = …	As proposed …
Thermally isolated sunrooms	Geometry, area, and orientation of fenestration, opaque wall, opaque ceiling/roof, and floor/foundation area: same as proposed Opaque ceiling and wall insulation: in accordance with Section R402.2.12 Opaque wall solar absorptance = 0.75 Opaque wall emittance = 0.90 Fenestration U-factor: in accordance with Section R402.3.5 Fenestration SHGC:in accordance with Table R402.1.1	As proposed

(Portions of code change proposal not shown remain unchanged)

Commenter's Reason: In the current code, there is no connection between the performance path and the prescriptive requirements for thermally isolated sunrooms. Including thermally isolated sunrooms in the standard reference design, if present in the proposed design, ensures a proper comparison against the code's associated prescriptive requirements and minimizes confusion about the applicability of the sunroom specifications for homes complying via the performance path.

This Public Comment addresses deficiencies raised at the Committee Action Hearing. SHGC was added to the modeling requirements. This proposal, as modified by this Public Comment, does not alter the stringency of the code, because the standard reference design is set to have the prescriptive requirements in section R402 of the code. This is consistent with the fundamental approach used to establish compliance via the performance path.

DOE posted its draft proposals and public comments for the IECC on its Building Energy Codes website prior to submitting to the ICC. Interested parties were provided a 30 day public review in June 2013, for which notice was published in the *Federal Register* (Docket No. EERE-2012-BT-BC-0030) and announced via the DOE Building Energy Codes news email list. In response to stakeholder input, DOE revised its proposals and public comments, as appropriate, and submitted to the ICC.

For more information on DOE proposals and public comments, including how DOE participates in the ICC code development process, please visit: http://www.energycodes.gov/development.

Revise as follows:

R405.1 Scope. This section establishes criteria for compliance using simulated energy performance analysis. ~~Such analysis shall include heating, cooling, and service water heating energy only.~~

TABLE R405.5.2(1) (N1105.5.2(1))
SPECIFICATIONS FOR THE STANDARD REFERENCE AND PROPOSED DESIGNS

BUILDING COMPONENT	STANDARD REFERENCE DESIGN	PROPOSED DESIGN[m]
Internal gains	IGain = ~~17,900 + 23.8 x *CFA* + 4104 x N_{br}~~ 16,600 + 12 x *CFA* + 8080 x N_{br} (Btu/day per dwelling unit) N_{br}=Number of bedrooms	Same as standard reference design.
Service Water Heating [f,g,h,j,l,m]	~~As proposed~~ Fuel type: same as proposed design Efficiency: in accordance with prevailing federal minimum standards Use: gal/day = 20 + (10 × N_{br}) Tank temperature: 120°F ~~Use: same as proposed design~~ N_{br}=Number of bedrooms	As proposed As proposed Use: Standard reference x SWHF ~~gal/day = 30 + (10 × N_{br})~~ Same as standard reference Design

BUILDING COMPONENT	STANDARD REFERENCE DESIGN	PROPOSED DESIGN[m]
Clothes washer [k, n]	550 kWh/yr	Either of the following: Same as standard reference design or (300 × IMEF), kWh
Lighting	300 + (0.43 x CFA), kWh/yr CFA = Conditioned floor area (ft^2)	Either of the following: Same as standard reference design and lighting is in compliance with Section R404.1 or 1 kWh/yr per watt of installed lighting
Refrigerator[n]	500 kWh / year	Either of the following: Same as standard reference design or As proposed

(Portions of table not shown remain unchanged)

j. SWHF = Service water heating factor. SWHF is the product of multiplying the hot water distribution efficiency factor and the drain water heat recovery factor.

Hot water distribution efficiency factor:

= 0.80
where a *demand recirculation water system* is installed for the hot water distribution system and the volume in the piping from the circulating hot water piping to the termination of the fixture supply for every fixture is less than or equal to 0.19 gallons (0.71 liters).

= 0.9
where the water volume in the piping from the water heater to the termination of the fixture supply for every fixture is less than or equal to 0.5 gallons (1.89 liters).

= 1.0
where the other conditions are not met.

Drain water heat recovery factor:

= (1 – (Drain water heat recovery unit efficiency x 0.36))
where one or more DWHR units receive the drain water from all showers in the building and the DHWR units are in accordance with Section R405.10.

= (1 – (Drain water heat recovery unit efficiency x 0.18))
where a DWHR unit receives the drain water from the primary shower but not all showers in the building and the DHWR unit is in accordance with Section R405.10.

= 1.0
where the other conditions are not met.

k. IMEF = integrated modified energy factor for the proposed clothes washer
l. Where more than one drain water heat recovery unit is used, the average efficiency of all drain water heater recovery units shall be used in the performance calculation.
m. Proposed design equipment and device efficiencies shall be in accordance with Section R405.7.
n. Where the proposed design includes more than one refrigerator or clothes washer, the energy use shall be summed.

Add new text as follows:

R405.7 (N1103.7) Equipment and device verification. The efficiency of the equipment and devices used for the proposed design shall be specified in the construction documents. The installed equipment and devices shall not be less than the efficiency specified in the construction documents. The efficiency of equipment and devices shall be indicated by the manufacturer on a label or on a specification sheet attached to the equipment or device. The equipment or device efficiency shall be readily observable for inspection after the equipment or device is installed. This section shall apply only to equipment and devices where the proposed design is different than the standard reference design for that equipment or device.

R405.8 (N1103.8) Hot water distribution verification. The construction documents for the building shall show plumbing diagrams that indicate water heaters, plumbing fixtures, plumbing appliances, pipe sizes and layouts for hot water supply and hot water circulating system piping. The layouts shall indicate the volume of water in the branches of the piping from the nearest source of hot water piping to the termination of the fixture supply pipe. This section shall apply only where the proposed design for the hot water distribution system is different than the standard reference design for the hot water distribution system.

R405.9 (N1103.9) Lighting verification. A schedule, by room, of lighting fixtures and lamps indicating the wattage of each fixture shall be provided for interior lighting and garage lighting. The sum of wattages on the schedule shall be used for the proposed design. This section shall apply only where the proposed design for lighting is different than the standard reference design for lighting.

R405.10 (N1103.10) Drain water heat recovery units. Drain water heat recovery units shall be tested by the manufacturer for efficiency and pressure loss at a flow rate of 2.5 gpm (9.5 L/m) through each water side flow path. The water side pressure loss shall not exceed 3 psi (20.7 kPa) for each flow path. The manufacturer shall indicate the efficiency and pressure loss of the unit on a label or specification sheet attached to the unit. This section shall apply only where the efficiency of drain water heat recovery is used in the performance calculation.

Reason: This code change proposal
-- expands the performance calculation to include options for energy savings from water heating, lighting, refrigerators and clothes washers.
-- updates water use, lighting and internal gains equations in the performance calculation table to reflect current equipment, and
-- specifies efficiency measures in a way that makes them enforceable.

The options in this proposal were picked because they have significant impact, can be specified in simple terms, and can be specified based on existing tests or standards. The performance section user can choose to use or not use any of these options. Options not used become neutral in the performance calculation, because the standard reference design and the proposed design become the same.

This proposed change includes four options for saving the energy used for service water heating:
-- efficient water heater,
-- efficient water heating distribution, also know as efficient hot water pipe layout,
-- recovery of heat from drain water, and
-- efficient clothes washer

The first hot water energy saving option is a water heater that exceeds the minimum Federal efficiency standard for water heaters. The efficient water heater is computed as it was in the 2006 IECC. Water heaters exceeding minimum Federal efficiency are widely available.

The second source of hot water savings is limiting the waste in delivering hot water to the point of water use. This does not limit hot water use, rather it limits hot water waste. Hot water must first flow through the pipes from the water heater to the point of use. Unless hot is water already in the pipes, the cool water in the pipes must be emptied and replaced by hot water, which wastes water. After use the hot water left in the pipes cools down, unless there is another use within about an hour. The cool down is wasted heat. Thus hot water distribution routinely wastes both energy and water. Piping layouts with less water volume between the water heater and water use inherently waste less heat and less water. The two "distribution efficiency factors" and their savings for limiting wasted hot water are adapted for the IECC from the ANSI consensus standard ICC 700-2012 (National Green Building Standard). The factors, 0.90 and 0.80, represent a 10% and 20% savings respectively. As an additional benefit, limiting hot water waste means better performance, because the hot-water-user's wait for the "cold water to get hot" is the time it takes to replace cool water in the pipes with hot water and smaller water volumes are replaced more quickly.

The third source of hot water energy savings is heat recovery from drain water. Drain water heat recovery (DWHR) works particularly well where heated water flows down the drain at the same time as water flows in that needs to be heated; this "coincident flow" occurs in homes with showering and lavatory use. Performance of a DWHR unit is characterized by both efficiency and pressure loss. It is important to ensure that DWHR devices do not have high pressure loss in order to minimize the impact on water pressure in the home. Given the available DWHR efficiencies, savings are typically 10% to 35% of the energy used for heating water. To put the "0.36" in the equation in perspective, the "coincident flow" in a residence is typically 50%-70% of the hot water use, so 0.36 (36%) times the device's efficiency is similar to saying the unit works well on showers and lavatories, and may also recover a portion of the rest of the hot water use in the home. The 0.36 also covers natural drain water heat loss and assumes the "worst-case" plumbing scenario for DWHR devices. This calculation of savings is conservative. Over 25,000 drain water heat recovery units have been installed in homes in Canada and the United States.

The fourth source of water heating savings is clothes washers. Clothes washer efficiency is rated by the Federally required IMEF rating.[1] The minimum Federal requirement at the time of the 2015 IECC will be an IMEF of 1.84.[2] IMEF is energy use divided by washer volume. The Federal standard presumes 295 loads per year. So the base case, the standard reference design, for a typical 3.5 cubic foot washer is 1.84 x 3.5 x 295 = 550 kWh/yr (rounded). One of the biggest savings in new clothes washers comes from the reduced water in washed clothes, which saves energy in clothes drying. The effect of reduced clothes dryer energy is included in the Federally required IMEF rating.

The hot water use equation in the IECC is updated to reflect lower water use rates. The IECC water use equation has not been updated since the 1995 Model Energy Code, making the equation over 20 years old by the time of the 2015 IECC. Water use per residence has been falling for a long time.[3] Various sources estimate the decline in water use at 0.5 to 3% per year. The reduction in water use is expected to continue.[4] The primary factors that contribute to the reduction in hot water use since the 1995 IECC are more efficient washing machines and dishwashers, and water-use efficient faucets and showers, all a result of the National Appliance Energy Conservation Act that took effect in the mid 1990s.

This proposal adds lighting as an optional part of the performance calculation. Lighting requires a "base case" in the standard reference design and a calculation based on the proposed design. The standard reference design lighting energy use is based on the RESNET equation[6] for interior lighting energy use in homes, including garages. The standard reference equation is adjusted[6] for the higher percentage of efficient lighting (high efficacy lighting) required by the IECC.

The proposed lighting energy use is calculated as hours of use times watts. An average use of 1000 hours per year (2.75 hours per day) is within the reported range for actual light use[5] and is presumed. The proposed lighting annual energy use is simply 1 kWh per watt of installed lighting.

To "opt out" of the lighting calculation, the code user meets the Section R404.1 lighting requirements, then the performance calculation presumes the standard reference design and the proposed design are the same for lighting.

This proposal adds a refrigerator option as part of the performance calculation. It requires a "base case" in the standard reference design and a proposed refrigerator. The refrigerator base case is fixed at 600 kWh/yr. For comparison, a 3 bedroom house in the RESNET procedures would have a base case energy use of 691 kWh/yr. Federal minimum refrigerator efficiency standards will increase in 2014 [8,9]. Refrigerators are reduced about 25% in 2014 by the upcoming Federal standard, so 600 kHz/yr is reasonable as a "base case".

The internal gains equation is updated by this change. Internal gains are heat from various sources besides the heating system, including heat produced as a byproduct of lighting and refrigeration. The IECC internal gains equation has not been updated since the 2003 IECC, so it will be more than 10 years old in the 2015 IECC. Big reductions have come from more efficient lighting, as required by Section R404.1. Refrigerators have also reduced their energy use greatly in the last ten years, with a further reduction coming in 2014. The new internal gains equation is revised based on the lighting and refrigeration specifications in this proposed change.[10]

One big issue with having options for more efficient equipment and devices is inspection and verification. The efficiency used must be easy to verify. A new section, Section R405.7, requires that the efficiency used in the proposed design be specified on construction documents. Any equipment or device that meets or exceeds the efficiency marked on construction documents will be acceptable. Code enforcement staff does not have the time to look up equipment or device model numbers to find an efficiency rating in a data base or book; therefore, the new Section R405.7 requires that the installed efficiency be "readily observable", which is very similar to "readily accessible". "Readily observable" is the term used in Section R303.1.2 and C303.1.2 for the insulation R-value.

The performance calculation user may choose to calculate lighting energy use based on the installed watts of lighting. Lighting wattage will need to be verifiable, as lighting savings are based on the watts of installed lighting. Code officials are unlikely to have the time to count watts in a house. Where the proposed lighting energy use is calculated, this change requires a schedule of lighting fixture/lamp watts divided by rooms, which gives enough detail to spot check a house. If the proponents of this proposal were verifying lighting, they would pick a room and spot check it.

The performance calculation user may choose to use a more efficient hot water distribution system based on limiting the hot water volume in pipes. Hot water piping volume will need to be verified. Code officials are unlikely to have the time to check all the pipe volume calculations in a house. This change requires plumbing layouts with pipe sizes on the construction documents. For each branch the fixture with the largest hot water supply volume and that fixture's volume is identified on the plans. This level of detail will enable spot checking of a plumbing branch. If the proponents of this proposal were verifying efficient plumbing layout, they would pick one of the plumbing branches and check it.

The measures of efficiency in this change are based on existing tests and standards. The water heater efficiency is measured by the EF (energy factor), which is a rating required by Federal law. The clothes washer efficiency is measured by the IMEF (integrated modified energy factor), which is a rating required by Federal law. The refrigerator efficiency is measured by annual energy use (kWh), which is a Federal rating required to be on the Energy Guide label (yellow labels). The hot water distribution efficiency (efficient piping) is adapted from ICC 700-2012.

Overall, this proposed change allows residences to achieve the energy efficiency in the IECC in a variety of ways. It comes with the philosophy of keeping the energy efficiency goal high, but allowing that goal to be reached in many ways. This change provides options that are practical in the context of the code.

References:
1. IMEF (integrated modified energy factor) is MEF plus standby electricity use and will be the required Federal rating in 2015. The "IMEF" will be used for both the Federal requirements and Energy Star.
2. Upcoming Federal requirement is described at: https://www.federalregister.gov/articles/2012/05/31/2012-12320/energy-conservation-program-energy-conservation-standards-for-residential-clothes-washers#h-9

5. *Updated Miscellaneous Electricity Loads and Appliance Energy Usage Profiles for Use in Home Energy Ratings, the Building America Benchmark Procedures and Related Calculations*. Danny Parker and Philip Fairey, Florida Solar Energy Center. Robert Hendron, National Renewable Energy Laboratory. FSEC-CR-1837-10 Revised June 10, 2011. Page 39.
6. The RESNET equation (kWh/yr = 445 + 0.8 x CFA) [5] presumes 10% of the lighting is fluorescent, while the IECC specifies 75% is high efficacy lighting. The most common light size is a 60 watt inconstant with an efficacy of about 13.3 lumens per watt (800/60). This can be replaced by a 14 watt compact fluorescent delivering the same level of light (lumens). The IECC requires lights of this size have an efficacy of 40 lumens per watt. Therefore high efficacy lamps use 13.3/40, or about 1/3 the power for the same lumen output. Overall, the RESNET equation is reduced by about 46% to account for the more efficient lighting. A short discussion of lumens per watt for incandescent and compact fluorescent lights is at: http://www.energystar.gov/index.cfm?c=cfls.pr_cfls_lumens
7. This will favor, but not require, refrigerators without though the door ice, with freezer on the top rather than side-to-side, and smaller refrigerators. Many 18 ft^3 models easily exceed this. A variety of large (25 ft^3 or more) models also qualify; examples of large refrigerators that easily exceed this are at: http://www.toptenusa.org/Top-Ten-Refrigerators/Top-Ten-XL-Refrigerators
8. An announcement and overview of the new refrigerator standard is at: http://energy.gov/articles/department-energy-joins-manufacturers-environmentalists-announce-new-efficiency-standards
9. The requirements for different types of refrigerators are at: http://www1.eere.energy.gov/buildings/appliance_standards/product.aspx/productid/43
10. Personal communication, Philip Fairey, Deputy Director, Florida Solar Energy Center.

Cost Impact: This code change proposal is expected to decrease the cost of construction by allowing the most cost-effective technologies and practices to be used in new homes.

R405.5.2(1)T-EC-CONNER-KLEIN-VANDECKER.DOC

Committee Action Hearing Results

Committee Action: Disapproved

Committee Reason: This proposal inappropriately allows a trade-off for envelope integrity with a piece of removable equipment. In addition, it raises the energy budget of the baseline standard reference design. Further, it does not stipulate "when the appliance is included…." This proposal provides not metrics relating the changes made to internal gains.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Craig Conner, Building Quality, representing self, requests Approval as Modified by this Public Comment.

Replace the proposal as follows:

R405.7 (N1103.7) Equipment and device verification. The efficiency of the equipment and devices used for the proposed design shall be specified in the construction documents. The efficiency of the installed equipment and devices shall not be less than the efficiency specified in the construction documents. The efficiency of equipment and devices shall be indicated by the manufacturer on a label or on a specification sheet attached to the equipment or device. The equipment or device efficiency shall be readily observable for inspection after the equipment or device is installed. This section shall apply only to equipment and devices where the efficiency of the proposed design is different than the efficiency of the standard reference design for that equipment or device.

Commenter's Reason: Efficient equipment and devices presumed in the performance calculation need to be verified. This new section requires clear statements in construction documents about the efficiency that is presumed in the performance calculation. The new section makes it easy to inspect for the presence of that efficiency without having to go to any source outside the residence. The term "readily observable" is already in the IECC in Section R303.1.2 on insulation inspection and would require the efficiency to be easily observable for inspection.

This section would only apply to equipment and devices for which the performance calculation takes credit.

Public Comment 2:

Gary Klein, Affiliated International Management, LLC, representing self and Gerald Van Decker, RenewABILITY Energy Inc, representing self, request Approval as Modified by this Public Comment.

Modify the proposal as follows:

R405.1 Scope. This section establishes criteria for compliance using simulated energy performance analysis.

TABLE R405.5.2(1) (N1105.5.2(1))
SPECIFICATIONS FOR THE STANDARD REFERENCE AND PROPOSED DESIGNS

BUILDING COMPONENT	STANDARD REFERENCE DESIGN	PROPOSED DESIGN[m]
~~Internal gains~~	~~IGain = 16,600 + 12 x *CFA* + 8080 x N_{br} (Btu/day per dwelling unit)~~ ~~N_{br}=Number of bedrooms~~	~~Same as standard reference design.~~
Service Water Heating [f, g, h, j, l]	Fuel type: same as proposed design Efficiency: in accordance with prevailing federal minimum standards Use: gal/day = 20 + (10 × N_{br}) Tank temperature: 120°F N_{br}=Number of bedrooms	As proposed As proposed Use: Standard reference x SWHF Same as standard reference Design
~~Clothes washer [k, n]~~	~~550 kWh/yr~~	~~Either of the following:~~ ~~Same as standard reference design~~ ~~or~~ ~~(300 × IMEF), kWh~~

~~Refrigerator[n]~~	~~500 kWh / year~~	~~Either of the following:~~ ~~Same as standard reference design~~ ~~or~~ ~~As proposed~~

Portions of table not shown remain unchanged.

Footnotes not shown remain unchanged

j. SWHF = Service water heating factor. SWHF is the product of multiplying the hot water distribution efficiency factor and the drain water heat recovery factor.

Hot water distribution efficiency factor:

= 0.80
where a *demand recirculation water system* is installed for the hot water distribution system and the volume in the piping from the circulating hot water piping to the termination of the fixture supply for every fixture is less than or equal to 0.19 gallons (0.71 liters).

= 0.9
where the water volume in the piping from the water heater to the termination of the fixture supply for every fixture is less than or equal to 0.5 gallons (1.89 liters).

= 1.0
where the other conditions are not met.

Drain water heat recovery factor:

= (1 – (Drain water heat recovery unit efficiency x 0.36))
where one or more DWHR units receive the drain water from all showers in the building and the DHWR units are in accordance with Section R405.10.

= (1 – (Drain water heat recovery unit efficiency x 0.18))
where a DWHR unit receives the drain water from the primary shower but not all showers in the building and the DHWR unit is in accordance with Section R405.10.

= 1.0
where the other conditions are not met.

~~k. IMEF = integrated modified energy factor for the proposed clothes washer~~

l. Where more than one drain water heat recovery unit is used, the average efficiency of all drain water heater recovery units shall be used in the performance calculation.

~~m. Proposed design equipment and device efficiencies shall be in accordance with Section R405.7.~~

~~n. Where the proposed design includes more than one refrigerator or clothes washer, the energy use shall be summed.~~

~~**R405.7 (N1103.7) Equipment and device verification.** The efficiency of the equipment and devices used for the proposed design shall be specified in the construction documents. The installed equipment and devices shall not be less than the efficiency specified~~

~~in the construction documents. The efficiency of equipment and devices shall be indicated by the manufacturer on a label or on a specification sheet attached to the equipment or device. The equipment or device efficiency shall be readily observable for inspection after the equipment or device is installed. This section shall apply only to equipment and devices where the proposed design is different than the standard reference design for that equipment or device.~~

R405.8 (N1103.8) Hot water distribution verification. The construction documents for the building shall show plumbing diagrams that indicate water heaters, plumbing fixtures, plumbing appliances, pipe sizes and layouts for hot water supply and hot water circulating system piping. The layouts shall indicate the volume of water in the branches of the piping from the nearest source of hot water piping to the termination of the fixture supply pipe. This section shall apply only where the proposed design for the hot water distribution system is different than the standard reference design for the hot water distribution system.

~~**R405.9 (N1103.9) Lighting verification.** A schedule, by room, of lighting fixtures and lamps indicating the wattage of each fixture shall be provided for interior lighting and garage lighting. The sum of wattages on the schedule shall be used for the proposed design. This section shall apply only where the proposed design for lighting is different than the standard reference design for lighting.~~

~~**R405.10 (N1103.10) Drain water heat recovery units.** Drain water heat recovery units shall be tested by the manufacturer for efficiency and pressure loss at a flow rate of 2.5 gpm (9.5 L/m) through each water side flow path. The water side pressure loss shall not exceed 3 psi (20.7 kPa) for each flow path. The manufacturer shall indicate the efficiency and pressure loss of the unit on a label or specification sheet attached to the unit. This section shall apply only where the efficiency of drain water heat recovery is used in the performance calculation.~~

Commenters' Reason: The Committee's reasons were for the entire proposal. This comment addresses their concerns by limiting the changes to Service Water Heating. Water heating is one of the largest energy uses in new homes. The purpose of this comment is to enable builders who use the performance method to trade off the water heater equipment efficiency, hot water distribution system efficiency and the use of drain water heat recovery systems with other energy elements. Each of these measures are optional and non-mandatory.

The Committee approved a trade-off for water heater equipment efficiency in RE166. It is also included here to harmonize these credit(s). The two additional measures: "hot water distribution efficiency" and "drain water heat recovery" are both long long-lasting infrastructural components in homes, that are relatively simple to include during construction but often difficult to retrofit later.

Hot water distribution system efficiency is important because it limits the waste in delivering hot water to the point of water use. This does not limit hot water use, rather it limits hot water waste. Hot water must first flow through the pipes from the water heater to the point of use. Unless hot is water already in the pipes, the cooler water in the pipes must be emptied and replaced by hot water, which wastes water. After use the hot water left in the pipes cools down, unless there is another use within about an hour. The cool down is wasted heat. Thus hot water distribution routinely wastes both energy and water. Piping layouts with less water volume between the water heater and water use inherently waste less heat and less water. The two "distribution efficiency factors" and their savings for limiting wasted hot water are adapted for the IECC from the ANSI consensus standard ICC 700-2012 (National Green Building Standard). The factors, 0.90 and 0.80, represent a 10% and 20% savings respectively. As an additional benefit, limiting hot water waste means better performance, because the hot-water-user's wait for the "cold water to get hot" is the time it takes to replace cool water in the pipes with hot water and smaller water volumes are replaced more quickly.

Drain water heat recovery (DWHR) works particularly well where heated water flows down the drain at the same time as water flows in that needs to be heated; this "coincident flow" occurs in homes with showering and lavatory use. Performance of a DWHR unit is characterized by both efficiency and pressure loss. Given the available DWHR efficiencies, savings are typically 10% to 35% of the energy used for heating water. To put the "0.36" in the equation in perspective, the "coincident flow" in a residence is typically 50%-70% of the hot water use, so 0.36 (36%) times the device's efficiency is similar to saying the unit works well on showers and lavatories, and may also recover a portion of the rest of the hot water use in the home. The 0.36 also covers natural drain water heat loss and assumes the "worst-case" plumbing scenario for DWHR devices. This calculation of savings is conservative. Over 25,000 drain water heat recovery units have been installed in homes in Canada and the United States.

It is important to ensure that DWHR devices do not have high pressure loss in order to minimize the impact on water pressure in the home. Although Section 405.10 has been taken out of this proposal, the safe installation of DWHR is still covered. The Committee approved CE273 Part III, which provides reference standards that cover DWHR technology safety and performance.

Public Comment 3:

Edward R. Osann, Natural Resources Defense Council, representing self, requests Disapproval.

Commenter's Reason: While the concept of this proposal has merit, the "hot water distribution efficiency factor" used to score the performance of hot water distribution systems is essentially arbitrary. More objective measures of the energy impacts of various hot water distribution configurations are needed to avoid over- or under-crediting such measures relative to better documented energy-saving measures.

a. Systems meeting current National Appliance Energy Conservation Act minimum efficiency requirements.

Add new standard to Chapter 5 as follows:

DOE U.S Department of Energy
c/o Superintendent of Documents
U.S. Government Printing Office
Washington, D.C 20402-9325

NAECA 87-(88) National Appliance Energy Conservation Act 1987 [Public Law 100-12 (with Amendments of 1988-P.L. 100-357)]

Reason: The intent of the IECC is clearly defined.

> **"Intent.** This code shall regulate the design and construction of buildings for the effective use and conservation of energy over the useful life of each building. This code is intended to provide flexibility to permit the use of innovative approaches and techniques to achieve this objective. This code is not intended to abridge safety, health or environmental requirements contained in other applicable codes or ordinances."
>
> Source: 2012 IECC. Sections C101.3 and R101.3.

The code focus is "energy use… over the useful life of the building". Buildings will perform to the requirements of this code for a long time. So the intent of the code focuses on "energy use" over the life of the building. Under the performance path, the IECC compares the energy use of a baseline building to the energy use of a proposed building.

This proposal addresses a lingering weakness in the code for those seeking to use innovative energy efficient systems. Simulations provide the means and methods to more fully understand, quantify and model actual energy use, whatever its form. This revision specifies a single standard reference design for heating, cooling, and service water heating systems, using technologies with low energy costs and high source energy efficiency as the baseline in each building component category.

The revised text and tables:

- Establish a single baseline building performance requirement
  - for all service hot water (SHW) and HVAC systems
  - independent of making the system choice for the proposed building
  - at a realistic and achievable level using code-compliant technologies.
- Addresses the inconsistent mix of multiple prescriptive baseline building technology performance requirements in the current standard.
- Provides equitable and consistent treatment of all SHW and HVAC system options, including conventional, renewable energy, hybrid technology, and waste heat recovery options.
- Is indifferent to the SHW and HVAC system choice in the proposed building, comparing all SHW and HVAC system options against a single energy efficient baseline building energy cost or source energy performance requirement.
- Aligns the SHW and HVAC system performance requirement methodology with the envelope single baseline performance requirement methodology.

- Achieves the goal of reducing the site energy cost, consumption of primary energy resources, and global greenhouse gas emissions related to the operation of the building in a cost-effective and equitable manner.

A single technology-blind baseline performance requirement is the most technically defensible methodology for performance path calculations, and it is critical for equitable implementation of the IECC Performance Alternative requirements Section R405. Shifting to a single baseline design provides an equitable credit to all technologies that have lower annual energy costs or source energy consumption compared to the single baseline level irrespective of energy form or technology design.

The current code structure does not facilitate equitable comparison of mechanical systems based energy cost or source energy consumption.

IECC Section R405 currently uses multiple baseline mechanical system performance requirements. The mechanical systems are compared using multiple baselines by separating both categories of equipment and fuel types used within each equipment category. For example, the current code has 14 different baseline configurations across the five SHW system categories that may be relevant to the residential sector, none of which results in the same annual energy cost or source energy budget for performance path calculations. This mix of equivalencies is a counter-productive and inconsistent approach that can be mitigated by shifting to a single baseline building design for all proposed building design alternatives. The existing Section R405 also may be subject to various interpretations on the appropriate baseline design building for advanced multi-fuel appliance options, waste heat recovery options, or emerging technologies that reduce energy costs or source energy consumption significantly compared to options that currently qualify.

The baseline mechanical systems in the revised Table R405 use a single efficient baseline design for all proposed building configurations. The revised Table R405.5.2(1) and additional Table R405.5.2(3) apply a single baseline energy cost requirement consistently to any proposed mechanical system. The baseline does not prohibit any technology options. It correctly allows all options, including higher operating cost options, but considers their strong energy cost or source energy consumption disadvantages compared to the single baseline performance requirement. A designer who chooses a higher energy cost or source energy consumption option for the proposed building would only need to reduce the overall building energy cost or source energy consumption to the baseline level, and could do so through any combination of improved energy performance options, including HVAC, SHW, and envelope improvements.

The existing HVAC and SHW provisions are also inconsistent with standard reference baseline design criteria for envelope building components. Those building element provisions do not prescribe specific technology categories or subcategories, but are true performance based requirements (e.g., envelope requirements in overall U value) that give the designer maximum flexibility BEFORE making technology choices in the design. The designer is free to choose the most cost-effective envelope technology (fiberglass, polyurethane foam) to meet the single energy target for the building without arbitrary technology class prescriptive requirements for fiberglass or foam insulation. Unfortunately, the existing provisions of HVAC and SHW tables impose technology category and subcategory prescriptive requirements when using the performance path instead of true performance-based requirements. The impact is to establish the reference design building AFTER prescriptive technology category and energy design choices are made. This is an inequitable application of prescriptive requirements in the performance path. This constraint eliminates the credit for creative design choices that would significantly reduce energy cost, primary energy use, and greenhouse gas emissions.

The revised tables and text completely decouple the proposed building design choices from the standard reference design building's energy cost or source energy performance requirement. The reference energy and technology choices in the revised section were selected to provide a practical and effective requirement to meet the intent of the standard while still offering appropriate incentives for the best available technologies based on their energy cost benefits. Encouraging rather than discouraging this design flexibility aligns closely with the IECC stated goal of reducing energy costs by 30 percent compared to the 2012 version.

Cost Impact: The code change proposal will not increase the cost of construction.

R405.5.2(1)T-EC-LESLIE.DOC

Committee Action Hearing Results

Committee Action: Disapproved

Committee Reason: This proposal could have the possible effect of preemption of Federal Standards.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Mark Krebs, Laclede Gas Company, representing self, requests Approval as Submitted.

Commenter's Reason: The committee's decision to disapprove this critical proposal is not based on facts and is inconsistent with the stated intent of the IECC to provide "model code regulations that will result in the optimal utilization of fossil fuel and nondepletable resources in all communities, large and small." The current provisions treat various technology options as equivalent to each other even though there are demonstrable and meaningful differences in energy cost and source energy use among the fuel choice and technology options, especially for electric resistance and natural gas options. This results in suboptimal utilization of fossil fuels because significantly more coal and natural gas are burned in power plants to provide electricity for inefficient qualifying electric technologies than would be consumed by burning natural gas directly in the home using the more source energy efficient and lower energy cost gas technology. The current provisions result in meaningful fuel bias that the proposal fully corrects by changing to fuel blind, single baseline compliance provisions.

The hearing committee erred in two significant ways in their stated rationale at the hearing and as reported in the summary of the hearing. The first error relates to the confusion about "lack of natural gas" in many areas of the country, and the resulting error by the committee rejecting the proposal as untenable for this reason. Natural gas availability is not the issue. Energy cost budget or source energy budget calculation is the correct issue for judging this proposal. Those metrics do not require natural gas availability in the proposed building for determining the compliance requirement. The necessary simulation for determination of the energy cost or source energy budget for the proposed home only requires that suitable natural gas cost or source energy information be available for use in the simulation. Natural gas cost information is already available and required by the IECC for other calculations in locations that have natural gas service availability. For locations that do not have natural gas service, a choice of local, state, provincial, or regional gas prices can easily be incorporated into the tool for determining the residential building's energy cost budget. It is even easier to implement when using the source energy path because the IECC already includes the necessary conversion factors for all locations and situations. The proposal is simple to implement and easily applied to all residential buildings.

The second error made by the committee is stated in the written summary as the only rationale for rejection: "This proposal could have the possible effect of preemption of Federal Standards." That rationale is completely false. There is no prohibition against any appliance as a result of this proposal, thus there is no possible federal preemption effect. This proposal allows determination of an efficient, equitable energy cost budget (or source energy budget) at a level of performance using low energy cost and source energy efficient options to determine the baseline performance level. The proposal is fuel and technology agnostic, and is completely consistent with Federal Standard preemption provisions. If the disapproval relied on the stated rationale, the disapproval is dismissive and non-responsive to the proposal's significant consumer and societal benefits.

The most useful comparison illustrating the inherent flaw in the IECC methodology is a minimally compliant electric storage water heater compared to a minimally compliant gas storage water heater. Homes using NAECA minimum efficiency electric resistance storage water heating qualify equally as a NAECA minimum gas storage water heater, even though both the annual energy costs and primary energy consumption are much higher for the resistance water heater than for the gas water heater (typically twice as high). Based on a typical home in Laclede's service territory, annual energy use for an NAECA minimum electric resistance water heater is 3,920 kWH, while a NAECA minimum gas water heater uses 205 therms. Using average Missouri energy rates available from EIA of $0.098 per kWh and $1.05 per therm, the electric water heater annual cost of operation is $384, while the natural gas water heater costs only $215 per year, a 79% increase in the energy cost budget for the electric water heater. Using the respective source energy conversion factors of 3.16 and 1.1 in the IECC, the source energy consumption of the electric water heater is 42.3 MBtu while the source energy consumption for the gas water heater is only 22.6 MBtu, an 87% increase in the source energy budget for the electric water heater. IECC considers them equal for compliance purposes because it uses a separate, biased reference home for determining compliance for electric water heating systems. The higher energy cost and source energy represent harmful costs to the consumers and society. It is this "best efforts" harmful bias that the proposed shift to a single baseline system methodology fully corrects.

ASHRAE Standard 90.1-2013 will include a new single baseline system methodology in the performance path for all new commercial buildings. This methodology is identical to the single baseline mechanical system methodology proposed in RE179. The 90.1 single baseline tables are more sophisticated than those in RE179 to accommodate the wide variety of building types and regional building practices in the commercial sector. By including the proposed methodology in the residential provisions of the 2014 IECC, the residential and commercial provisions will be internally consistent.

Public Comment 2:

Neil Leslie, Gas Technology Institute representing self, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

Table R405.5.2(1)
SPECIFICATION FOR THE STANDARD REFERENCE AND PROPOSED DESIGNS

BUILDING COMPONENT	STANDARD REFERENCE DESIGN	PROPOSED DESIGN
Heating systems[f]	Efficiency: from Table ~~C403.2.3(4)~~ C403.2.3 (2)	
Cooling systems[g]	Efficiency: from Table ~~C403.2.3(1)~~ C403.2.3(2)	

Table R405.5.2(3)
EQUIPMENT MAP

SYSTEM[a]	EQUIPMENT TYPE

Heating[a]	~~Warm air furnaces, natural gas fired~~ Air cooled (heating mode)
Cooling[a]	~~Air conditioners,~~ air cooled (cooling mode)
Service Water Heating[a]	~~Storage w~~Water heaters, ~~natural gas~~ electric, Resistance Subcategory

Commenter's Reason: The amendment to the single baseline system proposal in RE179-13 is intended to address the specific concerns expressed at the hearing and in the rationale for disapproval. By shifting to electric technologies for all baseline systems, there is no longer an issue (real or perceived) with fuel choice availability. Electric technologies are considered always available as long as electricity is provided to the home, either through the grid or through on site power generation.

The amendment also provides another way to allay fears about Federal Standard preemption. There is no prohibition against any appliance as a result of either the original proposal or this amendment, thus there is no possible federal preemption effect. However, this amendment allows determination of an equitable energy cost budget (or source energy budget) at a level of performance using compliant electric technology options with relatively more permissive energy cost and source energy budgets to determine the baseline performance level. The proposal and this amendment both are fuel and technology agnostic, and both are completely consistent with Federal Standard preemption provisions.

The key difference between the original proposal and this amendment is the choice between rewarding better performance or penalizing worse performance. The original proposal rewards exceptional performance while penalizing poorer performance relative to the more stringent energy cost and source energy budgets when using the natural gas baseline systems. In this amendment, appliance options such as natural gas heating and water heating systems that improve the energy performance of the home (i.e., lower energy cost or source energy consumption), are rewarded compared to the fully compliant baseline electric heat pump and resistance water heating systems. Tradeoffs based on the energy cost or source energy budget add flexibility to the design options and are more lenient than the original proposal. At the same time, options that are currently compliant under the separate, biased baseline budget methodology are not penalized because they are the baseline systems in this amendment.

With either the original proposal or this amendment, the IECC has already chosen the right metrics for energy performance, with the choice of energy cost budget (for adopting authorities mainly concerned about the homeowner's economic objectives), or source energy budget (for adopting authorities mainly concerned about the homeowner's energy consumption impacts on primary energy consumption). The proposal provides the critical single baseline budget methodology to implement these metrics correctly. It is only by implementing the correct metrics correctly through the single baseline methodology that the IECC can avoid adverse effects and unintended consequences on users of the standard.

There is another development in 2013 that corroborates the proposal and a shift to an equitable single baseline methodology for consistency. ASHRAE Standard 90.1-2013 (a deemed to comply option in IECC-2014) will include for the first time a new single baseline system methodology in the performance path for all new commercial buildings. This methodology is identical to the single baseline mechanical system methodology proposed in RE179. The 90.1 single baseline tables are more sophisticated than those in RE179 to accommodate the wide variety of building types and regional building practices in the commercial sector. By including the proposed methodology in the residential provisions of the 2014 IECC, the residential and commercial provisions will be internally consistent.

RE179-13

Final Action: AS AM AMPC____ D

RE181-13
Table R405.5.2(1) (IRC N1105.5.2(1))

Proposed Change as Submitted

Proponent: Jeff Sonne, Florida Solar Energy Center representing the Florida Solar Energy Center (jeff@fsec.ucf.edu)

Revise as follows:

TABLE R405.5.2(1) (N1105.5.2(1))
SPECIFICATIONS FOR THE STANDARD REFERENCE AND PROPOSED DESIGNS

BUILDING COMPONENT	STANDARD REFERENCE DESIGN	PROPOSED DESIGN
Glazing[a]	Total area[b] = ~~(a) The proposed glazing area; where proposed glazing area is less than 15% of the conditioned floor area.~~ ~~(b)~~ 15% of the conditioned floor area~~; where the proposed glazing area is 15% or more of the conditioned floor area.~~	As proposed

	SHGC: From Table R402.1.1 except that for climates with no requirement (NR) SHGC = 0.40 shall be used. Interior shade fraction: ~~0.92-(0.21 × SHGC for the standard reference design)~~	As proposed ~~0.92-(0.21 × SHGC as proposed)~~
	Summer: 0.70	Same as Standard Reference Design
	Winter: 0.85	Same as Standard Reference Design
	External shading: none	As proposed

(Portions of Table not shown remain unchanged)

Reason:

Glazing Area

Glazed areas are the least efficient and most costly components of homes. Even the best windows and glass doors admit much more solar heat gain than walls, roofs and floors. And even the best windows and doors have thermal conductances that are far inferior to walls, roofs and floors.

Table 1 below presents the 2012 IECC requirements for envelope components in IECC climate zone 2. While there are no IECC requirements for the SHGC of opaque envelope components like walls, ceilings and floors, an equivalent SHGC can be calculated using the component U-Factor, a reasonable sol-air temperature, a reasonable interior temperature (75 ^{o}F) and a reasonable incident solar radiation, as follows:

$$SHGC_{equiv} = U\text{-}Factor*(T_{sol\text{-}air} - T_{int}) / (Solar_{Incident})$$

For Table 1, the assumed sol-air temperatures were 140 ^{o}F for walls and 160 ^{o}F for roofs (ceilings) and the assumed incident solar radiation was 250 Btu/h for walls and 300 Btu/h for roofs (ceilings). Floors receive no solar radiation and thus do not experience heat gains due to direct solar radiation as do fenestration, walls and roofs (ceilings).

Table 1. Envelope Component Efficacies

Envelope Component	IECC* U-Factor	U-Factor Ratio	IECC* SHGC	SHGC Ratio
Fenestration	0.400	1.00	0.250	1.00
Frame walls	0.082	4.88	0.021**	11.73
Mass walls	0.165	2.42	0.043**	5.83
Ceilings	0.030	13.33	0.009**	29.41
Floors	0.064	6.25	0.000**	∞

* IECC U-Factor and SHGC values for Climate Zone 2
** Computed estimate

The U-Factor and SHGC ratios in Table 1 compare the heat retardation efficacy of each of the other envelope components to the heat retardation efficacy of fenestrations. These ratios show that the opaque envelope components are 2.42 to 13.33 times as efficacious in retarding heat flow by conductance as fenestrations and 5.83 to 29.41 times as efficacious in retarding solar heat gains as fenestrations.

Per unit area, fenestrations are also the most expensive envelope components in new homes. Estimates from the 2011 R.S. Means Residential Cost Data show typical code compliant concrete block wall construction prices to be about $15/ft^2 while typical code compliant window prices are somewhat more than double this amount, at about $32/ft^2.

The data show that fenestrations are relatively costly home amenities, which are not particularly energy efficient compared with other envelope components. The principle function of fenestration is to visually bring the outdoors into the comfort conditioned interior living space. Thus, cost is the principle determinant of fenestration area as a percentage of conditioned floor area, with larger fenestration percentages much more likely in high-end, expensive homes than in low-end, smaller homes.

Reductions in glazing area improve the energy performance of homes. If homes are evaluated on an energy performance basis then, all other things being equal, the home with the smaller window area will have less energy consumption. That being the case, a simulated performance alternative should recognize this smaller energy consumption rather than adjust the Standard Reference Design glazing area such that this smaller energy use is effectively disallowed as an energy performance characteristic of the home.

Most homes that choose smaller fenestration area are small, low-cost homes. Thus, the choice to incorporate less fenestration area is an economic decision – made to reduce the cost of the home. The fact that these homes are smaller than the typical new home also significantly reduces the energy use of the home compared to the more typical larger new home. As a result, this “sliding” glazing area in the 2012 IECC Standard Reference Design actually requires the smaller, low-cost home with less window area to meet a higher energy performance standard than the larger more energy intensive typical home. This constitutes a strong affirmation of the old saw that “no good deed shall go unpunished.”

For reasons of cost effectiveness and the equitable treatment of smaller, low-cost homes, the Code should set a single standard for glazing area in the Standard Reference Design and not allow it to “float down” with the window area of the Proposed Design.

<u>Interior Shading Coefficient</u>

The 2012 IECC modifies the interior shading coefficient of fenestrations as a function of the SHGC of the fenestration. It does this in both the Standard Reference Design and the Proposed Design. The equation for the 2012 IECC interior shading coefficient is as follows:

Interior Shade = 0.92 * (0.21*SHGC)

Compared with the 2009 IECC interior shading coefficients, which were not dependent on the SHGC of the fenestration but were based on the likely behavior of the home occupants, this equation effectively penalizes high performance windows in climates like Florida where lower SHGCs are desirable. The equation shows that the better the SHGC (lower is better in Florida), the lower the interior shading coefficient. Thus, a window with a SHGC of 0.5 would have an interior shading coefficient of 0.82 while a window with a SHGC of 0.2 would have an interior shading coefficient of 0.88. This results in the poorer performing window getting more energy performance credit from interior shading than the better performing window.

Table 2 examines how the change from the 2009 IECC interior shading coefficients to the 2012 IECC interior shading coefficients impact projected performance. A 2-story, 2400 ft^2, slab-on-grade frame wall IECC 2012 Standard Reference Design home is used for both sets of simulations. The only change is the manner in which interior shading is treated. The values in the table are the annual kWh for heating and cooling in the cities specified.

Table 2. H&C Interior Shading Example

Condition	Miami	Orlando	Tally
IECC 2009	4981	3507	3426
IECC 2012	5237	3685	3579
kWh change	256	178	153
% change	5.1%	5.1%	4.5%

Table 2 shows that these high performance (SHGC-0.25) windows show 4.5% - 5.1% greater energy use for the IECC 2012 interior shading coefficient specification than for the 2009 IECC interior shading coefficient specification. This means that these high-performance windows will achieve less energy performance credit using the 2012 IECC specification that they do using the 2009 IECC specification. Surely this was not the intent of the 2012 change to the IECC interior shading coefficient.

In addition to the performance differences shown in Table 2, the 2012 IECC interior shading coefficients also do not reflect the likely behavior of the occupants. Occupants are more likely to use shades and blinds principally for privacy reasons but are also likely to use somewhat more shades and blinds during the air conditioning season to keep the sun out of the living space and use somewhat less shades and blinds during the heating season to let the sun into the living space. This occupant behavior is reflected in the 2009 IECC interior shading coefficient specification but abandoned for unknown reasons in the 2012 IECC interior shading coefficient specification.

Based on this analysis, the proponent recommends that the IECC set a single, non-floating window area to conditioned floor area ratio of 15% for the Standard Reference Design and that the IECC 2009 specification for interior shading coefficient be maintained for both the Standard Reference Design and the Proposed Design.

Cost Impact: The code change proposal will not increase the cost of construction.

R405.5.2(1)T-EC-SONNE.DOC

Committee Action Hearing Results

Committee Action: Disapproved

Committee Reason: Consistent with action taken on RE181-13.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jeff Sonne representing Florida Solar Energy Center, requests Approval as Submitted.

Commenter's Reason: Proposal RE164-13 was approved as submitted. We have submitted a separate comment recommending that RE164-13 be disapproved, and repeat the comment here in support of alternative proposal RE181-13.

RE164-13 is inconsistent with the direction taken by all other programs having reference homes. DOE's Builder's Challenge program and EPA's EnergyStar program take exception with IECC and limit the percent glass of the reference home so that homes that use more energy due to large window areas have to make it up. It is difficult to consider the IECC as a serious energy code with unlimited glass areas receiving no penalty. In our experience it is large homes that tend to have 25% to 40% glass-to-floor area, requiring substantially more heating and air conditioning. Windows are better than they used to be, but they are a weak component in the building envelope. The agreement made in 2003 was erroneous. The prescriptive method should also have a window area limitation forcing the UA or performance method. Please don't make the code worse, reject RE164-13. We still stand behind RE181-13 as an appropriate solution.

RE181-13

Final Action: AS AM AMPC____ D

RE186-13
R202 (IRC N1101.9), R401.2 (IRC N1101.15), R406 (NEW) (IRC N1106 (NEW))

Proposed Change as Submitted

Proponent: William Fay, Energy Efficient Codes Coalition; Brian Dean, Energy Efficient Codes Coalition; Garrett Stone, Brickfield Burchette Ritts & Stone, PC; Jeff Harris, Alliance to Save Energy; Harry Misuriello, American Council for an Energy-Efficient Economy; and Bill Prindle, Energy Efficient Codes Coalition

Revise follows:

SECTION R401 (N1101)
GENERAL

R401.2 (IRC N1101.15)Compliance. Projects shall comply with Sections identified as "mandatory" and with either sections identified as "prescriptive" or the simulated performance alternative ~~approach~~ in Section R405. In addition, all projects shall comply with Section R406.

SECTION R406 (N1106)
ADDITIONAL ENERGY EFFICIENCY (MANDATORY)

R406.1 (N1106.1)Scope. This section establishes additional mandatory requirements applicable to all compliance approaches to achieve additional energy efficiency.

R406.2 (N1106.2)Points-based compliance. One or more energy efficiency measure(s) shall be installed in accordance with Section R406.3 that cumulatively equal or exceed 5 (five) Flex Points for the appropriate Climate Zone. Projects complying under the simulated performance alternative outlined in Section R405 shall demonstrate compliance with Section R405 without including in the proposed design any features that will be utilized to comply with Section R406.

Exception~~s~~: The requirements of this section shall not apply to:

1. Projects complying under the performance approach outlined in Section R405, where the *proposed design* under section R405.3 is shown to have an annual energy cost that is less than or equal to 95% of the annual energy cost of the *standard reference design.*
2. Projects with an on-site or building integrated renewable energy system installed that provides not less than 0.50 watts per square foot (5.4 W/m2) of *conditioned floor area*.
3. Additions with a *conditioned floor area* equal to or less than 1,000 square feet.
4. *Alterations*, renovations and *repairs* to an existing building.

R406.3 (N1106.3) Flex Points for additional energy efficiency. Measures shall be selected from the applicable Flex Points Table based on the applicable federal minimum equipment efficiency established by federal rule for that state that applies to the specified heating and cooling equipment on the date that a permit is issued. Each measure chosen shall receive credit for the Flex Points as indicated in the applicable Table for the specific Climate Zone. Interpolation of points between measures shall not be permitted.

R406.3.1 (N1106.3.1) Use of Flex Points Table R406.3.1. In states where the applicable federal minimum efficiencies are less than or equal to 80 AFUE for non-weatherized gas residential furnaces, equal to 7.7 HSPF for split system heat pumps, and equal to 13 SEER for split system air conditioners, Table R406.3.1 shall be used.

TABLE R406.3.1 (N1106.3.1)
FLEX POINTS FOR ADDITIONAL ENERGY EFFICIENCY

a. Climate Zone 4C is Climate Zone Marine 4.
b. The Total UA shall be calculated in accordance with Section R402.1.4 Total UA alternative.
c. Minimum Heat Recovery Ventilator (HRV) and Energy Recovery Ventilator (ERV) requirements, measured at the lowest tested net supply airflow, shall be ≥ 75% Sensible Recovery Efficiency (SRE), ≤ 1.1 W/CFM Fan Energy and shall not use recirculation as a defrost strategy. In addition, the Energy Recovery Ventilator (ERV) shall be ≥ 50% Latent Recovery/Moisture Transfer (LRMT).
d. To achieve 100% of the thermal distribution located in the actively conditioned space, no ducts or pipes used for the heating and cooling systems shall be located within walls or ceilings where losses are not directly regained into the conditioned space.
e. For multiple cooling systems, all systems shall meet or exceed the minimum efficiency requirements in Table R406.3.1 and shall be sized to serve 100% of the cooling design load. As an alternative, each system installed shall receive credit for the percentage of the Flex Points for the measure equal to the percentage of the cooling design load served by the system.
f. For multiple heating systems, all systems shall meet or exceed the minimum efficiency requirements in Table R406.3.1 and shall be sized to serve 100% of the heating design load. As an alternative, each system installed shall receive credit for the percentage of the Flex Points for the measure equal to the percentage of the heating design load served by the system.

R406.3.2 (N1106.3.2) Use of Flex Points Table R406.3.2.. In states where the applicable federal minimum efficiencies are less than or equal to 80 AFUE for non-weatherized gas residential furnaces, equal to 8.2 HSPF for split system heat pumps, and less than or equal to 14 SEER for split system air conditioners, Table R406.3.2 shall be used.

a. Climate Zone 4C is Climate Zone Marine 4.
b. The Total UA shall be calculated in accordance with Section R402.1.4 Total UA alternative.
c. Minimum Heat Recovery Ventilator (HRV) and Energy Recovery Ventilator (ERV) requirements, measured at the lowest tested net supply airflow, shall be ≥ 75% Sensible Recovery Efficiency (SRE), ≤ 1.1 W/CFM Fan Energy and shall not use recirculation as a defrost strategy. In addition, the Energy Recovery Ventilator (ERV) shall be ≥ 50% Latent Recovery/Moisture Transfer (LRMT).
d. To achieve 100% of the thermal distribution located in the actively conditioned space, no ducts or pipes used for the heating and cooling systems shall be located within walls or ceilings where losses are not directly regained into the conditioned space.
e. For multiple cooling systems, all systems shall meet or exceed the minimum efficiency requirements in Table R406.3.3 and shall be sized to serve 100% of the cooling design load. As an alternative, each system installed shall receive credit for the percentage of the Flex Points for the measure equal to the percentage of the cooling design load served by the system.
f. For multiple heating systems, all systems shall meet or exceed the minimum efficiency requirements in Table R406.3.3 and shall be sized to serve 100% of the heating design load. As an alternative, each system installed shall receive credit for the percentage of the Flex Points for the measure equal to the percentage of the heating design load served by the system.

Revise as follows:

SECTION R202 (IRC N1101.9)
GENERAL DEFINITIONS

CONDITIONED SPACE. An area ~~or room~~ within a building that is either *actively conditioned space* or *passively conditioned space* ~~being heated or cooled, containing uninsulated ducts, or with a fixed opening directly into an adjacent *conditioned space*~~.

ACTIVELY CONDITIONED SPACE. An area within a *building thermal envelope* that is directly heated or cooled, including any habitable room.

PASSIVELY CONDITIONED SPACE. An area within a *building thermal envelope* that is not directly heated or cooled, including wall cavities, floor cavities, ceiling cavities, storage rooms, closets, non-habitable attic, non-habitable basement, crawlspace, spaces or cavities that contain uninsulated ducts or thermal distribution systems or have an opening directly into an adjacent conditioned space.

Reason: The purpose of this code change is to establish a new mandatory section to achieve additional energy efficiency. This proposal will allow builders the flexibility to choose from a menu of options to achieve 5% or more in energy savings beyond compliance with the current prescriptive or performance paths in the 2012 *IECC*. The new mandatory set of points-based options are predicated on the notion that because the current residential I-Codes require a solid foundation of "whole house" efficiency features, builders should have flexibility to determine the improvements that add onto that foundation. In addition to bringing about a reasonable, but modest, improvement in energy efficiency in the 2015 *IECC*, the proposal will also lay the groundwork for emerging technologies and future improvements to the code. Similar options-based approaches are currently found in both the commercial provisions of the 2012 *IECC* (section C406) and in residential codes adopted in a number of states. As discussed below, this proposal improves the *IECC* in at least five important ways:

The proposal improves the overall energy efficiency of the *IECC* and *IRC* by about five percent, reducing the home's energy consumption and homeowner operating costs.

From a national energy policy standpoint, the need to improve the efficiency of America's buildings has not changed. Because buildings continue to consume over 50% of the natural gas and over 70% of the electricity consumed in America, the nation's building codes should incorporate reasonable measures to reduce energy use and peak demand wherever feasible. The residential requirements of the 2012 *IECC* represent significant improvements over previous editions of the code, and we believe that an additional 5% improvement in efficiency in the 2015 *IECC* is not only feasible, but is crucial to sound national energy policy and our nation's energy future. Each new building and substantial addition should bring the country one step closer to our national goal of energy independence.
In addition, energy efficient construction generates significant operating savings that quickly recoup the incremental cost of these improvements to new homebuyers. For example, when the US Department of Energy compared homes built to the 2012 *IECC* with homes built to the 2006 *IECC*, average homeowner life-cycle (30-year) cost savings ranged from $4,763 in Climate Zone 2 (the lowest savings in all climate zones) to $33,105 in Climate Zone 8 (the highest savings). And, even after accounting for the incremental up-front costs of mortgage fees and down payment, a homeowner's cumulative cash flow became positive within a year or two in all eight climate zones.

The proposal creates a highly flexible method to achieve additional energy savings that would be difficult to require in the current *IECC* and *IRC* structure.

Although there are many possible improvements beyond the 2012 *IECC*, some of these improvements would be impractical or difficult to include as prescriptive requirements at this time. For example, some emerging technologies may save energy, but because of limited availability, high cost, or federal laws, it may not be reasonable – or even legal – to require these technologies in every building. The *IECC* does not currently have an organized method for recognizing specific prescriptive options beyond the baseline requirements.
This proposal creates an approach and format that recognizes the energy savings potential of a range of systems and building features that otherwise would not be feasible to include in the baseline requirements at this time. For example, the proposal includes high-efficiency heating, cooling, and water heating options that could not be required outright because of federal preemption issues. The proposal also includes envelope-only measures that reward builders for going well beyond the current code requirements. The result is a reasonably flexible system of options that builders can choose from that goes beyond the 2012 *IECC* and *IRC*, provides incentives for good building practice and technologies, and gives jurisdictions an easily-adaptable, and easy to administer method to set ever-improving efficiency requirements.

The proposal lays the groundwork for future improvement in the code by establishing a structure for both prescriptive- and performance-based compliance options.

In order to maximize flexibility and prepare for future improvements to the code, this proposal establishes multiple methods of compliance for new buildings and additions of more than 1,000 square feet (smaller additions, alterations, renovations and repairs are currently proposed to be exempt to keep the proposal simpler).

- For code users who prefer a straightforward points-based approach to code compliance, Section R406 outlines a number of options for each climate zone that can be combined for a total of at least 5 points. Each point represents roughly a one percent decrease in the present value of energy costs over the life of the building (so 5 points equal roughly a 5% improvement in efficiency over the 2012 *IECC*).
- For code users who wish to use the simulated performance alternative in Section R405, the proposal also allows compliance where the proposed design demonstrates an energy cost less than or equal to 95% of the standard reference design. The proposal also allows compliance with the points system so long as the user does not "double count" in its performance analysis any improvements used in points compliance.
- Section R406 also creates a new option to demonstrate compliance through installation of renewable energy systems.

These compliance options can be easily updated in the future. For example, as additional technologies and building practices are improved in the future, these technologies can be added to the table, along with a corresponding point value, without a total rewrite of the code.
Points have been calculated based on the present value of energy cost savings over the current code (with recognition of relevant federal equipment standards), after reflecting the estimated useful life of each measure and an assumed 30-year life of the building for purposes of the analysis (consistent with a 30-year mortgage). This approach factors in the durability and useful life of each additional option chosen, recognizing that it is not the energy cost savings in the first year that is critical, but the cost savings over the life of the home that is most important. Although no building energy simulation on this scale will be perfect, the analysis behind the Flex Points tables is among the most sophisticated and detailed of its type. The analysis used the Department of Energy building analysis and present value calculation methodology, which will allow for easy updates to the table in the future. The analysis includes 105 TMY3 weather locations and 12 building types to account for varying stories, foundations and fuel types for each of the baseline and upgrade measures.

The proposal creates incentives for code users to consider installing high-efficiency heating, cooling, and water heating systems, as well as other alternatives, without degrading the thermal building envelope or violating federal law.

Code-writing organizations have long wrestled with the dilemma of how to incorporate high-efficiency heating, cooling, and water heating requirements into the code without violating federal law and without sacrificing improvements to the thermal envelope in return. In past code cycles, EECC was instrumental in removing the equipment trade-offs from the code to resolve the issues these trade-offs and the federal laws created. We remain strongly committed to that approach today. However, this proposal takes the next step by leaving the 2012 *IECC* baseline requirements intact, while offering code users the choice of equipment upgrades among several other potential improvements beyond the baseline requirements.
The proposal includes three Flex Points tables that correspond with current requirements and expected changes to HVAC equipment efficiency in the coming years. Although we hope to see improvements in federal efficiency standards for heating and cooling equipment take effect in the near future, it is not yet clear when (or in some cases if) new requirements that have been developed by U.S. DOE will actually become effective. It would not be appropriate to award “credit” for a measure already required by federal law. And U.S. DOE is working to replace national standards with regional-based standards that will vary from one region to the next.
The proposal addresses these complications in a relatively simple way. The point values in each table under Section R406 have been set according to the energy savings that would result based on a specific equipment efficiency baseline in all climate zones. The first table, Table R406(a), establishes a baseline set of the heating and cooling equipment efficiencies reflective of current efficiencies. When federal minimum efficiencies are increased for specific heating and/or cooling equipment, as is reflected under the latest federal rule, states will apply the appropriate table. The choice of tables will allow states to apply the appropriate Flex Points without recalculating the savings for each individual measure.

The proposal allows jurisdictions to “try out” a wide variety of efficiency measures that would be difficult to require as prescriptive requirements.

Innovative building practices or emerging technologies can benefit from being listed in state and local building codes. However, states may have difficulty prescriptively requiring new technologies or building practices for all homes that are not yet widely available. For example, ground-source heat pumps can offer significant energy savings, but because of geological features or regulatory issues, they may not be appropriate in all circumstances. The proposal above provides an incentive to consider installing a ground source heat pump as one of several compliance options under Section R406, but also offers many other comparable options or combinations of such options to achieve the same level of savings.
By incorporating several of these practices and technologies among the multiple options of Section R406, the proposal above essentially gives these emerging technologies and practices a foothold, and allows consumers and the market to determine the most feasible options for any given project. As emerging technologies become more mainstream, Section R406 may also be a good source for additional improvements to the prescriptive baseline in future code editions.

Cost Impact: The code change proposal will increase the cost of construction.

R401.2-EC-DEAN-HARRIS-MISURELLO-PRINDLE-STONEFNF-bd2(2).DOC

Committee Action Hearing Results

Committee Action: Disapproved

Committee Reason: The point system in ICC700 is simple, and workable, but there is no justification that the stringency of this code is achieved. ICC 700 can be used as an above code program now, with appropriate analysis.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Brian Dean, ICF International, representing the Energy Efficient Codes Coalition; Jeff Harris, Alliance to Save Energy; Harry Misuriello, American Council for an Energy-Efficient Economy (ACEEE); Bill Prindle, representing the Energy Efficient Codes Coalition; Garrett Stone, Brickfield, Burchette, Ritts & Stone, PC; Donald J. Vigneau, Northeast Energy Efficiency Partnerships Inc., request Approval as Modified by this Public Comment.

Modify the proposal as follows:

SECTION R401 (N1101)
GENERAL

R401.2 (IRC N1101.15) Compliance. Projects shall comply with Sections identified as "mandatory" and with either sections identified as "prescriptive" or the simulated performance alternative in Section R405. In addition, all projects shall comply with Section R406.

SECTION R406 (N1106)
ADDITIONAL ENERGY EFFICIENCY (MANDATORY)

R406.1 (N1106.1) Scope. This section establishes additional mandatory requirements applicable to all compliance approaches to achieve additional energy efficiency.

R406.2 (N1106.2) Points-based compliance. One or more energy efficiency measures shall be installed in accordance with Section R406.3 that cumulatively equal or exceed 5 Flex Points for the appropriate Climate Zone. Projects complying under the simulated performance alternative outlined in Section R405 shall demonstrate compliance with Section R405 without including in the proposed design any features that will be utilized to comply with Section R406.

Exceptions: The requirements of this section shall not apply to:

1. Projects complying under the performance approach outlined in Section R405, where the *proposed design* under Section R405.3 is shown to have an annual energy cost that is less than or equal to 95 percent of the annual energy cost of the *standard reference design.*
2. Projects with an on-site or building integrated renewable energy system installed that provides not less than 0.50 watts per square foot (5.4 W/m^2) of *conditioned floor area*.
3. Additions with a *conditioned floor area* equal to or less than 1,000 square feet.
4. *Alterations*, renovations and *repairs* to an existing building.

R406.3 (N1106.3) Flex Points for additional energy efficiency. Measures shall be selected from ~~the applicable Flex Points~~ Table R406.3.1~~based on the applicable federal minimum equipment efficiency established by federal rule for that state that applies to the specified heating and cooling equipment on the date that a permit is issued~~. Each measure chosen shall receive credit for the Flex Points as indicated in the ~~applicable~~ Table for the specific Climate Zone. Interpolation of points between measures shall not be permitted.

~~**R406.3.1 (N1106.3.1) Use of Flex Points Table R406.3.1.** In states where the applicable federal minimum efficiencies are less than or equal to 80 AFUE for non-weatherized gas residential furnaces, equal to 7.7 HSPF for split system heat pumps, and equal to 13 SEER for split system air conditioners, Table R406.3.1 shall be used.~~

a. Climate Zone 4C is Climate Zone Marine 4.
b. The Total UA shall be calculated in accordance with Section R402.1.4 Total UA alternative.
c. Minimum Heat Recovery Ventilator (HRV) and Energy Recovery Ventilator (ERV) requirements, measured at the lowest tested net supply airflow, shall be greater than or equal to 75 percent Sensible Recovery Efficiency (SRE), less than or equal to 1.1 W/CFM Fan Energy and shall not use recirculation as a defrost strategy. In addition, the Energy Recovery Ventilator (ERV) shall be greater than or equal to 50 percent Latent Recovery/Moisture Transfer (LRMT).
d. To achieve 100% of the thermal distribution located in the actively conditioned space, no ducts ~~or pipes~~ used for the heating and cooling systems shall be located within walls or ceilings where losses are not directly regained into the conditioned space.
e. For multiple cooling systems, all systems shall meet or exceed the minimum efficiency requirements in Table ~~R406.3.2~~ R406.3.1 and shall be sized to serve 100 percent of the cooling design load. As an alternative, each system installed shall receive credit for the percentage of the Flex Points for the measure equal to the percentage of the cooling design load served by the system.
f. For multiple heating systems, all systems shall meet or exceed the minimum efficiency requirements in Table ~~R406.3.2~~ R406.3.1 and shall be sized to serve 100 percent of the heating design load. As an alternative, each system installed shall receive credit for the percentage of the Flex Points for the measure equal to the percentage of the heating design load served by the system.

~~**R406.3.3 (N1106.3.3) Use of Flex Points Table R406.3.3.** In states where the applicable federal minimum efficiencies are equal to 90 AFUE for non-weatherized gas residential furnaces, equal to 8.2 HSPF for split system heat pumps, and less than or equal to 14 SEER for split system air conditioners, Table R406.3.3 shall be used.~~

~~TABLE R406.3.3 (N1106.3.3)~~

~~a. Climate Zone 4C is Climate Zone Marine 4.~~
~~b. The Total UA shall be calculated in accordance with Section R402.1.4 Total UA alternative.~~
~~c. Minimum Heat Recovery Ventilator (HRV) and Energy Recovery Ventilator (ERV) requirements, measured at the lowest tested net supply airflow, shall be ≥ 75% Sensible Recovery Efficiency (SRE), ≤ 1.1 W/CFM Fan Energy and shall not use recirculation as a defrost strategy. In addition, the Energy Recovery Ventilator (ERV) shall be ≥ 50% Latent Recovery/Moisture Transfer (LRMT).~~
~~d. To achieve 100% of the thermal distribution located in the actively conditioned space, no ducts or pipes used for the heating and cooling systems shall be located within walls or ceilings where losses are not directly regained into the conditioned space.~~
~~e. For multiple cooling systems, all systems shall meet or exceed the minimum efficiency requirements in Table R406.3.3 and shall be sized to serve 100% of the cooling design load. As an alternative, each system installed shall receive credit for the percentage of the Flex Points for the measure equal to the percentage of the cooling design load served by the system.~~
~~f. For multiple heating systems, all systems shall meet or exceed the minimum efficiency requirements in Table R406.3.3 and shall be sized to serve 100% of the heating design load. As an alternative, each system installed shall receive credit for the percentage of the Flex Points for the measure equal to the percentage of the heating design load served by the system.~~

SECTION R202 (IRC N1101.9)
GENERAL DEFINITIONS

CONDITIONED SPACE. An area within a building that is either *actively conditioned space* or *passively conditioned space*.

ACTIVELY CONDITIONED SPACE. An area within a *building thermal envelope* that is directly heated or cooled, including any habitable room.

PASSIVELY CONDITIONED SPACE. An area within a *building thermal envelope* that is not directly heated or cooled, including wall cavities, floor cavities, ceiling cavities, storage rooms, closets, non-habitable attic, non-habitable basement, crawlspace, spaces or cavities that contain uninsulated ducts or thermal distribution systems or have an opening directly into an adjacent conditioned space.

Commenter's Reason: We recommend approval of RE186 as modified by this public comment. The original reason statement for RE186 offers a comprehensive set of reasons why a points-based set of options provides maximum flexibility, while also improving the efficiency of the IECC by about 5%. As a result, we need not reiterate the reasons in this public comment.

However, based on the residential energy committee's reason statement, as well as misinformation raised in testimony by various stakeholders, we submit the following clarifications and further explanation:

- The residential energy committee's reason for recommending disapproval appears to reflect a mistaken understanding of this proposal. The EECC is not proposing to adopt ICC-700 or anything like it. In fact, we opposed incorporation of ICC-700 into the IECC in another code proposal (CE34).
- The "Flex Points" proposal is not an "above-code" program. Rather it is an additional efficiency requirement with the choice among a number of compliance options. The IECC commercial provisions already have a similar approach (see section C406).
- RE186 improves the 2012 IECC by 5% in two ways:
  - Homes can be built to the performance path and show an annual energy usage of no more than 95% of the standard reference design.
  - Homes can be built to the prescriptive or Total UA paths and show that they have installed sufficient additional energy efficiency measures to equal at least 5 Flex Points from the table column appropriate to the jurisdiction.
- For many builders, there will be no cost increase whatsoever, since many of the Flex Points options are commonly installed -- such as improved HVAC equipment or ducts located indoors – and can satisfy all 5 flex points (or more).
- The flex points measures in most cases are not appropriate to require in the base code, either because of federal preemption issues or a lack of market penetration for new efficient products.
- As indicated in our original reason statement, the analysis is based on the Department of Energy Methodology for Evaluated Cost-Effectiveness of Residential Energy Code Changes and the present value calculation methodology, which will allow for easy updates to the table in the future. The analysis first uses a present value analysis over a 30-year useful life of the building to determine the present value of energy cost savings for each measure – specifically, the analysis calculates the energy savings on a present value basis for the estimated life of each measure up to 30 years. Then the estimate of energy savings is converted into points for each measure. Each point is equal to the present value of 1% energy savings over 20 years; by using a 20 year benchmark, the points allow more flexibility among measures and provide some greater recognition to those measures with longer useful lives. While some measures have a longer life than 30 years, using a 30-year useful life ensures that savings are capped at a commonly used 30-year metric for homes, such as a typical 30 year mortgage, which is conservatively low for measures that last for the entire lifetime of the home.

In this public comment, we propose limited modifications to the original proposal to further simplify it. Most importantly we have deleted two of the tables as no longer necessary and modified the companion language accordingly. These changes will make application of the table simpler. The original three tables with options were necessary due to uncertainty regarding federal minimum equipment efficiencies when the proposal was in the process of preparation. At this point, minimum equipment requirements in 2015 are clear, requiring only one table that will apply nationwide.

No other proposal before the Governmental Members will produce an additional 5% savings from all residential buildings subject to the code, with the level of flexibility allowed by RE186. We urge approval of RE186 as modified.

RE186-13

Final Action: AS AM AMPC____ D

RE188-13
R202 (NEW) (IRC N1101.9 (NEW)), R401.2 (IRC N1101.15), R406 (NEW) (IRC N1106 NEW)

Proposed Change as Submitted

Proponent: Eric Makela, Britt Makela Group, Inc., David Goldstein, National Resource Defense Council (Eric@BrittMakela.com)

Revise as follows:

R401.2 (N1101.15) Compliance. Projects shall comply with Sections identified as “mandatory” and with either sections identified as “prescriptive”, ~~or~~ the performance approach in Section R405~~.~~ or an Energy Rating Index (ERI) approach in Section R406.

SECTION R406 (N1106)
ENERGY RATING INDEX COMPLIANCE ALTERNATIVE

R406.1 (N1106.1) Scope. This section establishes criteria for compliance using an Energy Rating Index analysis.

R406.2 (N1106.2) Mandatory requirements. Compliance with this section requires that the mandatory provisions identified in Section R401.2 and R403.4.2 be met. The building thermal envelope shall be greater than or equal to levels of efficiency and Solar Heat Gain Coefficient in Table 402.1.1 or 402.1.3 of the 2009 *International Energy Conservation Code.*

> **Exception:** Supply and return ducts not completely inside the building thermal envelope shall be insulated to a minimum of R-6.

R406.3 (N1106.3) Energy rating index. The energy rating index (ERI) shall be a numerical integer value that is based on a linear scale constructed such that the *ERI reference design* has an Index value of 100 and a residential building that uses no net purchased energy has an Index value of 0. Each integer value on the scale shall represent a one percent (1%) change in the total energy use of the *rated design* relative to the total energy use of the *ERI reference design*. The ERI shall consider all energy used in the residential building.

R406.3.1 (N1106.3.1) ERI reference design. The *ERI reference design* shall be configured such that is it meets the minimum requirements of the 2006 *International Energy Conservation Code* prescriptive requirements

The proposed residential building shall be shown to have an annual total normalized Modified Loads that are less than or equal to the annual total Loads of the *ERI reference design.*

R406.4 (N1106.4) ERI based compliance. Compliance based on an ERI analysis requires that the *rated design* be shown to have an ERI less than or equal to the appropriate value listed in Table R406.3, when compared to the *ERI reference design*.

TABLE R406.4 (N1106.4)
MAXIMUM ENERGY RATING INDEX

Climate Zone	Energy Rating Index
1	52
2	52
3	51
4	54
5	55
6	54
7	53
8	53

R406.5 (N1106.5) Verification by approved agency. Verification of compliance with Section R406 shall be completed by an *approved* third party.

R406.6 (N1106.6) Documentation. Documentation of the software used to determine the energy rating index and the parameters for the residential building shall be in accordance with Sections R406.6.1 through R406.6.3.

R406.6.1 (N1106.6.1) Compliance software tools. Documentation verifying that the methods and accuracy of the compliance software tools conform to the provisions of this section shall be provided to the *code official.*

R406.6.2 (N1106.6.2) Compliance report. Compliance software tools shall generate a report that documents that the energy rating index of the *rated design* complies with Sections R406.3 and R406.4. The compliance documentation shall include the following information:

1. Address or other identification of the residential building;
2. An inspection checklist documenting the building component characteristics of the *rated design*. The inspection checklist shall show results for both the *ERI reference design* and the *rated design,* and shall document all inputs entered by the user necessary to reproduce the results;
3. Name of individual completing the compliance report; and
4. Name and version of the compliance software tool.

Exception: Multiple orientations. When an otherwise identical building model is offered in multiple orientations, compliance for any orientation shall be permitted by documenting that the building meets the performance requirements in each of the four cardinal (north, east, south and west) orientations.

R406.6.3 (N1106.6.3) Additional documentation. The *code official* shall be permitted to require the following documents:

1. Documentation of the building component characteristics of the *ERI reference design.*
2. A certification signed by the builder providing the building component characteristics of the *rated design.*
3. Documentation of the actual values used in the software calculations for the *rated design.*

R406.7 (N1106.7) Calculation software tools. Calculation software, where used, shall be in accordance with Sections R406.7.1through R406.7.3.

R406.7.1 (N1106.7.1)Minimum capabilities. Calculation procedures used to comply with this section shall be software tools capable of calculating the energy rating index as described in Section R406.3, and shall include the following capabilities:

1. Computer generation of the *ERI reference design* using only the input for the *rated design.*

The calculation procedure shall not allow the user to directly modify the building component characteristics of the *ERI reference design.*

2. Calculation of whole-building, as a single *zone,* sizing for the heating and cooling equipment in the *ERI reference design* residence in accordance with Section R403.6.

3. Calculations that account for the effects of indoor and outdoor temperatures and part-load ratios on the performance of heating, ventilating and air-conditioning equipment based on climate and equipment sizing.

4. Printed *code official* inspection checklist listing each of the *rated design* component characteristics determined by the analysis to provide compliance, along with their respective performance ratings.

R406.7.2 (N1106.7.2) Specific approval. Performance analysis tools meeting the applicable sections of Section R406 shall be *approved.* Tools are permitted to be *approved* based on meeting a specified threshold for a jurisdiction. The *code official* shall approve tools for a specified application or limited scope.

R406.7.3 (N1106.7.3) Input values. When calculations require input values not specified by Sections R402, R403, R404 and R405, those input values shall be taken from an *approved* source.

Add new definitions as follows:

RATED DESIGN. A description of the proposed building used to determine the energy rating index.

ERI REFERENCE DESIGN. A version of the *rated design* that meets the minimum requirements of the 2006 *International Energy Conservation Code.*

Reason: The residential provisions of the IECC allows for varying methods for demonstrating compliance with the code. This includes both a prescriptive and simulated performance option in addition to allowing efficiency programs that are designed to go above the minimum code levels as “deemed to comply” programs. These above code programs must be approved by the code official to be used in the jurisdiction. Alternative programs that depend on an Energy Rating Index (ERI) have been approved as an alternative code or above code program in at least 6 states and in over 130 jurisdictions. These types of programs typically take the form of a Home Energy Rating System (HERS) program. Under the current code there is no guidance on setting Energy Rating Index scores, which will lead to inconsistent application of these types of programs based on climate zones.

The goal of this proposal is to introduce an Energy Rating Index with established rating numbers into the code that will allow alternative programs to be designed to meet these criteria. The proposal provides guidelines for the development of the index, documentation provided to ensure compliance and a requirement that an approved 3rd party verify that the building complies with the applicable Energy Rating Index. The reference house is based on a home built to the 2006 IECC which is consistent with ERI based programs.

The 2009 IECC residential envelope requirements have been set as the least efficient level of efficiency for potential trade-offs to ensure that minimum levels of efficiency that have proven to be cost effective are installed in all buildings and that some flexibility is allowed in the approach to alternative designs. This proposal also requires complying with the applicable mandatory requirements to be consistent with the Above Code section in the IECC. And because energy losses in the domestic hot water distribution system fall outside the scope of the energy rating index as it can be calculated with 2013 methodology, current code provisions relating to hot water pipe insulation are mandatory as well. We anticipate that these requirements can be folded into the energy rating index for the 2018 IECC and thus removed from the mandatory sections then.

This proposal is intended to produce substantial additional energy savings compared to the current or proposed levels of prescriptive requirements in the 2015 IECC while allowing considerably greater flexibility to builders using a method with which a large segment of the market is already familiar. This flexibility is likely to result in lower construction costs for any given level of energy efficiency. Builders who do not make use of this proposed method are still able to comply with the Code can still use any of the existing compliance pathways.

Cost Impact: The code change proposal will not increase the cost of construction.

R401.2-EC-GOLDSTEIN-MAKELA.DOC

Committee Action Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: This proposal, while providing 20% more stringency, provides a system that has considerably more flexibilitty for achieving energy efficiency. Rating systems are becoming a more common approach, with straightforward options that are being more widely used in the construction marketplace.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Brian Dean, ICF International, representing the Energy Efficient Codes Coalition; Jeff Harris, Alliance to Save Energy; Harry Misuriello, American Council for an Energy-Efficient Economy (ACEEE); Bill Prindle, representing the Energy Efficient Codes Coalition; Garrett Stone, Brickfield, Burchette, Ritts & Stone, PC; Donald J. Vigneau, Northeast Energy Efficiency Partnerships Inc., request Approval as Modified by this Public Comment.

Modify the proposal as follows:

R406.2 (N1106.2) Mandatory requirements. Compliance with this section also requires that sections identified as ~~the~~ "mandatory" in this chapter be met and that ~~provisions identified in Section R401.2 and R403.4.2 be met. The~~ the building thermal envelope shall ~~be greater than or equal to levels of efficiency~~ meet the prescriptive requirements of Section R402.1 of this code. ~~and Solar Heat Gain Coefficient in Table 402.1.1 or 402.1.3 of the 2009 International Energy Conservation Code.~~

(Portions of proposal not shown remain unchanged)

Commenter's Reason: We recommend that RE188 be modified in accordance with this public comment. This public comment does not address the specifics of the proposed new home energy rating compliance approach, but instead focuses on creating reasonable assurance that homes using the new method will install a reasonable thermal envelope. Although we recognize the efforts of the proponents to attempt to establish effective limitations on the ability to trade away the efficiency of the permanent thermal envelope for shorter-lived equipment and appliances under a home energy rating approach, we are concerned that the original proposal still has the potential to give away too much long-term energy efficiency. The permanent prescriptive thermal envelope of the 2012 IECC is considerably more robust than the 2009 IECC. Although the proposed home energy rating method includes thermal envelope components in its calculation, several other components are also part of the equation that are not currently allowed under the IECC. Using the proposed home energy rating method, builders may take credits for equipment, appliances, lighting and a different performance baseline, potentially leading to homes built with less-efficient thermal envelopes and more efficient short-lived products. As a result, we believe that there needs to be a better backstop in this proposal to avoid undoing the progress made in improving the permanent thermal envelope in the 2012 IECC.

The modification proposed above attempts to strike a balance between efficiency and flexibility. The modification updates the reference to minimum thermal performance (prescriptive R-values, U-factors and SHGCs) to the current IECC requirements (section R402.1) instead of the 2009 IECC, but the modification allows all prescriptive options for demonstrating compliance with the thermal envelope prescriptive requirements (including Total UA). This will allow builders the most flexibility in demonstrating that the thermal envelope meets or exceeds the 2012 IECC, while avoiding an unnecessary weakening of the thermal envelope requirements of the current code through equipment, appliance and other trade-offs.

Public Comment 2:

Eric Makela, Britt/Makela Group, representing self, Ron Burton, representing Leading Builders of America, David Goldstein, representing National Resource Defense Council, and Meg Waltner, representing National Resource Defense Council, request Approval as Modified by this Public Comment.

Modify the proposal as follows:

R406.4 ERI based compliance. Compliance based on an ERI analysis requires that the *rated design* be shown to have an ERI less than or equal to the appropriate value listed in Table R406.3, when compared to the *ERI reference design*.

Table R406.4 Maximum Energy Rating Index

Climate Zone	Energy Rating Index
1	~~52~~ 59
2	~~52~~ 59
3	~~51~~ 59
4	~~54~~ 63
5	~~55~~ 63
6	~~54~~ 62
7	~~53~~ 60
8	~~53~~ 60

(Portions of proposal not shown remain unchanged)

Public Comment 3:

Ryan Meres, Institute for Market Transformation, representing self, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

ERI REFERENCE DESIGN. A version of the *rated design* that meets the minimum requirements of Tables 404.5.2(1) and 404.5.2(2) of the 2006 International Energy Conservation Code.

SECTION R406
ENERGY RATING INDEX COMPLIANCE ALTERNATIVE

R406.1 Scope. This section establishes criteria for compliance using an Energy Rating Index analysis.

R406.2 Mandatory requirements. Compliance with this section requires that the mandatory provisions identified in Section R401.2 and the provisions identified in Section R403.4.2 be met. The building thermal envelope shall be greater than or equal to levels of efficiency ~~and Solar Heat Gain Coefficient~~ in Table 402.1.1 or 402.1.3 of the 2009 International Energy Conservation Code. Solar Heat Gain Coefficient shall be no greater than the levels in Table 402.1.1 of the 2009 International Energy Conservation Code.

Exceptions:

1. All supply and return ducts not completely inside the building thermal envelope shall be insulated to a minimum of R-6.

R406.3 Energy Rating Index. The ERI shall be a numerical integer value that is based on a linear scale constructed such that the *ERI reference design* has an Index value of 100 and a home that uses no net purchased energy has an Index value of 0. Each integer value on the scale shall represent a one percent (1%) change in the total energy use of the *rated design* relative to the total energy use of the *ERI reference design*. ~~The ERI shall consider all energy used in the dwelling unit.~~ The ERI shall consider all energy loads used in the dwelling unit as regulated by the provisions of this code including lighting and plug loads installed at the time of final inspection.

~~**R406.3.1 ERI Reference Design.** The *ERI reference design* shall be configured such that is it meets the minimum requirements of the 2006 International Energy Conservation Code prescriptive requirements~~
~~The proposed residence shall be shown to have an annual total normalized Modified Loads that are less than or equal to the annual total Loads of the *ERI reference design.*~~

R406.4 ERI based compliance. Compliance based on an ERI analysis requires that the *rated design* be shown to have an ERI less than or equal to the appropriate value listed in Table R406.3, when compared to the *ERI reference design*.

Table R406.4 Maximum Energy Rating Index

Climate Zone	Energy Rating Index
1	52
2	52
3	51
4	54
5	55
6	54
7	53
8	53

R406.4 Verification by approved agency. Verification of compliance with Section R406 shall be completed by an *approved* third party.

<u>**R406.4.1 Equipment and device verification.** The efficiency of the equipment and devices used for the proposed design shall be specified in the construction documents. The equipment or device efficiency shall be readily observable for inspection after the equipment or device is installed.</u>

R406.5 Documentation. Documentation of the software used to determine the energy rating index and the parameters for the building shall be in accordance with Sections R406.5.1through R406.5.3.

R406.5.1 Compliance software tools. Documentation verifying that the methods and accuracy of the compliance software tools conform to the provisions of this section shall be provided to the *code official.*

R406.5.2 Compliance report. Compliance software tools shall generate a report that documents that the energy rating index of the *rated design* complies with Sections R406.3 and R406.4. The compliance documentation shall include the following information:

1. Address or other identification of the residence;
2. An inspection checklist documenting the building component characteristics of the *rated design*. The inspection checklist shall show results for both the *ERI reference design* and the *rated design,* and shall document all inputs entered by the user necessary to reproduce the results;
3. Name of individual completing the compliance report; and
4. Name and version of the compliance software tool.

Exception: Multiple orientations. When an otherwise identical building model is offered in multiple orientations, compliance for any orientation shall be permitted by documenting that the building meets the performance requirements in each of the four cardinal (north, east, south and west) orientations.

R406.5.3 Additional documentation. The *code official* shall be permitted to require the following documents:

1. Documentation of the building component characteristics of the *ERI reference design.*
2. A certification signed by the builder providing the building component characteristics of the *rated design.*
3. Documentation of the actual values used in the software calculations for the *rated design.*

R406.6 Calculation software tools. Calculation software, where used, shall be in accordance with Sections R406.6.1through R406.6.3.

R406.6.1 Minimum capabilities. Calculation procedures used to comply with this section shall be software tools capable of calculating the energy rating index as described in Section R406.3, and shall include the following capabilities:

1. Computer generation of the *ERI reference design* using only the input for the *rated design.* The calculation procedure shall not allow the user to directly modify the building component characteristics of the *ERI reference design.*

2. Calculation of whole-building (as a single *zone)* sizing for the heating and cooling equipment in the *ERI reference design* residence in accordance with Section R403.6.

3. Calculations that account for the effects of indoor and outdoor temperatures and part-load ratios on the performance of heating, ventilating and air-conditioning equipment based on climate and equipment sizing.

4. Printed *code official* inspection checklist listing each of the *rated design* component characteristics determined by the analysis to provide compliance, along with their respective performance ratings.

5. <u>Calculations that account for the differences in the heating, cooling and hot water equipment efficiencies of the *reference design* and the *proposed design, and* normalize for the differences in fuel types.</u>

R406.6.2 Specific approval. Performance analysis tools meeting the applicable sections of Section R406 shall be *approved.* Tools are permitted to be *approved* based on meeting a specified threshold for a jurisdiction. The *authority having jurisdiction* shall approve tools for a specified application or limited scope.

R406.6.3 Input values. When calculations require input values not specified by Sections R402, R403, R404 and R405, those input values shall be taken from an *approved* source.

(Portions of proposed change not shown remain unchanged.)

Commenter's Reason: This Public Comment addresses some of the issues that were raised at the IECC Code Development Hearings and also input from key stakeholders. The public comment clarifies the language. It specifically accounts for all energy using features in the building as long as the feature is present and installed at the time of final inspection.

Alternative programs that depend on an Energy Rating Index (ERI) have been approved as an alternative code or above code program in at least 6 states and in over 130 jurisdictions. These types of programs typically take the form of a Home Energy Rating

System (HERS) program. Under the current code there is no guidance on setting Energy Rating Index scores, which will lead to inconsistent application of these types of programs based on climate zones.

The goal of this proposal is to introduce an Energy Rating Index with established rating numbers into the code that will allow alternative programs to be designed to meet these criteria. The proposal provides guidelines for the development of the index, documentation provided to ensure compliance and a requirement that an approved 3rd party verify that the building complies with the applicable Energy Rating Index. The reference house is based on a home built to the 2006 IECC which is consistent with ERI based programs.

The 2009 IECC residential envelope requirements have been set as the least efficient level of efficiency for potential trade-offs to ensure that minimum levels of efficiency that have proven to be cost effective are installed in all buildings and that some flexibility is allowed in the approach to alternative designs. This proposal also requires complying with the applicable mandatory requirements to be consistent with the Above Code section in the IECC. And because energy losses in the domestic hot water distribution system fall outside the scope of the energy rating index as it can be calculated with 2013 methodology, current code provisions relating to hot water pipe insulation are mandatory as well.

This proposal is intended to produce substantial additional energy savings compared to the current or proposed levels of prescriptive requirements in the 2015 IECC while allowing considerably greater flexibility to builders using a method with which a large segment of the market is already familiar. This flexibility is likely to result in lower construction costs for any given level of energy efficiency. Builders who do not make use of this proposed method are still able to comply with the Code can still use any of the existing compliance pathways.

The IECC Code Development committee had this to say about RE-188: "This proposal, while providing 20% more stringency, provides a system that has considerably more flexibility for achieving energy efficiency. Rating systems are becoming a more common approach, with straightforward options that are being more widely used in the construction marketplace."

Public Comment 4:

Craig Conner, Building Quality, representing self, requests Disapproval.

Commenter's reason:

(Conner): The reason statement makes it clear that the proponents are trying to promote alternative programs for code compliance, a worthy goal. I think we are all strongly in favor of enabling alternative programs / above-code programs to be used for code compliance. However, this proposal is vague, inconsistent, and too close to proprietary. Moreover, it has restrictions that are not justified, nor has the selection of the specific "energy reference index" values been justified.

This proposal attempts to regulate or at least include ""*all energy used in the residential building*" (new R406.3). How does one regulate appliances that may not even be present at the time of inspection? What would be the minimum energy efficiency for the nonexistent appliances? How does one regulate what is just plugged into the wall?

There is no analysis supporting the specific numbers in the new table titled "Maximum Energy Rating Index". Those values are the core of this proposal and the values appear to be arbitrary.

A specific HERS score is not an accurate predictor of code compliance. EPA and DOE reached a similar conclusion for the Energy Star and Builder's Challenge programs. Neither uses a specific HERS score for a climate zone. EPA said "Given a constant set of energy efficiency features, these design features can alter the HERS index up to several points for individual factors and greater than 15 points by combining several factors into configurations often encountered in the real world."[1] A summary of this EPA analysis is available.[2] The Energy Star response was to require that a HERS score be recomputed for every building, and not to allow the same score for specific climate zones.[3] Likewise DOE requires a HERS score to be recomputed to each residence and does not allow a single HERS score for a whole climate zone.[4]

The stated goal of this proposal is flexibility; however in some ways this code change proposes the opposite of flexibly. This proposal places restrictions on insulation levels and glazing based on not allowing tradeoffs below the levels in the 2009 IECC (new R406.2). In some cases the 2009 and 2012 have the same requirement, so that tradeoff is not allowed at all. Nowhere are those specific restrictions justified through data or analysis. Comparing the 2012 and 2009 IECC shows tradeoffs that would not be allowed. In Zone 1 insulation is not tradable, as the 2009 and 2012 are the same. Floor insulation could only be traded in zone 5. Basement wall insulation is tradable only in Zone 5? Why? What makes insulation tradeoffs for basements and floors very bad? The 2009 IECC itself would allow those same tradeoffs, made up somewhere else, based on UA calculations or its own performance path.

The Energy Rating Index is not defined in a usable or easily understood manner. Unreasonable restrictions are included. For example, why require (not allow, but require) a 100 to 0 decreasing scale? Why would other scales not be allowed if they demonstrated compliance? Examples of other scales:
--DOE has a Home Energy Score that goes from 1 to 10, with10 the best.[5]
--ICC's "National Green Building Standard" (ICC 700-2012) has points. Higher is better. 120 energy points is very good and not easy to get. 10 points would be a terrible home.
--The Energy Performance Score goes from 0 to at least 200.[6]

In the sentence "The ERI shall consider all energy used in the residential building." What does "consider" mean? "Consider" is not a good word for the I-codes.

It is odd to reference the 2006 IECC (new R406.3.1) and the 2009 IECC (new R406.2) in the 2015 IECC. If there are limitations on the 2018 IECC based on values from previous versions of the IECC, those limitations should be included in the 2015 code so that it becomes a standalone code.

The term "normalized Modified Loads" is not defined or explained (new R06.3.1). There are no calculations specified. It is not a term in common use. IECC Section R201.4 says "terms not defined … shall have ordinarily accepted meanings such as the context implies." In an energy context "normalized" most commonly refers to heating and cooling energy that is normalized for weather variation. The proposal also used the word "Modified". How and why are the loads modified? This change covers "*all* *energy used in the residential building*". How are "normalized" and "modified" applied to the lighting, or appliances not specifically named in the IECC (dishwasher, refrigerator, etc.). And how is what are usually called "*plug loads*" to be "*normalized*" or "*modified*"?

In using the term "*normalized Modified Loads*" the proponents appear to be attempting to reference something used by RESNET in its home energy ratings. If this is correct, they have named a different form of the adjustment or at least incorrectly named it. Do they mean the "*normalized Modified End Use Loads*"?[7] No other alternative program or above code program I can find uses this "normalized Modified Loads" or "normalized Modified End Use Loads".

As worded, this change is proprietary. Requiring a 0 to 100 decreasing metric and a "normalized Modified Load" (assuming the name was corrected) results in only one group's product meeting this criteria. That group is RESNET. We should avoid even the appearance of proprietary systems in the I-Codes. . There are many other programs, both local and national, and the code should not promote just one of them, picked arbitrarily by the proponents.

If somehow referencing HERS in the code is the goal, or one of the goals, the proponents should at least wait until RESNET completes its ANSI consensus review process. RESNET does not yet have any ANSI approved documents that could be referenced. Or the proponents could work through some part of the Chapter 1 alternative programs ("above code programs") process.

Public Comment 5:

Neil Leslie, Gas Technology Institute, representing self, requests Disapproval.

Commenter's reason: RE188-13 is incomplete and unenforceable because it does not provide citable standards necessary for proper implementation and enforcement. Specifically, RE188-13 requires that "The proposed residential building shall be shown to have an annual total normalized Modified Loads that are less than or equal to the annual total Loads of the ERI reference design." Yet there is no guidance on how to determine the normalized modified loads. For this reason alone, RE188-13 should be disapproved.

Despite the lack of guidance on normalized modified load calculations in RE188-13, it is nearly certain that the proposal intends to use the RESNET normalized modified end use loads (nMEUL) methodology fully detailed in BSR/RESNET 301-2013 "Standard for the Calculation and Labeling of the Energy Performance of Low-Rise Residential Buildings using the HERS Index." Assuming this is the basis of the compliance requirement, RE188-13 must be disapproved due the **technical flaws and biases** embodied in the RESNET nMEUL methodology.

Unfortunately for the code official, the technical flaws and biases embodied in RE188 are hidden from view. The flaws are in the "black box" that code officials are being asked to accept as an alternative compliance mechanism to the energy code requirements. For brevity, this reason statement will focus on ONE technical flaw (and subsequent biases) that should more than justify disapproval of RE188-13 by building officials.

First, the nMEUL methodology utilizes **separate, inequitable reference home configurations and requirements** for all-electric homes compared to homes that also use fossil fuels. This hurts homebuyers, home builders, and many others in that it ignores fuel-specific efficiency benefits by having different base cases depending on what fuel is used for heating, air conditioning and hot water. **This means a different set of rules depending on fuel source.** This is technically wrong and sends grossly inaccurate signals to the marketplace on ratings and fuel choices. It also puts the code official in the very awkward position of hoping that some rating number actually meets the requirements and intent of the code.

The rating methodology also contains biased normalized gas efficiency improvement potentials relative to the "baseline" electricity efficiency improvement potential for heating and water heating (but not cooling) appliances. A good example of this key technical deficiency in the nMEUL rating method is its treatment of the reference electric heating and water heating technologies as equivalent to natural gas technologies from a home energy performance rating perspective, even though their primary energy efficiencies (as well as consumer cost and associated greenhouse gas emissions) are significantly different. The authors of the nMEUL methodology acknowledge this inequitable treatment and attempt to address it for higher efficiency options based on available market "potential" for efficiency improvement. As a result, the nMEUL method gives excess credit to higher efficiency natural gas heating and water heating options (but not gas cooling) relative to the gas reference design.

A simple example will show these points. Homes using NAECA minimum efficiency electric resistance storage water heating receive an identical HERS score as a NAECA minimum gas storage water heater, even though both the annual energy costs and primary energy consumption are much higher for the resistance water heater than for the gas water heater (typically twice as high). This "separate but equivalent" bias was never fixed in the nMEUL methodology as it was rolled out in the RESNET programs. The other bias negatively and disproportionately affects fossil fuel appliances at conventional efficiency levels, but the normalizing biases favor ultra-high efficiency gas technologies (such as gas heat pumps) at the expense of equivalent electric technologies.

So this isn't about gas versus electricity. It is about a single reference building where all constructions and fuels can be equally and equitably compared. It is about technical flaws in the "black box". It is about putting code officials at risk, along with builders and buyers, who want assurance of energy code compliance on a level playing field. **RE188 fails these most basic code equity requirements. Disapprove RE188.**

Public Comment 6:

Steve Rosenstock, representing Edison Electric Institute, requests Disapproval.

Commenter's reason: This proposal should be disapproved for the following reasons:

-It is a "backdoor" attempt to allow the use of HERS as a compliance path. In other actions, the code development committee specifically voted against the use of HERS as a compliance path. Disapproval would be consistent with the other committee actions.

-There is no information about the costs or energy savings to obtain an "ERI" of 51-55, depending on the climate zone.

-Under this alternative, a building that uses "no net purchased energy has an index of 0". As a result, a building could use 5 or 10 or 20 times the amount of energy of another building (that is much more energy efficient) as long as it has enough on-site renewable energy to "net out" the energy purchased from the grid. This type of credit for on-site renewable energy will not lead to more energy efficient homes, especially if the prices of renewable energy systems keep dropping at a dramatic pace. Energy production is not the same as energy efficiency, and building codes should not mix them together.

RE188-13
Final Action: AS AM AMPC____ D

RE190-13
R406 (New) (IRC N1106 (New))

Proposed Change as Submitted

Proponent: Robby Schwarz, EnergyLogic Inc., Representing EnergyLogic, Inc. (robby@nrglogic.com)

Add new text as follows:

SECTION R406 (N1106)
SIMULATED PERFORMANCE BY
INDEX SCORE METHOD
(PERFORMANCE)

R406.1 (N1106.1) Scope. The simulated performance index score method in Section R406 shall be used for determining that a building complies with this code. Such methods shall include a whole house energy analysis resulting in comparative index scores.

R406.2 (N1106.2) Mandatory requirements. Use of the simulated performance index score alternative method for compliance to this code shall require all of the following:

1. Design and construction of the building in compliance with sections in this code that are indicated as mandatory.
2. Inspections, required for the generation of an index score, are performed including, but not limited to, inspection, by the entity or person performing the energy analysis, of insulation systems and air barriers prior to concealment.
3. Supply and return ducts not completely inside the *building thermal envelope* are insulated with not less than an *R-value* of R-8.
4. Ductwork, that is either partially or completely within the thermal layer of the wall system of the *building thermal envelope,* shall have insulation of a *R-value* of not less than R-10 on the side of the duct that is away from the conditioned space. Where the duct is in a wall cavity and the R-10 insulation does not completely fill the cavity, the remaining cavity space shall be filled with insulation to the extent that the requirement for insulating the exterior wall of the building is met or the cavity space is completely filled, whichever is less. Ductwork, that is either partially or completely within the thermal layer of a floor system of the *building thermal envelope,* shall have insulation of a *R-value* of not less than R-19 on the side of the duct that is away from the conditioned space. Floor cavity insulation shall be installed in accordance with Section R402.2.7. Where the duct is in a floor cavity and the R-19 insulation does not completely fill the cavity, the remaining cavity space shall be filled with insulation to the extent that the requirement for insulating the floor system of the building is met or the cavity space is completely filled, which ever is less.

R406.3 (N1106.3) Performance-based compliance. The proposed building (*proposed design*) shall be complaint witht his code where the index score generated by the energy analysis is less than or equal to the index score of the *standard reference design*. The *standard reference design* index score shall be determined by analyzing a building of identical geometry to the proposed building that has the features indicated in the *standard reference design* column of Table R405.5.2(1). The index score of the proposed design shall be calculated in accordance with RESNET Standards.

R406.3.1 (N1106.3.1) Compliance software tools. Software tools used to determine code compliance by the simulated performance index score method shall be accredited by the Residential Energy Services Network organization. Documentation showing the software accreditation shall be provided to the *code official.*

R406.4 (N1106.4) Compliance report and other documentation. Compliance reports and other documentation shall be provided in accordance with Sections R406.4.1 through R406.4.3. A compliance report on the *proposed design* shall be submitted with the application for the building permit. Upon completion of the building, a compliance report based upon the as-built condition of the building, shall be submitted to the *code official* before a certificate of occupancy is issued by the *code official*. Batch sampling of buildings to determine energy code compliance for all buildings in the batch shall be prohibited.

Compliance reports shall include information in accordance with Sections R405.4.2.1 and R405.4.2.2. Where the *proposed design* of a building could be built on different sites where the cardinal direction orientation of the building on each site is different, compliance of the *proposed design* for the purposes of the application for the building permit, shall be based upon the worst case orientation worst case configuration, worst case building air leakage and worse case duct leakage. Such worse case parameters shall be used as inputs to the compliance software for energy analysis.

R406.4.1 (N1106.4.1) Compliance report for permit application. A compliance report submitted with the application for building permit shall include all of the following:

1. Building street address, or other building site identification.
2. A statement indicating that the *proposed design* complies with Section R405.3.
3. An inspection checklist documenting the building component characteristics of the *proposed design* as indicated in Table R405.5.2(1). The inspection checklist shall show results for both the *standard reference design* and the *proposed design* with all user inputs to the compliance software to generate the results.
4. A site-specific energy analysis report that is in compliance with Section R405.3
5. Name of the individual performing the analysis and generating the report.
6. Name and version of the compliance software tool.

R406.4.2 (N1106.4.2) Compliance report for certificate of occupancy. A compliance report submitted for obtaining the certificate of occupancy shall include all of the following:

1. Building street address, or other building site identification
2. A statement indicating that the as-built building complies with Section R405.3.
3. A certificate indicating that the building meets the requirements of the home energy rating system, HERS, index matrix of the RESNET Standards for code compliance and the energy saving features of the buildings.
4. A site-specific energy analysis report that is in compliance with Section R405.3.
5. Name of the individual performing the analysis and generating the report.
6. Name and version of the compliance software tool.

R406.4.3 (N1106.4.3) Additional documentation. Upon request by the *code official,* the following documentation shall be provided along with compliance reports to the *code official*:

1. Documentation of the building component characteristics of the *standard reference design.*
2. A certification statement, signed by the builder, that lists the *proposed design* building component characteristics indicated in Table R405.5.2(1).

R406.5 (N1106.5) Calculation procedure. Calculations of the energy performance of a building design shall be in accordance with Sections R406.5.1 and R406.5.2.

R406.5.1 (N1106.5.1) Identical methods. The *standard reference design* and *proposed design* shall be configured and analyzed using identical methods and techniques to generate a separate index score for each configuration of the buildingThe methods and techniques shall be in accordance with the home energy efficiency rating system, HERS, guidelines in the RESNET Standards.

R406.5.2 (N1106.5.2) Building design specifications. The *standard reference design* and *proposed design* shall be configured and analyzed as indicated in Table R405.5.2(1).

R406.6 (N1106.6) Calculation software tools. Calculation software shall be in accordance with Sections R406.6.1 through R406.6.3.

R406.6.1 (N1106.6.1) Minimum capabilities. Software tools shall be capable of calculating the index score of all building elements that differ between the *standard reference design* and the *proposed design.* The software shall have the following capabilities:

1. Computer generation of a report for the *standard reference design* using only the input for the *proposed design.* The calculation software shall prohibit the user from directly modifying the building component characteristics of the *standard reference design.*
2. Calculation of whole-building sizing , as a single *zone,* for the heating and cooling equipment in the *standard reference design* building in accordance with Section R403.6.
3. Calculations that account for the effects of indoor and outdoor temperatures and part-load ratios on the performance of heating, ventilating and air-conditioning equipment based on climate and equipment sizing.
4. Printing an inspection checklist for the *code official* that lists the characteristic of each of the *proposed design* components indicated in Table R405.5.2(1) that was used to determine compliance. The component characteristics shall include the performamce rating for the component such as, but not limited to, *R-value*, *U-factor*, *SHGC*, heating seasonal performance factor-HSPF, annual fuel utilization efficiency-AFUE, seasonal energy efficiency ratio-SEER and energy factor-EF.

R406.6.2 (N1106.6.2) Specific approval. Energy performance analysis tools that do not have accreditation by the Residential Energy Services Network organization shall comply with all other requirements of Section 406 and such tools shall only be used where the tool is *approved*.

R406.6.3 (N1106.6.3) Input values. Where calculations or software programs require input values that are not specified in Sections R402, R403, R404, R405 and R406, the input values used shall be only from *approved* sources.

Add new standard to Chapter 5 as follows:

Residential Energy Services Network, Inc.
P.O. Box 4561
Oceanside, CA 92052-4561

RESNET

RESNET Standards-2013 RESNET Mortgage Industry National Home Energy Rating Standards.

Reason: The current annual energy cost matrix for demonstrating code compliance is flawed and may demonstrate that a house that should pass the energy code, based on actual geometry and energy specifications, may not only because the energy costs in a region have changed. More and more jurisdiction and builders across the country are turning to performance index scores to represent the efficiency of a home and to demonstrate code compliance. Performance scores in and of themselves do not necessarily demonstrate code compliance. However, if the score is imposed on the existing structure of the code as this new alternative compliance path section 406 does, the score can reflect code compliance simply as a means of demonstrating passing and failing.

The current structure of the simulated performance path requires that the mandatory sections of the IECC be complied with, thus ensuring that house performance is maintained and that the score is only a measure to demonstrate compliance. In addition, this new section 406 utilizes the code reference home as described in table 405.5.2(1) and therefore energy code compliance utilizing this pathway will have a score that is variable for each qualified home. This is accomplished through the 2015 IECC Reference Design outlined in table 405.5.2(1). When the builder’s proposed designed home is configured with the IECC reference design features and modeled using approved software, the resulting score becomes the basis for the performance score target for that home.

The EPA Energy Star program and the DOE Challenge Home program utilize this same matrix for demonstrating qualification for their programs and have demonstrated that the compliance path described in this new section 406 will set the score target for the performance path equal to the performance that would be achieved if the prescriptive path was followed for each individual home.

In this way jurisdictions can avoid developing a fixed value, or performance index score, which really has no bearing on compliance and instead set the index score threshold required for energy code compliance at the same value that the same house would earn if configured to the IECC prescriptive path, as outlined in table 405.5.2(1) Reference Design.
** Footnote to Energy Star and DOE Challenge Home program documents

Jurisdiction, Builders, third party inspection companies and others are not clear of the process for completing and utilizing the simulated performance path. With all pathways through the energy code one must in essence declare how they will meet the intent of the code. For the prescriptive path they simply say they are going prescriptive, for the UA trade off path they submit a document such as a RESCheck report, and for the simulated performance path they must currently submit a document demonstrating that the annual energy cost of the proposed design are less than or equal to the same home if it were built with the reference design specification. It becomes unclear how one demonstrates that they have carried out their proposed design. The revisions proposed for this section clearly outlines a process by which the proposed design is submitted, inspections take place, and additional analysis is preformed to ensure that the proposed design was achieved or bettered for the purposes of compliance.

Field inspection, in order to create an accurate computer generated energy analysis, should be required for following reasons:

1. For production building a plan is often mastered and that one plan may be built over 100 times. To ensure that each house meets the performance analysis each home must be inspected.
2. Computer generated energy analysis' utilizes worst case configuration of the proposed design and requires evaluations and inputs that must be confirmed in the specific home that is built to ultimately determine if the actually built home meets the intent of the energy code. Examples of this are worst case air leakage and duct leakage numbers but also orientation, window square footage, number of bedrooms, and foundation type.
3. The reality is that houses built from a set of plans change. The actual built home may generally reflect the homes plans but window square footage, orientation, and even insulation and mechanical equipment are often different from what was proposed. The inspection process ensures that the energy analysis is address and site specific which ultimately ensures that the home that received its permit from the proposed design's energy analysis has carried out what they have proposed, which is to meet the intent of the code, even if each component of the home is not exactly the same as what was on the set of plans.

Cost Impact: The code change proposal will not increase the cost of construction more than is already done by the current section R405 simulated performance path.

Analysis: A review of the standards proposed for inclusion in the code, RESNET Standards, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28) will be posted on the ICC website on or before April 1, 2013.

R406T (NEW)-EC-SCHARZ.DOC

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: The standard proposed for inclusion in the code does not comply with CP#28, Section 3.6.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Robby Schwarz, EnergyLogic, Inc., requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

SECTION R406 (N1106)

SIMULATED PERFORMANCE ~~BY~~
INDEX SCORE ~~METHOD~~ ALTERNATIVE
(PERFORMANCE)

R406.1 (N1106.1) Scope. ~~The simulated performance index score method in Section R406 shall be used for~~ This section establishes criteria using simulated energy performance analysis resulting in an Index score used to ~~determining that a building complies~~ determine compliance with this code. ~~Such~~ This ~~methods~~ method shall include a whole house energy analysis resulting in comparative index scores unique to the reference home and proposed design.

R406.2 (N1106.2) Mandatory requirements. Use of the simulated performance index score alternative ~~method~~ ~~for compliance to this code~~ shall require all of the following:

1. Design and construction of the building in compliance with sections in this code that are indicated as mandatory.
2. Inspections, required for the generation of an index score, are performed including, but not limited to, inspection, by the entity or person performing the energy analysis, of insulation systems and air barriers prior to concealment.
3. Supply and return ducts not completely inside the *building thermal envelope* are insulated with not less than an *R-value* of R-8.
4. ~~Ductwork, that is either partially or completely within the thermal layer of the wall system of the *building thermal envelope,* shall have insulation of a *R-value* of not less than R-10 on the side of the duct that is away from the conditioned space. Where the duct is in a wall cavity and the R-10 insulation does not completely fill the cavity, the remaining cavity space shall be filled with insulation to the extent that the requirement for insulating the exterior wall of the building is met or the cavity space is completely filled, whichever is less. Ductwork, that is either partially or completely within the thermal layer of a floor system of the *building thermal envelope,* shall have insulation of a *R-value* of not less than R-19 on the side of the duct that is away from the conditioned space. Floor cavity insulation shall be installed in accordance with Section R402.2.7. Where the duct is in a floor cavity and the R-19 insulation does not completely fill the cavity, the remaining cavity space shall be filled with insulation to the extent that the requirement for insulating the floor system of the building is met or the cavity space is completely filled, whichever is less.~~

R406.3 (N1106.3) Performance-based compliance. The proposed building (*proposed design*) shall be ~~complaint~~ compliant with this code ~~where~~ when the index score generated by the energy analysis is less than or equal to the index score of the *standard reference design*. The *standard reference design* index score shall be determined by analyzing a building of identical geometry to the proposed building that has the features indicated in the *standard reference design* column of Table R405.5.2(1). The index score of the proposed design shall be calculated in accordance with RESNET standards Chapter #3 " National Energy Rating Technical Standard" and shall only analyze the building components described in Table R405.5.2(1) that are common to both homes.

R406.3.1 (N1106.3.1) Compliance software tools. Software tools used to determine code compliance by the simulated performance index score ~~method~~ shall be accredited by the Residential Energy Services Network organization or its equivalent. Documentation showing the software accreditation shall be provided to the *code official.*

R406.4 (N1106.4) Compliance report and other documentation. Compliance reports and other documentation shall be provided in accordance with Sections R406.4.1 through R406.4.3. A compliance report on the *proposed design* shall be submitted with the application for the building permit. Upon completion of the building, a compliance report based upon the as-built condition of the building, shall be submitted to the *code official* before a certificate of occupancy is issued ~~by the *code official*~~.

Compliance reports shall include information in accordance with Sections R405.4.2.1 and R405.4.2.2. Where the *proposed design* of a building could be built on different sites where the cardinal direction orientation of the building on each site is different, compliance of the *proposed design* for the purposes of the application for the building permit, shall be based upon the worst case orientation worst case configuration, worst case building air leakage and worse case duct leakage. Such worse case parameters shall be used as inputs to the compliance software for energy analysis.

R406.4.1 (N1106.4.1) Compliance report for permit application. A compliance report submitted with the application for building permit shall include all of the following:

1. Building street address, or other building site identification.
2. A statement indicating that the *proposed design* complies with Section R405.3.
3. An inspection checklist documenting the building component characteristics of the *proposed design* as indicated in Table R405.5.2(1). The inspection checklist shall show results for both the *standard reference design* and the *proposed design* with all user inputs to the compliance software to generate the results.
4. A site-specific energy analysis report that is in compliance with Section R405.3
5. Name of the individual performing the analysis and generating the report.
6. Name and version of the compliance software tool.

R406.4.2 (N1106.4.2) Compliance report for certificate of occupancy. A compliance report submitted for obtaining the certificate of occupancy shall include all of the following: Batch sampling of buildings to determine energy code compliance for all buildings in the batch shall be prohibited.

1. Building street address, or other building site identification
2. A statement indicating that the as-built building complies with Section R405.3.
3. A certificate indicating that the building meets the requirements of the ~~home energy rating system, HERS,~~ index score ~~matrix of the RESNET Standards~~ for code compliance and the energy saving features of the buildings.
4. A site-specific energy analysis report that is in compliance with Section R405.3.
5. Name of the individual performing the analysis and generating the report.
6. Name and version of the compliance software tool.

R406.4.3 (N1106.4.3) Additional documentation. Upon request by the *code official,* the following documentation shall be provided along with compliance reports to the *code official*:

1. Documentation of the building component characteristics of the *standard reference design.*
2. A certification ~~statement, signed by the builder,~~ that lists the *proposed design* building component characteristics indicated in Table R405.5.2(1).

R406.5 (N1106.5) Calculation procedure. Calculations of the energy performance of a building design shall be in accordance with Sections R406.5.1 and R406.5.2.

R406.5.1 (N1106.5.1) Identical methods. The *standard reference design* and *proposed design* shall be configured and analyzed using identical methods and techniques to generate a separate index score for each configuration of the building. The methods and techniques shall be in accordance with the home energy efficiency rating system, HERS, guidelines in the RESNET Standards <u>Chapter #3 " National Energy Rating Technical Standard"</u>.

R406.5.2 (N1106.5.2) Building design specifications. The *standard reference design* and *proposed design* shall be configured and analyzed as indicated in Table R405.5.2(1).

R406.6 (N1106.6) Calculation software tools. Calculation software shall be in accordance with Sections R406.6.1 through R406.6.3.

R406.6.1 (N1106.6.1) Minimum capabilities. Software tools shall be capable of calculating the index score of all building elements that differ between the *standard reference design* and the *proposed design.* The software shall have the following capabilities:

1. Computer generation of a report for the *standard reference design* using only the input for the *proposed design.* The calculation software shall prohibit the user from directly modifying the building component characteristics of the *standard reference design.*
2. Calculation of whole-building sizing , as a single *zone,* for the heating and cooling equipment in the *standard reference design* building in accordance with Section R403.6*.*
3. Calculations that account for the effects of indoor and outdoor temperatures and part-load ratios on the performance of heating, ventilating and air-conditioning equipment based on climate and equipment sizing.
4. Printing an inspection checklist for the *code official* that lists the characteristic of each of the *proposed design* components indicated in Table R405.5.2(1) that was used to determine compliance. The component characteristics shall include the performance rating for the component such as, but not limited to<u>;</u> *R-value*, *U-factor*, *SHGC*, heating seasonal performance factor-HSPF, annual fuel utilization efficiency-AFUE, seasonal energy efficiency ratio-SEER and energy factor-EF.

R406.6.2 (N1106.6.2) Specific approval. Energy performance analysis tools that do not have accreditation by the Residential Energy Services Network organization shall comply with all other requirements of Section 406 and such tools shall only be used where the tool is *approved* <u>by the code official</u>.

R406.6.3 (N1106.6.3) Input values. Where calculations or software programs require input values that are not specified in Sections R402, R403, R404, R405 and R406, the input values used shall be only from *approved* sources.

Commenter's Reason: The committee stated that the original proposal did not comply with CP#28 section 3.6. I believe that CP#28 Code Development Section 3.6 is being followed here with regards to RESNET Standard <u>Chapter #3 " National Energy Rating Technical Standard"</u> and software accreditation. Specifically section 3.6.3.1 outlines the ability to include reference to a proposed new standard.

- "The standard shall be completed and readily available prior to Final Action Consideration based on the cycle of code development which includes the proposed code change proposal.
- In order for a new standard to be considered for reference by the Code, such standard shall be submitted in at least a consensus draft form in accordance with Section 3.4.
- If a new standard is not submitted in at least draft form, the code change shall be considered incomplete and shall not be processed.
- Updating of standards without corresponding code text changes shall be accomplished administratively in accordance with Section 4.5.

In addition CP#28 states that the standard shall be developed and maintained through a consensus process such as ASTM or ANSI and does not state that is has to be ASTM or ANSI. RESNET has repetealy assured me that Chapter 3 will achieve ANSI approval before the final action hearing in October. However, even if the standard does not it was created utilizing a consensus process as outlined in CP#28.

The current annual energy cost matrix for demonstrating code compliance is flawed and may demonstrate that a house that should pass the energy code, based on actual geometry and energy specifications, may not only because the energy costs in a region have changed. More and more jurisdiction and builders across the country are turning to performance index scores to represent the efficiency of a home and to demonstrate code compliance. Performance scores in and of themselves do not necessarily demonstrate code compliance. However, if the score is imposed on the existing structure of the code as this new alternative compliance path section 406 does, the score can reflect code compliance simply as a means of demonstrating passing and failing.

The current structure of the simulated performance path requires that the mandatory sections of the IECC be complied with, thus ensuring that house performance is maintained and that the score is only a measure to demonstrate compliance. In addition, this new section 406 utilizes the code reference home as described in table 405.5.2(1) and therefore energy code compliance utilizing this pathway will have a score that is variable for each qualified home. This is accomplished through the 2015 IECC Reference Design outlined in table 405.5.2(1). When the builder's proposed designed home is configured with the IECC reference design features and modeled using approved software, the resulting score becomes the basis for the performance score target for that home.

The EPA Energy Star program and the DOE Challenge Home program utilize this same matrix for demonstrating qualification for their programs and have demonstrated that the compliance path described in this new section 406 will set the score target for the performance path equal to the performance that would be achieved if the prescriptive path was followed for each individual home. In this way jurisdictions can avoid developing a fixed value, or performance index score, which really has no bearing on compliance and instead set the index score threshold required for energy code compliance at the same value that the same house would earn if configured to the IECC prescriptive path, as outlined in table 405.5.2(1) Reference Design.

** Footnote to Energy Star and DOE Challenge Home program documents

Jurisdictions, Builders, third party inspection companies do not have a consistent process for completing and utilizing the simulated performance path. With all pathways through the energy code one must in essence declare how they will meet the intent of the code. For the prescriptive path they simply say they are going prescriptive, for the UA trade off path they submit a document such as a RESCheck report, and for the simulated performance path they must currently submit a document demonstrating that the annual energy cost of the proposed design are less than or equal to the same home if it were built with the reference design specification. It becomes unclear how one demonstrates that they have carried out their proposed design. The revisions proposed for this section clearly outlines a process by which the proposed design is submitted, inspections take place, and additional analysis is preformed to ensure that the proposed design was achieved or bettered for the purposes of compliance.
Field inspection, in order to create an accurate computer generated energy analysis, should be required for following reasons:

1. For production building a plan is often mastered and that one plan may be built repeatedly over time. To ensure that each house meets the performance analysis each home must be inspected.
2. Computer generated energy analysis' utilizes worst case configuration of the proposed design and requires evaluations and inputs that must be confirmed in the specific home that is built to ultimately determine if the actually built home meets the intent of the energy code. Examples of this are worst case air leakage and duct leakage numbers but also orientation, window square footage, number of bedrooms, and foundation type.
3. The reality is that houses built from a set of plans change. The actual built home may generally reflect the homes plans but window square footage, orientation, and even insulation and mechanical equipment are often different from what was proposed. The inspection process ensures that the energy analysis is accurate and site specific. Ultimately a home that received its permit from a proposed design's energy analysis must be inspected to meet the intent of the code, as component's of the home may not be exactly the same as what was on the set of plans.

CP#28 Code Development Section 3.6 is being followed here with regards to RESNET Standard Chapter #3 " National Energy Rating Technical Standard" and software accreditation. Specifically section 3.6.3.1 outlines the ability to include reference to a proposed new standard.

- "The standard shall be completed and readily available prior to Final Action Consideration based on the cycle of code development which includes the proposed code change proposal.
- In order for a new standard to be considered for reference by the Code, such standard shall be submitted in at least a consensus draft form in accordance with Section 3.4.
- If a new standard is not submitted in at least draft form, the code change shall be considered incomplete and shall not be processed.
- Updating of standards without corresponding code text changes shall be accomplished administratively in accordance with Section 4.5.

In addition CP#28 states that the standard shall be developed and maintained through a consensus process such as ASTM or ANSI and does not state that is has to be ASTM or ANSI.

RE190-13
Final Action: AS AM AMPC____ D

RE191-13
R402.1.2, R402.1.4 (IRC N1102.1.2, N1102.1.4)

Proposed Change as Submitted

Proponent: Darren Meyers, P.E., International Energy Conservation Consultants, LLC, consultant to Illinois Energy Office – Department of Commerce & Economic Opportunity (dmeyers@ieccode.com)

Revise as follows:

R402.1.2 (N1102.1.2) Sum of the *R*-values ~~computation~~ of insulation only. Only the insulation material used in layers, such as framing cavity insulation and continuous insulating sheathing, shall be summed to compute the component *R*-value. The manufacturer's settled *R*-value shall be used for blown or loose-fill insulation. Computed *R*-values shall not include an *R*-value for other building materials or air films or the thermal bridging effects of framing materials. Fenestration *U*-factors and SHGC requirements shall comply with Table R402.1.1.

R402.1.3 (N1102.1.3)*U*-factor alternative. An assembly with a *U*-factor equal to or less than that specified in Table R402.1.3 shall be permitted as an alternative to the *R*-value in Table R402.1.1.

R402.1.4 (N1102.1.4)Total UA alternative. If the total *building thermal envelope* UA (sum of *U*-factor times assembly area) is less than or equal to the total UA resulting from using the *U*-factors in Table R402.1.3 (multiplied by the same assembly area as in the proposed building), the building shall be considered in compliance with Table R402.1.1. The UA calculation shall be done using a method consistent with the ASHRAE *Handbook of Fundamentals* with *R*-values and *U*-factors consistent with ASHRAE 90.1 Normative Appendix 'A', and shall include the thermal bridging effects of framing materials in accordance with ASHRAE 90.1, Normative Appendix 'A'. The *U*-factor and SHGC requirements shall be met in addition to UA compliance.

Reason: The additions further clarify the intentions of the framers of the 2004 IECC Supplement Edition that Section R402.1.2 expressly prohibits the use of computed R-values of materials "other than insulation as tested" in accordance with the U.S. Federal Trade Commission R-value Rule (CFR Title 16, Part 460) [R303.1.4], or framing correction factors rooted in accepted engineering practice and the use of *approved* consensus standards. This specifically precludes Authorities Having Jurisdiction from employing Section R102 "Alternate Materials and Methods" to permit a solicitor to gain advantage outside the public forum and debate of the *ICC Code Development Process for the International Codes* (CP-28), or through an ICC-ES-facilitated, environmental criteria, to condone the use of *R*-values for other building materials or air films or the thermal bridging effects of framing materials under IECC Section R402.1.2.

Reference to the ASHRAE 90.1 Standard establishes neutral measurements of the efficiency of thermal envelope components, either "as tested" in accordance with the U.S. Federal Trade Commission R-value Rule (CFR Title 16, Part 460) [R303.1.4], including ASHRAE's research into established framing correction factors based on in-situ studies and accepted engineering practice.

In February 2012, at the conclusion of Illinois' required 9-month review process of the 2012 IECC, the Illinois Energy Code Advisory Council (ECAC) performed an analysis of four (4) alternative proposals submitted the Coalition for Fair Energy Codes (CFEC). American Plywood Association (APA) Trustees representing structural panel producing members of the APA, and including participation by the American Wood Council (AWC) formed the coalition in January 2011 to address the perceived notion that the 2012 IECC has the potential to reduce annual demand for OSB and plywood wall sheathing by approximately 20 percent, or close to 1 billion sq. ft. in a normal housing demand year.

The premise of these proposals was to seek alternative criteria for various wall configurations on the basis of equivalence with the prescriptive residential building thermal envelope R-value requirements of Table 402.1.1 using R-value computations and framing correction factors unrecognized by Section 402.1.1.

It was the conclusion of IECC LLC that CFEC methodologies made use of assumptions predisposed to product-bias or preferential treatment of particular materials, or assemblies of materials, and were not, in the end, neutral measurements of the efficiency of thermal envelope components, either "as tested" in accordance with the U.S. Federal Trade Commission R-value Rule (CFR Title 16, Part 460) [R303.1.4], or based on accepted engineering practice and the use of *approved* consensus standards.

It was also the conclusion of Illinois ECAC that the CFEC approach sought to re-argue a few of the unsuccessful public comments in opposition to code change proposals (EC13-09/10 and EC47-09/10) debated in public forum at the *ICC Code Development Process for the International Codes*.

On May 31, 2012, the ICC-Evaluation Service (ICC-ES) issued a peculiar and lesser publicized 30-day request for comment on a proposal for a new environmental criteria under the alternative criteria process entitled: *Environmental Criteria for Determination* *of Opaque Framed Wall Assemblies Deemed as Equivalent to the Prescriptive Building Thermal Envelope Tables of the International Energy Conservation Code®* (Subject EC115-0612-R1).

At hearings of the ICC-ES Environmental Committee, held October 1, 2012 at the Hilton St. Louis Frontenac, the Environmental Committee approved Subject EC115-1012-R2 by a vote of 4 -2 with one vote In Abstentia, despite clear language in Section 402.1.2 to the contrary, and Interpretations from ICC-ES's parent company, the International Code Council and its technical staff as follows:

2009 IECC, Section 402.1.2 - R-value Co

2009 IECC, Section 402.1.2 - R-value Co

2009 IECC, Sections 402.1.3-402.1.4 - U-

It was identified later that the proposal was solicited by Weyerhaeuser Company, one of the world's largest forest products companies, and a contributing company to CFEC.

In summary, without this change, the proposed Subject EC115, having been solicited by a proponent with bias, has the potential to create unnecessary loopholes and weaknesses in the *International Energy Conservation Code* (potentially dating to its former editions, circa IECC 2004). Furthermore, the proposed Subject EC115-0612-R1 could distance the IECC and Illinois (as with other states and U.S. territories adopting the 2009 or 2012 IECC Editions) from our Governors' assurances to the U.S. Department of Energy under Section 410 of the American Recovery and Reinvestment Act of 2009 (H.R. 1) (ARRA) as a condition of receiving funding for State Energy Programs (SEP).

Cost Impact: The code change proposal will not increase the cost of construction.

R402.1.2-EC-MEYERS

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: The values in ASHRAE 90.1 are written for commercial buildings. There are some inconsistencies in ASHRAE 90.1 related to residential construction.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Darren Meyers, P.E., International Energy Conservation Consultants, LLC, representing Illinois Energy Office – Department of Commerce & Economic Opportunity, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R402.1.2 Sum of the *R*-values of insulation only. Only the insulation material used in layers, such as framing cavity insulation and continuous insulating sheathing, shall be summed to compute the component *R*-value. The manufacturer's settled *R*-value shall be used for blown or loose-fill insulation. Computed *R*-values shall not include an *R*-value for other building materials or air films or the thermal bridging effects of framing materials. Fenestration and skylight *U*-factor~~s~~ and glazed fenestration SHGC requirements shall comply with Table R402.1.1.

R402.1.3 *U*-factor alternative. An assembly with a *U*-factor equal to or less than that specified in Table R402.1.3 shall be permitted as an alternative to the *R*-value in Table R402.1.1.

R402.1.4 Total UA alternative. If the total *building thermal envelope* UA (sum of *U*-factor times assembly area) is less than or equal to the total UA resulting from using the *U*-factors in Table R402.1.3 (multiplied by the same assembly area as in the proposed building), the building shall be considered in compliance with Table R402.1.1. The UA calculation shall be done using a method consistent with the ASHRAE *Handbook of Fundamentals* with *R*-values and *U*-factors consistent with ASHRAE 90.1 Normative Appendix 'A', and shall include the thermal bridging effects of framing materials in accordance with ASHRAE 90.1, Normative Appendix 'A'. The ~~U-factor and~~ glazed fenestration SHGC requirements of Table R402.1.1 shall be met in addition to UA compliance.

Commenter's Reason: At the Dallas Public Hearings, the "ONLY" reason the IECC-R Committee recommended RE191-13 for "Disapproval" was that the Committee believed, "the values in ASHRAE 90.1 [to be] written for commercial buildings [only], and … [there was concern that] there were some inconsistencies in ASHRAE 90.1 related to residential construction."

The material properties, methods of construction, and correction factors set forth in ASHRAE 90.1 are founded on accepted engineering practice and the universally-accepted physical and thermal properties of construction materials in the known physical world.

NOTE: ASHRAE, founded in 1894, is a preeminent building technology society with more than 54,000 members worldwide. The Society and its members focus on building systems, energy efficiency, indoor air quality, refrigeration and sustainability within the industry. Simply put, and solely with regard to the physical and thermal properties of construction materials, ASHRAE does not declare that heat transfers differently through a wall constructed of the "SAME" materials simply because the <<INSERT MATERIAL HERE>> (wood, steel, concrete, plastic, glazed fenestration, clay- or concrete-masonry) is installed in a one-story, single-family home (RESIDENTIAL), or a one-story, professional office building (COMMERCIAL), all else being equal.

Therefore, our proposal clarifies:

1) That reference to the ASHRAE *Handbook of Fundamentals* and ASHRAE Standard 90.1, an ICC-*approved* consensus document, establish neutral measurements of the efficiency of thermal envelope components, either "as tested" in accordance with the U.S. Federal Trade Commission R-value Rule (CFR Title 16, Part 460) [R303.1.4], or founded upon ASHRAE's own research, standards writing, publishing and investigations into accepted engineering practices;
2) That Section R402.1.2 (R-value Method) expressly prohibits the use of computed R-values of materials "other than insulation" in accordance with the U.S. Federal Trade Commission R-value Rule (CFR Title 16, Part 460) [R303.1.4], to manipulate IECC-endorsed R-value and U-factor compliance methods;
3) That Section R401.2 (R-value Method) expressly prohibits the use of framing correction factors and air films to manipulate IECC-endorsed R-value and U-factor compliance methods;
4) That Sections R402.1.3 and 402.1.4 (U-factor and UA Methods, respectively) expressly prohibit the use of any material property including, but not limited to, framing correction factors, air films, R-Values and U-factors "other than those found in the ASHRAE *Handbook of Fundamentals* and the pre-calculated *R*-values and *U*-factors of ASHRAE 90.1 Normative Appendix 'A' to manipulate IECC-endorsed R-value and U-factor compliance methods; and that the SHGC requirements of glazed fenestration also be considered; and
5) That Section R102 "Alternate Materials and Methods," ICC-ES-facilitated reports or environmental criteria shall not be used by homebuilders, design professionals, or Authorities Having Jurisdiction to manipulate IECC-endorsed R-value and U-factor compliance methods.

R202, R403.5, R403.5.2 (New) through R403.5.7 (New) , Table R403.5.6(1) (New) (IRC Table N1103.5.6(1)(New), Table R403.5.6(2) (New)

Proposed Change as Submitted

Proponent: Darren Meyers, P.E., International Energy Conservation Consultants, LLC, consultant to Illinois Energy Office – Department of Commerce & Economic Opportunity (dmeyers@ieccode.com)

Revise as follows:

SECTION R202
GENERAL DEFINITIONS

LOCAL EXHAUST. An exhaust system that uses one or more fans to exhaust air from a specific room or rooms within a dwelling.

WHOLE HOUSE MECHANICAL VENTILATION SYSTEM. An exhaust system, supply system, or combination thereof that is designed in accordance with Section R403.5 to mechanically exchange indoor air for outdoor air when operating continuously or through a programmed intermittent schedule to satisfy the whole house ventilation rate. Outdoor air intakes and exhausts shall have automatic or gravity dampers that close when the ventilation system is not operating.

Revise as follows:

R403.5 Mechanical ventilation (Mandatory). The building shall be provided with ventilation that meets the requirements of ~~the *International Residential Code*~~ this section or for Group R-2, R-3 and R-4 buildings, ventilation that meets the requirements of the *International Mechanical Code*, as applicable. Outdoor air intakes and exhausts shall have automatic or gravity dampers that close when the ventilation system is not operating.

R403.5.1 Whole-house mechanical ventilation system fan efficacy. Mechanical ventilation system fans shall meet the efficacy requirements of Table R403.5.1.

Exception: Where mechanical ventilation fans are integral to tested and listed HVAC equipment, they shall be powered by an electronically commutated motor.

R403.5.2 Recirculation of air. Exhaust air from bathrooms and toilet rooms shall not be recirculated within a residence or to another *dwelling unit* and shall be exhausted directly to the outdoors. Exhaust air from bathrooms and toilet rooms shall not discharge into an *attic*, crawl space or other areas inside the building.

R403.5.3 Whole-house mechanical ventilation system. Whole-house mechanical ventilation systems shall be designed in accordance with Sections R403.5.4 through R403.5.6.

R403.5.4 System design. The whole-house ventilation system shall consist of one or more supply or exhaust fans, or a combination of such, and associated ducts and controls. Local exhaust or supply fans are permitted to serve as such a system. Outdoor air ducts connected to the return side of an air handler shall be considered to provide supply ventilation.

R403.5.5 System controls. The whole-house mechanical ventilation system shall be provided with controls that enable manual override.

R403.5.6 Mechanical ventilation rate. The whole house mechanical ventilation system shall provide outdoor air at a continuous rate of not less than that determined in accordance with Table R403.5.6(1).

> **Exception:** The whole-house mechanical ventilation system is permitted to operate intermittently where the system has controls that enable operation for not less than 25-percent of each 4-hour segment and the ventilation rate prescribed in Table R403.5.6(1) is multiplied by the factor determined in accordance with Table R403.5.6(2).

TABLE R403.5.6(1)
CONTINUOUS WHOLE-HOUSE MECHANICAL VENTILATION SYSTEM AIRFLOW RATE REQUIREMENTS

DWELLING UNIT FLOOR AREA (square feet)	NUMBER OF BEDROOMS				
	0 – 1	2 – 3	4 – 5	6 – 7	> 7
	Airflow in CFM				
< 1,500	30	45	60	75	90
1,501 – 3,000	45	60	75	90	105
3,001 – 4,500	60	75	90	105	120
4,501 – 6,000	75	90	105	120	135
6,001 – 7,500	90	105	120	135	150
> 7,500	105	120	135	150	165

For SI: 1 square foot = 0.0929 m_2, 1 cubic foot per minute = 0.0004719 m_3/s.

[RMP] TABLE R403.5.6(2) (Table N1103.5.6(1))

INTERMITTENT WHOLE-HOUSE MECHANICAL VENTILATION RATE FACTORS[a, b]

RUN-TIME PERCENTAGE IN EACH 4-HOUR SEGMENT	25%	33%	50%	66%	75%	100%
Factor[a]	4	3	2	1.5	1.3	1.0

a. For ventilation system run time values between those given, the factors are permitted to be determined by interpolation.
b. Extrapolation beyond the table is prohibited.

R403.5.7 Local exhaust rates. *Local exhaust* systems shall be designed to have the capacity to exhaust the minimum air flow rate determined in accordance with Table R403.5.7.

TABLE R403.5.7
MINIMUM REQUIRED LOCAL EXHAUST RATES FOR ONE- AND TWO-FAMILY DWELLINGS

AREA TO BE EXHAUSTED	EXHAUST RATES
Kitchens	100 cfm intermittent or 25 cfm continuous
Bathrooms-Toilet Rooms	Mechanical exhaust capacity of 50 cfm intermittent or 20 cfm continuous

For SI: 1 cubic foot per minute = 0.0004719 m_3/s.

Reason: As of January 1, 2013, the state of Illinois has made effective the 2012 Illinois Energy Conservation Code (2012 ICC IECC) through the *Illinois Energy Efficient Building Act* [20 ILCS 3125], similar to what the States of Maryland and Minnesota, and various jurisdictions in Arizona (Glendale, Peoria, Pima County), Colorado (Vail), Kansas (Overland Park), Missouri (Kansas City), New Hampshire (Durham) and Texas (El Paso) have done … *[[Not an all-inclusive list.]]*

For Illinois, The Act takes precedence over home-rule declarations in our state; even those of the City of Chicago. However, The Act does not usurp municipal or county authority to adopt a building code, more specifically the *International Residential Code* (IRC). As such, and over Illinois' required 9-month review process of the 2012 IECC, the Illinois Energy Code Advisory Council (ECAC) concluded that a technical infeasibility would amount from adopting energy efficiency codes like the 2012 IECC which require whole-house mechanical ventilation, coupled with existing and/or delayed municipal ordinances tied to editions of the IRC prior to 2012. The 2012 IRC is the only edition of the IRC which provides a whole-house mechanical ventilation solution for homes with air leakage rates less than 5 ACH50.

Accordingly for Illinois adoption of the 2012 IECC, and we suspect other states and municipalities considering 2015 IECC adoptions, the economy, coupled with an overall lack of political will and municipal indifference to the mandatory residential sprinkler requirements of the 2009 and 2012 editions of the IRC, a disconnect results for new homes subject to 2012 IECC for air tightness (5 ACH50 or less)—thus, whole-house mechanical ventilation—and antiquated IRC editions which have not kept pace with this approach and the resultant whole-house mechanical ventilation solution.

In summary, this change merely reproduces the appropriate technical provisions and appropriate code development committee maintenance duties to the 2015 IECC.

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis. The provisions in this proposal are duplicated from Section M1507.3. The proponent chooses to propose this change only to the IECC-R, and not Chapter 11 of the IRC, to avoid possible divergence of matching provisions already present within the IRC – For example, Section M1507.3 of the IRC.

R403.5-EC-MEYERS

Committee Action Hearing Results

Committee Action: Disapproved

Committee Reason: This code change proposal is a mechanical issue that belongs in the IRC-Mechanical Part or the IMC, not in the energy code. If local jurisdictions are having difficulty with this, then the issue needs to be solved locally.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Darren Meyers, P.E., International Energy Conservation Consultants, LLC, representing Illinois Energy Office – Department of Commerce & Economic Opportunity, requests Approval as Submitted.

Commenter's Reason: At the Dallas Public Hearings the "ONLY" reason the IECC-R Committee recommended RE192 for "Disapproval" was that the Committee believed the, "… proposal to be a mechanical issue that belongs in the IRC-Mechanical Part or the IMC, not in the energy code."

We are asking for "approval As Submitted," to simply and solely reproduce the appropriate technical provisions and code development maintenance duties for residential mechanical ventilation within the body of the 2015 IECC because:

1) States, regions, counties and local municipalities adopt energy codes (like the IECC) independently of residential construction codes (like the IRC). More often than not, the 2012 and 2015 Editions of the IRC, inclusive of the poison-pill that is "Mandatory Residential Sprinklers," are not adopted or overlooked as a result.
2) The 2012 and 2015 Editions of the IRC are the only editions of the IRC to require whole-house mechanical ventilation when the air leakage rate of the home is ≤ 5 ACH_{50}. The 2012 and 2015 Editions of the IECC are the only Editions of the IECC to require the air leakage rate of one- and two-family dwellings and townhouses to test-out at ≤ 5 ACH_{50}.
3) **IMPORTANT**: Construction of a home to the 2006 or 2009 Editions of the IRC in a State or jurisdiction that adopts the 2012 IECC or 2015 IECC CC will not provide adequate ventilation for human health. This proposal addresses this circumstance.

NOTE, this isn't the first time Mechanical or Plumbing provisions appear in the IECC:

4) Equipment load calculations to ACCA Manual J and selection and sizing to ACCA Manual S are mechanical issues, yet provisions exist in the IECC (**Section R403.6 Equipment Sizing**), because the implications of improper load calculation and incorrect equipment selection on building performance is within the scope of the energy code;
5) Duct insulation, duct leakage performance testing, and sealing are mechanical issues, yet provisions exist in the IECC (**Sections R403.2.1 Duct Insulation, R403.2.2 Duct Sealing,** and **R403.2.3 Building cavities**), because the implications of duct construction, insulation, and sealing on building performance is within the scope of the energy code;
6) Equipment efficiency is a mechanical issue, yet provisions exist in the IECC (**Section R405.3 Performance-based compliance**), because the implications of inadequate equipment performance on building design is within the scope of the energy code;

7) Piping insulation is both a mechanical and plumbing issue, yet provisions exist in the IECC (**Sections R403.3 Mechanical system piping insulation and R403.4.2 Hot water pipe insulation**), because the implications of inadequate piping insulation on building performance is within the scope of the energy code;

We ask for your support of "approval As Submitted," to simply and solely reproduce the appropriate technical provisions and code development maintenance duties for residential mechanical ventilation within the body of the 2015 IECC.

Public Comment 2:

Mike Moore, Newport Ventures, representing Broan-NuTone, requests Approval as Modified by this Public Comment.

Replace the proposal as follows:

R403.5 Mechanical ventilation (Mandatory). The building shall be provided with <u>mechanical</u> ventilation that meets the requirements of the *International Residential Code* or the *International Mechanical Code*, as applicable. Outdoor air intakes and exhausts shall have automatic or gravity dampers that close when the ventilation system is not operating.

Commenter's Reason: The original proposal sought to bring clarification to the mechanical ventilation requirements of the IRC and IMC that are referenced within this section. I would agree with the committee's disapproval on the basis that the specific mechanical ventilation requirements belong in the IMC and Chapter 15 of the IRC.

However, the clarification that does need to be made in this section is that the section with the heading of "Mechanical ventilation" really is referring to mechanical ventilation when it mentions "ventilation" within its subtext. As obvious as this sounds, this section is often misinterpreted because the word "mechanical" is not restated within the subtext. This change clears up this confusion

RE192-13

Final Action: AS AM AMPC____ D

RE193 – 13
R202 (IRC N1101.9), 403.10 (New) (IRC N1103.10 (New))

Proposed Change as Submitted

Proponent: Darren Meyers, P.E., International Energy Conservation Consultants, LLC, consultant to Illinois Energy Office – Department of Commerce & Economic Opportunity (dmeyers@ieccode.com)

Revise as follows:

SECTION R202 (N1101.9)
GENERAL DEFINITIONS

COMBUSTION APPLIANCE ZONE (CAZ). A contiguous air volume within a building that contains a containing a Category I or II atmospherically-vented appliance or a Category III or IV direct vent or integral vent appliance drawing combustion air from inside of the building or dwelling unit. The CAZ includes but is not limited to, a mechanical closet, mechanical room, or the main body of a house or dwelling unit.

DRAFT. The pressure difference existing between the *appliance* or any component part and the atmosphere, that causes a continuous flow of air and products of *combustion* through the gas passages of the *appliance* to the atmosphere.

Mechanical or induced draft. The pressure difference created by the action of a fan, blower or ejector that is located between the *appliance* and the *chimney* or vent termination.

Natural draft. The pressure difference created by a vent or *chimney* because of its height, and the temperature difference between the *flue gases* and the atmosphere.

SPILLAGE. Combustion gases emerging from an appliance or venting system into the combustion appliance zone during burner operation.

Add new text as follows:

R403.10 (N1103.10) Worst-case testing of atmospheric venting systems. Buildings or dwelling units containing a Category I or II atmospherically-vented appliance; or a Category III or IV direct vent or integral vent appliance drawing combustion air from inside of the building or dwelling unit, shall have the Combustion Appliance Zone (CAZ) tested for spillage, acceptable draft and carbon monoxide (CO) in accordance with this Section. Where required by the *code official*, testing shall be conducted by an *approved* third party. A written report of the results of the test shall be signed by the party conducting the test and provided to the *code official*. Testing shall be performed at any time after creation of all penetrations of the *building thermal envelope* and prior to final inspection.

> **Exception:** Buildings or dwelling units containing only Category III or IV direct vent or integral vent appliances that do not draw combustion air from inside of the building or dwelling unit.

The enumerated test procedure below shall be followed during test

1. Set all combustion appliances to the pilot setting or turn off the service disconnects for all combustion appliances. Close all exterior doors and windows and the fireplace damper. With the building or dwelling unit in this configuration, measure and record the baseline ambient pressure inside the building or dwelling unit CAZ. Compare the baseline ambient pressure of the CAZ to that of the outside ambient pressure, and record the difference (Pa).
2. Establish worst case by turning on the *clothes dryer* and all exhaust fans. Close all interior doors that make the CAZ pressure more negative. Turn on the air handler, where present, and leave on if as a result, the pressure in the CAZ becomes more negative. Check interior door positions again, closing only the interior doors that make the CAZ pressure more negative. Measure net change in pressure from the CAZ to outdoor ambient pressure, correcting for the base ambient pressure inside the home. Record "worst case depressurization" pressure and compare to Table R403.10(1).

Where CAZ depressurization limits are exceeded under worst-case conditions according to Table R403.10(1), additional combustion air must be provided or other modifications to building air-leakage performance or exhaust appliances such that depressurization is brought within the limits prescribed in Table R403.10(1).

3. Measure worst case spillage, acceptable draft, and carbon monoxide (CO) by firing the fuel-fired appliance with the smallest Btu capacity first.

   a. Test for spillage at the draft diverter with a mirror or smoke puffer. An appliance that continues to spill flue gases for more than 60 seconds fails the spillage test.
   b. Test for CO measuring undiluted flue gases, in the throat or flue of the appliance using a digital gauge in parts per million (ppm) at the 10 minute mark. Record CO ppm readings to be compared with Table R403.10(3) upon completion of Step 4. Where the spillage test fails under worst case, go to Step 4.
   c. Where spillage ends within 60 seconds, test for acceptable draft in the connector no less than one foot, but no more than two feet downstream of the draft diverter. Record draft pressure and compare to Table R403.10(2).
   d. Fire all other connected appliances simultaneously and test again at the draft diverter of each appliance for spillage, CO and acceptable draft using procedures 3a through 3c.

4. Measure spillage, acceptable draft, and carbon monoxide (CO) under natural conditions—without *clothes dryer* and exhaust fans on—according to the procedure outlined in Step 3, measuring the net change in pressure from worst case condition in Step 3 to natural in the CAZ to confirm the worst case depressurization taken in Step 2. Repeat the process for each appliance, allowing each vent system to cool between tests.
5. Monitor indoor ambient CO in the breathing zone continuously during testing, and abort the test where indoor ambient CO exceeds 35 ppm by turning off the appliance, ventilating the space, and evacuating the building. The CO problem must be corrected prior to completing combustion safety diagnostics.
6. Make recommendations based on test results and the retrofit action prescribed in Table R40310.3).

< 10	-2.5
10 – 90	(Outside Temperature ÷ 40) – 2.75
> 90	-0.5

For SI: 6894.76 Pa = 1.0 psi.

TABLE R403.10(3) (N1103.10(3))
ACCEPTABLE DRAFT TEST CORRECTION

CARBON DIOXIDE LEVEL (ppm)	**AND OR**	**SPILLAGE AND ACCEPTABLE DRAFT TEST RESULTS**	**RETROFIT ACTION**
0 – 25	and	Passes	Proceed with work
25 < x ≤ 100	and	Passes	Recommend that CO problem be resolved
25 < x ≤ 100	and	Fails in worst case only	Recommend an appliance service call and repairs to resolve the problem
100 < x ≤ 400	or	Fails under natural conditions	**Stop!** Work shall not proceed until appliance is serviced and problem resolved
> 400	and	Passes	**Stop!** Work shall not proceed until appliance is serviced and problem resolved
> 400	and	Fails under any condition	**Emergency!** Shut off fuel to appliance and call for service immediately

Reason: Energy efficiency improvements often have a direct impact on the building pressure boundary affecting the safe operation of combustion equipment. Routinely sealing up buildings without looking at the combustion equipment risk sooner or later will result in harming someone with back-drafted flue gas conditions.

This proposal is intended to provide clear guidance to builders, code officials and home performance contractors for worst-case testing of atmospheric venting systems where air-sealing techniques and air-leakage performance testing requirements of the 2015 IECC are employed. Worst case testing is used by home performance contractors to identify problems that weaken draft and restrict combustion air. Worst case vent testing uses the home's exhaust fans, air handling appliances and chimneys to create worst case depressurization in the combustion appliance zone (CAZ).

Language that is proposed for R403.10 is basically a distilled version of predominant combustion safety test procedures for atmospherically vented appliances found in readily available home performance programs across the country, such as EPA's Healthy Indoor Environments Protocols, EPA's Home Performance with Energy Star, DOE's Workforce Guidelines for Home Energy Upgrades, HUD's Community Development Block Grants and Weatherization Assistance Programs, BPI's Technical Standards for the Building Analyst Professional, and RESNET's Interim Guidelines for Combustion Appliance Testing and Writing Work Scopes. The proposed language is intended to take the combustion safety test procedures that are used most commonly by these home performance, weatherization, and beyond code programs, and reduce them to their simplest and most straightforward form for the purpose of combustion safety in IECC compliance and field assessment through the use of building diagnostic tools.

For Illinois, our required 9-month review process of the 2012 IECC resulted in the Illinois Energy Code Advisory Council (ECAC) concluding that reductions in building envelope air-leakage from 7 ACH50 (2009 IECC) to 5 ACH50 was a more conservative approach to take for the construction industry in our state than the more "aggressive" 7 ACH50 (2009 IECC) to 3 ACH50, as is the case with the 2012 IECC for Climate Zones 4 and 5.

While part of ECAC's consideration was the decision to insert the 2012 IRC's whole-house ventilation provisions based on ASHRAE 62.2 directly into the Illinois Energy Conservation Code, this proposal recognizes that under certain conditions, perhaps even those of forthcoming 2015 IECC, reduced natural air-leakage coupled with the installation of atmospheric combustion appliances will reduce air exchange to the outside with the potential to contribute to poor indoor air quality and possible health problems due to spillage, inadequate draft, or carbon monoxide concerns.

We suspect other states and municipalities considering 2015 IECC adoptions will seek similar building diagnostic-based solutions to combustion safety.

Cost Impact: The code change proposal will increase the cost of construction.

RE193-13

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

R403.10 (NEW)-EC-MEYERS

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: Addressment of the issue of combustion air issues is a mechanical code issue, rather than an energy code issue. The IECC committee is not qualified to deal with this issue.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Darren Meyers, P.E., International Energy Conservation Consultants, LLC, consultant to Illinois Energy Office – Department of Commerce & Economic Opportunity requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

IECC-R: Renumber definitions and sections of proposed text as a new "informative" Appendix A. The text of the new Appendix A would read as follows:

APPENDIX A
RECOMMENDED PROCEDURE FOR WORST-CASE TESTING OF ATMOSPHERIC VENTING SYSTEMS UNDER R402.4 OR R405 CONDITIONS ≤ 5ACH$_{50}$
(This appendix is informative and is not part of the code.)

SECTION A101
SCOPE

A101.1 General. This appendix is intended to provide guidelines for worst-case testing of atmospheric venting systems. Worst case testing is recommended to identify problems that weaken draft and restrict combustion air.

SECTION A202
GENERAL DEFINITIONS

COMBUSTION APPLIANCE ZONE (CAZ). A contiguous air volume within a building that contains a containing a Category I or II atmospherically-vented appliance or a Category III or IV direct vent or integral vent appliance drawing combustion air from inside of the building or dwelling unit. The CAZ includes but is not limited to, a mechanical closet, mechanical room, or the main body of a house or dwelling unit.

DRAFT. The pressure difference existing between the *appliance* or any component part and the atmosphere, that causes a continuous flow of air and products of *combustion* through the gas passages of the *appliance* to the atmosphere.

Mechanical or induced draft. The pressure difference created by the action of a fan, blower or ejector that is located between the *appliance* and the *chimney* or vent termination.

Natural draft. The pressure difference created by a vent or *chimney* because of its height, and the temperature difference between the *flue gases* and the atmosphere.

SPILLAGE. Combustion gases emerging from an appliance or venting system into the combustion appliance zone during burner operation.

A301.1 ~~R403.10~~ Worst-case testing of atmospheric venting systems. Buildings or dwelling units containing a Category I or II atmospherically-vented appliance; or a Category III or IV direct vent or integral vent appliance drawing combustion air from inside of the building or dwelling unit, shall have the Combustion Appliance Zone (CAZ) tested for spillage, acceptable draft and carbon monoxide (CO) in accordance with this Section. Where required by the *code official*, testing shall be conducted by an *approved* third party. A written report of the results of the test shall be signed by the party conducting the test and provided to the *code official*. Testing shall be performed at any time after creation of all penetrations of the *building thermal envelope* and prior to final inspection.

> **Exception:** Buildings or dwelling units containing only Category III or IV direct vent or integral vent appliances that do not draw combustion air from inside of the building or dwelling unit.

The enumerated test procedure below shall be followed during test

1. Set all combustion appliances to the pilot setting or turn off the service disconnects for all combustion appliances. Close all exterior doors and windows and the fireplace damper. With the building or dwelling unit in this configuration, measure and record

the baseline ambient pressure inside the building or dwelling unit CAZ. Compare the baseline ambient pressure of the CAZ to that of the outside ambient pressure, and record the difference (Pa).

2. Establish worst case by turning on the *clothes dryer* and all exhaust fans. Close all interior doors that make the CAZ pressure more negative. Turn on the air handler, where present, and leave on if as a result, the pressure in the CAZ becomes more negative. Check interior door positions again, closing only the interior doors that make the CAZ pressure more negative. Measure net change in pressure from the CAZ to outdoor ambient pressure, correcting for the base ambient pressure inside the home. Record "worst case depressurization" pressure and compare to Table A301.1(1) ~~R403.10(1)~~.

   Where CAZ depressurization limits are exceeded under worst-case conditions according to Table A301.1(1) ~~R403.10(1)~~, additional combustion air must be provided or other modifications to building air-leakage performance or exhaust appliances such that depressurization is brought within the limits prescribed in Table A301.1(1) ~~R403.10(1)~~.

3. Measure worst case spillage, acceptable draft, and carbon monoxide (CO) by firing the fuel-fired appliance with the smallest Btu capacity first.

   a. Test for spillage at the draft diverter with a mirror or smoke puffer. An appliance that continues to spill flue gases for more than 60 seconds fails the spillage test.
   b. Test for CO measuring undiluted flue gases, in the throat or flue of the appliance using a digital gauge in parts per million (ppm) at the 10 minute mark. Record CO ppm readings to be compared with Table A301.1(3) ~~R403.10(3)~~ upon completion of Step 4. Where the spillage test fails under worst case, go to Step 4.
   c. Where spillage ends within 60 seconds, test for acceptable draft in the connector no less than one foot, but no more than two feet downstream of the draft diverter. Record draft pressure and compare to Table A301.1(2) ~~R403.10(2).~~
   d. Fire all other connected appliances simultaneously and test again at the draft diverter of each appliance for spillage, CO and acceptable draft using procedures 3a through 3c.

4. Measure spillage, acceptable draft, and carbon monoxide (CO) under natural conditions—without *clothes dryer* and exhaust fans on—according to the procedure outlined in Step 3, measuring the net change in pressure from worst case condition in Step 3 to natural in the CAZ to confirm the worst case depressurization taken in Step 2. Repeat the process for each appliance, allowing each vent system to cool between tests.
5. Monitor indoor ambient CO in the breathing zone continuously during testing, and abort the test where indoor ambient CO exceeds 35 ppm by turning off the appliance, ventilating the space, and evacuating the building. The CO problem must be corrected prior to completing combustion safety diagnostics.
6. Make recommendations based on test results and the retrofit action prescribed in Table A301.1(3) ~~R403.10(3).~~

Public Comment 2:

Darren Meyers, P.E., International Energy Conservation Consultants, LLC, consultant to Illinois Energy Office – Department of Commerce & Economic Opportunity requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

IRC: Renumber definitions and sections of proposed text as a new "informative" Appendix R. The text of the new Appendix R would read as follows:

APPENDIX R
RECOMMENDED PROCEDURE FOR WORST-CASE TESTING OF ATMOSPHERIC VENTING SYSTEMS UNDER N1102.4 OR N1105 CONDITIONS ≤ $5ACH_{50}$
(This appendix is informative and is not part of the code.)

SECTION AR101
SCOPE

AR101.1 General. This appendix is intended to provide guidelines for worst-case testing of atmospheric venting systems. Worst case testing is recommended to identify problems that weaken draft and restrict combustion air.

SECTION AR202 ~~(N1101.9)~~
GENERAL DEFINITIONS

COMBUSTION APPLIANCE ZONE (CAZ). A contiguous air volume within a building that contains a containing a Category I or II atmospherically-vented appliance or a Category III or IV direct vent or integral vent appliance drawing combustion air from inside of the building or dwelling unit. The CAZ includes but is not limited to, a mechanical closet, mechanical room, or the main body of a house or dwelling unit.

DRAFT. The pressure difference existing between the *appliance* or any component part and the atmosphere, that causes a continuous flow of air and products of *combustion* through the gas passages of the *appliance* to the atmosphere.

Mechanical or induced draft. The pressure difference created by the action of a fan, blower or ejector that is located between the *appliance* and the *chimney* or vent termination.

Natural draft. The pressure difference created by a vent or *chimney* because of its height, and the temperature difference between the *flue gases* and the atmosphere.

SPILLAGE. Combustion gases emerging from an appliance or venting system into the combustion appliance zone during burner operation.

AR301.1 ~~**N1103.10**~~ **Worst-case testing of atmospheric venting systems.** Buildings or dwelling units containing a Category I or II atmospherically-vented appliance; or a Category III or IV direct vent or integral vent appliance drawing combustion air from inside of the building or dwelling unit, shall have the Combustion Appliance Zone (CAZ) tested for spillage, acceptable draft and carbon monoxide (CO) in accordance with this Section. Where required by the *code official*, testing shall be conducted by an *approved* third party. A written report of the results of the test shall be signed by the party conducting the test and provided to the *code official*. Testing shall be performed at any time after creation of all penetrations of the *building thermal envelope* and prior to final inspection.

> **Exception:** Buildings or dwelling units containing only Category III or IV direct vent or integral vent appliances that do not draw combustion air from inside of the building or dwelling unit.

The enumerated test procedure below shall be followed during test

1. Set all combustion appliances to the pilot setting or turn off the service disconnects for all combustion appliances. Close all exterior doors and windows and the fireplace damper. With the building or dwelling unit in this configuration, measure and record the baseline ambient pressure inside the building or dwelling unit CAZ. Compare the baseline ambient pressure of the CAZ to that of the outside ambient pressure, and record the difference (Pa).

2. Establish worst case by turning on the *clothes dryer* and all exhaust fans. Close all interior doors that make the CAZ pressure more negative. Turn on the air handler, where present, and leave on if as a result, the pressure in the CAZ becomes more negative. Check interior door positions again, closing only the interior doors that make the CAZ pressure more negative. Measure net change in pressure from the CAZ to outdoor ambient pressure, correcting for the base ambient pressure inside the home. Record "worst case depressurization" pressure and compare to Table AR301.1(1) ~~N1103.10(1)~~.

   Where CAZ depressurization limits are exceeded under worst-case conditions according to Table AR301.1(1) ~~N1103.10(1)~~, additional combustion air must be provided or other modifications to building air-leakage performance or exhaust appliances such that depressurization is brought within the limits prescribed in AR301.1(1) ~~R403.10(1)~~.

3. Measure worst case spillage, acceptable draft, and carbon monoxide (CO) by firing the fuel-fired appliance with the smallest Btu capacity first.

   a. Test for spillage at the draft diverter with a mirror or smoke puffer. An appliance that continues to spill flue gases for more than 60 seconds fails the spillage test.
   b. Test for CO measuring undiluted flue gases, in the throat or flue of the appliance using a digital gauge in parts per million (ppm) at the 10 minute mark. Record CO ppm readings to be compared with Table AR301.1(3) ~~R403.10(3~~) upon completion of Step 4. Where the spillage test fails under worst case, go to Step 4.
   c. Where spillage ends within 60 seconds, test for acceptable draft in the connector no less than one foot, but no more than two feet downstream of the draft diverter. Record draft pressure and compare to Table AR301.1(2) ~~N1103.10(2)~~.
   d. Fire all other connected appliances simultaneously and test again at the draft diverter of each appliance for spillage, CO and acceptable draft using procedures 3a through 3c.

4. Measure spillage, acceptable draft, and carbon monoxide (CO) under natural conditions—without *clothes dryer* and exhaust fans on—according to the procedure outlined in Step 3, measuring the net change in pressure from worst case condition in Step 3 to natural in the CAZ to confirm the worst case depressurization taken in Step 2. Repeat the process for each appliance, allowing each vent system to cool between tests.
5. Monitor indoor ambient CO in the breathing zone continuously during testing, and abort the test where indoor ambient CO exceeds 35 ppm by turning off the appliance, ventilating the space, and evacuating the building. The CO problem must be corrected prior to completing combustion safety diagnostics.
6. Make recommendations based on test results and the retrofit action prescribed in Table AR301.1(3) ~~N1103.10(3)~~.

TABLE AR301.1(1) ~~N1103.10(1)~~
CAZ DEPRESSURIZATION LIMITS

VENTING CONDITION	LIMIT (Pa)
Category I, atmospherically-vented water heater	-2.0
Category I or II atmospherically-vented boiler or furnace common-vented with a Category I atmospherically-vented water heater	-3.0

TABLE AR301.1(3) ~~N1103.10(3)~~
ACCEPTABLE DRAFT TEST CORRECTION

CARBON DIOXIDE LEVEL (ppm)	AND OR	SPILLAGE AND ACCEPTABLE DRAFT TEST RESULTS	RETROFIT ACTION
0 – 25	and	Passes	Proceed with work
25 < x ≤ 100	and	Passes	Recommend that CO problem be resolved
25 < x ≤ 100	and	Fails in worst case only	Recommend an appliance service call and repairs to resolve the problem
100 < x ≤ 400	or	Fails under natural conditions	**Stop!** Work shall not proceed until appliance is serviced and problem resolved
> 400	and	Passes	**Stop!** Work shall not proceed until appliance is serviced and problem resolved
> 400	and	Fails under any condition	**Emergency!** Shut off fuel to appliance and call for service immediately

Commenter's Reason: At the Dallas Public Hearings, and shortly after the IECC-R Committee deemed themselves "unqualified" to deal with the topic, the reason they cited for recommending RE193-13 for "Disapproval" was that the Committee believed the "… proposal to be a mechanical issue belonging to the IRC-Mechanical Part or the IMC, not in the energy code."

Others, representing the fuel gas industry, deemed the issue a matter belonging to the IRC-Fuel Gas Part or even the IFGC;" despite key takeaways from AGA's presentation to a Building America Expert Meeting on Combustion Safety identifying a "gap" in the IFGC (a.k.a., IFGS-ANSI Z223.1-NFPA 54), where combustion air guidelines were last revised circa 2001 to account for lower infiltration rates in newly constructed homes.

The Expert Meeting took place in June 2012, with the report from the Gas Technology Institute's (GTI's) Partnership for Advanced Residential Retrofit (PARR), issued nine-months later in March 2013. Another key takeaway from the March 2013 PARR report reads, "It might be appropriate to revisit these assumptions as houses are built tighter (gap)."

The PARR Report goes on to identify a key point in Section 2.5.2, "More than 5 Pa of depressurization reverses most [atmospheric] vent[ing] systems. That is equivalent to a dryer operating in a closed house tested at 450 CFM at 50 Pascal of depressurization. Water heaters spill more in warmer weather than colder weather because of the physics of buoyancy [convection] …," and cites "[u]nbalanced central returns in the HVAC system [as] a significant cause of depressurization."

We request approval As Modified by this Public Comment (AMPC) in that:

1) Combustion safety testing is an important part of the test-in and test-out process in new IRC/IECC construction projects when atmospherically vented appliances are used and houses are being tightened at or below 5ACH50 in accordance with the 2012/2015 IRC or the 2012/2015 IECC;
2) It is clear that the pace of air-sealing to nationally-adopted, consensus-developed energy codes has outpaced the capacity of consensus developed fuel gas standards in response;
3) This proposal provides clear guidance to builders, code officials and home-energy performance contractors for worst-case testing of atmospheric venting systems where air-sealing techniques and air-leakage performance testing requirements of the 2012 or 2015 IRC/IECC are employed.
4) This proposal avoids the "one-size-fits-all" solution of "enclosure" ($), or use of a separately-enclosed and insulated mechanical room surrounding the atmospherically vented appliances, with direct combustion air connections, and located either in a basement or adjacent to the home; and
5) It is not likely the Building America Program, an Expert Panel, or PARR will be ready to provide a nationally-harmonized methodology for combustion safety testing to 2012 or 2015 IRC/IECC envelopes (i.e., ≤ 5ACH50) before the beginning of the 2018 Group 'A' I-Code Hearings (Deadline–January, 2015), with the 2018 Editions of I-Codes published, May 2017;

If your State or jurisdiction has adopted, or is contemplating adoption of, a 2012 or 2015 Edition of the IRC/IECC, can you or the national building regulatory community afford to wait? Note also, that the original proposal has been revised from mandatory code language to an informative (non-mandatory) appendix.

We request your support in approving of RE191-13 As Modified by this Public Comment (AMPC)

RE193-13
Final Action: AS AM AMPC____ D

RE195-13
Table R402.1.2 (IRC N1102.1.2)

Proposed Change as Submitted

Proponent: Matt Dobson, Representing Vinyl Siding Institute

Revise as follows:

R402.1.2 (N1102.1.2) R-value computation. Insulation material used in layers, such as framing cavity insulation, insulating sheathing and <u>insulated siding</u> shall be summed to compute the component R-value. The manufacturer's settled R-value shall be used for blown insulation. Computed R-values shall not include an R-value for other building materials or air films. <u>For the purpose of complying with Table R402.1.1, the manufacturer's labeled R-value shall be reduced by R-0.6 for insulated siding.</u>

Reason: This simple addition to the paragraph allows insulated siding to be used as part of the calculation. This is important, as prior to the advent of insulated siding, the prescriptive approach prohibits including the siding's R-value. This change will help to create more innovative ways to meet the energy code requirements and improve energy efficiency.

Because the R-value for siding is already credited as part of the prescriptive compliance method used with Table R402.1.1, that amount, R-0.6, must be deducted from the manufacturer labeled R-value of the insulated siding. This would mean that if the insulated siding's tested R-value (based on an ASTM C1363 test) were R-3.6, that only R-3.0 could be used to help comply through the prescriptive method of Table R402.1.1. Additionally, it should be understood that air films (both on the front and back of the insulated siding) are not taken into account during the R-value testing for insulated siding, so credits for those air films in the prescriptive section should remain in place.

For more information about insulated siding, go to www.insulatedsiding.info.

Cost Impact: The code change proposal will not increase the cost of construction and could potentially reduce costs by offering an additional option for compliance with the prescriptive path.

R402.1.2-EC-DOBSON

Committee Action Hearing Results

Committee Action: **Approved as Modified**

Modify the proposal as follows:

R402.1.2 (N1102.1.2) R-value computation. Insulation material used in layers, such as framing cavity insulation, ~~insulating sheathing and insulated siding~~ <u>or continuous insulation</u> shall be summed to compute the component R-value. The manufacturer's settled R-value shall be used for blown insulation. Computed R-values shall not include an R-value for other building materials or air films. ~~For the purpose of complying with Table R402.1.1, the manufacturer's labeled R-value shall be reduced by R-0.6 for insulated siding.~~ <u>Where insulated siding is used for the purpose of complying with the continuous insulation requirements of Table R402.1.1, the manufacturer's labeled R-Value for insulated siding shall be reduced by R-0.6.</u>

Committee Reason: Committee Reason: This proposal will add more information about a product that can be used to meet code envelope requirements. This gives builders more flexibility with more products that can be used to meet the code requirements. The modification is a rewrite to clarify proponent's intent.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Craig Conner, Building Quality, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

R402.1.2 (N1102.1.2) R-value computation. Insulation material used in layers, such as framing cavity insulation, or continuous insulation shall be summed to compute the component R-value. The manufacturer's settled R-value shall be used for blown insulation. Computed R-values shall not include an R-value for other building materials or air films. Where insulated siding is used for the purpose of complying with the continuous insulation requirements of Table R402.1.1, the manufacturer's labeled insulation R-Value ~~for insulated siding~~ shall be ~~reduced by R-0.6~~ used.

Commenter's Reason: For R-value the IECC requires an R-value that only includes the insulation. CE67 was modified to include a manufacturer's insulation-only R-value label. Therefore the 0.6 reduction here would be a double reduction and is not needed.

IECC Section R402.1.2 "R-value computation" says "Insulation material used in layers, such as framing cavity insulation and insulating sheathing, shall be summed to compute the component Rvalue. The manufacturer's settled R-value shall be used for blown insulation. **Computed R -values shall not include an R-value for other building materials or air films**

Proposed Change as Submitted

Proponent: David S. Collins, FAIA, The Preview Group, Inc. (dcollins@preview-group.com), The American Institute of Architects and Robert J Davidson, Davidson Code Concepts, LLC

Revise as follows:

CHAPTER 3
COMPLIANCE METHODS, APPLICABILITY AND MINIMUM REQUIREMENTS

301.1 General. The *repair*, *alteration*, *change of occupancy*, *addition* or relocation of all *existing buildings* shall comply with one of the methods listed in Sections 301.1.1 through 301.1.3 as selected by the applicant in addition to complying with the minimum requirements in Sections 302 and 303. Application of a method shall be the sole basis for assessing the compliance of work performed under a single permit unless otherwise approved by the *code official*. Sections 301.1.1 through 301.1.3 shall not be applied in combination with each other. Where this code requires consideration of the seismic force-resisting system of an existing building subject to *repair*, *alteration*, *change of occupancy*, *addition* or relocation of *existing buildings*, the seismic evaluation and design shall be based on Section 301.1.4 regardless of which compliance method is used.

> **Exception:** Subject to the approval of the *code official*, *alterations* complying with the laws in existence at the time the building or the affected portion of the building was built shall be considered in compliance with the provisions of this code unless the building is undergoing more than a limited structural alteration as defined in Section 907.4.3. New structural members added as part of the *alteration* shall comply with the *International Building Code*. *Alterations* of *existing buildings* in *flood hazard areas* shall comply with Section 701.3.

SECTION 302
ADDITIONAL CODES AND REQUIREMENTS

~~**301.2 Additional codes**~~ **302.1 General.** *Alterations, repairs, additions* and *changes of occupancy* to, or relocation of, *existing buildings* and structures shall comply with the provisions for *alterations, repairs, additions* and *changes of occupancy* or relocation, respectively, in this code and the *International Energy Conservation Code*, *International Fire Code, International Fuel Gas Code, International Mechanical Code, International Plumbing Code, International Property Maintenance Code, International Private Sewage Disposal Code*, *International Residential Code* and NFPA 70. Where provisions of the other codes conflict with provisions of this code, the provisions of this code shall take precedence.

302.1.1 Accessibility. Level 1 alterations shall comply with the 2015 ANSI A117.1 to the extent of the altered element. Areas of an existing building that are outside the specific work area or otherwise unaffected by alterations Level 1, 2 or 3, that are required to be accessible by Chapter 7 shall comply with the 2003 ANSI A117.1.
Work performed under Level 2 and 3 alterations shall comply with the 2015 ANSI A117.1 and all spaces that change configuration as part of the alterations shall comply with the 2015 ANSI A117.1.

SECTION 303
EXISTING BUILDING MINIMUM REQUIREMENTS

303.1 Administration. Sections 303.1.1 through 303.1.4 shall set the scope, intent and administration of provisions related to minimum requirements that are applicable to existing buildings.

303.1.1 ([F] 1101.1) Scope. The provisions of this Section shall apply to existing buildings constructed prior to the adoption of this code.

303.1.2 ([F] 1101.2) Intent. The intent of this Section is to provide a minimum degree of fire and life safety to persons occupying existing buildings by providing minimum construction requirements where such existing buildings do not comply with the minimum requirements of the International Building Code.

303.1.3 ([F] 1101.3) Permits. Permits for alterations necessary to conform with this Section shall be required as set forth in Sections 105.1.

303.1.4 ([F] 1101.4) Owner notification. When a building is found to be in noncompliance with this chapter, the code official shall duly notify the owner of the building. Upon receipt of such notice, the owner shall, subject to the following time limits, take necessary actions to comply with the provisions of this chapter.

303.1.4.1 ([F] 1101.4.1) Construction documents. Construction documents necessary to comply with this chapter shall be completed and submitted within a time schedule approved by the code official.

303.1.4.2 ([F] 1101.4.2) Completion of work. Work necessary to comply with this chapter shall be completed within a time schedule approved by the code official.

303.1.4.3 ([F] 1101.4.3) Extension of time. The code official is authorized to grant necessary extensions of time when it can be shown that the specified time periods are not physically practical or pose an undue hardship. The granting of an extension of time for compliance shall be based on the showing of good cause and subject to the filing of an acceptable systematic plan of correction with the code official.

303.2 ([F] SECTION 1103) Fire safety requirements for existing buildings. Minimum fire safety requirements for existing buildings shall be in provided in accordance with Sections 303.2.1 through 303.2.9.

303.2.1 ([F] 1103.1) Required construction. Existing buildings shall comply with not less than the minimum provisions specified in Table 303.2.1 and as further enumerated in Sections 303.2.2 through 303.2.9.

The provisions of this chapter shall not be construed to allow the elimination of fire protection systems or a reduction in the level of fire safety provided in buildings constructed in accordance with previously adopted codes.

Exception: Group U occupancies.

TABLE 303.2.1 ([F] TABLE 1103.1)
OCCUPANCY AND USE REQUIREMENTS[a]

a. Existing buildings shall comply with the Sections identified as "Required" (R) based on occupancy classification or use, or both, whichever is applicable.

R = The building is required to comply.

303.2.2 ([F] 1103.2) Emergency responder radio coverage in existing buildings. Existing buildings that do not have approved radio coverage for emergency responders within the building based upon the existing coverage levels of the public safety communication systems of the jurisdiction at the exterior of the building, shall be equipped with such coverage according to one of the following:

1. Whenever an existing wired communication system cannot be repaired or is being replaced, or where not approved in accordance with Section 510.1, Exception 1 of the *International Fire Code*.
2. Within a time frame established by the adopting authority.

Exception: Where it is determined by the ~~fire~~ code official that the radio coverage system is not needed.

303.2.3 ([F] 1103.3) Elevator operation. Existing elevators with a travel distance of 25 feet (7620 mm) or more above or below the main floor or other level of a building and intended to serve the needs of emergency personnel for fire-fighting or rescue purposes shall be provided with emergency operation in accordance with ASME A17.3.

303.2.4 ([F] 1103.4) Vertical openings. Interior vertical shafts, including but not limited to stairways, elevator hoistways, service and utility shafts, that connect two or more stories of a building, shall be enclosed or protected as specified in Sections 303.2.4.1 through 303.2.4.7.

303.2.4.1 ([F] 1103.4.1) Group I occupancies. In Group I occupancies, interior vertical openings connecting two or more stories shall be protected with 1-hour fire-resistance-rated construction.

303.2.4.2 ([F] 1103.4.2) Three to five stories. In other than Group I occupancies, interior vertical openings connecting three to five stories shall be protected by either 1-hour fire-resistance-rated construction or an automatic sprinkler system shall be installed throughout the building in accordance with Section 903.3.1.1 or 903.3.1.2 of the *International Building Code*.

Exceptions:
1. Vertical opening protection is not required for Group R-3 occupancies.
2. Vertical opening protection is not required for open parking garages and ramps.

3. Vertical opening protection for escalators shall be in accordance with Section 303.2.4.5, 303.2.4.6 or 303.2.4.7.

303.2.4.3 ([F] 1103.4.3) More than five stories. In other than Group I occupancies, interior vertical openings connecting more than five stories shall be protected by 1-hour fire-resistance-rated construction.

Exceptions:

1. Vertical opening protection is not required for Group R-3 occupancies.
2. Vertical opening protection is not required for open parking garages and ramps.
3. Vertical opening protection for escalators shall be in accordance with Section 303.2.4.5, 303.2.4.6 or 303.2.4.7.

303.2.4.4 ([F] 1103.4.4) Atriums and covered malls. In other than Group I occupancies, interior vertical openings in a covered mall building or a building with an atrium shall be protected by either 1-hour fire-resistance-rated construction or an automatic sprinkler system shall be installed throughout the building in accordance with Section 903.3.1.1 or 903.3.1.2 of the *International Building Code*.

Exceptions:

1. Vertical opening protection is not required for Group R-3 occupancies.
2. Vertical opening protection is not required for open parking garages and ramps.

303.2.4.5 ([F] 1103.4.5) Escalators in Group B and M occupancies. Escalators creating vertical openings connecting any number of stories shall be protected by either 1-hour fire-resistance-rated construction or an automatic sprinkler system in accordance with Section 903.3.1.1 of the *International Building Code* installed throughout the building, with a draft curtain and closely spaced sprinklers around the escalator opening.

303.2.4.6 ([F] 1103.4.6) Escalators connecting four or fewer stories. In other than Group B and M occupancies, escalators creating vertical openings connecting four or fewer stories shall be protected by either 1-hour fire-resistance-rated construction or an automatic sprinkler system in accordance with Section 903.3.1.1 or 903.3.1.2 of the *International Building Code* shall be installed throughout the building, and a draft curtain with closely spaced sprinklers shall be installed around the escalator opening.

303.2.4.7 ([F] 1103.4.7) Escalators connecting more than four stories. In other than Group B and M occupancies, escalators creating vertical openings connecting five or more stories shall be protected by 1-hour fire-resistance-rated construction.

303.2.5 ([F] 1103.5) Sprinkler systems. An automatic sprinkler system shall be provided in existing buildings in accordance with Sections 303.2.5.1 and 303.2.5.2.

303.2.5.1 ([F] 1103.5.1) Pyroxylin plastics. An automatic sprinkler system shall be provided throughout existing buildings where cellulose nitrate film or pyroxylin plastics are manufactured, stored or handled in quantities exceeding 100 pounds (45 kg). Vaults located within buildings for the storage of raw pyroxylin shall be protected with an approved automatic sprinkler system capable of discharging 1.66 gallons per minute per square foot (68 L/min/m^2) over the area of the vault.

303.2.5.2 ([F] 1103.5.2) Group I-2. An automatic sprinkler system shall be provided throughout existing Group I-2 fire areas. The sprinkler system shall be provided throughout the floor where the Group I-2 occupancy is located, and in all floors between the Group I-2 occupancy and the level of exit discharge.

303.2.6 ([F] 1103.6) Standpipes. Where required by Sections 303.2.6.1 or 303.2.6.2, standpipes shall be installed in accordance with Section 905 of the *International Building Code*. The code official is authorized to approve the installation of manual standpipe systems to achieve compliance with this Section where the responding fire department is capable of providing the required hose flow at the highest standpipe outlet.

303.2.6.1 ([F] 1103.6.1) Existing multiple-story buildings. Existing buildings with occupied floors located more than 50 feet (15 240 mm) above the lowest level of fire department access or more than 50 feet (15 240 mm) below the highest level of fire department access shall be equipped with standpipes.

303.2.6.2 ([F] 1103.6.2) Existing helistops and heliports. Existing buildings with a rooftop helistop or heliport located more than 30 feet (9144 mm) above the lowest level of fire department access to the roof level on which the helistop or heliport is located shall be equipped with standpipes in accordance with Section 905.3.6 of the *International Building Code*.

303.2.7 ([F] 1103.7) Fire alarm systems. An approved fire alarm system shall be installed in existing buildings and structures where required by Sections 303.2.7.1 through 303.2.7.7 and provide occupant notification in accordance with Section 907.6 of the *International Building Code* unless other requirements are provided by other Sections of this code.

Exception: Occupancies with an existing, previously approved fire alarm system.

303.2.7.1 ([F] 1103.7.1) Group E. A fire alarm system shall be installed in existing Group E occupancies in accordance with Section 907.2.3.

Exceptions:

1. A manual fire alarm system is not required in a building with a maximum area of 1,000 square feet (93 m^2) that contains a single classroom and is located no closer than 50 feet (15 240 mm) from another building.
2. A manual fire alarm system is not required in Group E occupancies with an occupant load less than 50.

303.2.7.2 ([F] 1103.7.2) Group I-1. An automatic fire alarm system shall be installed in existing Group I-1 residential care/assisted living facilities in accordance with Section 907.2.6.1 of the *International Building Code*.

Exceptions:

1. Manual fire alarm boxes in resident or patient sleeping areas shall not be required at exits if located at all nurses' control stations or other constantly attended staff locations, provided such stations are visible and continuously accessible and that travel distances required in Section 907.5.2 of the *International Building Code* are not exceeded.
2. Where each sleeping room has a means of egress door opening directly to an exterior egress balcony that leads directly to the exits in accordance with Section 1019 of the *International Building Code*, and the building is not more than three stories in height.

303.2.7.3 ([F] 1103.7.3) Group I-2. An automatic fire alarm system shall be installed in existing Group I-2 occupancies in accordance with Section 907.2.6.2 of the *International Building Code*..

Exception: Manual fire alarm boxes in resident or patient sleeping areas shall not be required at exits if located at all nurses' control stations or other constantly attended staff locations, provided such stations are visible and continuously accessible and that travel distances required in Section 907.5.2.1 of the *International Building Code* are not exceeded.

303.2.7.4 ([F] 1103.7.4) Group I-3. An automatic and manual fire alarm system shall be installed in existing Group I-3 occupancies in accordance with Section 907.2.6.3 of the *International Building Code*.

303.2.7.5 ([F] 1103.7.5) Group R-1. A fire alarm system and smoke alarms shall be installed in existing Group R-1 occupancies in accordance with Sections 303.2.7.5.1 through 303.2.7.5.2.1.

303.2.7.5.1 ([F] 1103.7.5.1) Group R-1 hotel and motel manual fire alarm system. A manual fire alarm system that activates the occupant notification system in accordance with Section 907.6 of the

International Building Code shall be installed in existing Group R-1 hotels and motels more than three stories or with more than 20 sleeping units.

Exceptions:

1. Buildings less than two stories in height where all sleeping units, attics and crawl spaces are separated by 1-hour fire-resistance-rated construction and each sleeping unit has direct access to a public way, egress court or yard.
2. Manual fire alarm boxes are not required throughout the building when the following conditions are met:
    - 2.1. The building is equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.3.1.2 of the *International Building Code*;
    - 2.2. The notification appliances will activate upon sprinkler water flow; and
    - 2.3. At least one manual fire alarm box is installed at an approved location.

303.2.7.5.1.1 ([F] 1103.7.5.1.1) Group R-1 hotel and motel automatic smoke detection system. An automatic smoke detection system that activates the occupant notification system in accordance with Section 907.6 of the *International Building Code* shall be installed in existing Group R-1 hotels and motels throughout all interior corridors serving sleeping rooms not equipped with an approved, supervised sprinkler system installed in accordance with Section 903 of the *International Building Code*.

Exception: An automatic smoke detection system is not required in buildings that do not have interior corridors serving sleeping units and where each sleeping unit has a means of egress door opening directly to an exit or to an exterior exit access that leads directly to an exit.

303.2.7.5.2 ([F] 1103.7.5.2) Group R-1 boarding and rooming houses manual fire alarm system. A manual fire alarm system that activates the occupant notification system in accordance with Section 907.6 of the *International Building Code* shall be installed in existing Group R-1 boarding and rooming houses.

Exception: Buildings less than two stories in height where all sleeping units, attics and crawl spaces are separated by 1-hour fire-resistance-rated construction and each sleeping unit has direct access to a public way, egress court or yard.

303.2.7.5.2.1 ([F] 1103.7.5.2.1) Group R-1 boarding and rooming houses automatic smoke detection system. An automatic smoke detection system that activates the occupant notification system in accordance with Section 907.6 of the *International Building Code* shall be installed in existing Group R-1 boarding and rooming houses throughout all interior corridors serving sleeping units not equipped with an approved, supervised sprinkler system installed in accordance with Section 903 of the *International Building Code*.

Exception: Buildings equipped with single-station smoke alarms meeting or exceeding the requirements of Section 907.2.11.1 of the *International Building Code* and where the fire alarm system includes at least one manual fire alarm box per floor arranged to initiate the alarm.

303.2.7.6 ([F] 1103.7.6) Group R-2. A manual fire alarm system that activates the occupant notification system in accordance with Section 907.6 of the *International Building Code* shall be installed in existing Group R-2 occupancies more than three stories in height or with more than 16 dwelling or sleeping units.

Exceptions:

1. Where each living unit is separated from other contiguous living units by fire barriers having a fire-resistance rating of not less than 0.75 hour, and where each living unit has either its own independent exit or its own independent stairway or ramp discharging at grade.
2. A separate fire alarm system is not required in buildings that are equipped throughout with an approved supervised automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.3.1.2 of the *International Building Code* and having a local alarm to notify all occupants.

3. A fire alarm system is not required in buildings that do not have interior corridors serving dwelling units and are protected by an approved automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.3.1.2 of the *International Building Code*, provided that dwelling units either have a means of egress door opening directly to an exterior exit access that leads directly to the exits or are served by open-ended corridors designed in accordance with Section 1026.6, Exception 4 of the *International Building Code*.

303.2.7.7 ([F] 1103.7.7) Group R-4. A manual fire alarm system that activates the occupant notification system in accordance with Section 907.6 of the *International Building Code* shall be installed in existing Group R-4 residential care/assisted living facilities in accordance with Section 907.2.10.1 of the *International Building Code*.

Exceptions:

1. Where there are interconnected smoke alarms meeting the requirements of Section 907.2.11 of the *International Building Code* and there is at least one manual fire alarm box per floor arranged to continuously sound the smoke alarms.
2. Other manually activated, continuously sounding alarms approved by the code official.

303.2.8 ([F] 1103.8) Single- and multiple-station smoke alarms. Single- and multiple-station smoke alarms shall be installed in existing Group I-1 and R occupancies in accordance with Sections 303.2.8.1 through 303.2.8.3.

303.2.8.1 ([F] 1103.8.1) Where required. Existing Group I-1 and R occupancies shall be provided with single-station smoke alarms in accordance with Section 907.2.11 of the *International Building Code*, except as provided in Sections 303.2.8.2 or 303.2.8.3.

Exceptions:

1. Where the code that was in effect at the time of construction required smoke alarms and smoke alarms complying with those requirements are already provided.
2. Where smoke alarms have been installed in occupancies and dwellings that were not required to have them at the time of construction, additional smoke alarms shall not be required provided that the existing smoke alarms comply with requirements that were in effect at the time of installation.
3. Where smoke detectors connected to a fire alarm system have been installed as a substitute for smoke alarms.

303.2.8.2 ([F] 1103.8.2) Interconnection. Where more than one smoke alarm is required to be installed within an individual dwelling or sleeping unit, the smoke alarms shall be interconnected in such a manner that the activation of one alarm will activate all of the alarms in the individual unit. Physical interconnection of smoke alarms shall not be required where listed wireless alarms are installed and all alarms sound upon activation of one alarm. The alarm shall be clearly audible in all bedrooms over background noise levels with all intervening doors closed.

Exceptions:

1. Interconnection is not required in buildings that are not undergoing alterations, repairs or construction of any kind.
2. Smoke alarms in existing areas are not required to be interconnected where alterations or repairs do not result in the removal of interior wall or ceiling finishes exposing the structure, unless there is an attic, crawl space or basement available which could provide access for interconnection without the removal of interior finishes.

303.2.8.3 ([F] 1103.8.3) Power source. Single-station smoke alarms shall receive their primary power from the building wiring provided that such wiring is served from a commercial source and shall be equipped with a battery backup. Smoke alarms with integral strobes that are not equipped with battery backup shall be connected to an emergency electrical system. Smoke alarms shall emit a signal when the batteries are low. Wiring shall be permanent and without a disconnecting switch other than as required for overcurrent protection.

Exceptions:

1. Smoke alarms are permitted to be solely battery operated in existing buildings where no construction is taking place.
2. Smoke alarms are permitted to be solely battery operated in buildings that are not served from a commercial power source.
3. Smoke alarms are permitted to be solely battery operated in existing areas of buildings undergoing alterations or repairs that do not result in the removal of interior walls or ceiling finishes exposing the structure, unless there is an attic, crawl space or basement available which could provide access for building wiring without the removal of interior finishes.

303.2.9 ([F] 1103.9) Carbon monoxide alarms. Existing Group I or R occupancies located in a building containing a fuel-burning appliance or a building which has an attached garage shall be equipped with single-station carbon monoxide alarms. The carbon monoxide alarms shall be listed as complying with UL 2034, and be installed and maintained in accordance with NFPA 720 and the manufacturer's instructions. An open parking garage, as defined in the International Building Code, or an enclosed parking garage ventilated in accordance with Section 404 of the *International Mechanical Code* shall not be deemed to be an attached garage.

Exception: Sleeping units or dwelling units which do not themselves contain a fuel-burning appliance or have an attached garage, but which are located in a building with a fuel-burning appliance or an attached garage, need not be equipped with single-station carbon monoxide alarms provided that:

1. The sleeping unit or dwelling unit is located more than one story above or below any story that contains a fuel-burning appliance or an attached garage;
2. The sleeping unit or dwelling unit is not connected by duct work or ventilation shafts to any room containing a fuel-burning appliance or to an attached garage; and
3. The building is provided with a common area carbon monoxide alarm system.

303.3 ([F] 1104.1). Means of egress. Means of egress in existing buildings shall comply with the minimum egress requirements when specified in Table 303.2.1 as further enumerated in Sections 303.3.1 through 303.3.23, and the building code that applied at the time of construction. Where the provisions of this chapter conflict with the building code that applied at the time of construction, the most restrictive provision shall apply. Existing buildings that were not required to comply with a building code at the time of construction shall comply with the minimum egress requirements when specified in Table 303.2.1 as further enumerated in Sections 303.3.1 through 303.3.23.

303.3.1 ([F] 1104.2) Elevators, escalators and moving walks. Elevators, escalators and moving walks shall not be used as a component of a required means of egress.

Exceptions:

1. Elevators used as an accessible means of egress where allowed by Section 1007.4 of the *International Building Code*.
2. Previously approved escalators and moving walks in existing buildings.

303.3.2 ([F] 1104.3) Exit sign illumination. Exit signs shall be internally or externally illuminated. The face of an exit sign illuminated from an external source shall have an intensity of not less than 5 footcandles (54 lux). Internally illuminated signs shall provide equivalent luminance and be listed for the purpose.

Exception: Approved self-luminous signs that provide evenly illuminated letters shall have a minimum luminance of 0.06 foot-lamberts (0.21 cd/m2).

303.3.3 ([F] 1104.4) Power source. here emergency illumination is required in Section 303.3.4, exit signs shall be visible under emergency illumination conditions.

> **Exception:** Approved signs that provide continuous illumination independent of external power sources are not required to be connected to an emergency electrical system.

303.3.4 ([F] 1104.5) Illumination emergency power. The power supply shall normally be provided by the premises' electrical supply. In the event of power supply failure, illumination shall be automatically provided from an emergency system for the following occupancies where such occupancies require two or more means of egress:

1. Group A having 50 or more occupants.

   Exception: Assembly occupancies used exclusively as a place of worship and having an occupant load of less than 300.

2. Group B buildings three or more stories in height, buildings with 100 or more occupants above or below a level of exit discharge serving the occupants or buildings with 1,000 or more total occupants.
3. Group E in interior stairs, corridors, windowless areas with student occupancy, shops and laboratories.
4. Group F having more than 100 occupants.

   Exception: Buildings used only during daylight hours which are provided with windows for natural light in accordance with the International Building Code.

5. Group I.
6. Group M.

   Exception: Buildings less than 3,000 square feet (279 m2) in gross sales area on one story only, excluding mezzanines.

7. Group R-1.

   Exception: Where each sleeping unit has direct access to the outside of the building at grade.

8. Group R-2.

   Exception: Where each dwelling unit or sleeping unit has direct access to the outside of the building at grade.

9. Group R-4.

   Exception: Where each sleeping unit has direct access to the outside of the building at ground level.

303.3.4.1 ([F] 1104.5.1) Emergency power duration and installation. In other than Group I-2, the emergency power system shall provide power for not less than 60 minutes and consist of storage batteries, unit equipment or an on-site generator. In Group I-2, the emergency power system shall provide power for not less than 90 minutes and consist of storage batteries, unit equipment or an on-site generator. The installation of the emergency power system shall be in accordance with Section 1006.3 of the *international Building Code*.

303.3.5 ([F] 1104.6) Guards. Guards complying with this Section shall be provided at the open sides of means of egress that are more than 30 inches (762 mm) above the floor or grade below.

303.3.5.1 ([F] 1104.6.1) Height of guards. Guards shall form a protective barrier not less than 42 inches (1067 mm) high.

Exceptions:

1. Existing guards on the open side of stairs shall be not less than 30 inches (760 mm) high.
2. Existing guards within dwelling units shall be not less than 36 inches (910 mm) high.
3. Existing guards in assembly seating areas.

303.3.5.2 ([F] 1104.6.2) Opening limitations. Open guards shall have balusters or ornamental patterns such that a 6-inch-diameter (152 mm) sphere cannot pass through any opening up to a height of 34 inches (864 mm).

Exceptions:

1. At elevated walking surfaces for access to, and use of, electrical, mechanical or plumbing systems or equipment, guards shall have balusters or be of solid materials such that a sphere with a diameter of 21 inches (533 mm) cannot pass through any opening.
2. In occupancies in Group I-3, F, H or S, the clear distance between intermediate rails measured at right angles to the rails shall not exceed 21 inches (533 mm).
3. Approved existing open guards.

303.3.6 ([F] 1104.7) Size of doors. The minimum width of each door opening shall be sufficient for the occupant load thereof and shall provide a clear width of not less than 28 inches (711 mm). Where this Section requires a minimum clear width of 28 inches (711 mm) and a door opening includes two door leaves without a mullion, one leaf shall provide a clear opening width of 28 inches (711 mm). The maximum width of a swinging door leaf shall be 48 inches (1219 mm) nominal. Means of egress doors in an occupancy in Group I-2 used for the movement of beds shall provide a clear width not less than 41.5 inches (1054 mm). The height of doors shall not be less than 80 inches (2032 mm).

Exceptions:

1. The minimum and maximum width shall not apply to door openings that are not part of the required means of egress in occupancies in Groups R-2 and R-3.
2. Door openings to storage closets less than 10 square feet (0.93 m^2) in area shall not be limited by the minimum width.
3. Width of door leafs in revolving doors that comply with Section 1008.1.4.1 shall not be limited.
4. Door openings within a dwelling unit shall not be less than 78 inches (1981 mm) in height.
5. Exterior door openings in dwelling units, other than the required exit door, shall not be less than 76 inches (1930 mm) in height.
6. Exit access doors serving a room not larger than 70 square feet (6.5 m^2) shall be not less than 24 inches (610 mm) in door width.

303.3.7 ([F] 1104.8) Opening force for doors. The opening force for interior side-swinging doors without closers shall not exceed a 5-pound (22 N) force. For other side-swinging, sliding and folding doors, the door latch shall release when subjected to a force of not more than 15 pounds (66 N). The door shall be set in motion when subjected to a force not exceeding 30 pounds (133 N). The door shall swing to a full-open position when subjected to a force of not more than 50 pounds (222 N). Forces shall be applied to the latch side.

303.3.8 ([F] 1104.9) Revolving doors. Revolving doors shall comply with the following:

1. A revolving door shall not be located within 10 feet (3048 mm) of the foot or top of stairs or escalators. A dispersal area shall be provided between the stairs or escalators and the revolving doors.
2. The revolutions per minute for a revolving door shall not exceed those shown in Table 303.3.8.
3. Each revolving door shall have a conforming side-hinged swinging door in the same wall as the revolving door and within 10 feet (3048 mm).

Exceptions:

1. A revolving door is permitted to be used without an adjacent swinging door for street-floor elevator lobbies provided a stairway, escalator or door from other parts of the building does not discharge through the lobby and the lobby does not have any occupancy or use other than as a means of travel between elevators and a street.
2. Existing revolving doors are permitted where the number of revolving doors does not exceed the number of swinging doors within 20 feet (6096 mm).

303.3.8 TABLE ([F] 1104.9)
REVOLVING DOOR SPEEDS

INSIDE DIAMETER (feet-inches)	POWER-DRIVEN-TYPE SPEED CONTROL (rpm)	MANUAL-TYPE SPEED CONTROL (rpm)
6-6	11	12
7-0	10	11
7-6	9	11
8-0	9	10
8-6	8	9
9-0	8	9
9-6	7	8
10-0	7	8

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

303.3.8.1 ([F] 1104.9.1) Egress component. A revolving door used as a component of a means of egress shall comply with Section 1104.9 and all of the following conditions:

1. Revolving doors shall not be given credit for more than 50 percent of the required egress capacity.
2. Each revolving door shall be credited with not more than a 50-person capacity.
3. Revolving doors shall be capable of being collapsed when a force of not more than 130 pounds (578 N) is applied within 3 inches (76 mm) of the outer edge of a wing.

303.3.9 ([F] 1104.10) Stair dimensions for existing stairs. Existing stairs in buildings shall be permitted to remain if the rise does not exceed 81/4 inches (210 mm) and the run is not less than 9 inches (229 mm). Existing stairs can be rebuilt.

Exception: Other stairs approved by the code official.

303.3.9.1 ([F] 1104.10.1) Dimensions for replacement stairs. The replacement of an existing *stairway* in a structure shall not be required to comply with the new *stairway* requirements of Section 1009 of the International Building Code where the existing space and construction will not allow a reduction in pitch or slope.

303.3.10 ([F] 1104.11) Winders. Existing winders shall be allowed to remain in use if they have a minimum tread depth of 6 inches (152 mm) and a minimum tread depth of 9 inches (229 mm) at a point 12 inches (305 mm) from the narrowest edge.

303.3.11 ([F] 1104.12) Circular stairways. Existing circular stairs shall be allowed to continue in use provided the minimum depth of tread is 10 inches (254 mm) and the smallest radius shall not be less than twice the width of the stairway.

303.3.12 ([F] 1104.13) Stairway handrails. Stairways shall have handrails on at least one side. Handrails shall be located so that all portions of the stairway width required for egress capacity are within 44 inches (1118 mm) of a handrail.

Exception: Aisle stairs provided with a center handrail are not required to have additional handrails.

303.3.12.1 ([F] 1104.13.1) Height. Handrail height, measured above stair tread nosings, shall be uniform, not less than 30 inches (762 mm) and not more than 42 inches (1067 mm).

303.3.13 ([F] 1104.14) Slope of ramps. Ramp runs utilized as part of a means of egress shall have a running slope not steeper than one unit vertical in 10 units horizontal (10-percent slope). The slope of other ramps shall not be steeper than one unit vertical in eight units horizontal (12.5-percent slope).

303.3.14 ([F] 1104.15) Width of ramps. Existing ramps are permitted to have a minimum width of 30 inches (762 mm) but not less than the width required for the number of occupants served as determined by the *International Building Code.*

303.3.15 ([F] 1104.16) Fire escape stairs. Fire escape stairs shall comply with Sections 303.3.15.1 through 303.15.7.

303.3.15.1 ([F] 1104.16.1) Existing means of egress. Fire escape *stairs* shall be permitted in existing buildings but shall not constitute more than 50 percent of the required *exit* capacity.

303.3.15.2 ([F] 1104.16.2) Protection of openings. Openings within 10 feet (3048 mm) of fire escape stairs shall be protected by opening protectives having a minimum $^3/_4$-hour fire protection rating.

> **Exception:** In buildings equipped throughout with an approved automatic sprinkler system, opening protection is not required.

303.3.15.3 ([F] 1104.16.3) Dimensions. Fire escape *stairs* shall meet the minimum width, capacity, riser height and tread depth as specified in Section 303.3.9.

303.3.15.4 ([F] 1104.16.4) Access. Access to a fire escape *stair* from a *corridor* shall not be through an intervening room. Access to a fire escape *stair* shall be from a door or window meeting the criteria of Section 1005.1 of the *International Building Code*. Access to a fire escape *stair* shall be directly to a balcony, landing or platform. These shall be no higher than the floor or window sill level and no lower than 8 inches (203 mm) below the floor level or 18 inches (457 mm) below the window sill.

303.3.15.5 ([F] 1104.16.5) Materials and strength. Components of fire escape *stairs* shall be constructed of noncombustible materials. Fire escape *stairs* and balconies shall support the dead load plus a live load of not less than 100 pounds per square foot (4.78 kN/m^2). Fire escape *stairs* and balconies shall be provided with a top and intermediate handrail on each side.

303.3.15.5.1 ([F] 1104.16.5.1) Examination. Fire escape *stairs* and balconies shall be examined for structural adequacy and safety in accordance with Section 303.15.5 by a registered design professional or others acceptable to the *fire code official* every five years, or as required by the *fire code official*. An inspection report shall be submitted to the *fire code official* after such examination.

303.3.15.6 ([F] 1104.16.6) Termination. The lowest balcony shall not be more than 18 feet (5486 mm) from the ground. Fire escape *stairs* shall extend to the ground or be provided with counterbalanced *stairs* reaching the ground.

> **Exception:** For fire escape *stairs* serving 10 or fewer occupants, an *approved* fire escape ladder is allowed to serve as the termination.

303.3.15.7 ([F] 1104.16.7) Maintenance. Fire escapes shall be kept clear and unobstructed at all times and shall be maintained in good working order.

303.3.16 ([F] 1104.17) Corridors. Corridors serving an occupant load greater than 30 and the openings therein shall provide an effective barrier to resist the movement of smoke. Transoms, louvers, doors and other openings shall be kept closed or self-closing.

Exceptions:

1. Corridors in occupancies other than in Group H, which are equipped throughout with an approved automatic sprinkler system.
2. Patient room doors in corridors in occupancies in Group I-2 where smoke barriers are provided in accordance with the *International Building Code*.
3. Corridors in occupancies in Group E where each room utilized for instruction or assembly has at least one-half of the required means of egress doors opening directly to the exterior of the building at ground level.
4. Corridors that are in accordance with the *International Building Code*.

303.3.16.1 ([F] 1104.17.1) Corridor openings. Openings in corridor walls shall comply with the requirements of the International Building Code.

Exceptions:

1. Where 20-minute fire door assemblies are required, solid wood doors at least 1.75 inches (44 mm) thick or insulated steel doors are allowed.
2. Openings protected with fixed wire glass set in steel frames.
3. Openings covered with 0.5-inch (12.7 mm) gypsum wallboard or 0.75-inch (19.1 mm) plywood on the room side.
4. Opening protection is not required when the building is equipped throughout with an approved automatic sprinkler system.

303.3.16.2 ([F] 1104.17.2) Dead ends. Where more than one exit or exit access doorway is required, the exit access shall be arranged such that dead ends do not exceed the limits specified in Table 303.16.2.

Exception: A dead-end passageway or corridor shall not be limited in length where the length of the dead-end passageway or corridor is less than 2.5 times the least width of the dead-end passageway or corridor.

303.3.16.2 TABLE ([F] 1104.17.2)
COMMON PATH, DEAD-END AND TRAVEL DISTANCE LIMITS (by occupancy)

OCCUPANCY	COMMON PATH LIMIT		DEAD-END LIMIT		TRAVEL DISTANCE LIMIT	
	Unsprinklered (feet)	Sprinklered (feet)	Unsprinklered (feet)	Sprinklered (feet)	Unsprinklered (feet)	Sprinklered (feet)
Group A	20/75[a]	20/75[a]	20[b]	20[b]	200	250
Group B[f]	75	100	50	50	200	300
Group E	75	100	50	50	200	300
Group F-1, S-1[d,f]	75	100	50	50	200	250
Group F-2, S-2[d,f]	75	100	50	50	300	400
Group H-1	25	25	0	0	75	75
Group H-2	50	100	0	0	75	100
Group H-3	50	100	20	20	100	150
Group H-4	75	75	20	20	150	175
Group H-5	75	75	20	50	150	200
Group I-1	75	75	20	50	200	250
Group I-2 (Health care)	NR[e]	NR[e]	NR	NR	150	200[c]
Group I-3 (Detention and correctional – Use Conditions II, III, IV, V)	100	100	NR	NR	150[c]	200[c]
Group I-4 (Day care centers)	NR	NR	20	20	200	250
Group M (Covered or open mall)	75	100	50	50	200	400
Group M (Mercantile)	75	100	50	50	200	250
Group R-1 (Hotels)	75	75	50	50	200	250
Group R-2	75	125	50	50	200	250

(Apartments)						
Group R-3 (One- and two-family)	NR	NR	NR	NR	NR	NR
Group R-4 (Residential care/assisted living)	NR	NR	NR	NR	NR	NR
Group U	75	100	20	50	300	400

NR = No requirements.
For SI: 1 foot = 304.8 mm, 1 square foot = 0.0929 m2.

a. 20 feet for common path serving 50 or more persons; 75 feet for common path serving less than 50 persons.
b. See Section 1028.9.5 for dead-end aisles in Group A occupancies.
c. This dimension is for the total travel distance, assuming incremental portions have fully utilized their allowable maximums. For travel distance within the room, and from the room exit access door to the exit, see the appropriate occupancy chapter.
d. See the International Building Code for special requirements on spacing of doors in aircraft hangars.
e. Any patient sleeping room, or any suite that includes patient sleeping rooms, of more than 1,000 square feet shall have at least two exit access doors placed a distance apart equal to not less than one-third of the length of the maximum overall diagonal dimension of the patient sleeping room or suite to be served, measured in a straight line between exit access doors.
f. Where a tenant space in Group B, S and U occupancies has an occupant load of not more than 30, the length of a common path of egress travel shall not be more than 100 feet.

303.3.17 ([F] 1104.18) Exit access travel distance. Exits shall be located so that the maximum length of exit access travel, measured from the most remote point to an approved exit along the natural and unobstructed path of egress travel, does not exceed the distances given in Table 301.3.12.15.2.

303.3.18 ([F] 1104.19) Common path of egress travel. The common path of egress travel shall not exceed the distances given in Table 301.3.12.15.2.

303.3.19 ([F] 1104.20) Stairway discharge identification. An interior exit stairway or ramp which continues below its level of exit discharge shall be arranged and marked to make the direction of egress to a public way readily identifiable.

Exception: Stairs that continue one-half story beyond their levels of exit discharge need not be provided with barriers where the exit discharge is obvious.

303.3.20 ([F] 1104.21) Exterior stairway protection. Exterior exit stairs shall be separated from the interior of the building as required in Section 1026.6 of the *International Building Code*. Openings shall be limited to those necessary for egress from normally occupied spaces.

Exceptions:

1. Separation from the interior of the building is not required for buildings that are two stories or less above grade where the level of exit discharge serving such occupancies is the first story above grade.
2. Separation from the interior of the building is not required where the exterior stairway is served by an exterior balcony that connects two remote exterior stairways or other approved exits, with a perimeter that is not less than 50 percent open. To be considered open, the opening shall be a minimum of 50 percent of the height of the enclosing wall, with the top of the opening not less than 7 feet (2134 mm) above the top of the balcony.
3. Separation from the interior of the building is not required for an exterior stairway located in a building or structure that is permitted to have unenclosed interior stairways in accordance with Section 1022 of the *International Building Code*.
4. Separation from the interior of the building is not required for exterior stairways connected to open-ended corridors, provided that:
   - 4.1. The building, including corridors and stairs, is equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 or 903.3.1.2 of the *International Building Code*.
   - 4.2. The open-ended corridors comply with Section 1018.2 of the *International Building Code*.

4.3. The open-ended corridors are connected on each end to an exterior exit stairway complying with Section 1026 of the *International Building Code*.

4.4. At any location in an open-ended corridor where a change of direction exceeding 45 degrees (0.79 rad) occurs, a clear opening of not less than 35 square feet (3 m2) or an exterior stairway shall be provided. Where clear openings are provided, they shall be located so as to minimize the accumulation of smoke or toxic gases.

303.3.21 ([F] 1104.22) Minimum aisle width. The minimum clear width of aisles shall be:

1. Forty-two inches (1067 mm) for aisle stairs having seating on each side.

   Exception: Thirty-six inches (914 mm) where the aisle serves less than 50 seats.

2. Thirty-six inches (914 mm) for stepped aisles having seating on only one side.

   Exception: Thirty inches (760 mm) for catchment areas serving not more than 60 seats.

3. Twenty inches (508 mm) between a stepped aisle handrail or guard and seating when the aisle is subdivided by the handrail.

4. Forty-two inches (1067 mm) for level or ramped aisles having seating on both sides.

   Exception: Thirty-six inches (914 mm) where the aisle serves less than 50 seats.

5. Thirty-six inches (914 mm) for level or ramped aisles having seating on only one side.

   Exception: Thirty inches (760 mm) for catchment areas serving not more than 60 seats.

6. Twenty-three inches (584 mm) between a stepped stair handrail and seating where an aisle does not serve more than five rows on one side.

303.3.22 ([F] 1104.23) Stairway floor number signs. Existing stairs shall be marked in accordance with Section 1022.8 of the *International Building Code*.

303.3.23 ([F] 1104.24) Egress path markings. Existing high-rise buildings of Group A, B, E, I, M and R-1 occupancies shall be provided with luminous egress path markings in accordance with Section 1024 of the *International Building Code*.

Exception: Open, unenclosed stairwells in historic buildings designated as historic under a state or local historic preservation program.

303.4 ([F] 1105) Requirements for outdoor operations. Outdoor operations shall be in accordance with Section 303.4.1 through 303.4.1.2.

303.4.1 ([F] 1105.1) Tire storage yards. Existing tire storage yards shall be provided with fire apparatus access roads in accordance with Sections 1105.1.1 and 1105.1.2 of the *International Building Code*.

303.4.1.1 ([F] 1105.1.1 Access to piles. Access roadways shall be within 150 feet (45 720 mm) of any point in the storage yard where storage piles are located, at least 20 feet (6096 mm) from any storage pile.

303.4.1.2 ([F] 1105.1.2) Location within piles. Fire apparatus access roads shall be located within all pile clearances identified in Section 3405.4 and within all fire breaks required in Section 3405.5 of the *International Fire Code*.

705.1 General. An area being altered within a facility that is altered shall comply with the applicable provisions in Sections 705.1.1 through 705.1.14, and Chapter 11 of the International Building Code unless it is technically infeasible. Where compliance with this Section is technically infeasible, the alteration shall provide access to the maximum extent that is technically feasible. Accessibility for existing buildings shall be determined as required by Section 302.1.1.

Add new standards to Chapter 16 as follows:

NFPA National Fire Protection Association
1 Batterymarch Park
Quincy, MA 02169-7471

NFPA 720-09 Standard for the installation of carbon monoxide(co) detection and warning equipment

UL Underwriters Laboratories, Inc.
333 Pfingsten Road
Northbrook, IL 60062-2096

UL 2034-08 Single and Multiple Station Carbon Monoxide Alarms with revisions through February 2009

Reason: This proposal does several things which include the following:

1. Revises the chapter title to more clearly reflect the content of the chapter
2. Restructures the requirements to more clearly point out the additional code requirements and make room for the existing minimum requirements
3. Adds some clarity on the applicable accessibility provisions
4. Places the minimum existing requirements from the fire code in the IEBC.

Title Change. The new title will make it more clear that the chapter both explains applicability and provides minimum requirements that apply to all methods of compliance.
Restructuring. Currently the additional code reference is lost at the end of the chapter. This will provide more visibility to this requirement. This also provides a better structure for future requirements such as those proposed for accessibility. In addition, it is felt that the provisions from Chapter 11 of the IFC which represent minimum existing requirements for all buildings, as applicable, should be stand alone for clarity.
Accessibility. Significant changes are being developed in the 2015 Edition of ANSI A117.1 Standard. No existing buildings have been designed to meet these standards and would be considered inaccessible under the new standard despite having complied with the 2003 standard. For example, Section 705.1.1 provides an exception for bringing an entrance into compliance if there is an accessible entrance elsewhere. A fully complying entrance under the older A117.1 would no longer be considered accessible under the new standard. Similarly, 705.2 requires the accessible route to conform where alterations are made to a primary function. Fully compliant access routes under the 2003 standard will not conform to the 2011 standard because of the changes to the minimum clearances reflecting the changed clear floor space.
With this change those elements that were compliant with the 2009 standard would continue to be considered compliant after the 2015 standard is made mandatory. This philosophy has been used with the changes in the new 2010 ADA Standard. Any existing building that conformed to the older standard is considered compliant under the new standard.
Existing requirements from IFC. Currently the IEBC only includes requirements for when an existing building is being repaired, altered or is undergoing a change of occupancy. The IFC includes minimum requirements for existing buildings in Chapter 11 that are applicable to all buildings. This change duplicates those requirements and moves them into the requirements for compliance in Chapter 3 of the IEBC so that owners and designers are aware of the additional minimums that may be imposed on an existing building beyond those required for the work anticipated. The intent is that these changes remain under the purview of the IFC Code Development Committee and are simply placed here to provide clarity to the code user that additional requirements may apply to the building if these minimums are not already met.
Changes from the IFC are only due to duplicate provisions that are already a part of the IEBC. For reference only we have included the original IFC Section number parenthetically.

- Fire code official has been revised to code official to address the fact that the authority enforcing this code may not be a fire code official.

- New Section 303.1.3 is based on IFC Section [F] 1101.3 that indicates that permits must be obtained per Sections 105.6 and 105.7 of the IFC and the IBC. The two referenced IFC Sections are not requiring permits for alterations necessary to conform, but for occupancies or systems in a building. A correction is made in this change to reference the IEBC permit requirements and a companion change is being submitted to make the same change to the IFC.

Cost Impact: This code change proposal will not increase the cost of construction.

Analysis: The proposed referenced standards are already referenced in the *International Building Code*.

301.1-EB-COLLINS.doc

Committee Action Hearing Results

Committee Action: Disapproved

Committee Reason: The committee felt that the IEBC is a construction code and adding operational requirements as found in the IFC Chapter 11 was inappropriate. Generally, the proposal was seen as too extensive and beyond the current scope and intent of the IEBC. There was some preference to the concept to instead provide a link to chapter 11 of the IFC to indicate the retroactive requirements.

Staff Analysis: This code change proposal goes beyond the scope of the IEBC by adding retroactive requirements to the code. If a public comment for approval as submitted or approval as modified is successful during the public comment hearings the result will be limited to an advisory recommendation to the ICC Board of Directors who will determine the final disposition on this proposed change.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Name: David S. Collins, The Preview Group, representing The American Institute of Architects and Robert J. Davidson, Davidson Code Concepts, LLC request Approval as Modified by this Public Comment.

Replace the proposal as follows:

CHAPTER 3
COMPLIANCE METHODS, APPLICABILITY AND MINIMUM REQUIREMENTS

301.1 General. The *repair*, *alteration*, *change of occupancy*, *addition* or relocation of all *existing buildings* shall comply with one of the methods listed in Sections 301.1.1 through 301.1.3 as selected by the applicant in addition to complying with the minimum requirements in Sections 302 and 303. Application of a method shall be the sole basis for assessing the compliance of work performed under a single permit unless otherwise approved by the *code official*. Sections 301.1.1 through 301.1.3 shall not be applied in combination with each other. Where this code requires consideration of the seismic force-resisting system of an existing building subject to *repair*, *alteration*, *change of occupancy*, *addition* or relocation of *existing buildings*, the seismic evaluation and design shall be based on Section 301.1.4 regardless of which compliance method is used.

> **Exception:** Subject to the approval of the *code official*, *alterations* complying with the laws in existence at the time the building or the affected portion of the building was built shall be considered in compliance with the provisions of this code unless the building is undergoing more than a limited structural alteration as defined in Section 907.4.3. New structural members added as part of the *alteration* shall comply with the *International Building Code*. *Alterations* of *existing buildings* in *flood hazard areas* shall comply with Section 701.3.

SECTION 302
ADDITIONAL CODES AND REQUIREMENTS

~~**301.2 Additional codes**~~ **302.1 General.** *Alterations, repairs, additions* and *changes of occupancy* to, or relocation of, *existing buildings* and structures shall comply with the provisions for *alterations, repairs, additions* and *changes of occupancy* or relocation, respectively, in this code and the *International Energy Conservation Code*, *International Fire Code, International Fuel Gas Code, International Mechanical Code, International Plumbing Code, International Property Maintenance Code, International Private Sewage Disposal Code*, *International Residential Code* and NFPA 70. Where provisions of the other codes conflict with provisions of this code, the provisions of this code shall take precedence.

SECTION 303
FIRE SAFETY AND MEANS OF EGRESS REQUIREMENTS FOR EXISTING BUILDINGS

303.1 ([F] SECTION 1103) Fire safety requirements for existing buildings. Minimum fire safety requirements for existing buildings shall be in provided in accordance with Sections 303.2 through 303.10.20.

303.2 ([F] 1103.1) Required construction. Existing buildings shall comply with not less than the minimum provisions specified in Table 303.2 and as further enumerated in Sections 303.3 through 303.9.

The provisions of this chapter shall not be construed to allow the elimination of fire protection systems or a reduction in the level of fire safety provided in buildings constructed in accordance with previously adopted codes.

Exception: Group U occupancies.

TABLE 303.2 ([F] TABLE 1103.1)
OCCUPANCY AND USE REQUIREMENTS[a]

SECTION	USE			OCCUPANCY CLASSIFICATION																		
	High rise	Atrium or covered mall	Under-ground building	A	B	E	F	H1	H-2	H-3	H-4	H-5	I-1	I-2	I-3	I-4	M	R-1	R-2	R-3	R-4	S

302.7.12.4.1	R	R	R	R	R	R	R	R	R	R	-	-	R	R	R	R	R	R	R	R	R	R

a. Existing buildings shall comply with the sections identified as "Required" (R) based on occupancy classification or use, or both, whichever is applicable.
R = The building is required to comply.

303.3 ([F] 1103.2) Emergency responder radio coverage in existing buildings. Existing buildings that do not have approved radio coverage for emergency responders within the building based upon the existing coverage levels of the public safety communication systems of the jurisdiction at the exterior of the building, shall be equipped with such coverage according to one of the following:

1. Whenever an existing wired communication system cannot be repaired or is being replaced, or where not approved in accordance with Section 510.1, Exception 1 of the *International Fire Code*.

2. Within a time frame established by the adopting authority.

   Exception: Where it is determined by the code official that the radio coverage system is not needed.

303.4 ([F] 1103.3) Elevator operation. Existing elevators with a travel distance of 25 feet (7620 mm) or more above or below the main floor or other level of a building and intended to serve the needs of emergency personnel for fire-fighting or rescue purposes shall be provided with emergency operation in accordance with ASME A17.3.

303.5 ([F] 1103.4) Vertical openings. Interior vertical shafts, including but not limited to stairways, elevator hoistways, service and utility shafts, that connect two or more stories of a building, shall be enclosed or protected as specified in Sections 303.5.1 through 303.5.7.

303.5.1 ([F] 1103.4.1) Group I occupancies. In Group I occupancies, interior vertical openings connecting two or more stories shall be protected with 1-hour fire-resistance-rated construction.

303.5.2 ([F] 1103.4.2) Three to five stories. In other than Group I occupancies, interior vertical openings connecting three to five stories shall be protected by either 1-hour fire-resistance-rated construction or an automatic sprinkler system shall be installed throughout the building in accordance with Section 903.3.1.1 or 903.3.1.2 of the *International Building Code*.

Exceptions:

1. Vertical opening protection is not required for Group R-3 occupancies.
2. Vertical opening protection is not required for open parking garages and ramps.
3. Vertical opening protection for escalators shall be in accordance with Section 303.5.5, 303.5.6 or 303.5.7.

303.5.3 ([F] 1103.4.3) More than five stories. In other than Group I occupancies, interior vertical openings connecting more than five stories shall be protected by 1-hour fire-resistance-rated construction.

Exceptions:

1. Vertical opening protection is not required for Group R-3 occupancies.
2. Vertical opening protection is not required for open parking garages and ramps.
3. Vertical opening protection for escalators shall be in accordance with Section 303.5.5, 303.5.6 or 303.5.7.

303.5.4 ([F] 1103.4.4) Atriums and covered malls. In other than Group I occupancies, interior vertical openings in a covered mall building or a building with an atrium shall be protected by either 1-hour fire-resistance-rated construction or an automatic sprinkler system shall be installed throughout the building in accordance with Section 903.3.1.1 or 903.3.1.2 of the *International Building Code*.

Exceptions:

1. Vertical opening protection is not required for Group R-3 occupancies.
2. Vertical opening protection is not required for open parking garages and ramps.

303.5.5 ([F] 1103.4.5) Escalators in Group B and M occupancies. Escalators creating vertical openings connecting any number of stories shall be protected by either 1-hour fire-resistance-rated construction or an automatic sprinkler system in accordance with Section 903.3.1.1 of the *International Building Code* installed throughout the building, with a draft curtain and closely spaced sprinklers around the escalator opening.

303.5.6 ([F] 1103.4.6) Escalators connecting four or fewer stories. In other than Group B and M occupancies, escalators creating vertical openings connecting four or fewer stories shall be protected by either 1-hour fire-resistance-rated construction or an automatic sprinkler system in accordance with Section 903.3.1.1 or 903.3.1.2 of the *International Building Code* shall be installed throughout the building, and a draft curtain with closely spaced sprinklers shall be installed around the escalator opening.

303.5.7 ([F] 1103.4.7) Escalators connecting more than four stories. In other than Group B and M occupancies, escalators creating vertical openings connecting five or more stories shall be protected by 1-hour fire-resistance-rated construction.

303.6 ([F] 1103.5) Sprinkler systems. An automatic sprinkler system shall be provided in existing buildings in accordance with Sections 303.6.1 and 303.6.2.

303.6.1 ([F] 1103.5.1) Pyroxylin plastics. An automatic sprinkler system shall be provided throughout existing buildings where cellulose nitrate film or pyroxylin plastics are manufactured, stored or handled in quantities exceeding 100 pounds (45 kg). Vaults located within buildings for the storage of raw pyroxylin shall be protected with an approved automatic sprinkler system capable of discharging 1.66 gallons per minute per square foot (68 L/min/m^2) over the area of the vault.

303.6.2([F] 1103.5.2) Group I-2. An automatic sprinkler system shall be provided throughout existing Group I-2 fire areas. The sprinkler system shall be provided throughout the floor where the Group I-2 occupancy is located, and in all floors between the Group I-2 occupancy and the level of exit discharge.

303.7 ([F] 1103.6) Standpipes. Where required by Sections 303.7.1 or 303.7.2, standpipes shall be installed in accordance with Section 905 of the *International Building Code*. The code official is authorized to approve the installation of manual standpipe systems to achieve compliance with this section where the responding fire department is capable of providing the required hose flow at the highest standpipe outlet.

303.7.1 ([F] 1103.6.1) Existing multiple-story buildings. Existing buildings with occupied floors located more than 50 feet (15 240 mm) above the lowest level of fire department access or more than 50 feet (15 240 mm) below the highest level of fire department access shall be equipped with standpipes.

303.7.2 ([F] 1103.6.2) Existing helistops and heliports. Existing buildings with a rooftop helistop or heliport located more than 30 feet (9144 mm) above the lowest level of fire department access to the roof level on which the helistop or heliport is located shall be equipped with standpipes in accordance with Section 905.3.6 of the *International Building Code*.

303.8 ([F] 1103.7) Fire alarm systems. An approved fire alarm system shall be installed in existing buildings and structures where required by Sections 303.8.1 through 303.8.7 and provide occupant notification in accordance with Section 907.6 of the *International Building Code* unless other requirements are provided by other sections of this code.

Exception: Occupancies with an existing, previously approved fire alarm system.

303.8.1 ([F] 1103.7.1) Group E. A fire alarm system shall be installed in existing Group E occupancies in accordance with Section 907.2.3.

Exceptions:

1. A manual fire alarm system is not required in a building with a maximum area of 1,000 square feet (93 m^2) that contains a single classroom and is located no closer than 50 feet (15 240 mm) from another building.
2. A manual fire alarm system is not required in Group E occupancies with an occupant load less than 50.

303.8.2 ([F] 1103.7.2) Group I-1. An automatic fire alarm system shall be installed in existing Group I-1 residential care/assisted living facilities in accordance with Section 907.2.6.1 of the *International Building Code*.

Exceptions:

1. Manual fire alarm boxes in resident or patient sleeping areas shall not be required at exits if located at all nurses' control stations or other constantly attended staff locations, provided such stations are visible and continuously accessible and that travel distances required in Section 907.5.2 of the *International Building Code* are not exceeded.
2. Where each sleeping room has a means of egress door opening directly to an exterior egress balcony that leads directly to the exits in accordance with Section 1019 of the *International Building Code*, and the building is not more than three stories in height.

303.8.3 ([F] 1103.7.3) Group I-2. An automatic fire alarm system shall be installed in existing Group I-2 occupancies in accordance with Section 907.2.6.2 of the *International Building Code*..

Exception: Manual fire alarm boxes in resident or patient sleeping areas shall not be required at exits if located at all nurses' control stations or other constantly attended staff locations, provided such stations are visible and continuously accessible and that travel distances required in Section 907.5.2.1 of the *International Building Code* are not exceeded.

303.8.4 ([F] 1103.7.4) Group I-3. An automatic and manual fire alarm system shall be installed in existing Group I-3 occupancies in accordance with Section 907.2.6.3 of the *International Building Code*.

303.8.5 ([F] 1103.7.5) Group R-1. A fire alarm system and smoke alarms shall be installed in existing Group R-1 occupancies in accordance with Sections 303.8.5.1 through 303.8.5.2.1.

303.8.5.1 ([F] 1103.7.5.1) Group R-1 hotel and motel manual fire alarm system. A manual fire alarm system that activates the occupant notification system in accordance with Section 907.6 of the *International Building Code* shall be installed in existing Group R-1 hotels and motels more than three stories or with more than 20 sleeping units.

Exceptions:

1. Buildings less than two stories in height where all sleeping units, attics and crawl spaces are separated by 1-hour fire-resistance-rated construction and each sleeping unit has direct access to a public way, egress court or yard.
2. Manual fire alarm boxes are not required throughout the building when the following conditions are met:
   - 2.1. The building is equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.3.1.2 of the *International Building Code*;
   - 2.2. The notification appliances will activate upon sprinkler water flow; and
   - 2.3. At least one manual fire alarm box is installed at an approved location.

303.8.5.1.1 ([F] 1103.7.5.1.1) Group R-1 hotel and motel automatic smoke detection system. An automatic smoke detection system that activates the occupant notification system in accordance with Section 907.6 of the *International Building Code* shall be installed in existing Group R-1 hotels and motels throughout all interior corridors serving sleeping rooms not equipped with an approved, supervised sprinkler system installed in accordance with Section 903 of the *International Building Code*.

Exception: An automatic smoke detection system is not required in buildings that do not have interior corridors serving sleeping units and where each sleeping unit has a means of egress door opening directly to an exit or to an exterior exit access that leads directly to an exit.

303.8.5.2 ([F] 1103.7.5.2) Group R-1 boarding and rooming houses manual fire alarm system. A manual fire alarm system that activates the occupant notification system in accordance with Section 907.6 of the *International Building Code* shall be installed in existing Group R-1 boarding and rooming houses.

> **Exception**: Buildings less than two stories in height where all sleeping units, attics and crawl spaces are separated by 1-hour fire-resistance-rated construction and each sleeping unit has direct access to a public way, egress court or yard.

303.8.5.2.1 ([F] 1103.7.5.2.1) Group R-1 boarding and rooming houses automatic smoke detection system. An automatic smoke detection system that activates the occupant notification system in accordance with Section 907.6 of the *International Building Code* shall be installed in existing Group R-1 boarding and rooming houses throughout all interior corridors serving sleeping units not equipped with an approved, supervised sprinkler system installed in accordance with Section 903 of the *International Building Code*.

> **Exception:** Buildings equipped with single-station smoke alarms meeting or exceeding the requirements of Section 907.2.11.1 of the *International Building Code* and where the fire alarm system includes at least one manual fire alarm box per floor arranged to initiate the alarm.

303.8.6 ([F] 1103.7.6) Group R-2. A manual fire alarm system that activates the occupant notification system in accordance with Section 907.6 of the *International Building Code* shall be installed in existing Group R-2 occupancies more than three stories in height or with more than 16 dwelling or sleeping units.

Exceptions:

1. Where each living unit is separated from other contiguous living units by fire barriers having a fire-resistance rating of not less than 0.75 hour, and where each living unit has either its own independent exit or its own independent stairway or ramp discharging at grade.
2. A separate fire alarm system is not required in buildings that are equipped throughout with an approved supervised automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.3.1.2 of the *International Building Code* and having a local alarm to notify all occupants.
3. A fire alarm system is not required in buildings that do not have interior corridors serving dwelling units and are protected by an approved automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.3.1.2 of the *International Building Code*, provided that dwelling units either have a means of egress door opening directly to an exterior exit access that leads directly to the exits or are served by open-ended corridors designed in accordance with Section 1026.6, Exception 4 of the *International Building Code*.

303.8.7 ([F] 1103.7.7) Group R-4. A manual fire alarm system that activates the occupant notification system in accordance with Section 907.6 of the *International Building Code* shall be installed in existing Group R-4 residential care/assisted living facilities in accordance with Section 907.2.10.1 of the *International Building Code*.

Exceptions:

1. Where there are interconnected smoke alarms meeting the requirements of Section 907.2.11 of the *International Building Code* and there is at least one manual fire alarm box per floor arranged to continuously sound the smoke alarms.
2. Other manually activated, continuously sounding alarms approved by the code official.

303.8.8 ([F] 1103.8) Single- and multiple-station smoke alarms. Single- and multiple-station smoke alarms shall be installed in existing Group I-1 and R occupancies in accordance with Sections 303.8.8.1 through 303.8.8.3.

303.8.8.1 ([F] 1103.8.1) Where required. Existing Group I-1 and R occupancies shall be provided with single-station smoke alarms in accordance with Section 907.2.11 of the *International Building Code*, except as provided in Sections 303.8.8.2 or 303.8.8.3.

Exceptions:

1. Where the code that was in effect at the time of construction required smoke alarms and smoke alarms complying with those requirements are already provided.
2. Where smoke alarms have been installed in occupancies and dwellings that were not required to have them at the time of construction, additional smoke alarms shall not be required provided that the existing smoke alarms comply with requirements that were in effect at the time of installation.
3. Where smoke detectors connected to a fire alarm system have been installed as a substitute for smoke alarms.

303.8.8.2 ([F] 1103.8.2) Interconnection. Where more than one smoke alarm is required to be installed within an individual dwelling or sleeping unit, the smoke alarms shall be interconnected in such a manner that the activation of one alarm will activate all of the alarms in the individual unit. Physical interconnection of smoke alarms shall not be required where listed wireless alarms are installed and all alarms sound upon activation of one alarm. The alarm shall be clearly audible in all bedrooms over background noise levels with all intervening doors closed.

Exceptions:

1. Interconnection is not required in buildings that are not undergoing alterations, repairs or construction of any kind.

2. Smoke alarms in existing areas are not required to be interconnected where alterations or repairs do not result in the removal of interior wall or ceiling finishes exposing the structure, unless there is an attic, crawl space or basement available which could provide access for interconnection without the removal of interior finishes.

303.8.8.3 ([F] 1103.8.3) Power source. Single-station smoke alarms shall receive their primary power from the building wiring provided that such wiring is served from a commercial source and shall be equipped with a battery backup. Smoke alarms with integral strobes that are not equipped with battery backup shall be connected to an emergency electrical system. Smoke alarms shall emit a signal when the batteries are low. Wiring shall be permanent and without a disconnecting switch other than as required for overcurrent protection.

Exceptions:

1. Smoke alarms are permitted to be solely battery operated in existing buildings where no construction is taking place.
2. Smoke alarms are permitted to be solely battery operated in buildings that are not served from a commercial power source.
3. Smoke alarms are permitted to be solely battery operated in existing areas of buildings undergoing alterations or repairs that do not result in the removal of interior walls or ceiling finishes exposing the structure, unless there is an attic, crawl space or basement available which could provide access for building wiring without the removal of interior finishes.

303.9 ([F] 1103.9) Carbon monoxide alarms. Existing Group I or R occupancies located in a building containing a fuel-burning appliance or a building which has an attached garage shall be equipped with single-station carbon monoxide alarms. The carbon monoxide alarms shall be listed as complying with UL 2034, and be installed and maintained in accordance with NFPA 720 and the manufacturer's instructions. An open parking garage, as defined in the International Building Code, or an enclosed parking garage ventilated in accordance with Section 404 of the *International Mechanical Code* shall not be deemed to be an attached garage.

Exception: Sleeping units or dwelling units which do not themselves contain a fuel-burning appliance or have an attached garage, but which are located in a building with a fuel-burning appliance or an attached garage, need not be equipped with single-station carbon monoxide alarms provided that:

1. The sleeping unit or dwelling unit is located more than one story above or below any story that contains a fuel-burning appliance or an attached garage;

2. The sleeping unit or dwelling unit is not connected by duct work or ventilation shafts to any room containing a fuel-burning appliance or to an attached garage; and

3. The building is provided with a common area carbon monoxide alarm system.

303.10 ([F] 1104.1) Means of egress for existing buildings. Means of egress in existing buildings shall comply with the minimum egress requirements when specified in Table 303.2 as further enumerated in Sections 303.10.1 through 303.10.20, and the building code that applied at the time of construction. Where the provisions of this chapter conflict with the building code that applied at the time of construction, the most restrictive provision shall apply. Existing buildings that were not required to comply with a building code at the time of construction shall comply with the minimum egress requirements when specified in Table 303.2 as further enumerated in Sections 303.10.1 through 303.10.20.

303.10.1 ([F] 1104.2) Elevators, escalators and moving walks. Elevators, escalators and moving walks shall not be used as a component of a required means of egress.

Exceptions:

1. Elevators used as an accessible means of egress where allowed by Section 1007.4 of the *International Building Code*.
2. Previously approved escalators and moving walks in existing buildings.

303.10.2 ([F] 1104.3) Exit sign illumination. Exit signs shall be internally or externally illuminated. The face of an exit sign illuminated from an external source shall have an intensity of not less than 5 footcandles (54 lux). Internally illuminated signs shall provide equivalent luminance and be listed for the purpose.

Exception: Approved self-luminous signs that provide evenly illuminated letters shall have a minimum luminance of 0.06 foot-lamberts (0.21 cd/m2).

303.10.3 ([F] 1104.5) Illumination emergency power. The power supply shall normally be provided by the premises' electrical supply. In the event of power supply failure, illumination shall be automatically provided from an emergency system for the following occupancies where such occupancies require two or more means of egress:

1. Group A having 50 or more occupants.

   Exception: Assembly occupancies used exclusively as a place of worship and having an occupant load of less than 300.

2. Group B buildings three or more stories in height, buildings with 100 or more occupants above or below a level of exit discharge serving the occupants or buildings with 1,000 or more total occupants.

3. Group E in interior stairs, corridors, windowless areas with student occupancy, shops and laboratories.

4. Group F having more than 100 occupants.

   Exception: Buildings used only during daylight hours which are provided with windows for natural light in accordance with the International Building Code.

5. Group I.

6. Group M.

   Exception: Buildings less than 3,000 square feet (279 m2) in gross sales area on one story only, excluding mezzanines.

7. Group R-1.

   Exception: Where each sleeping unit has direct access to the outside of the building at grade.

8. Group R-2.

   Exception: Where each dwelling unit or sleeping unit has direct access to the outside of the building at grade.

9. Group R-4.

   Exception: Where each sleeping unit has direct access to the outside of the building at ground level.

303.10.3.1 ([F] 1104.4) Power source. Where emergency illumination is required in Section 303.10.3, exit signs shall be visible under emergency illumination conditions.

Exception: Approved signs that provide continuous illumination independent of external power sources are not required to be connected to an emergency electrical system.

303.10.3.2 ([F] 1104.5.1) Emergency power duration and installation. In other than Group I-2, the emergency power system shall provide power for not less than 60 minutes and consist of storage batteries, unit equipment or an on-site generator. In Group I-2, the emergency power system shall provide power for not less than 90 minutes and consist of storage batteries, unit equipment or an on-site generator. The installation of the emergency power system shall be in accordance with Section 1006.3 of the *international Building Code*.

303.10.4([F] 1104.6) Guards. Guards complying with this section shall be provided at the open sides of means of egress that are more than 30 inches (762 mm) above the floor or grade below.

303.10.4.1 ([F] 1104.6.1) Height of guards. Guards shall form a protective barrier not less than 42 inches (1067 mm) high.

Exceptions:

1. Existing guards on the open side of stairs shall be not less than 30 inches (760 mm) high.
2. Existing guards within dwelling units shall be not less than 36 inches (910 mm) high.
3. Existing guards in assembly seating areas.

303.10.4.2 ([F] 1104.6.2) Opening limitations. Open guards shall have balusters or ornamental patterns such that a 6-inch-diameter (152 mm) sphere cannot pass through any opening up to a height of 34 inches (864 mm).

Exceptions:

1. At elevated walking surfaces for access to, and use of, electrical, mechanical or plumbing systems or equipment, guards shall have balusters or be of solid materials such that a sphere with a diameter of 21 inches (533 mm) cannot pass through any opening.
2. In occupancies in Group I-3, F, H or S, the clear distance between intermediate rails measured at right angles to the rails shall not exceed 21 inches (533 mm).
3. Approved existing open guards.

303.10.5 ([F] 1104.7) Size of doors. The minimum width of each door opening shall be sufficient for the occupant load thereof and shall provide a clear width of not less than 28 inches (711 mm). Where this section requires a minimum clear width of 28 inches (711 mm) and a door opening includes two door leaves without a mullion, one leaf shall provide a clear opening width of 28 inches (711 mm). The maximum width of a swinging door leaf shall be 48 inches (1219 mm) nominal. Means of egress doors in an occupancy in Group I-2 used for the movement of beds shall provide a clear width not less than 41.5 inches (1054 mm). The height of doors shall not be less than 80 inches (2032 mm).

Exceptions:

1. The minimum and maximum width shall not apply to door openings that are not part of the required means of egress in occupancies in Groups R-2 and R-3.
2. Door openings to storage closets less than 10 square feet (0.93 m2) in area shall not be limited by the minimum width.
3. Width of door leafs in revolving doors that comply with Section 1008.1.4.1 shall not be limited.
4. Door openings within a dwelling unit shall not be less than 78 inches (1981 mm) in height.
5. Exterior door openings in dwelling units, other than the required exit door, shall not be less than 76 inches (1930 mm) in height.
6. Exit access doors serving a room not larger than 70 square feet (6.5 m2) shall be not less than 24 inches (610 mm) in door width.

303.10.5.1 ([F] 1104.8) Opening force for doors. The opening force for interior side-swinging doors without closers shall not exceed a 5-pound (22 N) force. For other side-swinging, sliding and folding doors, the door latch shall release when subjected to a force of not more than 15 pounds (66 N). The door shall be set in motion when subjected to a force not exceeding 30 pounds (133 N). The door shall swing to a full-open position when subjected to a force of not more than 50 pounds (222 N). Forces shall be applied to the latch side.

303.10.5.2 ([F] 1104.9) Revolving doors. Revolving doors shall comply with the following:

1. A revolving door shall not be located within 10 feet (3048 mm) of the foot or top of stairs or escalators. A dispersal area shall be provided between the stairs or escalators and the revolving doors.
2. The revolutions per minute for a revolving door shall not exceed those shown in Table 303.10.5.2.
3. Each revolving door shall have a conforming side-hinged swinging door in the same wall as the revolving door and within 10 feet (3048 mm).

Exceptions:

1. A revolving door is permitted to be used without an adjacent swinging door for street-floor elevator lobbies provided a stairway, escalator or door from other parts of the building does not discharge through the lobby and the lobby does not have any occupancy or use other than as a means of travel between elevators and a street.
2. Existing revolving doors are permitted where the number of revolving doors does not exceed the number of swinging doors within 20 feet (6096 mm).

303.10.5.2 TABLE ([F] 1104.9)
REVOLVING DOOR SPEEDS

INSIDE DIAMETER (feet-inches)	POWER-DRIVEN-TYPE SPEED CONTROL (rpm)	MANUAL-TYPE SPEED CONTROL (rpm)
6-6	11	12
7-0	10	11
7-6	9	11
8-0	9	10
8-6	8	9
9-0	8	9
9-6	7	8
10-0	7	8

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm.

303.10.5.2.1 ([F] 1104.9.1) Egress component. A revolving door used as a component of a means of egress shall comply with Section 303.10.5.2 and all of the following conditions:

1. Revolving doors shall not be given credit for more than 50 percent of the required egress capacity.
2. Each revolving door shall be credited with not more than a 50-person capacity.
3. Revolving doors shall be capable of being collapsed when a force of not more than 130 pounds (578 N) is applied within 3 inches (76 mm) of the outer edge of a wing.

303.10.6 ([F] 1104.10) Stair dimensions for existing stairs. Existing stairs in buildings shall be permitted to remain if the rise does not exceed 81/4 inches (210 mm) and the run is not less than 9 inches (229 mm). Existing stairs can be rebuilt.

Exception: Other stairs approved by the code official.

303.10.7 ([F] 1104.11) Winders. Existing winders shall be allowed to remain in use if they have a minimum tread depth of 6 inches (152 mm) and a minimum tread depth of 9 inches (229 mm) at a point 12 inches (305 mm) from the narrowest edge.

303.10.8 ([F] 1104.12) Circular stairways. Existing circular stairs shall be allowed to continue in use provided the minimum depth of tread is 10 inches (254 mm) and the smallest radius shall not be less than twice the width of the stairway.

303.10.9 ([F] 1104.13) Stairway handrails. Stairways shall have handrails on at least one side. Handrails shall be located so that all portions of the stairway width required for egress capacity are within 44 inches (1118 mm) of a handrail.

Exception: Aisle stairs provided with a center handrail are not required to have additional handrails.

303.10.9.1([F] 1104.13.1) Height. Handrail height, measured above stair tread nosings, shall be uniform, not less than 30 inches (762 mm) and not more than 42 inches (1067 mm).

303.10.10[F] 1104.14) Slope of ramps. Ramp runs utilized as part of a means of egress shall have a running slope not steeper than one unit vertical in 10 units horizontal (10-percent slope). The slope of other ramps shall not be steeper than one unit vertical in eight units horizontal (12.5-percent slope).

303.10.11 ([F] 1104.15) Width of ramps. Existing ramps are permitted to have a minimum width of 30 inches (762 mm) but not less than the width required for the number of occupants served as determined by the *International Building Code.*

303.10.12 ([F] 1104.16) Fire escape stairs. Fire escape stairs shall comply with Sections 805.3.1.2.

303.10.13 ([F] 1104.17) Corridors. Corridors serving an occupant load greater than 30 and the openings therein shall provide an effective barrier to resist the movement of smoke. Transoms, louvers, doors and other openings shall be kept closed or self-closing.

Exceptions:

1. Corridors in occupancies other than in Group H, which are equipped throughout with an approved automatic sprinkler system.
2. Patient room doors in corridors in occupancies in Group I-2 where smoke barriers are provided in accordance with the *International Building Code*.
3. Corridors in occupancies in Group E where each room utilized for instruction or assembly has at least one-half of the required means of egress doors opening directly to the exterior of the building at ground level.
4. Corridors that are in accordance with the *International Building Code*.

303.10.13.1 ([F] 1104.17.1) Corridor openings. Openings in corridor walls shall comply with the requirements of the International Building Code.

Exceptions:

1. Where 20-minute fire door assemblies are required, solid wood doors at least 1.75 inches (44 mm) thick or insulated steel doors are allowed.
2. Openings protected with fixed wire glass set in steel frames.
3. Openings covered with 0.5-inch (12.7 mm) gypsum wallboard or 0.75-inch (19.1 mm) plywood on the room side.
4. Opening protection is not required when the building is equipped throughout with an approved automatic sprinkler system.

303.10.13.2 ([F] 1104.17.2) Dead ends. Where more than one exit or exit access doorway is required, the exit access shall be arranged such that dead ends do not exceed the limits specified in Table 303.10.13.2.

Exception: A dead-end passageway or corridor shall not be limited in length where the length of the dead-end passageway or corridor is less than 2.5 times the least width of the dead-end passageway or corridor.

303.10.13.2 TABLE ([F] 1104.17.2)
COMMON PATH, DEAD-END AND TRAVEL DISTANCE LIMITS (by occupancy)

OCCUPANCY	COMMON PATH LIMIT		DEAD-END LIMIT		TRAVEL DISTANCE LIMIT	
	Unsprinklered (feet)	Sprinklered (feet)	Unsprinklered (feet)	Sprinklered (feet)	Unsprinklered (feet)	Sprinklered (feet)
Group A	20/75[a]	20/75[a]	20[b]	20[b]	200	250
Group B[f]	75	100	50	50	200	300
Group E	75	100	50	50	200	300
Group F-1, S-1[d,f]	75	100	50	50	200	250
Group F-2, S-2[d,f]	75	100	50	50	300	400
Group H-1	25	25	0	0	75	75
Group H-2	50	100	0	0	75	100
Group H-3	50	100	20	20	100	150
Group H-4	75	75	20	20	150	175
Group H-5	75	75	20	50	150	200
Group I-1	75	75	20	50	200	250
Group I-2 (Health care)	NR[e]	NR[e]	NR	NR	150	200[c]
Group I-3 (Detention and correctional – Use Conditions II, III, IV, V)	100	100	NR	NR	150[c]	200[c]

Group I-4 (Day care centers)	NR	NR	20	20	200	250
Group M (Covered or open mall)	75	100	50	50	200	400
Group M (Mercantile)	75	100	50	50	200	250
Group R-1 (Hotels)	75	75	50	50	200	250
Group R-2 (Apartments)	75	125	50	50	200	250
Group R-3 (One- and two-family)	NR	NR	NR	NR	NR	NR
Group R-4 (Residential care/assisted living)	NR	NR	NR	NR	NR	NR
Group U	75	100	20	50	300	400

NR = No requirements.
For SI: 1 foot = 304.8 mm, 1 square foot = 0.0929 m2.

a. 20 feet for common path serving 50 or more persons; 75 feet for common path serving less than 50 persons.
b. See Section 1028.9.5 for dead-end aisles in Group A occupancies.
c. This dimension is for the total travel distance, assuming incremental portions have fully utilized their allowable maximums. For travel distance within the room, and from the room exit access door to the exit, see the appropriate occupancy chapter.
d. See the International Building Code for special requirements on spacing of doors in aircraft hangars.
e. Any patient sleeping room, or any suite that includes patient sleeping rooms, of more than 1,000 square feet shall have at least two exit access doors placed a distance apart equal to not less than one-third of the length of the maximum overall diagonal dimension of the patient sleeping room or suite to be served, measured in a straight line between exit access doors.
f. Where a tenant space in Group B, S and U occupancies has an occupant load of not more than 30, the length of a common path of egress travel shall not be more than 100 feet.

303.10.14 F] 1104.18) Exit access travel distance. Exits shall be located so that the maximum length of exit access travel, measured from the most remote point to an approved exit along the natural and unobstructed path of egress travel, does not exceed the distances given in Table 303.10.13.2.

303.10.15 ([F] 1104.19) Common path of egress travel. The common path of egress travel shall not exceed the distances given in Table 303.10.13.2.

303.10.16 ([F] 1104.20) Stairway discharge identification. An interior exit stairway or ramp which continues below its level of exit discharge shall be arranged and marked to make the direction of egress to a public way readily identifiable.

Exception: Stairs that continue one-half story beyond their levels of exit discharge need not be provided with barriers where the exit discharge is obvious.

303.10.17 ([F] 1104.21) Exterior stairway protection. Exterior exit stairs shall be separated from the interior of the building as required in Section 1026.6 of the *International Building Code*. Openings shall be limited to those necessary for egress from normally occupied spaces.

Exceptions:

1. Separation from the interior of the building is not required for buildings that are two stories or less above grade where the level of exit discharge serving such occupancies is the first story above grade.
2. Separation from the interior of the building is not required where the exterior stairway is served by an exterior balcony that connects two remote exterior stairways or other approved exits, with a perimeter that is not less than 50 percent open. To be considered open, the opening shall be a minimum of 50 percent of the height of the enclosing wall, with the top of the opening not less than 7 feet (2134 mm) above the top of the balcony.
3. Separation from the interior of the building is not required for an exterior stairway located in a building or structure that is permitted to have unenclosed interior stairways in accordance with Section 1022 of the *International Building Code*.
4. Separation from the interior of the building is not required for exterior stairways connected to open-ended corridors, provided that:
    - 4.1. The building, including corridors and stairs, is equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 or 903.3.1.2 of the *International Building Code*.
    - 4.2. The open-ended corridors comply with Section 1018.2 of the *International Building Code*.
    - 4.3. The open-ended corridors are connected on each end to an exterior exit stairway complying with Section 1026 of the *International Building Code*.
    - 4.4. At any location in an open-ended corridor where a change of direction exceeding 45 degrees (0.79 rad) occurs, a clear opening of not less than 35 square feet (3 m2) or an exterior stairway shall be provided.

Where clear openings are provided, they shall be located so as to minimize the accumulation of smoke or toxic gases.

303.10.18 ([F] 1104.22) Minimum aisle width. The minimum clear width of aisles shall be:

1. Forty-two inches (1067 mm) for aisle stairs having seating on each side.

   Exception: Thirty-six inches (914 mm) where the aisle serves less than 50 seats.

2. Thirty-six inches (914 mm) for stepped aisles having seating on only one side.

   Exception: Thirty inches (760 mm) for catchment areas serving not more than 60 seats.

3. Twenty inches (508 mm) between a stepped aisle handrail or guard and seating when the aisle is subdivided by the handrail.

4. Forty-two inches (1067 mm) for level or ramped aisles having seating on both sides.

   Exception: Thirty-six inches (914 mm) where the aisle serves less than 50 seats.

5. Thirty-six inches (914 mm) for level or ramped aisles having seating on only one side.

   Exception: Thirty inches (760 mm) for catchment areas serving not more than 60 seats.

6. Twenty-three inches (584 mm) between a stepped stair handrail and seating where an aisle does not serve more than five rows on one side.

303.10.19 ([F] 1104.23) Stairway floor number signs. Existing stairs shall be marked in accordance with Section 1022.8 of the *International Building Code*.

303.10.20 ([F] 1104.24) Egress path markings. Existing high-rise buildings of Group A, B, E, I, M and R-1 occupancies shall be provided with luminous egress path markings in accordance with Section 1024 of the *International Building Code*.

Exception: Open, unenclosed stairwells in historic buildings designated as historic under a state or local historic preservation program.

Commenter's Reason: (Collins-Davidson) During testimony at the hearings in Dallas it was indicated that these provisions included requirements that weren't necessary because the reference to the IFC covered these provisions. Similar to other provisions that are found in multiple codes, these minimum requirements for existing buildings should be obvious to anyone using the code, whether they are found in the IFC or the IEBC. Users of codes should not be subject to "gotcha" provisions found in other codes that will have a significant impact on the design and use of these buildings. Worse, the application of these provisions may not occur until after the project has been permitted and or even occupied.

Also, with the modification of the ADM provision to update the A117.1 to keep the reference to the 2009 edition, the changes that the 2015 edition would have imposed on existing buildings will not have to be addressed until the 2018 edition.

Public Comment 2:

Maureen Traxler, City of Seattle Department of Planning & Development, representing Washington Association of Building Officials Technical Code Development Committee, requests Approval as Modified by this Public Comment.

Replace the proposal as follows:

SECTION 302
EXISTING BUILDING MINIMUM REQUIREMENTS

302.1 Required construction. Buildings undergoing repairs, alterations, changes of occupancy, additions and relocations shall comply with Chapter 11 of the International Fire Code in addition to the requirements of this Code.

Commenter's Reason: The original proposal dealt with 2 issues: accessibility and IFC Chapter 11 retroactive requirements. This public comment only addresses the second of those issues. The original proposal brought all of IFC Chapter 11 into the IEBC. However, Chapter 11's provisions are retroactive and apply even when a building is not undergoing repair, alteration, addition, change of occupancy or relocation. All of those provisions are outside the scope of the IEBC. IEBC Section 101.2 states "**101.2 Scope.** The provisions of the International Existing Building Code **shall apply to the repair, alteration, change of occupancy, addition and relocation** of existing buildings." (emphasis added)

The proponents of this code change proposal raised an important point—IFC Chapter 11 applies to all buildings, regardless of whether any work or change of occupancy is being proposed for the building. Building owners and designers may not be aware of Chapter 11, especially in jurisdictions where it is not actively enforced, but they are still obligated by law to comply with it. This proposal states that Chapter 11 provides minimum standards that apply to work within the scope of the IEBC without introducing retroactive requirements into the IEBC. This proposal would enhance enforcement of IFC Chapter 11 without exceeding the scope of the IEBC.

EB3-13

Final Action: AS AM AMPC____ D

EB5-13
504.1.1 (NEW)

Proposed Change as Submitted

Proponent: David S. Collins, FAIA, The Preview Group, Inc., representing The American Institute of Architects

Add new text as follows:

504.1 Scope. Level 2 *alterations* include the reconfiguration of space, the addition or elimination of any door or window, the reconfiguration or extension of any system, or the installation of any additional equipment.

<u>**504.1.1** Except where aisles required in Groups B and M, table seating per Sections 1017.3 and 1017.4 of the *International Building Code* or assembly seating per Section 1028 of the *International Building Code*, are reconfigured, the movement, addition or removal of furniture, movable partitions less than 5 feet 9 inches in height, or fixtures within a space shall not be considered reconfiguration of space.</u>

Reason: Reconfiguration of a space can occur simply by movement of furniture. It isn't the intent of the IEBC to require that furniture rearrangement be included as an alteration, except where the IBC specifically limits aisles, table seating or assembly seating. By this change the rearrangement of furniture is not a trigger for application of the requirement for Level 2 Alterations.

Cost Impact: This code change proposal will not increase the cost of construction.

504.1.1 (NEW)-EB-COLLINS.doc

Committee Action Hearing Results

Committee Action: Disapproved

Committee Reason: The lead in language was confusing and the terms "shall not" were not appropriate. In addition, there was concern with the high fire hazard furniture being addressed in this exception.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

David S. Collins, FAIA, The Preview Group, Inc, representing The American Institute of Architects requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

504.1.1 ~~Except where Aisles required in Groups B and M, table seating per Sections 1017.3 and 1017.4 of the *International Building Code* or assembly seating per Section 1028 of the *International Building Code*, are reconfigured, the movement, addition or removal of furniture, movable partitions less than 5 feet 9 inches in height, or fixtures within a space shall not be considered reconfiguration of space.~~

<u>The movement, addition or removal of furniture, movable partitions that are less than 5 feet 9 inches tall, measured from the floor, or where fixtures within a space are moved, shall not be considered reconfiguration of space.</u>

Movement, addition or removal of furniture and partitions shall not obstruct the minimum aisles required by the *International Building Code* in Groups B or M occupancies. Table seating shall be in accordance with Sections 1017.3 and 1017.4 of the *International Building Code* and assembly seating shall be in accordance with Section 1028 of the *International Building Code* .

Commenter's Reason: The committee felt that the language was not clear. In my zeal to not create exceptions it was difficult to understand what was intended. Hopefully, this revision will clear up the confusion, and clarify the code for users to be aware when furnishings can cause a problem that would be considered reconfiguration of space.

EB5-13
Final Action: AS AM AMPC____ D

EB6-13
505.1

Proposed Change as Submitted

Proponent: Charles S. Bajnai, Chesterfield County, VA, ICC Building Code Action Committee

Revise as follows:

505.1 Scope. Level 3 *alterations* apply where the *work area* exceeds 50 percent of the aggregate ~~area of the building~~ *building area* of all stories in the building.

Reason: This proposal is submitted by the ICC Building Code Action Committee (BCAC) The BCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance an assigned International Code or portion thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the BCAC has held 6 open meetings and numerous workgroup calls which included members of the BCAC as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: http://www.iccsafe.org/cs/BCAC/Pages/default.aspx.

This is the BCAC's attempt to clarify the scoping provisions for level 3 alterations. Some code users claim that the differing phrases used relative to area within the IEBC is confusing when those phrases are not one of the defined phrases. The BCAC believes that concern can best be addressed by referring to the defined term/phrase "building area" instead of the currently used phrase "aggregate area of the building". Because the phrase "building area" is already defined, by embedding that phrase in the modified text, the concerns of confusion and lack of consistency will be eliminated without changing the original intent. The BCAC is also aware that the current language located within IEBC Sections 410.4, 410.6, and 410.8.9 would benefit from a change to mimic the language being proposed by this code change, but cannot propose those changes at this time because those sections are located within the Group A changes. It is the intent of the BCAC to propose corresponding changes to those sections in the next code change cycle.

Cost Impact: This code change proposal will not increase the cost of construction.

505.1-EB-BAJNAI-BCAC.doc

Committee Action Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The proposal clarifies that all stories of the building are included when determining whether the alteration is considered level 3. Building area is a defined term.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

David Bonowitz, S.E, representing NCSEA Code Advisory Committee, Existing Buildings Subcommittee requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

505.1 Scope. Level 3 *alterations* apply where the *work area* exceeds 50 percent of the ~~aggregate~~ *building area* ~~of all stories in the building~~.

Commenter's Reason: Here is what the proposers said in their original reason statement: "The BCAC believes that concern can best be addressed by referring to the defined term/phrase 'building area' instead of the currently used phrase 'aggregate area of the building'."

That reasoning was completely right: The code text should use the defined term. Unfortunately, the proposal as submitted does exactly the opposite of what it intends. It both fails to fix the problem of potential confusion and actually obfuscates further by using a defined term – *building area* – together with unnecessary and misleading modifiers.

First, the term *building area* is already defined in the IBC, and hence in the IEBC as well, as follows: “The area included within surrounding *exterior walls* (or *exterior walls* and *fire walls*) exclusive of vent *shafts* and *courts*. Areas of the building not provided with surrounding walls shall be included in the building area if such areas are included within the horizontal projection of the roof or floor above.”

Is it not clear that this *already* means the whole building? There is no reason to think otherwise. If EB 6 is approved as submitted, the rational user will read “aggregate building area of all stories in the building” and will wonder, “Is that different from *building area*? It must be, or else they would have just said *building area* here in 505.1.” Hence, confusion. In fact, the intended meaning of “aggregate building area of all stories in the building” is precisely the same as the already defined meaning of *building area*. There is no value or purpose to the extra words, and they should be deleted.

Second, if it is not sufficiently clear that the current definition of *building area* already means the whole building, one need only note that the IBC also already defines *floor area* as a similar term that can be applied to portions of a building.

Third, a quibble: There is no such thing as “story area” or “area of a story.” Thus, there is no such thing as the “aggregate building area of all stories.”

The code has defined terms. We should use them. Not to do so – or worse, to use them in a squishy way – negates the whole point of defining them in the first place. If *building area*, already defined, is not clear enough, then make a proposal to revise the definition, but don’t undo the definition with sloppy usage.

Public Comment 2:

David S. Collins, FAIA, The Preview Group, Inc, representing The American Institute of Architects, requests Disapproval.

Commenter’s Reason: The wording of the section is confusing. The aggregate area of stories doesn't exist in code requirements. In the IBC, the area of a story has no application, and is not defined. The aggregate area of a building includes the “building area per story,” or the allowable area multiplied by the number of stories.

Several questions would arise for users of the code by this language regarding whether the area includes light wells, shafts, etc. which have no floor, but by definition are included in the area of a building per the IBC.

EB6-13

Final Action: AS AM AMPC____ D

EB7-13
505.1

Proposed Change as Submitted

Proponent: David S. Collins, FAIA, The Preview Group, Inc., representing The American Institute of Architects

Revise as follows:

505.1 Scope. Level 3 *alterations* ~~apply~~ include the reconfiguration of space*,* where the ~~work~~ reconfigured area exceeds 50 percent of the aggregate area of the building, and shall include the reconfiguration or extension of any system that serves more than 50 percent of the aggregate area of the building.

Reason: In a separate change the definition of "work area" is being removed from the IEBC because it's lack of specificity and the confusion it causes when used in this section. We have submitted a series of changes to provide the type of direction needed to make the code more effective. This language is proposed to provide the needed guidance in Section 505.1 for what is within the scope of a Level 3 alteration.

Cost Impact: There is no cost impact associated with this change.

505.1-EB-COLLINS.doc

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee agreed with the concept of clarifying level 3 alterations but the last portion of the proposed language seemed more extensive than intended. For instance, if a plumbing fixture such as a sink serves more than 50% of the building the movement of the sink would be considered a level 3 alteration by this revised language.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

David S. Collins, FAIA, The Preview Group, Inc, representing The American Institute of Architects requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

505.1 Scope. Level 3 *alterations* include the reconfiguration of space*,* where the reconfigured area exceeds 50 percent of the aggregate area of the building~~, and shall include the reconfiguration or extension of any system that serves more than 50 percent of the aggregate area of the building.~~

Commenter's Reason: The committee felt that the last portion of the change was too expansive and perhaps wasn't what was originally intended. This change limits the scope to the portion of the building where reconfiguration exceeds 50 percent of the aggregate area of the building.

EB7-13
Final Action: AS AM AMPC____ D

EB8-13
602.3 (NEW)

Proposed Change as Submitted

Proponent: Rebecca Morley, National Center for Healthy Housing

Add new text as follows:

602.3 Moisture and Mold. Surfaces such as but not limited to wood, textiles, paint, cellulose insulation, and paper, including paper-faced gypsum board, shall have no signs of excessive moisture after the material has been repaired. Materials that are discolored or deteriorated by mold or mildew shall be cleaned, dried and repaired and the underlying cause shall be determined and corrected. If the material is structurally unsound it shall be removed and replaced and the underlying cause shall be determined and corrected*.*

Reason: Mold typically grows in buildings affected by water damage. According to the Institute of Medicine of the National Academies' *Damp Indoor Spaces and Health* (2004), mold and damp indoor environments are associated with asthma symptoms in sensitized persons, coughing, wheezing, and upper respiratory tract symptoms. *See www.nap.edu/books/0309091934/html/*

In December 2007, the National Center for Healthy Housing (NCHH) and the U.S. Centers for Disease Control and Prevention (CDC) convened an Expert Panel consistent with National Institute of Health guidelines to assess the effectiveness of various interventions to make homes healthier and safer. NCHH and CDC published the report of the experts in January 2009. See www.nchh.org/LinkClick.aspx?fileticket=2lvaEDNBIdU%3d&tabid=229 for the full report.

The Expert Panel reviewed five peer-reviewed research studies on the issue of mold and allergens and concluded that "when implemented together, eliminating moisture intrusion and leaks and removal of moldy items were found to be effective in reducing asthma triggers and reducing exposures." Other provisions of the IPMC address eliminating moisture intrusion. But no provisions require action on building materials with chronic moisture issues including those materials that have failed beyond repair.

This proposal implements the Expert Panel's recommendation while providing flexibility in response to actual conditions – repair for reparable material, replacement for failed material. To ensure the health of the building's occupants, mitigation of moisture problems must be a part of the code.

Cost Impact: This code change proposal will increase the cost of maintenance.

602.1-EB-MORLEY.doc

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: The term "excessive" was felt unenforceable. There was concern with what would be considered "clean." These types of provisions were felt more appropriate for the IPMC. If the requirements were felt appropriate for the IEBC they would be better located in Chapter 3.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jane Malone, National Center for Healthy Housing, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

SECTION 602
BUILDING ELEMENTS AND MATERIALS

602.1 Existing building materials. Materials already in use in a building in compliance with requirements or approvals in effect at the time of their erection or installation shall be permitted to remain in use unless determined by the *code official* to render the building or structure unsafe or *dangerous* as defined in Chapter 2.<u>Carpet, paper-faced gypsum board, and other porous material that is discolored or deteriorated by persistent moisture shall be dried and repaired, and the underlying cause of the moisture shall be corrected. If deteriorated material has decayed or failed beyond repair, it shall be removed and replaced.</u>

~~**602.3 Moisture and Mold.** Surfaces such as but not limited to wood, textiles, paint, cellulose insulation, and paper, including paper-faced gypsum board, shall have no signs of excessive moisture after the material has been repaired. Materials that are discolored or deteriorated by mold or mildew shall be cleaned, dried and repaired and the underlying cause shall be determined and corrected. If the material is structurally unsound it shall be removed and replaced and the underlying cause shall be determined and corrected.~~

Commenter's Reason: Elimination of moisture problems in building materials is important to ensuring the health of the building's occupants. Requiring attention to these problems when a building undergoes repair work should be a part of the code. The trigger is the repair work.

`We addressed the committee's concerns by deleting the words "cleaned" and "excessive."

EB8-13

Final Action: AS AM AMPC____ D

EB10-13
603.1, 604.1, 605.1, 703.1, 704.1

Proposed Change as Submitted

Proponent: Charles S. Bajnai, Chesterfield County, VA, ICC Building Code Action Committee

Revise as follows:

603.1 General. Repairs shall be done in a manner that maintains the level of fire protection provided <u>before the repair was undertaken</u>.

604.1 General. Repairs shall be done in a manner that maintains the level of protection provided for the means of egress <u>before the repair was undertaken</u>.

605.1 General. Repairs shall be done in a manner that maintains the level of accessibility <u>provided before the repair was undertaken</u>.

703.1 General. Alterations shall be done in a manner that maintains the level of fire protection provided <u>before the alteration was undertaken</u>.

704.1 General. Alterations shall be done in a manner that maintains the level of protection provided for the means of egress <u>before the alteration was undertaken</u>.

Reason: This proposal is submitted by the ICC Building Code Action Committee (BCAC) The BCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance an assigned International Code or portion thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the BCAC has held 6 open meetings and numerous workgroup calls which included members of the BCAC as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: http://www.iccsafe.org/cs/BCAC/Pages/default.aspx.

The current text is missing the language that tells users of the code to what level the various subjects are to be maintained. The intent that a modification should not make a condition worse than before the work started is clear. That concept is stated in IEBC sections 603.1, 604.1, 605.1, 703.1 and 704.1. By adding the proposed text to each section, that original intent is not only made clearer, it is done so in a consistent manner.

Cost Impact: This code change proposal will not increase the cost of construction.

603.1-EB-BAJNAI-BCAC.doc

Committee Action Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: This proposal clarifies the language to denote to what extent to maintain the level of safety or accessibility when a repair or alteration is undertaken.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

David Bonowitz, S.E., representing NCSEA Code Advisory Committee, Existing Buildings Subcommittee, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

603.1 General. Repairs shall be done in a manner that maintains the level of fire protection provided before the occurrence of the damage that is being repaired ~~repair was undertaken~~.

604.1 General. Repairs shall be done in a manner that maintains the level of protection provided for the means of egress before the occurrence of the damage that is being repaired ~~repair was undertaken~~.

605.1 General. Repairs shall be done in a manner that maintains the level of accessibility provided before the occurrence of the damage that is being repaired ~~repair was undertaken~~.

(Portions of code change proposal not shown remain unchanged)

Commenter's Reason: The modification corrects the unintended meaning of the approved wording. The approved wording talks about the condition "before the repair was undertaken." But when you think about it, the condition "before the repair was undertaken" means the condition with the damage in place. The intent of the proposal is obviously to restore the condition that existed before the damage occurred, not before the repair was started. The proposed modification thus makes more sense and better reflects the intent of the proposal.

EB10-13

Final Action: AS AM AMPC____ D

EB12-13
608.3(New), 708(New)

Proposed Change as Submitted

Proponent: Andrew Scott Jones, President, A Better Deal Heating and Air Conditioning, Inc., a Texas Corporation, representing self

Add new text as follows:

608.3 Cleanouts. Where new condensate drain lines are installed as a result of the repair, such condensate drain lines shall be configured to permit the clearing of blockages and performance of maintenance without requiring the drain line to be cut.

SECTION 708
MECHANICAL

708.1 Cleanouts. Where new condensate drain lines are installed as a result of a level 1 alteration, such condensate drain lines shall be configured to permit the clearing of blockages and performance of maintenance without requiring the drain line to be cut.

Reason: This language is identical to the language of M 32-12 which was recently adopted In Portland, Oregon. We are advised by JB Engineering that this language will be in the IMC and IPC for 2015.

Similar language has been submitted to the IRC.

Cost Impact: The code change will increase the cost of construction, totaling an estimated $15.00 per unit.

XXX-EB-JONES.doc

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee disapproved the code change as the provisions were very specific and felt unnecessary. The concern is that adding such specific requirements would lead to a laundry list of specific requirements which was not the intent of the IEBC. Additionally, Section 301.2, which references other I-codes, currently addresses this issue.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Andrew Scott Jones, A Better Deal Heating and Air Conditioning, Inc, requests Approval as Submitted.

Commenter's Reason: The Committee Stated in response to EB12-13 that "…the provisions were very specific and felt unnecessary. …" There is a real problem with cutting clogged drain lines, as water can leak all over insulation, not to mention the time consumed in cutting, clearing the drain and repairing the cut with a collar. Eventually, the line will have to be replaced itself.

Drain line stoppages in evaporative coils drain pan drain lines are unavoidable and common occurrences requiring clearing the drain line. Clearing these lines almost always involves cutting the drain line itself, causing water to leak into the attic or closet where the drain is located, possibly collected in a bucket or soaked up with rags or paper towels. Then the technician blows compressed air through the drain line in both directions from the cut. The cut must be repaired by resealing the drain line with a PVC coupling and solvent.

This process exposes the surrounding area to water leakage and spilling with the risk of damage, mold, spilling, as well as, the extra time and effort of carrying extra equipment, parts and flammable solvent. The process takes extra time and costs the homeowner more money.

With a device that permits the introduction of compressed air or nitrogen directly into the drain system, permitting clearing in both directions, there is no spillage of water, no cost for the couplings or solvent and no risk of water damage or mold. The entire process requires less than ten minutes.

Typically the cost of clearing a drain equipped with such a device is at least 50% less to the homeowner than the cost of clearing a blockage through the common method of cutting the pipe, attempting to collect the condensate water and repairing the cut in the drain line.

Each time a drain line is cleared through the cutting/repair process, the repair could be accomplished by installing a $15.00 line clearing device rather than a simple coupling. Drain lines can also be plumbed without installing a device at the time of installation.

Also, if clearing the drain lines were part of regular maintenance, line blockages could largely be prevented in the first place.

EB12-13

Final Action: AS AM AMPC____ D

EB15-13
702.4 (NEW), 702.5 (NEW)

Proposed Change as Submitted

Proponent: Jeff Inks, Window & Door Manufacturers Association (jinks@wdma.com)

Revise as follows:

702.1 Interior finishes. All newly installed interior wall and ceiling finishes shall comply with Chapter 8 of the *International Building Code*.

702.2 Interior floor finish. New interior floor finish, including new carpeting used as an interior floor finish material, shall comply with Section 804 of the *International Building Code*.

702.3 Interior trim. All newly installed interior trim materials shall comply with Section 806 of the *International Building Code*.

702.4 Window opening control devices. In Group R-2 or R-3 buildings containing dwelling units and one- and two-family dwellings and townhouses regulated by the *International Residential Code*, window opening control devices complying with ASTM F2090 shall be installed where an existing window is replaced and where all the following apply to the replacement window:

1. The window is operable;
2. The window replacement includes replacement of the sash and the frame;
3. The top of the sill of the window opening is at a height less than 36 inches (915 mm) above the finished floor;
4. The window will permit openings that will allow passage of a 4-inch diameter (102 mm) sphere when the window is in its largest opened position; and
5. The vertical distance from the top of the sill of the window opening to the finished grade or other surface below, on the exterior of the building, is greater than 72 inches (1829 mm).

The window opening control device, after operation to release the control device allowing the window to fully open, shall not reduce the minimum net clear opening area of the window unit to less than the area required by the International Building Code.

Exceptions:

1. Operable windows where the top of the sill of the window opening is located more than 75 feet (22.86 m) above the finished grade or other surface below, on the exterior of the room, space or building, and that are provided with window fall prevention devices that comply with ASTM F 2006.
2. Operable windows with openings that are provided with window fall prevention devices that comply with ASTM F2090.

702.5 Emergency escape and rescue openings. Where windows are required to provide emergency escape and rescue openings in Group R-2 and R-3 occupancies and one- and two-family dwellings and townhouses regulated by the *International Residential Code*, replacement windows shall be exempt from the requirements of Sections 1029.2, 1029.3 and 1029.5 of the *International Building Code* and Sections R310.1.1, R310.1.2, R310.1.3 and R310.2 of the *International Residential Code* accordingly provided the replacement window meets the following conditions:

1. The replacement window is the manufacturer's largest standard size window that will fit within the existing frame or existing rough opening. The replacement window shall be permitted to be of the same operating style as the existing window or a style that provides for an equal or greater window opening area than the existing window.

2. The replacement of the window is not part of a change of occupancy.

Window opening control devices complying with ASTM F 2090 shall be permitted for use on windows required to provide *emergency escape and rescue openings.*

Reason: The intent of this proposal is to ensure window replacements meet the requirements for new construction for window fall protection and emergency escape and rescue openings when practical and avoid discouraging or preventing the replacement of windows when it is not -- provided there is no reduction in existing safety.

With respect to the proposed provisions for window opening control devices on replacement windows, they are intended to ensure window fall protection is provided where required for new construction when windows, including sash and frame, are replaced. The proposed WOCD provisions have already been approved for Chap. 4 of the IEBC (during the Group A proceedings) and are also being proposed for IRC Appendix J by us and the ICC CTC.

With respect to the proposed emergency escape and rescue opening provisions, they are based on Minnesota's residential code which actually (and effectively) incorporates them into the main body of the code in Chapter 3, under Section 310.1. The same provisions have also already been approved for Chap. 4 of the IEBC (during the Group A proceedings) and we, as well as the ICC CTC are also proposing the same provisions for IRC Appendix J (in addition to this proposal for the IEBC). Most importantly, it's important to note that the provisions do not allow for any decrease in safety and will help ensure improvements in safety can be made.

More specifically, the intent of this proposal is to ensure that the IRC does not discourage or prevent improvements in emergency escape and rescue openings, especially for fire safety, in older residential occupancies by requiring replacement windows to meet all of the provisions of Section 310 when doing so can only be accomplished by increasing the size of the rough opening or altering the interior wall.

Because many of these older buildings were constructed under codes that did not include the same emergency escape and rescue opening provisions that the IBC or IRC now require for new construction, the only way to fully meet all of the requirements of IBC Section 1029 or IRC Section 310 for new construction if required when windows are replaced, is to enlarge the rough opening and/or make significant alterations to the interior wall in order to accommodate any increase in window size or lowering of a sill.

At the very least, the significant cost and design challenges of altering the rough opening or interior wall can discourage or prevent window replacement and at worst can discourage or prevent the replacement of older windows that are harder to operate or inoperable all together because of their age or poor maintenance and, that are significantly less energy efficient. When that happens, improvements to safety as well as to energy efficiency are needlessly compromised.

Furthermore and on the whole, while some bedroom windows in older homes may not provide the full clear opening that is required for new construction or may have a sill height above 44 inches, they nonetheless still provide a viable emergency and escape rescue opening which is the primary intent of the code. Replacement of these windows with the same type of operating window or other type that can provide an equal or greater clear opening than the existing window -- even if they do not fully meet the clear opening or sill height requirements of IBC Section 1029 or IRC Section 310 accordingly – is always an improvement in safety, especially when a replacement opening can provide a larger clear opening than the existing window. Such improvements in safety should not be discouraged or prevented by overly onerous requirements for replacement windows.

This proposal will help ensure that doesn't happen by providing limited exceptions to the requirements of IBC Section 1029 and IRC Section 310 accordingly that can only be applied when certain conditions are met and that as already noted, will not result in a decrease in safety.

The requirements for new construction that emergency escape and rescue openings be provided as well as the operational requirements of IBC Section 1029 and IRC Section 310 respectively are maintained and still applicable to replacement windows.

Cost Impact: This code change proposal will not increase the cost of construction.

702.4 (NEW)-EB-INKS.doc

Committee Action Hearing Results

Committee Action: Approved as Modified

Modify the proposal as follows:

702.4 Window opening control devices. In Group R-2 or R-3 buildings containing dwelling units and one- and two-family dwellings and townhouses regulated by the *International Residential Code*, window opening control devices complying with ASTM F2090 shall be installed where an existing window is replaced and where all the following apply to the replacement window:

1. The window is operable;
2. The window replacement includes replacement of the sash and the frame;
3. In Group R-2 or R-3 buildings containing dwelling units, the top of the sill of the window opening is at a height less than 36 inches (915 mm) above the finished floor, or in one- and two-family dwellings and townhouses regulated by the *International Residential Code*, the top of the sill of the window opening is at a height less than 24 inches (610 mm) above the finished floor;
4. The window will permit openings that will allow passage of a 4-inch diameter (102 mm) sphere when the window is in its largest opened position; and
5. The vertical distance from the top of the sill of the window opening to the finished grade or other surface below, on the exterior of the building, is greater than 72 inches (1829 mm).

The window opening control device, after operation to release the control device allowing the window to fully open, shall not reduce the minimum net clear opening area of the window unit to less than the area required by the *International Building Code*.

Exceptions:

1. Operable windows where the top of the sill of the window opening is located more than 75 feet (22.86 m) above the finished grade or other surface below, on the exterior of the room, space or building, and that are provided with window fall prevention devices that comply with ASTM F 2006.
2. Operable windows with openings that are provided with window fall prevention devices that comply with ASTM F2090.

702.5 Emergency escape and rescue openings. Where windows are required to provide emergency escape and rescue openings in Group R-2 and R-3 occupancies and one- and two-family dwellings and townhouses regulated by the *International Residential Code*, replacement windows shall be exempt from the requirements of Sections 1029.2, 1029.3 and 1029.5 of the *International Building Code* and Sections R310.1.1, R310.1.2, R310.1.3 and R310.2 of the *International Residential Code* accordingly provided the replacement window ~~meets the following conditions: 1. The replacement window~~ is the manufacturer's largest standard size window that will fit within the existing frame or existing rough opening. The replacement window shall be permitted to be of the same operating style as the existing window or a style that provides for an equal or greater window opening area than the existing window.
~~2. The replacement of the window is not part of a change of occupancy.~~

Window opening control devices complying with ASTM F 2090 shall be permitted for use on windows required to provide *emergency escape and rescue openings.*

Committee Reason: The proposal was preferred to EB9-13. The provisions were seen necessary to address the replacement windows with regard to fall safety and emergency escape and rescue openings in existing buildings. The proposal was similar to EB9-13 but did not add revisions to Section 602.3 or one and two family dwelling. One and two family dwellings can be addressed by the IEBC. The modification adds clarification that the window opening control device requirement has a different applicability to one and two family dwellings than Group R-2 or R-3 buildings. One and two family dwellings are permitted to have a window opening as low as 24 inches above the finished floor versus 36 inches. This is more consistent with the IRC as a trigger for window opening control devices.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Maureen Traxler, City of Seattle Department of Planning & Development, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

702.4 Window opening control devices. In Group R-2 or R-3 buildings containing dwelling units and one- and two-family dwellings and townhouses regulated by the *International Residential Code*, window opening control devices complying with ASTM F2090 shall be installed where an existing window is replaced and where all the following apply to the replacement window:

1. The window is operable;
2. The window replacement includes replacement of the sash and the frame;
3. <u>One of the following applies:</u>
   - <u>3.1</u>. In Group R-2 or R-3 buildings containing dwelling units<u> regulated by the International Building Code</u>, the top of the sill of the window opening is at a height less than 36 inches (915 mm) above the finished floor, or
   - <u>3.2.</u> In one- and two-family dwellings and townhouses regulated by the *International Residential Code*, the top of the sill of the window opening is at a height less than 24 inches (610 mm) above the finished floor;
4. The window will permit openings that will allow passage of a 4-inch diameter (102 mm) sphere when the window is in its largest opened position; and
5. The vertical distance from the top of the sill of the window opening to the finished grade or other surface below, on the exterior of the building, is greater than 72 inches (1829 mm).

The window opening control device, after operation to release the control device allowing the window to fully open, shall not reduce the minimum net clear opening area of the window unit to less than the area required by the *International Building Code*.

Exceptions:

1. Operable windows where the top of the sill of the window opening is located more than 75 feet (22.86 m) above the finished grade or other surface below, on the exterior of the room, space or building, and that are provided with window fall prevention devices that comply with ASTM F 2006.

2. Operable windows with openings that are provided with window fall prevention devices that comply with ASTM F2090.

Commenter's Reason: This is an editorial change to make item 3 clearer and easier to read.

EB15-13

Final Action: AS AM AMPC____ D

EB16-13
705 (NEW)

Proposed Change as Submitted

Proponent: Rebecca Morley, National Center for Healthy Housing

Add new text as follows:

SECTION 705
CARBON MONOXIDE ALARMS

705.1 General. Carbon monoxide alarms shall be installed in existing Group I or R occupancies in accordance with Section 1103.9 of the *International Fire Code.*

Reason: **Carbon monoxide (CO) is an odorless, tasteless, invisible gas that kills more than 300 people in homes each year. Thousands more are admitted to the hospital with carbon monoxide poisoning. This is a serious issue that affects people nationwide is all regions of the country. The International Residential Code requires CO alarms for residences with fuel-fired appliances or attached garages. This change would make the IEBC consistent with the IRC.**

The following states have required CO alarms in existing residences: Alaska, California, Colorado, Illinois, Massachusetts, Michigan, Minnesota, Montana, New Jersey, New York, North Carolina, Oklahoma, Oregon, Rhode Island, Vermont and Wisconsin. Deaths from CO are spread throughout the country as residents unwittingly use dangerous methods to stay warm in unusually cold weather.

Cost Impact: Yes, this code change proposal will increase the cost of property maintenance. A carbon monoxide alarm typically costs approximately $25.

705 (NEW)-EB-MORLEY.doc

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: This proposal requiring CO in Group I and R occupancies was felt to be excessive with Level 1 Alteration requirements. There was also concern that this particular requirement to add CO alarms retroactively may not be applicable in all states. Note that it was pointed out that if Chapter 11 of the IFC is adopted these requirements would be applicable regardless of whether an alteration is undertaken.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jane Malone, National Center for Healthy Housing, requests Approval as Submitted.

Commenter's Reason: While not needed in jurisdictions that have adopted the *International Fire Code*, the requirement is needed for Level 1 Alterations where the IFC is not in effect.

EB16-13
Final Action: AS AM AMPC____ D

EB17-13

705.1, 905.1, 905.4 (NEW), 905.4.1 (NEW), 1005.2 (NEW), 1105 (NEW)

Proposed Change as Submitted

Proponent: Gene Boecker, Code Consultants, Inc., representing self

705.1 General. A *facility* that is altered shall comply with the applicable provisions in Sections 705.1.1 through 705.1.14, and Chapter 11 of the *International Building Code* unless it is *technically infeasibl*e. Where compliance with this section is *technically infeasible*, the alteration shall provide access to the maximum extent that is technically feasible. A *facility* that is constructed or altered to be accessible shall be maintained accessible during occupancy. A facility shall not be altered such that the existing accessible means of egress is reduced.

Exceptions:

1. The altered element or space is not required to be on an accessible route unless required by Section 705.2.
2. Accessible means of egress required by Chapter 10 of the *International Building Code* are not required to be added ~~provided~~ in existing buildings undergoing less than a level 3 alteration.
3. Type B dwelling or sleeping units required by Section 1107 of the *International Building Code* are not required to be provided in existing *facilities* undergoing less than a Level 3 *alteration*.
4. The alteration to Type A individually owned dwelling units within a Group R-2 occupancy shall meet the provisions for Type B dwelling units.

905.1 General. The means of egress shall comply with the requirements of Section 805 except as specifically required in Sections 905.2 ~~and 905.3~~ through 905.4.

905.4 Accessible means of egress. Not less than one accessible means of egress shall be provided in accordance with Section 905.4.1 and Section 1007 of the International Building Code in alterations affecting an area containing a primary function and in additions.

Exceptions:

1. Level 1 and Level 2 alterations.
2. Historic buildings.
3. Accessible means of egress is not required to exceed 20 percent of the costs of the alterations including any costs associated with compliance for Section 410.7. Where the costs to provide accessibility cannot accommodate compliance with both this Section and Section 410.7, Section 410.7 shall take precedence.
4. Alterations limited solely to windows, hardware, operating controls, electrical outlets and signs.
5. Alterations limited solely to mechanical systems, electrical systems, installation or alteration of fire protection systems and abatement of hazardous materials.
6. Alterations undertaken for the primary purpose of increasing the accessibility of a facility.
7. Altered areas limited to Type B dwelling and sleeping units

905.4.1 Means of egress through an existing building. Where the accessible means of egress from an portion of a building being alteration or addition requires occupants to egress through portions of existing building, compliance with Section 1007 of the *International Building Code* is required through the existing building, unless technically infeasible. Where compliance with this provision is technically infeasible, the accessible means of egress through the existing building shall provide access to the maximum extent technically feasible.

1005.2 Accessible means of egress. Where a change of occupancy includes a Level 3 Alteration to an area containing a primary function, at least one accessible means of egress shall be provided in compliance with Section 905.

SECTION 1105
MEANS OF EGRESS

1105.1 General. The means of egress shall comply with the requirements of Section 905.4.1 and Chapter 10 of the *International Building Code*.

Reason: During last code change cycle, a proposal similar to this was presented. The committee felt it was too confusing and that it did not address the concept of disproportionate cost effectively. This proposal seeks to address those issues more clearly. Where possible the language was changed to be uniform among the various codes and sections.

Common sense should dictate that where major alterations occur consideration for at least one accessible means of egress should be provided. Additionally, the simple idea that an accessible means of egress should be intentionally denied to a segment of the population does not seem appropriate. As the codes now stand, a building can be completely gutted with only the facades remaining and no accessible means of egress must be provided.

It is important to remember that the new construction requirements in the IBC only require a maximum of two accessible means of egress as noted in Section 1007.1 (assuming travel distance compliance is accommodated).

With the deletion of Chapter 34 from the IBC it is incumbent on the IEBC to address these issues.

705.1: A change was made to the second exception to indicate that means of egress requirements for existing building are not required for lesser alterations, similar to exception #3.
905.1: A change is made to address the added section.
905.4: A new section is added to specifically address accessible means of egress. Rather than the blanket statement in Section 1007.1 of the building code, this section will address the scope and extent of work necessary to address accessible means of egress for existing buildings. It directs the code user to Section 1007 for the technical requirements when an accessible means of egress is necessary as well as clearly delineate that when an alteration occurs affecting an area containing a primary function, an accessible means of egress must be provided. The threshold is limited to alterations affecting a primary function because that threshold relates to the importance of changes to an area and is understood due to its relationship with the Federal accessibility regulations for the past 20 years. The intent is to provide at least one accessible means of egress.
905.4, exception #1: Alterations with some magnitude should address accessible means of egress; if the alteration is relatively small then there is reason to limit the requirement. Even if the accessible means of egress would not be a disproportionate cost (exception #2), in small alterations the area required to create the accessible means of egress may be disproportionate to the space allowed for the alteration. If so, it may "steal" too much space from an otherwise small area and would not be appropriate.
905.4, exception #2: The exception makes it clear that an accessible means of egress is not required for alterations to historic buildings. To do so, may alter the historic character. While an accessible means of egress should be provided wherever possible, the exception recognizes that in historic buildings the ability to make the necessary changes to comply may be detrimental to the historic integrity.
905.4, exception #3: Existing buildings come in all shapes and sizes and the work proposed for creating an accessible means of egress can be a small part or major portion of the effort. This exception identifies that and uses the same 20% rule for the accessible route relative to the primary use area. The exception also clarifies that where funds cannot provide the accessible route *and* an accessible means of egress, it is more important to provide the accessible route. This maintains consistency with the Federal requirements for alterations affecting an area containing a primary function.
905.4, exceptions #4, #5, #6, #7: These are the same as exceptions #2, #3, #4 and #5 in Section 705.2 for alterations affecting an area containing a primary function. These are included here for consistency.
905.4.1: If an addition is designed such that the means of egress must enter the existing building then the general rule is that the egress design in the existing building must meet the requirements for egress as it passes through the existing building. This is simply the continuation of the means of egress from the addition for egress width, panic hardware (as applicable) and similar concerns. The same should be true for the design of the accessible means of egress. If one of the accessible egress paths leads through the existing building, it too needs to meet/continue the level of protection as designed in the addition. The limitation to this is that if the effort to make the existing means of egress accessible is "technically infeasible" then work should be done to what is possible. One example of this may be making sure that the slopes along the egress path in the existing building's corridor are proper even if the width cannot be altered to allow the proper maneuverability approach to the exit door.
1005.2: A change of occupancy by itself is not sufficient to trigger the requirement for an accessible means of egress. However, if a change in occupancy also includes a Level 3 Alteration, then it should be subject to the same requirements as any other Level 3 Alteration. This provision is added as a clarification to that effect.
1105.1: Chapter 11 (Additions) does not address means of egress specifically. A reference to compliance with the means of egress provisions in Chapter 10 of the IBC is included. This is similar to the first sentence in Section 402.1 which requires additions to comply with the requirements of the IBC for new construction but more specific as is done for the "non-prescriptive" methods. The added language in inserted before the accessibility section to make it consistent with its placement in other chapters.

The codes identify the minimums necessary for life safety. These proposed changes provide the disabled community with similar levels of life safety to the general public and still sets reasonable thresholds based on the extent of work for the project. With the adoption of the new 2010 ADA Standards for Accessible Design, it is clear that the IBC will set the standard for accessible means of egress. This organization has a responsibility to act in the best interests of the general public in all its diversity. Where major changes are proposed to an existing building due to a large alteration or an addition, it should be the desire of the ICC to incorporate appropriate accessible means of egress where possible.

Cost Impact: The code change proposal will increase the cost of construction in many situations but may have no effect in others.

Cost Impact Discussion: It is not easy to address what costs could be affecting this due to the myriad possible configurations for a building. A building that is a single story at grade may have no additional cost. Because an accessible entrance would be required, it would function as the accessible means of egress. Hence, a single story building with a total internal renovation may be unaffected cost-wise by this proposal.

The main costs are those involving an elevator of adequate size on emergency standby power and a two-way communications system. If the elevator is too small, the costs to alter that would be disproportionate and it would not be required according to IEBC Section 905.4, exception #3.

At the opposite end of the spectrum could be a nine story high-rise building that is being gutted on five floors. It would be required to have an accessible route to the upper floors. The IFC would require the emergency power for fire fighter operation so that cost for that part of the accessible means of egress is covered. In that situation only the two-way communication systems costs would apply.

Buildings without elevators would likely similarly fall into the category of disproportionate costs since the addition of an elevator can be costly. Moreover, the accessible means of egress is tied into alterations that affect an area containing a primary function. This already has accessibility requirements for access such as toilet room and accessible route renovations. If the costs to add an elevator are within the 20 percent cap but the cost to add emergency standby power would be beyond the 20 percent, the exceptions in IEBC Section 905.4, exception #3 make it clear that the costs for access take precedence over the costs for egress and that combined they are not required to exceed the 20 percent figure.

In many cases the 20 percent cap will be met by the required access features and there may be no funds remaining for an accessible egress. The important thing is that we should recognize the need to provide a means of egress for all of the occupants within the building to the greatest extent possible. No definitive numbers can be provided because the variations are so many. This discussion attempts to address only the possibilities.

1007.1 #1-E-BOECKER.doc

<u>Committee Action Hearing Results</u>

Committee Action: Disapproved

Committee Reason: A similar proposal failed to be adopted in Group A and by approving this proposal would make the IBC inconsistent with the IEBC. In addition, there was concern that these provisions would be more restrictive than federal requirements. The verbiage in Section 905.4.2 is in need of editorial corrections. Also the committee felt it to be inappropriate to have level 3 alterations included in exception 2 of Section 705.1. Chapter 7 deals with level 1 alterations.

Assembly Action: None

<u>Individual Consideration Agenda</u>

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Gene Boecker, Code Consultants, Inc, representing self, requests Approval as Modified by this Public Comment.

Replace the proposal as follows:

705.1 General. A *facility* that is altered shall comply with the applicable provisions in Sections 705.1.1 through 705.1.14, and Chapter 11 of the *International Building Code* unless it is *technically infeasibl*e. Where compliance with this section is *technically infeasible*, the alteration shall provide access to the maximum extent that is technically feasible. A *facility* that is constructed or altered to be accessible shall be maintained accessible during occupancy. <u>A facility shall not be altered such that the existing accessible means of egress is reduced.</u>

Exceptions:

1. The altered element or space is not required to be on an accessible route unless required by Section 705.2.
2. Accessible means of egress required by Chapter 10 of the *International Building Code* are not required to be provided in existing buildings.
3. Type B dwelling or sleeping units required by Section 1107 of the *International Building Code* are not required to be provided in existing *facilities* undergoing less than a Level 3 *alteration*.

4. The alteration to Type A individually owned dwelling units within a Group R-2 occupancy shall meet the provisions for Type B dwelling units.

Commenter's Reason: This is an important aspect of the proposal and did not receive any negative comments. It is reasonable to require existing facilities with accessible means of egress to maintain the accessible means of egress just like it is currently required to maintain all other aspects of the means of egress. This requires no correlation with the IBC since it is simply stating not to reduce or eliminate what is currently in place.

Public Comment 2:

Gene Boecker, Code Consultants, Inc, representing self, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

705.1 General. A *facility* that is altered shall comply with the applicable provisions in Sections 705.1.1 through 705.1.14, and Chapter 11 of the *International Building Code* unless it is *technically infeasibl*e. Where compliance with this section is *technically infeasible*, the alteration shall provide access to the maximum extent that is technically feasible. A *facility* that is constructed or altered to be accessible shall be maintained accessible during occupancy. ~~A facility shall not be altered such that the existing accessible means of egress is reduced.~~

Exceptions:

1. The altered element or space is not required to be on an accessible route unless required by Section 705.2.
2. Accessible means of egress required by Chapter 10 of the *International Building Code* are not required to be added to ~~in~~ existing buildings undergoing less than a level 3 alteration.
3. Type B dwelling or sleeping units required by Section 1107 of the *International Building Code* are not required to be provided in existing *facilities* undergoig less than a Level 3 *alteration*.

The alteration to Type A individually owned dwelling units within a Group R-2 occupancy shall meet the provisions for Type B dwelling units.

905.1 General. The means of egress shall comply with the requirements of Section 805 except as specifically required in Sections 905.2 through 905.4.

905.4 Accessible means of egress. Not less than one accessible means of egress shall be provided in accordance with Section 905.4.1 and Section 1007 of the International Building Code in alterations affecting an area containing a primary function and in additions.

Exceptions:

1. Level 1 and Level 2 alterations.
2. Historic buildings.
3. Costs to provide the accessible means of egress ~~is~~ are not required to exceed 20 percent of the costs of the alterations including any costs associated with compliance with Section 410.7. Where the costs to provide accessibility cannot accommodate compliance with both this Section and Section 410.7, Section 410.7 shall take precedence.
4. Alterations limited solely to windows, hardware, operating controls, electrical outlets and signs.
5. Alterations limited solely to mechanical systems, electrical systems, installation or alteration of fire protection systems and abatement of hazardous materials.
6. Alterations undertaken for the primary purpose of increasing the accessibility of a facility.
7. Altered areas limited to Type B dwelling and sleeping units

905.4.1 Means of egress through an existing building. Where the accessible means of egress from a portion of a building ~~being~~ alteration or addition requires occupants to egress through portions of an existing building, compliance with Section 1007 of the *International Building Code* is required through an ~~the~~ existing building for the continuation of the accessible means of egress, unless technically infeasible. Where compliance with this provision is technically infeasible, the accessible means of egress through the existing building shall provide access to the maximum extent technically feasible.

Exception: An accessible means of egress is not required from an addition through the existing building where at least one accessible means of egress is provided from the addition that is independent of the existing building.

1005.2 Accessible means of egress. Where a change of occupancy includes a Level 3 Alteration to an area containing a primary function, at least one accessible means of egress shall be provided in compliance with Section ~~905~~ 905.4.

SECTION 1105
MEANS OF EGRESS

1105.1 General. The means of egress shall comply with the requirements of Section 905.4.1 and Chapter 10 of the *International Building Code*.

Commenter's Reason: The committee and testimony raised several questions regarding the proposal. The following responds those comments and what changes have been made to the text to address those committee and testimony statements.

Group A Activity. The fact that a similar proposal failed in Group A is irrelevant to the actions by the IEBC committee (and ultimately the ICC membership). The Group A actions eventually resulted in the deletion of the technical provisions within Chapter 34 in their entirety (G201–12), deferring to the IEBC. The ICC Board of Directors has approved this action. Therefore, the reasons for disapproval of proposals in the Group A hearings are moot. It is clear that it is now entirely up to the actions within the IEBC code change activity to address issues relative to existing buildings. Therefore, the proposal must be viewed on its own merit.

IBC coordination. I have been informed by ICC staff that the provisions of exception #1 to Section 1007.1 of the IBC would be changed through a correlation committee; referring to the IEBC for direction on what to do about accessible means of egress in existing buildings. The specific language would be determined by the correlation committee.

Federal requirements for accessible means of egress. There are no technical federal requirements on this subject. The US Department of Justice, in its adoption of the 2010 ADA Standards for Accessible Design includes language that refers to the IBC for the method to address accessible means of egress. The text reads:

> ***207.1 General.*** *Means of egress shall comply with section 1003.2.13 of the International Building Code (2000 edition and 2001 Supplement) or section 1007 of the International Building Code (2003 edition) (incorporated by reference, see "Referenced Standards" in Chapter 1).*
>
> ***EXCEPTIONS: 1.*** *Where means of egress are permitted by local building or life safety codes to share a common path of egress travel, accessible means of egress shall be permitted to share a common path of egress travel.*
> ***2.*** *Areas of refuge shall not be required in detention and correctional facilities.*

Therefore, it is this body, the ICC, which bears the responsibility to determine what is necessary for means of egress for the disabled. No conflict would occur for two reasons. First, the federal requirements refer to older editions of the IBC. Second providing additional egress (stricter requirements) does not reduce the minimum of the federal provisions. As it stands, the existing federal requirements would not require accessible means of egress in existing facilities due to the reference to the older codes. The proposed change could include a requirement for accessible egress, providing added safety to those in the disabled community. In future adoptions/updates by the US DoJ they can decide whether or not to include the requirement as they have done for areas of refuge in detention and correctional facilities.

705.1, Exception #3. The committee noted that they felt it inappropriate to mention level 3 alterations in exception #2 of Section 705.1. The current exception #3 already includes reference to Level 3 alterations. It is necessary to modify the language in Chapter 7 to address the language about Level 3 alterations because the text in Section 906.1 refers back to Section 705 as the basis for what to do about accessibility. Without the reference in Chapter 7, any language in Chapter 9 to provide an accessible means of egress would be referring back to a section that would state that an accessible means of egress is not required.

905.4, Exception #3. Exception #3 is a very important one. It piggybacks onto the intent to spend up to 20% on accessibility when there is an alteration affecting a Primary Function Area. The proposal seeks to use that same 20% factor but states that it includes the costs for the accessible route. The maximum is 20%. If the accessible route in requires an expenditure of 20% then no additional funds would be needed to make an effort to provide an accessible means of egress. The obligation is met. If, 15% of the cost satisfies the need to provide a route in, then 5 percent would be available to provide an accessible means of egress. Eventually, as alterations continue, the accessible route in will require an ever-decreasing portion of the construction costs and the percentage available for the accessible means of egress will be greater. It is important to start somewhere. Even if 5% of the alteration costs would not provide an entire accessible egress route, including tactile exit signage and a two-way communications system at the elevator lobby would go a long way to increasing safety without having to add areas of refuge or revising stairways. Something is better than nothing and nothing is what we have now.

905.4.1. Language in the proposed Section 905.4.1 has been revised to address the committee's concern about grammar errors.

905.4.1 Exception. An exception was added based on feedback from public testimony. The exception clarifies the intent for a single accessible means of egress in existing buildings.

1005.2. The requirement for an accessible means of egress would not be triggered unless the change included an extensive renovation - a Level 3 Alteration. This text has not changed from the original proposal.

1105.1. The added notation makes it clear that the intent was to insert this new language and not supplant the existing text for accessibility in Additions. Other Chapters of the IEBC are organized in similar fashion. This Chapter did not include any specific reference to Means of Egress so the Section was added.

Conclusion: It is time that the ICC acts to address this condition. The provisions of building accessibility have been required on a federal level for over two decades and have been included in the legacy codes long before that. Accessible means of egress for new construction has been in the ICC for new construction since its inception and, before that, in the legacy codes. If we, as an organization, wish to address safety issues for existing buildings, we should address safety issues for all its potential occupants and not ignore that portion of the population with disabilities.

EB17-13
Final Action: AS AM AMPC____ D

EB21-13
705.1, 705.1.15 (NEW)

Proposed Change as Submitted

Proponent: Carl Baldassarra, P.E., Chair, ICC Code Technology Committee (cbaldassarra@rjagroup.com)

Revise as follows:

705.1 General. A *facility* that is altered shall comply with the applicable provisions in Sections 705.1.1 through ~~705.1.14~~ 705.1.15, and Chapter 11 of the *International Building Code* unless it is *technically infeasibl*e. Where compliance with this section is *technically infeasible*, the alteration shall provide access to the maximum extent that is technically feasible.

A *facility* that is constructed or altered to be accessible shall be maintained accessible during occupancy.

Exceptions:
1. The altered element or space is not required to be on an accessible route unless required by Section 705.2.
2. Accessible means of egress required by Chapter 10 of the *International Building Code* are not required to be provided in existing *facilities*.
3. Type B dwelling or sleeping units required by Section 1107 of the *International Building Code* are not required to be provided in existing *facilities* undergoing less than a Level 3 *alteration*.
4. The alteration to Type A individually owned dwelling units within a Group R-2 occupancy shall meet the provisions for Type B dwelling units.

705.1.15 Amusement rides. Where the structural or operational characteristics of an amusement ride are altered to the extent that the amusement ride's performance differs from that specified by the manufacturer or the original design, the amusement ride shall comply with requirements for new construction in the International Building Code, Section 1110.4.7.

Reason: The accessibility requirements for new construction for Amusement rides have been proposed to the IBC as part of a coordination effort with the 2010 ADA Standard for Accessible Design and 2009 ICC A117.1 Chapter 11, Recreation**.** The overall intent is to provide access to recreational facilities so that persons with mobility impairments can participate to the best of their ability. The requirements are not intended to change any essential aspects of that recreational activity.

The intent of this public comment is to match the provisions for existing amusement rides proposed and approved for IBC Chapter 34 and IEBC Chapter 4. This way the provisions for existing buildings will be consistent between Chapter 4 and 7 of the IEBC. Technical criteria can be found in the 2009 edition of the ICC A117.1, Section 1102 and includes accessible routes, load and unload areas, wheelchair spaces on rides, seats for transfer, and transfer devices.

The ICC Board established the ICC Code Technology Committee (CTC) as the venue to discuss contemporary code issues in a committee setting which provides the necessary time and flexibility to allow for full participation and input by any interested party. The code issues are assigned to the CTC by the ICC Board as “areas of study”. Information on the CTC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CTC effort can be downloaded from the following website: http://www.iccsafe.org/cs/CTC/Pages/default.aspx. Since its inception in April/2005, the CTC has held twenty five meetings - all open to the public.

Cost Impact: This code change proposal will not increase the cost of construction. This will be required by the 2010 ADA Standard for Accessible Design.

705.1-EB-BALDASSARRA-CTC.doc

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: There was concern that this was not appropriate for level 1 alterations. Concerns were raised that the IEBC would begin to regulate outdoor amusement rides. Generally, there was concern that adopting these requirements for amusement rides increases the scope of the IEBC beyond that intended.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Carl Baldassarra, ICC Code Technologies Committee, requests Approval as Submitted

Commenter's Reason: There was an objection at the hearings that we do not address outdoor amusement rides. Permanent amusement rides are now scoped specifically in IBC Chapter 11 (E208 -12). This includes both indoor and outdoor permanent rides; there is no distinction made in the code. Portable amusement rides are specifically exempt.

The committee was concerned over this exception being in Level I. The accessibility provisions in Level I, II and III build on each other. The text in the proposed 705.1.15 will address when the application is appropriate.

Below is the IBC text for amusement rides.

1110.4.8 Amusement rides. Amusement rides that moves persons through a fixed course within a defined area shall comply with Section 1110.4.8.1 through 1110.4.8.3.
Exception: Mobile or portable amusement rides shall not be required to be accessible.

1110.4.8.1 Load and unload areas. Load and unload areas serving amusement rides shall be accessible and be on an accessible route. Where load and unload areas have more than one loading or unloading position, at least one loading and unloading position shall be on an accessible route.

1110.4.8.1.1 Wheelchair spaces, ride seats designed for transfer, and transfer devices. Where amusement rides are in the load and unload position, the position serving a wheelchair spaces, amusement ride seats designed for transfer and transfer devices shall be on an accessible route.

1110.4.8.2 Minimum number. Amusement rides shall provide at least one wheelchair space, amusement ride seat designed for transfer, or transfer device.

Exceptions:

1. Amusement rides that are controlled or operated by the rider are not required to comply with this section.
2. Amusement rides designed primarily for children, where children are assisted on and off the ride by an adult, are not required to comply with this section.
3. Amusement rides that do not provide seats that are built-in or mechanically fastened shall not be required to comply with this section.

The proposed exception is already approved in Chapter 4 of the IEBC (section 410.8.1.5).

3411.8.15 (IEBC [B] 410.8.15) Amusement rides. Where the structural or operational characteristics of an amusement ride are altered to the extent that the amusement ride's performance differs from that specified by the manufacturer or the original design, the amusement ride shall comply with requirements for new construction in Section 1110.4.8.

Not having this in Chapter 7, would result in a conflict between chapters. The proposed text is effectively an exception that would allow one method to have a break that the other did not.

EB21-13
Final Action: AS AM AMPC____ D

<u>EB24</u>-13
803.1

<u>Proposed Change as Submitted</u>

Proponent: David S. Collins, FAIA, The Preview Group, Inc., representing The American Institute of Architects

Revise as follows:

803.1 Scope. The requirements of this section are limited to ~~*work areas* in which Level 2 alterations are being performed, and shall apply beyond the work area where specified~~. <u>alterations per Section 504.1</u>.

Reason: Section 504.1 describes the scope of Level 2 alterations. Chapter 8 simply enumerates the items required for such alterations to conform to the code, and isn't required to restate what is included. The entire section should be eliminated, but for simplicity we are only referencing Section 504.1 for a scope, removing any conflict or confusion in the code.

Cost Impact: This code change proposal will not increase the cost of construction.

803.1-EB-COLLINS.doc

<u>Committee Action Hearing Results</u>

Committee Action: **Approved as Submitted**

Committee Reason: This proposal clears up redundant and potentially confusing language already addressed in Chapter 5. The proposal still provides a clear link to the scope of level 2 alterations.

Assembly Action: **None**

<u>Individual Consideration Agenda</u>

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

David Bonowitz, S.E., representing NCSEA Code Advisory Committee, Existing Buildings Subcommittee, requests Disapproval.

Commenter's Reason: The proposal as submitted would change the triggered scope of Level 2 alterations. Instead of applying in a careful way to both the intended alteration itself and other relevant areas, any triggered work would apply only to the alteration area itself.

The proposal should be disapproved for three reasons:

1. The committee's reason for approval is plainly false. It reads, in part, **"**This proposal clears up redundant and potentially confusing language already addressed in Chapter 5." Actually, there is no redundancy, because Chapter 5 merely defines the Level 2 Alteration but does not set the triggered scope of work. More important, the proposal doesn't "clear up" anything. One needs only to look at the next section to see why: "**803.2.2 Supplemental shaft and floor opening enclosure requirements.** Where the *work area* on any floor exceeds 50 percent of that floor area, the enclosure requirements of Section 803.2 shall apply to vertical openings other than stairways throughout the floor."

The provision clearly requires work "throughout the floor" – that is, even in areas *beyond the work area*. The 2012 language clearly contemplates this and gets it right. The proposal would miss this and would introduce confusion.

2. Disapproval of EB 24 is consistent with disapproval of related proposals EB 7 and EB 45. These three proposals were intended to be coordinated with the (ill-advised) removal of the key term *work area*, but they were found not to achieve their purpose. EB 24 was the first one heard at the Dallas hearings. Once EB 7 and EB 45 were disapproved, it became clear that EB 24 should have been disapproved as well.

3. EB 24 (like EB 7 and EB 45) misses the essential point of having different Alteration levels. The purpose of the levels is to allow different intended scopes of work to trigger appropriate levels of work *outside* the intended work area. The example in reason 1 above is just one of many cases where an intended alteration triggers appropriate work outside the alteration work area. Even Level 1 Alterations follow this basic IEBC philosophy (see, for example, the structural mitigation measures in section 706.) Thus, the key language that EB 24 would remove – "shall apply beyond the work area" – is vital to the *work area* concept and to the Work Area method.

EB24-13

Final Action: AS AM AMPC____ D

EB26-13
803.6 (NEW)

<u>Proposed Change as Submitted</u>

Proponent: Robert J. Davidson, Davidson Code Concepts, LLC, representing self (rjd@davidsoncodeconcepts.com) and David S. Collins, FAIA, The Preview Group, Inc. (dcollins@preview-group.com), representing The American Institute of Architects

Add new text as follows:

<u>**803.6 Fire-resistance ratings.** Where approved by the code official, buildings where an automatic sprinkler system installed in accordance with Section 903.3.1.1 of the *International Building* has been added, and the building is now sprinklered throughout, the required fire-resistance ratings of building elements and materials shall be permitted to meet the requirements of the current building code. The building is required to meet the other applicable fire protection requirements of Chapter 9 of the *International Building Code*.</u>

<u>Plans, investigation and evaluation reports, and other data shall be submitted indicating which building elements and materials the applicant is requesting the code official to review and approve for determination of applying the current building code fire-resistance ratings. Any special construction features, conditions of occupancy, approved modifications or approved alternative materials, design and methods of construction, and equipment applying to the building that impact required fire-resistance ratings shall be identified in the evaluation reports submitted.</u>

Reason: The topic of allowing the ability to apply sprinkler protection trade-offs that exist in the current code has been a matter of discussion in the code development arena for some time. How to apply the allowance for a potential reduction in fire-resistance ratings and in what code they belong have been discussed without a consensus.

The concept is that once a building without sprinkler protection has been sprinklered throughout, whether due to renovations or retroactive code application, the designer should be permitted to allow the same fire resistance rating provisions for new construction in an existing sprinklered building. The issue is how to provide for that application of code and ensure a proper review by the building code official is performed to ensure there are no impediments to granting an approval that may result in the reduction of existing levels of protection.

This proposal attempts to provide for that process by adding a new section to the IEBC under Section 806 Building Elements and Materials. The suggested language provides that once an existing building is sprinklered throughout and meets the other fire protection requirements of Chapter 9 of the IBC, plans, investigation and evaluation reports, and other data can be submitted seeking approval of the code official for the assignment of the new fire-resistance ratings which might me a reduction, or potentially an increase.

The suggested language also requires that any special construction features, conditions of occupancy, approved modifications or approved alternative materials, design and methods of construction, and equipment applying to the building that impact required fire-resistance ratings shall be identified in the evaluation reports submitted. This is to ensure special conditions are identified that may prevent a reduction in fire-resistance ratings.

Cost Impact: This code change proposal will not increase the cost of construction.

803.6 (NEW)-EB-DAVIDSON.doc

<u>Committee Action Hearing Results</u>

Committee Action: **Approved as Modified**

Modify the proposal as follows:

803.6 Fire-resistance ratings. Where approved by the code official, buildings where an automatic sprinkler system installed in accordance with Section 903.3.1.1 <u>or 903.3.1.2</u> of the *International Building* has been added, and the building is now sprinklered throughout, the required fire-resistance ratings of building elements and materials shall be permitted to meet the requirements of the current building code. The building is required to meet the other applicable fire protection requirements of Chapter 9 of the *International Building Code*.

Plans, investigation and evaluation reports, and other data shall be submitted indicating which building elements and materials the applicant is requesting the code official to review and approve for determination of applying the current building code fire-resistance ratings. Any special construction features, conditions of occupancy, approved modifications or approved alternative materials, design and methods of construction, and equipment applying to the building that impact required fire-resistance ratings shall be identified in the evaluation reports submitted.

Committee Reason: The proposal was approved based upon the fact that it provides flexibility in existing buildings and encourages the installation of sprinkler systems. The proposal was preferred to F212 Part II. It was noted that it would be more consistent if this method was also allowed for the other compliance methods found in the IEBC. The modification simply recognizes this allowance for both NFPA 13 and NFPA 13R systems.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Tony Crimi, A.C. Consulting Solutions Inc, representing International Firestop Council (IFC), requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

803.6 Fire-resistance ratings. Where approved by the building code official, buildings where an automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.3.1.2 of the *International Building Code* has been added, and the building is now sprinklered throughout, the required fire-resistance ratings of building elements and materials shall be permitted to meet the requirements of the current building code provided, the building ~~is required to meet~~ also complies with the other applicable fire protection requirements of Chapter 9 and Chapter 10 of the *International Building Code*.

Plans, investigation and evaluation reports, and other data shall be submitted indicating which building elements and materials the applicant is requesting the code official to review and approve for determination of applying the current building code fire-resistance ratings. Any special construction features, conditions of occupancy, approved modifications or approved alternative materials, design and methods of construction, and equipment applying to the building that impact required fire-resistance ratings shall be identified in the evaluation reports submitted.

Commenter's Reason: This modification adds a critical element that is lacking in the current proposal. The proponents have indicated, the proposed change is intended to add minimum requirements for existing hospitals (Group I-2, Condition 2) into Chapter 11. However, as a revision to Chapter 8 of the IEBC, this proposal will in fact apply to all buildings undergoing Level 2 alterations.

The current proposal as modified by the Committee would permit all of the sprinkler tradeoffs permitted for new construction in the IBC, even though the means of egress of the existing building have not been evaluated. If a building falls short of the IBC's requirements for means of egress (IBC Chapter 10), allowing that building to then take all of the IBC's sprinkler trade-offs and cease maintenance of fire safety features that would be traded away for sprinklers will result in reducing the level of fire safety of that existing building well below its current levels, and well below the level envisioned by the IBC. The minimum requirements of the IBC for means of egress are clearly stipulated in Chapter 10. These minimums are assumed to be in place and thus required before the sprinkler tradeoff provisions are permitted in other sections of the Code. The IBC goes as far as to state the following:

> "**1001.2 Minimum requirements.** It shall be unlawful to alter a building or structure in a manner that will reduce the number of *exits* or the capacity of the *means of egress* to less than required by this code."

By attempting to take advantage of all of the permitted reductions in fire-resistance ratings permitted by the IBC under these assumptions, this proposal needs to ensure that the base level of fire safety is also maintained. A fully adequate (safe) means of egress is an absolute bare minimum requirement. With a building already having egress deficiencies as compared to the current IBC, there should not be a possibility to further reduce fire safety features in that building.

As just one example, if an existing building had egress stairs that were narrower than the current IBC would allow, then allowing existing fire-rated egress corridors to lose their fire resistance rating could be a very detrimental loss of an essential fire safety feature for the evacuating occupants, who could be forced to wait much longer in the corridors before being able to enter the stairway.

An additional part of this Code Change Comment clarifies that the responsibility for reviewing these evaluations, which are based solely on the new construction requirements of the IBC, rests with the Building Official rather than the Fire Code Official. It is the building officials that have the training and experience to review a building for compliance to the IBC. It cannot be assumed that all Fire Official have the required knowledge of the IBC to critically evaluate a building against IBC requirements.

Public Comment 2:

William E. Koffel, P.E., Koffel Associates, Inc. representing Firestop Contractors International Association (FCIA), requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

803.6 Fire-resistance ratings. Where approved by the code official, buildings where an automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.3.1.2 of the *International Building* has been added, and the building is now sprinklered throughout, the required fire-resistance ratings of building elements and materials shall be permitted to meet the requirements of the current building code. The building is required to meet the other applicable ~~fire protection~~ requirements ~~of Chapter 9~~ of the *International Building Code*.

Plans, investigation and evaluation reports, and other data shall be submitted indicating which building elements and materials the applicant is requesting the code official to review and approve for determination of applying the current building code fire-resistance ratings. Any special construction features including fire resistance rated assemblies and smoke resistive assemblies, conditions of occupancy, means of egress conditions, fire code deficiencies, approved modifications or approved alternative materials, design and methods of construction, and equipment applying to the building that impact required fire-resistance ratings shall be identified in the evaluation reports submitted.

Commenter's Reason: Referring solely to Chapter 9 is problematic in that in one sense it is limiting and can infer that other provisions of the IBC need not be considered. In a similar manner, there may be requirements in Chapter 9 that are not relevant to the construction feature being evaluated. In lieu of creating a laundry list of code requirements to be met, the proposed language relies on the evaluation report addressing the issues to be considered and evaluated.

With respect to fire code deficiencies, the IEBC requires compliance with the IFC. However, as an existing building there may be some deficiencies that are existing but part of plan for correction. These should be included in the evaluation reports.

Public Comment 3:

Vickie Lovell, InterCode Inc, representing Fire Safe North America, formerly known as Alliance for Fire and Smoke Containment and Control requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

803.6 Fire-resistance ratings. Where approved by the code official, buildings where an automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.3.1.2 of the International Building has been added, and the building is now sprinklered throughout, the required fire-resistance ratings of building elements and materials shall be permitted to meet the requirements of the current building code. The building is required to meet the other applicable fire and smoke features in Chapter 7, the fire protection requirements of Chapter 9, and the means of egress requirements in Chapter 10 of the *International Building Code* as determined by a registered design professional.

Plans, investigation and evaluation reports, and other data shall be submitted indicating which building elements and materials the applicant is requesting the code official to review and approve for determination of applying the current building code fire-resistance ratings. Any special construction features, conditions of occupancy, approved modifications or approved alternative materials, design and methods of construction, and equipment applying to the building that impact required fire-resistance ratings shall be identified in the evaluation reports submitted.

Commenter's Reason: The current proposal as modified by the committee is very limited as to how the requirements of Chapter 9 are to be applied, and very non-specific about who decides which requirements of Chapter 9 are to be applied. This modification clarifies that neither the owner nor a code or fire official can arbitrarily determine what provisions of the code should apply, but that a design professional should make the determination. The code official approves the design. It also requires that the relevant information in Chapter 7 for fire and smoke containment features and also the essential components of the means of egress in chapter 10 be considered. It is not intended to require that ALL requirements in these chapter should apply; only what is appropriate and applicable as determine by a design professional.

Public Comment 4:

Maureen Traxler, City of Seattle Department of Planning & Development, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

301.3 ~~803.6~~ Fire-resistance ratings. Where approved by the code official, buildings where an automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.3.1.2 of the *International Building* has been added, and the building is now sprinklered throughout, the required fire-resistance ratings of building elements and materials shall be permitted to meet the requirements of the current building code. The building is required to meet the other applicable fire protection requirements of Chapter 9 of the *International Building Code*.

Plans, investigation and evaluation reports, and other data shall be submitted indicating which building elements and materials the applicant is requesting the code official to review and approve for determination of applying the current building code fire-resistance ratings. Any special construction features, conditions of occupancy, approved modifications or approved alternative materials, design and methods of construction, and equipment applying to the building that impact required fire-resistance ratings shall be identified in the evaluation reports submitted.

Commenter's Reason: This modification would move the language of the proposal to Chapter 3 where it would apply to all three of the IEBC's compliance methods. The rationale for the proposal is not specific to the work area method, and we can see no reason it should not apply to the prescriptive and performance methods.

Public Comment 5:

John Williams, ICC Ad Hoc Committee on Health Care, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

803.6 Fire-resistance ratings. Where approved by the code official, buildings where an automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.3.1.2 of the *International Building* has been added, and the building is now sprinklered throughout, the required fire-resistance ratings of building elements and materials shall be permitted to meet the requirements of the current building code. ~~The building is required to meet the other applicable fire protection requirements of Chapter 9 of the *International Building Code*.~~

Plans, investigation and evaluation reports, and other data shall be submitted indicating which building elements and materials the applicant is requesting the code official to review and approve for determination of applying the current building code fire-resistance ratings. Any special construction features, conditions of occupancy, approved modifications or approved alternative materials, design and methods of construction, and equipment applying to the building that impact required fire-resistance ratings shall be identified in the evaluation reports submitted.

Reason: While the AdHoc Healthcare (AHC) committee supports this change, The AHC believes the language in the 1st paragraph needs clarification. Fire protection is addressed in IEBC Section 804. IEBC Section 803 deals with building elements and materials, a reference to Chapter 9 may be out of place here. A reference to IBC Chapter 9 could be interpreted to require pressurized stairways, fire command centers, or smoke control in other parts of the building – which have little or no effect on the fire-resistance ratings of building elements. The plans, investigation and evaluation reports required in the second in the second paragraph will provide the code official with the information needed to determine where it is reasonable to consider the requirements of the new building code.

This proposal is submitted by the ICC Ad Hoc Committee for Healthcare (AHC). The AHC was established by the ICC Board of Directors to evaluate and assess contemporary code issues relating to hospitals and ambulatory healthcare facilities. The AHC is composed of building code officials, fire code officials, hospital facility engineers, and state healthcare enforcement representatives. The goals of the committee are to ensure that the ICC family of codes appropriately addresses the fire and life safety concerns of a highly specialized and rapidly evolving healthcare delivery system. This process is part of a joint effort between ICC and the American Society for Healthcare Engineering, a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. Since its inception in April 2011, the AHC has held 8 open meetings and over 150 workgroup calls which included members of the AHC as well as any interested party to discuss and debate the proposed changes. All meeting materials and reports are posted on the AHC website at: http://www.iccsafe.org/cs/AHC/Pages/default.aspx.

Public Comment 6:

Thomas S. Zaremba, Roetzel & Andress, representing Alliance of Primary Fire Rated Glazing Manufacturers, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

803.6 Fire-resistance ratings. Where approved by the code official, buildings where an automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.3.1.2 of the *International Building* <u>*Code*</u> has been added, and the building is now sprinklered throughout, the required fire-resistance ratings of building elements and materials shall be permitted to meet the requirements of the current building code. The building is required to meet the other applicable fire protection requirements of Chapter 9 of the *International Building Code* <u>and such other provisions of the current building code as required by the code official</u>.

Plans, investigation and evaluation reports, and other data shall be submitted indicating which building elements and materials the applicant is requesting the code official to review and approve for determination of applying the current building code fire-resistance ratings. Any special construction features, conditions of occupancy, approved modifications or approved alternative materials, design and methods of construction, and equipment applying to the building that impact required fire-resistance ratings shall be identified in the evaluation reports submitted. <u>Such evaluation reports shall be submitted by the applicant and the code official is authorized, without charge to the jurisdiction, to require such evaluation reports to be prepared by, or adopted by, and bear the stamp of, a registered design professional.</u>

Commenter's Reason: Three modifications to the proposal are being added to the modification made by the Committee in order to provide the code official with greater flexibility and control over the outcome of alterations involving sprinkler retrofits of existing buildings.

The first change, simply, adds the word "Code" in the first paragraph since it appears to have been inadvertently left out in the original proposal.

Second, while the original proposal provides that the "building is required to meet "the other applicable fire protection requirements of Chapter 9 of the *International Building Code*," there are provisions in other Chapters of the current building code that the code official may want the building to comply with as a condition of allowing fire-resistance ratings to meet current code. For example, although sprinklered throughout, the existing building may not be in compliance with a variety of means of egress requirements found in Chapter 10 of the current code. Without including the additional language proposed in paragraph 1, the code official would have no basis to require compliance with provisions of Chapter 10.

Third, the second paragraph of the proposal requires supporting "plans, investigation and evaluation reports and other data" to be submitted to the code official. The code official should have the option, under this paragraph, to require those supporting evaluation reports to be prepared or adopted by a registered design professional. Otherwise, the code official is tasked with verifying the accuracy and quality of the supporting evaluation reports. While there may be cases where the code official is willing to do that, the proposed modification provides the code official with the option of requiring the involvement of a registered design professional in the application process. (References to the use of registered design professionals in connection with evaluation reports such as these can be found throughout the International Codes. For example, *see* sections 104.2.1.1 and 106.1 of the *International Existing Building Code*; section 104.7.2 of the *International Fire Code*; and *section 107.3.4 of* the *International Building Code*).

I urge you to vote against the standing motion to approve as modified by the Committee, and to vote in favor of approving this proposal as modified by this Public Comment.

EB26-13

Final Action: AS AM AMPC____ D

EB29-13
804.2.2

Proposed Change as Submitted

Proponent: Dave Frable, U.S. General Services Administration Public Buildings Service (dave.frable@gsa.gov)

Revise as follows:

804.2.2 Groups A, B, E, F-1, H, I, M, R-1, R-2, R-4, S-1 and S-2. In buildings with occupancies in Groups A, B, E, F-1, H, I, M, R-1, R-2, R-4, S-1 and S-2, work areas that have exits or corridors shared by more than one tenant or that have exits or corridors serving an occupant load greater than 30 shall be provided with automatic sprinkler protection where all of the following conditions occur:

1. The *work area* is required to be provided with automatic sprinkler protection in accordance with the *International Building Code* as applicable to new construction; and
2. The *work area* exceeds 50 percent of the floor area.

Exceptions:

1. Work areas in Group R occupancies three stories or less in height.
2. If the building does not have sufficient municipal water supply for design <u>and installation</u> of a fire sprinkler system available ~~to the floor without installation of a new fire pump,~~ <u>at the site</u> *work areas* shall be protected by an automatic smoke detection system throughout all occupiable spaces other than sleeping units or individual dwelling units that activates the occupant notification system in accordance with Sections 907.4, 907.5 and 907.6 of the *International Building Code*.

Reason: The intent of this code change is to attempt to address a concern that the municipal water supply must be available at the floor where the work area is located without the installation of a new fire pump. This code change revises the subject text such that if a municipal water supply is available at the building site, and the work area exceeds 50% of the floor area, the installation of a new fire pump if needed to supplement the necessary flow and pressure for the sprinkler system should not be the deciding factor to address the need to increase the current degree of public safety in existing buildings.

Cost Impact: This code change proposal will increase the cost of construction.

804.2.2-EB-FRABLE.doc

Committee Action Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The current allowance that would not require automatic sprinkler installation if a pump was required was felt inappropriate. Instead it was felt that the requirement for the installation of automatic sprinklers should be based upon the availability of onsite water.

Assembly Action: **Disapproved**

Individual Consideration Agenda

This code change proposal is on the agenda for individual consideration because the proposal received a successful assembly action of Disapproved and a public comment was submitted.

Public Comment:

Steven Orlowski, National Association of Home Builders, requests Disapproval.

Commenter's Reason: We disagree with the committee's action to remove the long standing exception that dates back to the 2000 IEBC. There has always been an understanding that there needs to be a sense of rational in applying new construction requirements to existing building, especially code provisions which would have a significant impact on the reuse or cost of altering an existing building. To now require level II alterations where the work area exceeds 50% of a floor to install a suppressions system and possibly an additional water lateral, emergency power source, fire pump and the protection of the fire pump is disproportional to the type of alteration taking place. In many cases, to sprinkler what could amount to be a very small portion of a building is regressive in that the added cost imposed by this modification may well become disproportionate to the protection provided and to the value of the building. We encourage the assembly to overturn the committee's action and reinstate the exception.

EB29-13
Final Action: AS AM AMPC____ D

EB30-13
804.2.3

Proposed Change as Submitted

Proponent: Dave Frable, U.S. General Services Administration, Public Buildings Service (dave.frable@gsa.gov)

Revise as follows:

804.2.3 Windowless stories. Work located in a windowless story, as determined in accordance with the *International Building Code*, shall be sprinklered where the *work area* is required to be sprinklered under the provisions of the *International Building Code* for newly constructed buildings and the building has a sufficient municipal water supply ~~without installation of a new fire pump~~ for design and installation of a fire sprinkler system available at the site.

Reason: The intent of this code change is to attempt to address a concern that the municipal water supply must be available at the floor where the work area is located without the installation of a new fire pump. This code change revises the subject text such that if a municipal water supply is available at the building site, and the work area exceeds 50% of the floor area, the installation of a new fire pump if needed to supplement the necessary flow and pressure for the sprinkler system should not be the deciding factor to address the need to increase the current degree of public safety in existing windowless buildings.

Cost Impact: This code change proposal will increase the cost of construction.

804.2.3-EB-FRABLE.doc

Committee Action Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The committee approved this proposal based upon the action taken on EB29-12.

Assembly Action: **Disapproved**

Individual Consideration Agenda

This code change proposal is on the agenda for individual consideration because the proposal received a successful assembly action of Disapproved.

EB32-13
804.2.4

Proposed Change as Submitted

Proponent: Dave Frable, U.S. General Services Administration Public Buildings Service (dave.frable@gsa.gov)

Revise as follows:

804.2.4 Other required automatic sprinkler systems. In buildings and areas listed in Table 903.2.11.6 of the *International Building Code*, *work areas* that have exits or corridors shared by more than one tenant or that have exits or corridors serving an occupant load greater than 30 shall be provided with an automatic sprinkler system under the following conditions:

1. The *work area* is required to be provided with an automatic sprinkler system in accordance with the *International Building Code* applicable to new construction; and
2. The building has sufficient municipal water supply for design and installation of an automatic sprinkler system available ~~to the floor without installation of a new fire pump~~. at the site.

Reason: The intent of this code change is to attempt to address a concern that the municipal water supply must be available at the floor where the work area is located without the installation of a new fire pump. This code change revises the subject text such that if a municipal water supply is available at the building site, and the work area exceeds 50% of the floor area, the installation of a new fire pump if needed to supplement the necessary flow and pressure for the sprinkler system should not be the deciding factor to address the need to increase the current degree of public safety in existing buildings.

Cost Impact: This code change proposal will increase the cost of construction.

804.2.4-EB-FRABLE.doc

Committee Action Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The committee approved this proposal based upon the action taken on EB29-12.

Assembly Action: **Disapproved**

Individual Consideration Agenda

This code change proposal is on the agenda for individual consideration because the proposal received a successful assembly action of Disapproved.

EB33-13
804.4.1.3

Proposed Change as Submitted

Proponent: John Williams, CBO, Chair, ICC Ad Hoc Committee on Healthcare (John.Williams@DOH.WA.GOV) and Carl Baldassarra, P.E., FSFPE, Chair, ICC Code Technology Committee (cbaldassarra@rjagroup.com)

Revise as follows:

804.4.1 Occupancy requirements. A fire alarm system shall be installed in accordance with Sections 804.4.1.1 through 804.4.1.7. Existing alarm-notification appliances shall be automatically activated throughout the building. Where the building is not equipped with a fire alarm system, alarm-notification appliances within the *work area* shall be provided and automatically activated.

Exceptions:

1. Occupancies with an existing, previously approved fire alarm system.
2. Where selective notification is permitted, alarm notification appliances shall be automatically activated in the areas selected.

804.4.1.3 Group I-2. A fire alarm system shall be installed in work areas of Group I-2 occupancies as required by the International Fire Code for ~~existing~~ new Group I-2 occupancies.

Reason: This proposed change is a joint proposal from the ICC Ad Hoc Committee on Healthcare (AHC) and the Code Technology Committee (CTC). The scope of the AHC deals with Group I-2 hospitals (now Group I-2 Condition 2 as a result of approved code change G257-12) and the scope of the CTC's investigation of the area of study entitled "Care Facilities" addresses Group I-1 and Group I-2 Condition 1 (nursing homes).

This section in the IEBC refers you to the IFC for fire alarm requirements in existing buildings undergoing a Level 2 Alteration. Section 1103.7.3 of the IFC refers back to the new construction requirements of Section 907.2.6.2. This proposal removes the circuitous references by stipulating that the fire alarm system needs to be installed as required for new construction.

This is a joint proposal submitted by the ICC Ad Hoc Committee for Healthcare and the ICC Code Technology Committee.

The AHC was established by the ICC Board of Directors to evaluate and assess contemporary code issues relating to hospitals and ambulatory healthcare facilities. The AHC is composed of building code officials, fire code officials, hospital facility engineers, and state healthcare enforcement representatives. The goals of the committee are to ensure that the ICC family of codes appropriately addresses the fire and life safety concerns of a highly specialized and rapidly evolving healthcare delivery system. This process is part of a joint effort between ICC and the American Society for Healthcare Engineering, a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. Since its inception in April 2011, the AHC has held 8 open meetings and over 150 workgroup calls which included members of the AHC as well as any interested party to discuss and debate the proposed changes. All meeting materials and reports are posted on the AHC website at: http://www.iccsafe.org/cs/AHC/Pages/default.aspx.

The ICC Board established the ICC Code Technology Committee (CTC) as the venue to discuss contemporary code issues in a committee setting which provides the necessary time and flexibility to allow for full participation and input by any interested party. This proposal is submitted by the ICC Code Technology Committee. The ICC Board established the ICC Code Technology Committee (CTC) as the venue to discuss contemporary code issues in a committee setting which provides the necessary time and flexibility to allow for full participation and input by any interested party. The code issues are assigned to the CTC by the ICC Board as "areas of study". Information on the CTC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CTC effort can be downloaded from the following website: http://www.iccsafe.org/cs/CTC/Pages/default.aspx. Since its inception in April/2005, the CTC has held twenty-five meetings - all open to the public. In 2012, three of the 25 face-to face meetings were held. In addition to the CTC meetings, the CTC established Study Groups (SG) of interested parties for each of the areas of study. These SG's are responsible for reviewing the available information and making recommendations to the CTC. All totaled, the SG's held over 70 conference calls in 2012.

Cost Impact: This code change proposal will not increase the cost of construction.

804.4.1.3-EB-BALDASSARRA-WILLIAMS-ADHOC.doc

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: This proposal was felt to conflict with the IFC for existing Group I-2 occupancies. Other concerns related to the fact that this provision should be dealt with in the change of occupancy requirements for new installations.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

John Williams, CBO, Chair, ICC Ad Hoc Committee on Health Care and Carl Baldassarra, P.E., FSFPE, Chair, ICC Code Technology Committee, request Approval as Modified by this Public Comment.

Replace the proposal as follows:

804.4.1 Occupancy requirements. A fire alarm system shall be installed in accordance with Sections 804.4.1.1 through 804.4.1.7. Existing alarm-notification appliances shall be automatically activated throughout the building. Where the building is not equipped with a fire alarm system, alarm-notification appliances within the *work area* shall be provided and automatically activated.

Exceptions:

1. Occupancies with an existing, previously approved fire alarm system.
2. Where selective notification is permitted, alarm notification appliances shall be automatically activated in the areas selected.

804.4.1.3 Group I-2. A fire alarm system shall be installed ~~in work areas of~~ <u>throughout</u> Group I-2 occupancies as required by the International Fire Code ~~for existing Group I-2 occupancies~~.

Commenter's Reason: The proposal was not intended to address new vs. existing occupancies. The intent is to send the designer to the correct location for fire alarms as required in IFC and maintaining correlation in the codes. Section 804.4.1 could be confusing for designers. Fire Codes and CMS require fire alarms throughout a Group I-2 already. See IFC Section 907.2.6.2 reprinted below. By virtue of this reference the difference is that you will pick up manual fire alarm pull stations. Note that the existing requirements in Section 1103.7 would permit a previously approved fire alarm system to remain. Whereas, this proposed language would require the fire alarm system to be upgraded to new standards based on rehabilitation work.

907.2.6.2 Group I-2. An automatic smoke detection system shall be installed in *corridors* in nursing homes, long-term care facilities, detoxification facilities and spaces permitted to be open to the *corridors* by Section 407.2 of the *International Building Code*. The system shall be activated in accordance with Section 907.5. Hospitals shall be equipped with smoke detection as required in Section 407 of the *International Building Code*.

Exceptions:

1. *Corridor* smoke detection is not required in smoke compartments that contain *sleeping units* where such units are provided with smoke detectors that comply with UL 268. Such detectors shall provide a visual display on the *corridor* side of each *sleeping unit* and shall provide an audible and visual alarm at the care provider station attending each unit.
2. *Corridor* smoke detection is not required in smoke compartments that contain *sleeping units* where *sleeping unit* doors are equipped with automatic door-closing devices with integral smoke detectors on the unit sides installed in accordance with their listing, provided that the integral detectors perform the required alerting function.

EB33-13

Final Action: AS AM AMPC____ D

EB35-13
805.3.1.1

Proposed Change as Submitted

Proponent: Steve Thomas, Colorado Code Consulting, LLC (sthomas@coloradocode.net)

Revise as follows:

805.3.1.1 Single-exit buildings. Only one exit is required from buildings and spaces of the following occupancies:

1. In Group A, B, E, F, M, U and S occupancies, a single exit is permitted in the story at the level of exit discharge when the occupant load of the story does not exceed 50 and the exit access travel distance does not exceed 75 feet (22 860 mm).
2. Group B, F-2, and S-2 occupancies not more than two stories in height that are not greater than 3,500 square feet per floor (326 m^2), when the exit access travel distance does not exceed 75 feet (22 860 mm). The minimum fire-resistance rating of the exit enclosure and of the opening protection shall be 1 hour.
3. Open parking structures where vehicles are mechanically parked.
4. In community residences for the developmentally disabled, the maximum occupant load excluding staff is 12.
5. Groups R-1 and R-2 not more than ~~two~~ three stories in height, when there are not more than four dwelling units per floor and the exit access travel distance does not exceed ~~50~~ 125 feet (~~15 240 mm~~ 38,100 mm). The minimum fire-resistance rating of the exit enclosure and of the opening protection shall be 1 hour. Each dwelling unit shall be provided with emergency escape and rescue openings in accordance with Section 1029 of the *International Building Code*.

(Portions of text not shown remain unchanged)

Reason: This change is intended to create consistency between the IEBC and the IBC. The travel distances for Group R-2 occupancies in Table 1021.2(1) were changed in the 2012 IBC. This change is consistent with that change. It eliminates any potential conflicts between the codes. We have also added the requirement for emergency escape and rescue openings to the section to be consistent with the footnote a of IBC Table 1021.2(1) for consistency as well.

Cost Impact: The code change proposal will not increase the cost of construction. It will reduce the cost of construction.

805.3.1.1-EB-THOMAS

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: The proposal was disapproved due to the concern with the increase in stories from two to three. This exception as currently written is for both sprinklered and non sprinklered buildings. Similar provisions in the IBC would require automatic sprinklers.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Steve Thomas, Colorado Code Consulting, LLC, representing Colorado Chapter ICC, requests Approval as Modified by this Public Comment.

Replace the proposal as follows:

805.3.1.1 Single-exit buildings. Only one exit is required from buildings and spaces of the following occupancies:

1. In Group A, B, E, F, M, U and S occupancies, a single exit is permitted in the story at the level of exit discharge when the occupant load of the story does not exceed 50 and the exit access travel distance does not exceed 75 feet (22 860 mm).

2. Group B, F-2, and S-2 occupancies not more than two stories in height that are not greater than 3,500 square feet per floor (326 m2), when the exit access travel distance does not exceed 75 feet (22 860 mm). The minimum fire-resistance rating of the exit enclosure and of the opening protection shall be 1 hour.

3. Open parking structures where vehicles are mechanically parked.

4. In community residences for the developmentally disabled, the maximum occupant load excluding staff is 12.

5. Groups R-1 and R-2 not more than two stories in height, when there are not more than four dwelling units per floor and the exit access travel distance does not exceed 50 feet (15 240 mm). The minimum fire-resistance rating of the exit enclosure and of the opening protection shall be 1 hour.

<u>6. Group R-2 occupancies not more than three stories in height which comply with all of the following:</u>

<u>6.1. There are not more than four dwelling units per story</u>
<u>6.2. The building is provided with a fire sprinkler system in accordance with Section 903.3.1.1 or 903.3.1.2 of the *International Building Code.*</u>
<u>6.3 The exit access travel distance from each dwelling unit to an approved exit does not exceed 125 feet (15,240 mm).</u>
<u>6.4 Each dwelling unit shall be provided with emergency escape and rescue openings in accordance with Section 1029 of the International Building Code.</u>

Commenter's Reason: The committee had concerns with the revision increasing the number of stories in the section and the lack of sprinkler requirements. Our intent was to provide consistency with the International Building Code (IBC). Therefore, we are proposing that we replace the original proposal with the language above. The current language in Item 5 of Section 805.3.1.1 is not being revised. We are adding an additional item to the section that coincides with the current language in the IBC Table 1021.2(1). This proposal eliminates any potential conflicts between the IBC and IEBC.

EB35-13
Final Action: AS AM AMPC____ D

EB38-13
805.6

<u>Proposed Change as Submitted</u>

Proponent: Gerald Anderson, City of Overland Park, Kansas (jerry.anderson@opkansas.org)

Revise as follows:

805.6 Dead-end corridors. Dead-end corridors in any *work area* <u>created as a result of the alteration</u> shall not exceed ~~35~~ <u>20</u> feet (6096 mm).<u>Existing dead-end corridors in any work area shall not exceed 35 feet (10 670 mm).</u>

Exceptions:

1. Where dead-end corridors of greater length are permitted by the *International Building Code*.
2. In other than Group A and H occupancies, the maximum length of an existing dead-end corridor shall be 50 feet (15 240 mm) in buildings equipped throughout with an automatic fire alarm system installed in accordance with the *International Building Code*.
3. In other than Group A and H occupancies, the maximum length of an existing dead-end corridor shall be 70 feet (21 356 mm) in buildings equipped throughout with an automatic sprinkler system installed in accordance with the *International Building Code*.
4. In other than Group A and H occupancies, the maximum length of an existing, newly constructed, or extended dead-end corridor shall not exceed 50 feet (15 240 mm) on floors equipped with an automatic sprinkler system installed in accordance with the *International Building Code*.

Reason: The intent of the code change is to make the base requirement for the allowable length of a dead-end corridor to be the same as the International Building code. The IBC limits dead-end corridors to 20 feet. The new wording will continue to make allowances for existing situations where existing dead-end corridor are found to be 35 feet length or less in length. It seems terribly inconsistent to require dead-end corridors on new construction be limited to 20 feet, and then yet allow for an alteration with a 35 foot dead end corridor.

Cost Impact: The code change proposal will not increase the cost of construction.

805.6-EB-ANDERSON

<u>Committee Action Hearing Results</u>

Committee Action: **Disapproved**

Committee Reason: The committee understood the concerns raised by the proposal but as currently written may be difficult to apply and would be inconsistent with the IBC. It was encouraged that more work occur on the proposal in the form of a public comment. One particular concern raised was dealing with a newly constructed corridor in an existing building that due to the layout of the building could not meet the 20 foot requirement in a practical way.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Gerald Anderson, City of Overland Park, Kansas, representing self, requests Approval as Modified by this Public Comment.

Replace the proposal as follows:

805.6 Dead-end corridors. <u>Existing</u> dead-end corridors in any *work area* shall not exceed 35 feet (6096 mm).

Exceptions:

1. Where dead-end corridors of greater length are permitted by the *International Building Code*.
2. In other than Group A and H occupancies, the maximum length of an existing dead-end corridor shall be 50 feet (15 240 mm) in buildings equipped throughout with an automatic fire alarm system installed in accordance with the *International Building Code*.
3. In other than Group A and H occupancies, the maximum length of an existing dead-end corridor shall be 70 feet (21 356 mm) in buildings equipped throughout with an automatic sprinkler system installed in accordance with the *International Building Code*.
4. In other than Group A and H occupancies, the maximum length of an existing, newly constructed, or extended dead-end corridor shall not exceed 50 feet (15 240 mm) on floors equipped with an automatic sprinkler system installed in accordance with the *International Building Code*.

Commenter's Reason: The purpose of the code change is to clarify what I believe is the intent of the code. The current language can be read to as allow for construction of dead end corridors 35 ft in length. That reading of the code would be in conflict with the IBC which limits dead-end corridors to 20 feet. By adding the word 'existing" the code would still will make allowances for existing situations where existing dead-end corridor are found to be 35 feet length or less in length but would not allow for the construction of a dead end corridor in excess of that allowed by the IBC.

This is a much needed change. It seems terribly inconsistent to restrict dead-end corridors in new construction to 20 feet, and then turn around and allow the construction of a 35 foot dead end corridor when the IEBC is used.

EB38-13

Final Action: AS AM AMPC____ D

EB42-13
806.2

Proposed Change as Submitted

Proponent: Carl Baldassarra, P.E., Chair, ICC Code Technology Committee (cbaldassarra@rjagroup.com)

Revise as follows:

806.2 Stairs and escalators in existing buildings. In *alterations* where an escalator or stair is added where none existed previously, an accessible route shall be provided in accordance with ~~Sections~~ Section 1104.4 ~~and 1104.5~~ of the *International Building Code*.

Reason: The intent of this provisions is that the accessible route will be permitted to be provided in the same area as the new construction, and is not require it to be located elsewhere in the building. A reference to Section 1104.5 could require the accessible route to be provided in another part of the building is the new stairway was not on a general circulation route. A correlative change has been proposed and approved for IBC Section 3411.8.4/IEBC 410.8.4.

The ICC Board established the ICC Code Technology Committee (CTC) as the venue to discuss contemporary code issues in a committee setting which provides the necessary time and flexibility to allow for full participation and input by any interested party. The code issues are assigned to the CTC by the ICC Board as "areas of study". Information on the CTC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CTC effort can be downloaded from the following website: http://www.iccsafe.org/cs/CTC/Pages/default.aspx. Since its inception in April/2005, the CTC has held twenty five meetings - all open to the public.

Cost Impact: The code change proposal will not increase the cost of construction.

806.2-EB-BALDASSARRA-CTC

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: There were concerns that without the reference to Section 1104.5 the route could potentially be located outside the building which was inappropriate.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Carl Baldassarra, ICC Code Technologies Committee, requests Approval as Submitted.

Commenter's Reason: The requirement in Section 1104.5 for a "general" circulation path location (Section 1104.5) could require the accessible route to be constructed considerably outside of the work area. Therefore, the intent of the deletion of the reference to Section 1104.5 is to allow for the vertical route, typically an elevator or platform lift, to be installed within the area of alteration, rather than possibly requiring the route somewhere else in the building. This would allow design flexibility and options.

Also, this language is currently in IEBC Section 410.8.4. The revision was approved in G241-12. This needs to be approved for correlation in the code. 2015 text is below.

IBC 1104.5 Location. *Accessible routes* shall coincide with or be located in the same area as a <u>general</u> *circulation path*. Where the *circulation path* is interior, the *accessible route* shall also be interior. Where only one *accessible route* is provided, the *accessible route* shall not pass through kitchens, storage rooms, restrooms, closets or similar spaces.

Exceptions:

1. *Accessible routes* from parking garages contained within and serving *Type B units* are not required to be interior.
2. A single *accessible route* is permitted to pass through a kitchen or storage room in an *Accessible unit*, *Type A unit* or *Type B unit*.

IEBC 410.8.4 Stairs and escalators in existing buildings. In *alterations* where an escalator or stair is added where none existed previously, an accessible route shall be provided in accordance with Section 1104.4 of the *International Building Code*.

EB42-13
Final Action: AS AM AMPC____ D

EB43-13
806.3, 806.4, 806.5, 906.2

Proposed Change as Submitted

Proponent: Carl Baldassarra, P.E., Chair, ICC Code Technology Committee

Revise as follows:

~~806.3~~ 1105.2 Accessible dwelling units and sleeping units. Where Group I-1, I-2, I-3, R-1, R-2 or R-4 dwelling or sleeping units are being added, the requirements of Section 1107 of the *International Building Code* for accessible units and Chapter 9 of the *International Building Code* for visible alarms apply only to the quantity of spaces being added.

~~806.4~~ 1105.3 Type A dwelling or sleeping units. Where more than 20 Group R-2 dwelling or sleeping units are being added, the requirements of Section 1107 of the *International Building Code* for Type A units and Chapter 9 of the *International Building Code* for visible alarms apply only to the quantity of the spaces being added.

~~806.5~~ 1105.4 Type B dwelling or sleeping units. Where four or more Group I-1, I-2, R-1, R-2, R-3 or R-4 dwelling or sleeping units are being added, the requirements of Section 1107 of the *International Building Code* for Type B units and Chapter 9 of the *International Building Code* for visible alarms apply only to the quantity of the spaces being added.

906.2 Type B dwelling or sleeping units. Where four or more Group I-1, I-2, R-1, R-2, R-3 or R-4 dwelling or sleeping units are being altered ~~or added~~, the requirements of Section 1107 of the *International Building Code* for Type B units and Chapter 9 of the *International Building Code* for visible alarms apply only to the quantity of the spaces being altered ~~or added~~.

Reason: The intent of this change is to clarify when Accessible, Type A and Type B units are required in alterations and additions.

Units being added within an existing structure are considered an alteration; therefore, Accessible and Type A units that are added as part of a renovation are adequately addressed in Section 705.1.8 and 705.1.9, and the language in 806.3 and 806.4 is not needed.

Additions adjacent to or above a building must comply with new construction. Therefore, Section 806.3, 806.4 and 806.5 should be relocated to Section 1105. This clarifies that just the addition is considered for the number of units, not the addition plus the number of existing units. Section 705.1.14, Extent of application, would allow for a situation where Accessible and Type A units were provided in sufficient numbers, including the addition, in the existing building.

Type B units are currently required in existing building undergoing a Level 3 alteration, with or without a change of occupancy. This requirement will remain the same (see Section 705.1, Exception 3, Section 906.2 and the exception to Section 1012.8).

For reference these are the related sections with revisions included.

Level I Alterations

705.1 General. A *facility* that is altered shall comply with the applicable provisions in Sections 705.1.1 through 705.1.14, and Chapter 11 of the *International Building Code* unless it is *technically infeasibl*e. Where compliance with this section is *technically infeasible*, the alteration shall provide access to the maximum extent that is technically feasible. A *facility* that is constructed or altered to be accessible shall be maintained accessible during occupancy.

Exceptions:
1. The altered element or space is not required to be on an accessible route unless required by Section 705.2.
2. Accessible means of egress required by Chapter 10 of the *International Building Code* are not required to be provided in existing *facilities*.
3. Type B dwelling or sleeping units required by Section 1107 of the *International Building Code* are not required to be provided in existing *facilities* undergoing less than a Level 3 *alteration*.
4. The alteration to Type A individually owned dwelling units within a Group R-2 occupancy shall meet the provisions for Type B dwelling units.

705.1.8 Accessible dwelling or sleeping units. Where Group I-1, I-2, I-3, R-1, R-2 or R-4 dwelling or sleeping units are being altered, the requirements of Section 1107 of the *International Building Code* for accessible units and Chapter 9 of the *International Building Code* for visible alarms apply only to the quantity of the spaces being altered.

705.1.9 Type A dwelling or sleeping units. Where more than 20 Group R-2 dwelling or sleeping units are being altered, the requirements of Section 1107 of the *International Building Code* for Type A units and Chapter 9 of the *International Building Code* for visible alarms apply only to the quantity of the spaces being altered.

Level II Alterations

806.1 General. A building, *facility*, or element that is altered shall comply with this section and Section 705.

Level III Alterations

906.1 General. A building, *facility* or element that is altered shall comply with this section and Sections 705 and 806.

906.2 Type B dwelling or sleeping units. Where four or more Group I-1, I-2, R-1, R-2, R-3 or R-4 dwelling or sleeping units are being altered ~~or added~~, the requirements of Section 1107 of the *International Building Code* for Type B units and Chapter 9 of the *International Building Code* for visible alarms apply only to the quantity of the spaces being altered ~~or added~~.

Change of Occupancy

1006.1 General. Accessibility in portions of buildings undergoing a *change of occupancy* classification shall comply with Section 1012.8.

1012.8 Accessibility. *Existing buildings* that undergo a change of group or occupancy classification shall comply with this section.

> **Exception:** Type B dwelling or sleeping units required by Section 1107 of the *International Building Code* are not required to be provided in existing buildings and facilities undergoing a *change of occupancy* in conjunction with less than a Level 3 *alteration*.

Additions

1105.1 Minimum requirements. Accessibility provisions for new construction shall apply to additions. An addition that affects the accessibility to, or contains an area of, *primary function* shall comply with the requirements of Sections 705, 806 and 906, as applicable.

<u>1105.2</u> ~~806.3~~ Accessible dwelling units and sleeping units. Where Group I-1, I-2, I-3, R-1, R-2 or R-4 dwelling or sleeping units are being added, the requirements of Section 1107 of the *International Building Code* for accessible units and Chapter 9 of the *International Building Code* for visible alarms apply only to the quantity of spaces being added.

<u>1105.3</u> ~~806.4~~ Type A dwelling or sleeping units. Where more than 20 Group R-2 dwelling or sleeping units are being added, the requirements of Section 1107 of the *International Building Code* for Type A units and Chapter 9 of the *International Building Code* for visible alarms apply only to the quantity of the spaces being added.

<u>1105.4</u> ~~806.5~~ Type B dwelling or sleeping units. Where four or more Group I-1, I-2, R-1, R-2, R-3 or R-4 dwelling or sleeping units are being added, the requirements of Section 1107 of the *International Building Code* for Type B units and Chapter 9 of the *International Building Code* for visible alarms apply only to the quantity of the spaces being added.

The ICC Board established the ICC Code Technology Committee (CTC) as the venue to discuss contemporary code issues in a committee setting which provides the necessary time and flexibility to allow for full participation and input by any interested party. The code issues are assigned to the CTC by the ICC Board as "areas of study". Information on the CTC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CTC effort can be downloaded from the following website: http://www.iccsafe.org/cs/CTC/Pages/default.aspx. Since its inception in April/2005, the CTC has held twenty five meetings - all open to the public.

Cost Impact: This code change proposal will not increase the cost of construction.

906.2-EB-BALDASSARRA-CTC.doc

<u>Committee Action Hearing Results</u>

Committee Action: Disapproved

Committee Reason: There was concern that moving these requirements to the chapter on additions would create a potential gap in the IEBC for Accessible, Type A and Type B dwelling and sleeping units.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Carl Baldassarra, ICC Code Technologies Committee, requests Approval as Submitted.

Commenter's Reason: The IEBC development committee felt that there was a possible gap in the requirements for accessible units. The CTC carefully reviewed the proposal to identify any gaps and found none. The CTC committee felt that this change would not create a gap in the provisions, but would clarify what happens with additions. Where units are added as part of an addition, should be addressed in the IEBC Chapter on additions, not in the chapter for Level 2 alterations. Section 1105.4 for Type B units is consistent with Fair Housing Requirements and is part of the safe harbor evaluation.

Dwelling and sleeping units added within a building as part of change of occupancy are alterations and will addressed in the current text in Level I for Accessible and Type A and Level III for Type B.

This is how the language would be related in the IEBC –

Level I Alterations

705.1 General. A *facility* that is altered shall comply with the applicable provisions in Sections 705.1.1 through 705.1.14, and Chapter 11 of the *International Building Code* unless it is *technically infeasibl*e. Where compliance with this section is *technically infeasible*, the alteration shall provide access to the maximum extent that is technically feasible. A *facility* that is constructed or altered to be accessible shall be maintained accessible during occupancy.

Exceptions:

1. The altered element or space is not required to be on an accessible route unless required by Section 705.2.
2. Accessible means of egress required by Chapter 10 of the *International Building Code* are not required to be provided in existing *facilities*.
3. Type B dwelling or sleeping units required by Section 1107 of the *International Building Code* are not required to be provided in existing *facilities* undergoing less than a Level 3 *alteration*.
4. The alteration to Type A individually owned dwelling units within a Group R-2 occupancy shall meet the provisions for Type B dwelling units.

705.1.8 Accessible dwelling or sleeping units. Where Group I-1, I-2, I-3, R-1, R-2 or R-4 dwelling or sleeping units are being altered, the requirements of Section 1107 of the *International Building Code* for accessible units and Chapter 9 of the *International Building Code* for visible alarms apply only to the quantity of the spaces being altered.

705.1.9 Type A dwelling or sleeping units. Where more than 20 Group R-2 dwelling or sleeping units are being altered, the requirements of Section 1107 of the *International Building Code* for Type A units and Chapter 9 of the *International Building Code* for visible alarms apply only to the quantity of the spaces being altered.

Level II Alterations

806.1 General. A building, *facility*, or element that is altered shall comply with this section and Section 705.

Level III Alterations

906.1 General. A building, *facility* or element that is altered shall comply with this section and Sections 705 and 806.

906.2 Type B dwelling or sleeping units. Where four or more Group I-1, I-2, R-1, R-2, R-3 or R-4 dwelling or sleeping units are being altered ~~or added~~, the requirements of Section 1107 of the *International Building Code* for Type B units and Chapter 9 of the *International Building Code* for visible alarms apply only to the quantity of the spaces being altered ~~or added~~.

Change of Occupancy

1006.1 General. Accessibility in portions of buildings undergoing a *change of occupancy* classification shall comply with Section 1012.8.

1012.8 Accessibility. *Existing buildings* that undergo a change of group or occupancy classification shall comply with this section.

Exception: Type B dwelling or sleeping units required by Section 1107 of the *International Building Code* are not required to be provided in existing buildings and facilities undergoing a *change of occupancy* in conjunction with less than a Level 3 *alteration*.

Additions

1105.1 Minimum requirements. Accessibility provisions for new construction shall apply to additions. An addition that affects the accessibility to, or contains an area of, *primary function* shall comply with the requirements of Sections 705, 806 and 906, as applicable.

1105.2 ~~806.3~~ Accessible dwelling units and sleeping units. Where Group I-1, I-2, I-3, R-1, R-2 or R-4 dwelling or sleeping units are being added, the requirements of Section 1107 of the *International Building Code* for accessible units and Chapter 9 of the *International Building Code* for visible alarms apply only to the quantity of spaces being added.

1105.3 ~~806.4~~ Type A dwelling or sleeping units. Where more than 20 Group R-2 dwelling or sleeping units are being added, the requirements of Section 1107 of the *International Building Code* for Type A units and Chapter 9 of the *International Building Code* for visible alarms apply only to the quantity of the spaces being added.

1105.4 ~~806.5~~ Type B dwelling or sleeping units. Where four or more Group I-1, I-2, R-1, R-2, R-3 or R-4 dwelling or sleeping units are being added, the requirements of Section 1107 of the *International Building Code* for Type B units and Chapter 9 of the *International Building Code* for visible alarms apply only to the quantity of the spaces being added.

EB43-13
Final Action: AS AM AMPC____ D

EB45-13
901.2, 903.2.1, 903.3

Proposed Change as Submitted

Proponent: David S. Collins, FAIA, The Preview Group, Inc., representing The American Institute of Architects

Revise as follows:

901.2 Compliance. In addition to the provisions of this chapter, work shall comply with all of the requirements of Chapters 7 and 8. The requirements of Sections 803, 804 and 805 shall apply ~~within all *work areas*~~ to all Level 3 alteration work per Section 505.1, whether or not they include exits and corridors shared by more than one tenant and regardless of the occupant load.

> **Exception:** Buildings in which the reconfiguration of space affecting exits or shared egress access is exclusively the result of compliance with the accessibility requirements of Section 705.2 shall not be required to comply with this chapter.

903.2.1 Separation required. Where the ~~*work area*~~ Level 3 alteration work is in any attached dwelling unit in Group R-3 or any multiple single-family dwelling (townhouse), walls separating the dwelling units that are not continuous from the foundation to the underside of the roof sheathing shall be constructed to provide a continuous fire separation using construction materials consistent with the existing wall or complying with the requirements for new structures. All work shall be performed on the side of the dwelling unit wall that is part of the *work area*.

> **Exception:** Where *alterations* or *repairs* do not result in the removal of wall or ceiling finishes exposing the structure, walls are not required to be continuous through concealed floor spaces.

903.3 Interior finish. Interior finish in exits serving the ~~*work area*~~ Level 3 alterations shall comply with Section 803.4 between the highest floor on which there is ~~a *work area*~~ an *alteration* to the floor of exit discharge.

Reason: This change is part of the package of changes to help clarify how alteration work is described and within what limitations they are to be applied. Section 505.1 will include the limitations for the 50 percent reconfiguration of space, along with the reconfiguration or extension of systems that serve more than 50 percent of the space in a building.

Cost Impact: The code change proposal will not increase the cost of construction. This will lower the cost of construction by eliminating confusion.

901.2-EB-COLLINS.doc

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee understood the concerns with the term and definition of "work area" but this particular strategy of stating "level 3 alteration" was not felt to solve the problem.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

David S. Collins, FAIA, The Preview Group, Inc. representing The American Institute of Architects, requests Approval as Submitted.

Commenter's Reason: EB24 was passed for level 2 alterations, removing the unnecessary and confusing terminology of work area from the IEBC, this change would coordinate those changes for the level 3 alterations

EB45-13

Final Action: AS AM AMPC____ D

EB46-13
902.2, 902.2.1

Proposed Change as Submitted

Proponent: Carl Baldassarra, P.E., Chair, ICC Code Technology Committee

Revise as follows:

902.2 Boiler and furnace equipment rooms. Boiler and furnace equipment rooms adjacent to or within Groups I-1, I-2, I-4, R-1, R-2 and R-4 occupancies ~~the following facilities~~ shall be enclosed by 1-hour fire-resistance-rated construction: ~~day nurseries, children's shelter facilities, residential childcare facilities, and similar facilities with children below the age of 21/2 years or that are classified as Group I-2 occupancies, shelter facilities, residences for the developmentally disabled, group homes, teaching family homes, transitional living homes, rooming and boarding houses, hotels, and multiple dwellings~~ .

Exceptions:

1. ~~Furnace and~~ Steam boiler equipment ~~of low-pressure type,~~ operating at pressures of 15 pounds per square inch gauge (psig) (103.4 KPa) or less ~~for steam equipment or~~ is not required to be enclosed.
2. Hot water boilers operating at pressures of 170 psig (1171 KPa) or less ~~for hot water equipment, when installed in accordance with manufacturer recommendations~~ are not required to be enclosed.
3. ~~2.~~ Furnace and boiler equipment ~~of residential R-3 type~~ with ~~200,000~~ 400,000 British thermal units (Btu) (~~2.11~~ 4.22 × 108 J) per hour input rating or less is not required to be enclosed.
4. ~~3.~~ Furnace rooms protected with automatic ~~sprinkler protection~~ fire-extinguishing system are not required to be enclosed.

~~**902.2.1 Emergency controls.** Emergency controls for boilers and furnace equipment shall be provided in accordance with the *International Mechanical Code* in all buildings classified as day nurseries, children's shelter facilities, residential childcare facilities, and similar facilities with children below the age of 21/2 years or that are classified as Group I-2 occupancies, and in group homes, teaching family homes, and supervised transitional living homes in accordance with the following:~~

1. ~~Emergency shutoff switches for furnaces and boilers in basements shall be located at the top of the stairs leading to the basement; and~~
2. ~~Emergency shutoff switches for furnaces and boilers in other enclosed rooms shall be located outside of such room.~~

Reason: The list of occupancies is outdated and unclear in both Section 902.2 and 902.2.1. The exceptions in 902.2 should be consistent with IBC Table 508.2.5 for new construction, not have a much lower threshold for renovations versus new. The remainder of the revisions is a clarification of the existing language. Emergency controls for boilers and furnace equipment is never required in the IMC, so Section 902.2.1 should be deleted.

The ICC Board established the ICC Code Technology Committee (CTC) as the venue to discuss contemporary code issues in a committee setting which provides the necessary time and flexibility to allow for full participation and input by any interested party. The code issues are assigned to the CTC by the ICC Board as "areas of study". Information on the CTC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CTC effort can be downloaded from the following website: http://www.iccsafe.org/cs/CTC/Pages/default.aspx. Since its inception in April/2005, the CTC has held twenty five meetings - all open to the public.

Cost Impact: This code change proposal will not increase the cost of construction.

902.2-EB-BALDASSARRA-CTC.doc

Committee Action Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: This proposal was approved as it fixes out dated descriptions of occupancies that are now clearly addressed by the IBC. These revisions were felt to make application of the I-Codes more consistent.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jeffrey M. Hugo, CBO, National Fire Sprinkler Association, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

902.2 Boiler and furnace equipment rooms. Boiler and furnace equipment rooms adjacent to or within Groups I-1, I-2, I-4, R-1, R-2 and R-4 occupancies shall be enclosed by 1-hour fire-resistance-rated construction:

Exceptions:

1. Steam boiler equipment operating at pressures of 15 pounds per square inch gauge (psig) (103.4 KPa) or less or is not required to be enclosed.
2. Hot water boilers operating at pressures of 170 psig (1171 KPa) or less are not required to be enclosed.
3. Furnace and boiler equipment of with 400,000 British thermal units (Btu) (4.22 × 108 J) per hour input rating or less is not required to be enclosed.
4. Furnace rooms protected with an automatic sprinkler ~~fire-extinguishing~~ system are not required to be enclosed.

Commenter's Reason: The term "automatic sprinkler system" is consistent with Table 509 (or Table 508.2 in 2009 IBC).

EB46-13

Final Action:	AS	AM	AMPC____	D

EB49-13
904.2

Proposed Change as Submitted

Proponent: Charles S. Bajnai, Chesterfield County, VA, ICC Building Code Action Committee

Revise as follows:

904.2 Fire alarm and detection systems. Fire alarm and detection systems ~~complying with Sections 804.4.1 and 804.4.3~~ shall be provided ~~throughout the building~~ in accordance with <u>Section 907 of</u> the *International Building Code* <u>as required for new construction</u>.

Reason: This proposal is submitted by the ICC Building Code Action Committee (BCAC) The BCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance an assigned International Code or portion thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the BCAC has held 6 open meetings and numerous workgroup calls which included members of the BCAC as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: http://www.iccsafe.org/cs/BCAC/Pages/default.aspx.

The reference back to Section 804.4.1 through 804.4.3 misses critical upgrades of alarm systems for other occupancies. The intent of this proposal is to eliminate the reference to Chapter 8 of the IEBC because the reference creates confusion. Section 904.2.1 implies that an alarm system for all occupancies in accordance with the IBC would be required, however the reference to Section 804.4 implies that only those occupancies found in Section 804.4 are required to have them installed. Section 804.4 does not cover the fire alarm requirements for all occupancies in the IBC. An alteration level 3 to an existing A occupancy is a significant change to more than 50% of the area of a building and an alarm system would not be required with the current reference to Section 804.4 left in the code.

Cost Impact: This code change proposal will increase the cost of construction.

904.2-EB-BAJNAI-BCAC.doc

Committee Action Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The committee approved the proposal based upon the proponent's reason. In addition, it was noted that level 3 alterations were substantial enough and fire alarm systems should be as required for new construction.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Maureen Traxler, City of Seattle Department of Planning & Development, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

904.2 Fire alarm and detection systems. Fire alarm and detection systems shall be provided <u>throughout the building</u> in accordance with Section 907 of the *International Building Code* as required for new construction.

Commenter's Reason: We are proposing to reinsert the phrase "throughout the building" into this code section because it clarifies that the requirements for fire alarm systems are not limited to the work area. Section 904.2 of the 2012 IEBC requires alarms throughout, but the rest of Chapter 9 applies either to the work area only or to areas from the work area to the level of exit discharge. The phrase "as required for new construction" clarifies that "throughout the building" means that a fire alarm system is only required where Section 904.2 would require it for new construction.

EB49-13

Final Action: AS AM AMPC____ D

EB52-13

202, 1001.1, 1001.2, 1001.2.1, 1001.3, 1001.3.1

Proposed Change as Submitted

Proponent: Gerald Anderson, City of Overland Park, Kansas representing self (jerry.anderson@opkansas.org)

Revise as follows:

SECTION 202
GENERAL DEFINITIONS

CHANGE OF OCCUPANCY. A change in the ~~purpose or level of activity within a building that involves a change in application of the requirements of this code~~ use of the building or a portion a building. A change of occupancy shall include any change of occupancy classification, any change from one group to another group within an occupancy classification or any change in an allowable use within a given group for a specific occupancy classification.

Revise as follows:

1001.1 Scope. The provisions of this chapter shall apply where a *change of occupancy* occurs, as defined in Section 202, ~~including:~~

1. ~~Where the occupancy classification is not changed; or~~
2. ~~Where there is a change in occupancy classification of the occupancy group designations changes~~

1001.2 Change in occupancy ~~with no change of occupancy classification.~~ A change in ~~occupancy, as defined in Section 202, with no *change of occupancy* classification~~ use shall not be made to any structure ~~that will subject the structure to any special provisions of the applicable *International Codes*, including the provisions of Sections 1002 through 1011,~~ without the approval of the *code official*. A certificate of occupancy shall be issued where it has been determined that the requirements for the change in occupancy have been met.

1001.2.1 ~~Repair and alteration~~ Change in Occupancy with no change of occupancy classification. Any ~~repair or alteration~~ work undertaken in connection with a change ~~of occupancy~~ in use that does not involve a *change of occupancy* classification or a change to another group within a given occupancy classification shall conform to the applicable requirements for the work as classified in Chapter 4 and to the requirements of Section 1002 through 1011.

Exception: As modified in Section 1205 for *historic buildings*.

~~1001.3~~ 1001.2.2 Change of occupancy classification. Where the occupancy classification of a building changes, the provisions of Sections 1002 through 1012 shall apply. This includes a *change of occupancy* classification within a group as well as a *change of occupancy* classification from one group to a different group.

~~1001.3.1~~ 1001.2.2.1 Partial change of occupancy classification. Where a portion of an *existing building* is changed to a new occupancy classification, Section 1012 shall apply.

Reason: The purpose of the code change is to bring the IEBC definition for a change in occupancy more in line with the IBC definition for a change in occupancy. The additional portions of the code change clarify the intent of the code.

Definition: The definition for a change in occupancy should include all things that would constitute a change in occupancy. The IBC uses the words "use, groups and occupancy classification. For consistency and clarity it is important to stick with language used in the building code thus I changed out the word purpose with use. Example: Occupancy classifications are A,B,H,R,I,M,S &

U. The different occupancy classifications can be divided into Groups, i.e. A-1, A-2, A-3 etc. and within the various groups there are examples of allowed uses for a particular group. Such as under group A-3, we find are art galleries, dance halls, & bowling alleys.

Some other reasons for changing the definition: The words "level of activity" is vague. It would also appear that a change in occupancy is somehow dependent on whether there are other code requirements for the new occupancy. A change in occupancy should be a yes or no question. If the answer is yes then one proceeds to determine what new code provisions are applicable if any.

Section 1001.1 Scope. The stricken language is no longer necessary because the bullets points have been included in the definition. With the proposed language, I am trying to make a simple statement that the use of a building cannot be changed without the approval of the code official.

Section 1001.2. The current language is vague. It appears that the existing language is trying to address a change in use. I have inserted the word use in order to make it clear as to what the code is trying to address. It is not necessary to speak to the special provisions of the applicable International codes whatever they are. A change in use is not dependent on special provisions of the code.

Section 1001.2.1. The current language is confusing and is in conflict with 1001.3. With the new wording, I am clarify that when there is a change of use that does not involve a change in occupancy classification or a change from one group to another in a given occupancy classification the code then refers one back to chapter 4 and sections 1002 through 1011. . It is not necessary to talk about "repair and alteration" for that is not the subject. The subject matter is change in occupancy which has resulted from a change in use.

I have renumbered the existing sections 1001.3 and 1001.3.1 making them subsections of 1001.2. All of the sections are addressing different types of occupancy change so it seems more appropriate to have one section with various subsections.

Cost Impact: This code change proposal will not increase the cost of construction.

1001.1-EB-ANDERSON.doc

Committee Action Hearing Results

Committee Action: Approved as Submitted

Committee Reason: This proposal was approved to be consistent with the Chapter 4 of the IEBC (Previously Chapter 34 of the IBC) regarding change of occupancy.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Maureen Traxler, City of Seattle Department of Planning & Development, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

CHANGE OF OCCUPANCY. A change in the use of the building or a portion of a building. A change of occupancy shall include any change of occupancy classification, any change from one group to another group within an occupancy classification or any change in ~~an allowable~~ use within a ~~given~~ group for a specific occupancy classification.

1001.1 Scope. The provisions of this chapter shall apply where a *change of occupancy* occurs, as defined in Section 202.

1001.2 Certificate of ~~Change in~~ occupancy. A change ~~in use~~ of occupancy shall not be made to any structure without the approval of the *code official*. A certificate of occupancy shall be issued where it has been determined that the requirements for the change ~~in~~ of occupancy have been met.

1001.2.1 Change of use ~~in~~ **~~occupancy with no change of occupancy classification~~**. Any work undertaken in connection with a change in use that does not involve a *change of occupancy* classification or a change to another group within an ~~given~~ occupancy classification shall conform to the applicable requirements for the work as classified in Chapter ~~4~~ 5 and to the requirements of Section 1002 through 1011.

Exception: As modified in Section 1205 for *historic buildings*.

1001.2.2 Change of occupancy classification or group. Where the occupancy classification or group of a building changes, the provisions of Sections 1002 through 1012 shall apply. This includes a *change of occupancy* classification; ~~within a group as well as~~ and a *change* ~~*of occupancy*~~ ~~classification from one group to a different group.~~ to another group within an occupancy classification.

1001.2.2.1 Partial change of occupancy ~~classification~~. Where <u>the occupancy classification or group of</u> a portion of an *existing building* is changed ~~to a new occupancy classification~~, Section 1012 shall apply.

Commenter's Reason: This proposal does a very good job of clarifying the rules for change of occupancy. It's always been a confusing subject but this proposal lays out a logical way of organizing changes of occupancy into 3 categories. The definition sets up a hierarchy as explained in the reason for the original proposal. The hierarchy is:

- Classification (A, B, E, etc.)
  - Group (numbered subset within some classifications A-1, F-2, etc.)
    - Use (B animal hospital vs. B post office)

As stated in the original definition, change of occupancy "…shall include any change of occupancy classification [e.g. B to R], any change from one group to another group within an occupancy classification [e.g. R-1 to R-2] or any change in an allowable use within a given group [e.g. R-2 dormitory to R-2 boarding house]." The text in brackets was added.

This comment makes the original proposal a little clearer and straightens out some inconsistencies within the section.

- In the definition "allowable" is deleted because the rules for change of occupancy should apply even if the original use was not allowed.
- Section titles are changed to better reflect the subject of the sections.
- "Change in occupancy" is changed to "change of occupancy" for consistency.
- In 1001.2 "change in use" is changed to "chance of occupancy" because the section should apply to changes of occupancy, not only to change of use.
- 1001.2.2 corrects on instance where the original proposal misused the terms, and simplifies the language. The modification uses language similar to 1001.2.1.
- Section 1001.2.2.1 is modified so that Section 1012 applies to partial change of occupancy in the same way as it applies when an entire building changes.

EB52-13

Final Action: AS AM AMPC____ D

EB53-13
1001.1, 1001.2, 1004.1, 1012.1, 1012.1.1.1, 1012.1.1.2, 1012.2.1, 1012.2.2

Proposed Change as Submitted

Proponent: Robert J Davidson, Davidson Code Concepts, LLC, representing self (rjd@davidsoncodeconcepts.com)

Revise as follows:

1001.1 Scope. The provisions of this chapter shall apply where a change of occupancy occurs, as defined in Section 202, including:

1. Where the occupancy classification is not changed; ~~or~~
2. Where there is a change in occupancy classification or the occupancy group designation changes~~.~~ ; or
3. Where there is a change in use or occupancy with a fire protection threshold requirement in Chapter 9 of the *International Building Code*.

1001.2 Change in occupancy with no change of occupancy classification. A change in occupancy, as defined in Section 202, with no *change of occupancy* classification or where there is a change in use or occupancy with a fire protection threshold requirement in Chapter 9 of the *International Building Code* shall not be made to any structure that will subject the structure to any special provisions of the applicable *International Codes*, including the provisions of Sections 1002 through 1011, without the approval of the *code official*. A certificate of occupancy shall be issued where it has been determined that the requirements for the change in occupancy have been met.

1004.1 General. Fire protection requirements of Section 1012 shall apply where a building or portions thereof undergo a *change of occupancy* classification or where there is a change in use or occupancy with a fire protection threshold requirement in Chapter 9 of the *International Building Code*.

1012.1 General. The provisions of this section shall apply to buildings or portions thereof undergoing a change of occupancy classification. This includes a change of occupancy classification within a group as well as a change of occupancy classification from one group to a different group or where there is a change in use or occupancy with a fire protection threshold requirement in Chapter 9 of the *International Building Code*. Such buildings shall also comply with Sections 1002 through 1011. The application of requirements for the change of occupancy shall be as set forth in Sections 1012.1.1 through 1012.1.4. A *change of occupancy*, as defined in Section 202, without a corresponding change of occupancy classification shall comply with Section 1001.2.

1012.1.1 Compliance with Chapter 9. The requirements of Chapter 9 shall be applicable throughout the building for the new occupancy classification based on the separation conditions set forth in Sections 1012.1.1.1 and 1012.1.1.2.

1012.1.1.1 Change of occupancy classification without separation. Where a portion of an *existing building* is changed to a new occupancy classification or where there is a change in use or occupancy with a fire protection threshold requirement in Chapter 9 of the *International Building Code* and that portion is not separated from the remainder of the building with fire barriers having a fire-resistance rating as required in the *International Building Code* for the separate occupancy, the entire building shall comply with all of the requirements of Chapter 9 applied throughout the building for the most restrictive occupancy classification in the building and with the requirements of this chapter.

1012.1.1.2 Change of occupancy classification with separation. Where a portion of an *existing building* that is changed to a new occupancy classification or where there is a change in use or occupancy with a fire protection threshold requirement in Chapter 9 of the *International Building Code* and that portion is separated from the remainder of the building with fire barriers having a fire-resistance rating as required in the *International Building Code* for the separate occupancy, that portion shall comply with all of the requirements of Chapter 9 for the new occupancy classification and with the requirements of this chapter.

1012.2 Fire protection systems. Fire protection systems shall be provided in accordance with Sections 1012.2.1 and 1012.2.2.

1012.2.1 Fire sprinkler system. Where a change in occupancy classification occurs or where there is a change in use or occupancy with a fire protection threshold requirement in Chapter 9 of the *International Building Code* that requires an automatic fire sprinkler system to be provided based on the new occupancy in accordance with Chapter 9 of the *International Building Code*, such system shall be provided throughout the area where the *change of occupancy* occurs.

1012.2.2 Fire alarm and detection system. Where a change in occupancy classification occurs or where there is a change in use or occupancy with a fire protection threshold requirement in Chapter 9 of the *International Building Code* that requires a fire alarm and detection system to be provided based on the new occupancy in accordance with Chapter 9 of the *International Building Code*, such system shall be provided throughout the area where the *change of occupancy* occurs. Existing alarm notification appliances shall be automatically activated throughout the building. Where the building is not equipped with a fire alarm system, alarm notification appliances shall be provided throughout the area where the *change of occupancy* occurs and shall be automatically activated.

Reason: This proposed change is a result of the NIST analysis and report on the Charleston Sofa Store Fire. Recommendation 4 of the NIST report reads as follows:

"NIST recommends that model codes require sprinkler systems and that state and local authorities adopt and aggressively enforce this provision:

a) for all new commercial retail furniture stores regardless of size; and
b) for existing retail furniture stores with any single display area of greater than 190 m^2 (2000 ft^2).

An installed fire sprinkler system that complied with a national standard such as NFPA 13 [3] would have activated and would have controlled the fire growth. If the showrooms had been divided into smaller areas with fire barriers, the compartmentation would have slowed the spread of the fire as well."

Upon investigation of recommendation 4 of the NIST report, a review of where in the family of I codes to put requirements for upgrading to automatic sprinkler protection for occupancies manufacturing, storing or merchandizing upholstered furniture and mattresses occurred. During this review it was noted that the International Existing Building Code applies the concept of "change of occupancy" broadly and not only to capture a change in the Group, but a change in the occupancy classification with a change in the Group, (see the classification breakdowns under each Group in Chapter 3 of the International Building Code).

The definition for Change of Occupancy drills down to a change "in the purpose of level of activity" for applying more current requirements of the IEBC and the IBC.

CHANGE OF OCCUPANCY. A change in the purpose or level of activity within a building that involves a change in application of the requirements of this code.

SECTION 1001
GENERAL

1001.1 Scope. The provisions of this chapter shall apply where a change of occupancy occurs, as defined in Section 202, including:

1. Where the occupancy classification is not changed; or
2. Where there is a change in occupancy classification or the occupancy group designation changes.

SECTION 1012
CHANGE OF OCCUPANCY CLASSIFICATION

1012.1 General. The provisions of this section shall apply to buildings or portions thereof undergoing a change of occupancy classification. This includes a change of occupancy classification within a group as well as a change of occupancy classification from one group to a different group.

What I noted was that when applying principals of fire protection, Chapter 9 of the International Building Code has use and levels of activity breakdowns separate and, in some cases, distinct from the occupancy classifications found in Chapter 3 of the International Building Code. In many cases these breakdowns are more significant than those found in Chapter 3 of the International Building Code.

What this proposal does is to suggest the insertion of language into Chapter 10 of the International Existing Building Code that would provide for capturing the fire protection thresholds found in Chapter 9 of the International Building Code as additional, and in many cases more accurate, triggers for the installation of fire protection systems and devices when a change of use or occupancy occurs within an existing building.

Cost Impact: This code change proposal will increase the cost of construction.

1001.1-EB-DAVIDSON.doc

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: There was concern that this proposal was excessive. In addition it was unclear what occurs when a change of occupancy has a "fire protection threshold requirement in Chapter 9 of the IBC." In other words what is required to occur. More language to clarify how chapter 9 of the IBC would apply is necessary. Generally the proposal would increase the scope of what would need to comply with the IBC when a change of occupancy or change of occupancy classification occurs.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Robert J. Davidson, Davidson Code Concepts, LLC, representing self, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

1001.1 Scope. The provisions of this chapter shall apply where a change of occupancy occurs, as defined in Section 202, including:

1. Where the occupancy classification is not changed; or
2. Where there is a change in occupancy classification or the occupancy group designation changes. ; or
3. Where there is a change in use or occupancy ~~with~~ within a space where there is a different ~~a~~ fire protection system threshold requirement in Chapter 9 of the *International Building Code*.

1001.2 Change in occupancy with no change of occupancy classification. A change in occupancy, as defined in Section 202, with no *change of occupancy* classification or where there is a change in use or occupancy ~~with~~ within a space where there is a different ~~a~~ fire protection system threshold requirement in Chapter 9 of the *International Building Code* shall not be made to any structure that will subject the structure to any special provisions of the applicable *International Codes*, including the provisions of Sections 1002 through 1011, without the approval of the *code official*. A certificate of occupancy shall be issued where it has been determined that the requirements for the change in occupancy have been met.

1004.1 General. Fire protection requirements of Section 1012 shall apply where a building or portions thereof undergo a *change of occupancy* classification or where there is a change in use or occupancy ~~with~~ within a space where there is a different ~~a~~ fire protection system threshold requirement in Chapter 9 of the *International Building Code*.

1012.1 General. The provisions of this section shall apply to buildings or portions thereof undergoing a change of occupancy classification. This includes a change of occupancy classification within a group as well as a change of occupancy classification from one group to a different group or where there is a change in use or occupancy ~~with~~ within a space where there is a different ~~a~~ fire protection system threshold requirement in Chapter 9 of the *International Building Code*. Such buildings shall also comply with Sections 1002 through 1011. The application of requirements for the change of occupancy shall be as set forth in Sections 1012.1.1 through 1012.1.4. A *change of occupancy*, as defined in Section 202, without a corresponding change of occupancy classification shall comply with Section 1001.2.

1012.1.1 Compliance with Chapter 9. The requirements of Chapter 9 shall be applicable throughout the building for the new occupancy classification based on the separation conditions set forth in Sections 1012.1.1.1 and 1012.1.1.2.

1012.1.1.1 Change of occupancy classification without separation. Where a portion of an *existing building* is changed to a new occupancy classification or where there is a change in use or occupancy ~~with~~ within a space where there is a different ~~a~~ fire protection system threshold requirement in Chapter 9 of the *International Building Code* and that portion is not separated from the remainder of the building with fire barriers having a fire-resistance rating as required in the *International Building Code* for the separate occupancy, the entire building shall comply with all of the requirements of Chapter 9 applied throughout the building for the most restrictive occupancy classification in the building and with the requirements of this chapter.

1012.1.1.2 Change of occupancy classification with separation. Where a portion of an *existing building* that is changed to a new occupancy classification or where there is a change in use or occupancy ~~with~~ within a space where there is a different ~~a~~ fire protection system threshold requirement in Chapter 9 of the *International Building Code* and that portion is separated from the remainder of the building with fire barriers having a fire-resistance rating as required in the *International Building Code* for the separate occupancy, that portion shall comply with all of the requirements of Chapter 9 for the new occupancy classification and with the requirements of this chapter.

1012.2 Fire protection systems. Fire protection systems shall be provided in accordance with Sections 1012.2.1 and 1012.2.2.

1012.2.1 Fire sprinkler system. Where a change in occupancy classification occurs or where there is a change in use or occupancy ~~with~~ within a space where there is a different ~~a~~ fire protection system threshold requirement in Chapter 9 of the *International Building Code* that requires an automatic fire sprinkler system to be provided based on the new occupancy in accordance with Chapter 9 of the *International Building Code*, such system shall be provided throughout the area where the *change of occupancy* occurs.

1012.2.2 Fire alarm and detection system. Where a change in occupancy classification occurs or where there is a change in use or occupancy ~~with~~ within a space where there is a different ~~a~~ fire protection system threshold requirement in Chapter 9 of the *International Building Code* that requires a fire alarm and detection system to be provided based on the new occupancy in accordance with Chapter 9 of the *International Building Code*, such system shall be provided throughout the area where the *change of occupancy* occurs. Existing alarm notification appliances shall be automatically activated throughout the building. Where the building is not equipped with a fire alarm system, alarm notification appliances shall be provided throughout the area where the *change of occupancy* occurs and shall be automatically activated.

Commenter's Reason: In response to committee concerns the language has been clarified to address use changes within a space and to clarify that the trigger is a different threshold for the installation of a fire protection system. The language addresses the trigger, the base requirements for what actions to take remain unchanged in the existing IEBC language.

Below are two examples where the fire protection threshold triggers would be different then the simple listing of different activities found in Chapter 3 which is covered by the current language. In the case of an F-1, a woodworking operation in an existing space may change by increasing the area it is operated in and because the use of the space or occupancy classification did not change, the need for the added fire protection would not be triggered. By adding the new language to the IEBC as suggested, these thresholds will get captured.

[F] 903.2.4 Group F-1.

An automatic sprinkler system shall be provided throughout all buildings containing a Group F-1 occupancy where one of the following conditions exists:

1. *A Group F-1 fire area exceeds 12,000 square feet (1115 m2).*
2. *A Group F-1 fire area is located more than three stories above grade plane.*
3. *The combined area of all Group F-1 fire areas on all floors, including any mezzanines, exceeds 24,000 square feet (2230 m2).*
4. *A Group F-1 occupancy used for the manufacture of upholstered furniture or mattresses exceeds 2,500 square feet (232 m2).*

[F] 903.2.4.1 Woodworking operations.

An automatic sprinkler system shall be provided throughout all Group F-1 occupancy fire areas that contain woodworking operations in excess of 2,500 square feet (232 m2) in area which generate finely divided combustible waste or use finely divided combustible materials.

A similar example would a be a S-1 Group automobile repair garage where the only occupancy classification listing is:

"Motor vehicle repair garages complying with the maximum allowable quantities of hazardous materials listed in Table 307.1(1) (see Section 406.8)"

If the activity introduces commercial vehicle repair which has a lower square footage threshold than passenger automobile repair, the existing IEBC language will not capture the need for the improved fire protection. The suggested new language will.

[F] 903.2.9 Group S-1.

An automatic sprinkler system shall be provided throughout all buildings containing a Group S-1 occupancy where one of the following conditions exists:

1. *A Group S-1 fire area exceeds 12,000 square feet (1115 m2).*
2. *A Group S-1 fire area is located more than three stories above grade plane.*
3. *The combined area of all Group S-1 fire areas on all floors, including any mezzanines, exceeds 24,000 square feet (2230 m2).*
4. *A Group S-1 fire area used for the storage of commercial trucks or buses where the fire area exceeds 5,000 square feet (464 m2).*
5. *A Group S-1 occupancy used for the storage of upholstered furniture or mattresses exceeds 2,500 square feet (232 m2).*

[F] 903.2.9.1 Repair garages.

An automatic sprinkler system shall be provided throughout all buildings used as repair garages in accordance with Section 406, as shown:

1. Buildings having two or more stories above grade plane, including basements, with a fire area containing a repair garage exceeding 10,000 square feet (929 m2).
2. Buildings no more than one story above grade plane, with a fire area containing a repair garage exceeding 12,000 square feet (1115 m2).
3. Buildings with repair garages servicing vehicles parked in basements.
4. A Group S-1 fire area used for the repair of commercial trucks or buses where the fire area exceeds 5,000 square feet (464 m2).

[F] 903.2.9.2 Bulk storage of tires.

Buildings and structures where the area for the storage of tires exceeds 20,000 cubic feet (566 m3) shall be equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1.

Overall, this is not a major increase in requirements, the majority of the IBC/IFC Chapter 9 thresholds would be captured with occupancy classification changes. This suggested language plugs a small hole in the application of fire protection requirements.

EB53-13
Final Action: AS AM AMPC____ D

EB57-13
1012.2.1.1 (NEW)

Proposed Change as Submitted

Proponent: Charles S. Bajnai, Chesterfield County, VA, ICC Building Code Action Committee

Add new text as follows:

1012.2.1 Fire sprinkler system. Where a change in occupancy classification occurs that requires an automatic fire sprinkler system to be provided based on the new occupancy in accordance with Chapter 9 of the International Building Code, such system shall be provided throughout the area where the change of occupancy occurs.

1012.2.1.1 Fire sprinkler system Group A occupancy. Where the new occupancy classification requiring an automatic sprinkler system is Group A-1, A-2, A-3 or A-4, an automatic sprinkler system shall be provided throughout the area where the Group A-1, A-2, A-3 or A-4 occupancy is located, and throughout all floors from the Group A occupancy to, and including, the nearest level of exit discharge serving the Group A occupancy.

Reason: This proposal is submitted by the ICC Building Code Action Committee (BCAC) The BCAC was established by the ICC Board of Directors to pursue opportunities to improve and enhance an assigned International Code or portion thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the BCAC has held 6 open meetings and numerous workgroup calls which included members of the BCAC as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the BCAC website at: http://www.iccsafe.org/cs/BCAC/Pages/default.aspx.

In almost all cases where Chapter 9 of the IBC specifies the need for a fire suppression system it is due to the inherent fire hazard of the use itself, thus justifying the protection only within the changed area. The exception to that rule is in the Assembly Groups. The trigger for the Assembly Groups A-1, A-2, A-3 and A-4 is the occupant load and it is clear from the expanded requirements found in IBC Section 903.2.1, the protection is to also include the intervening spaces and floors so their egress path is not compromised by a fire located in those areas. We feel that the IEBC should also reflect that intent by adding this new subsection.

Cost Impact: This code change proposal will increase the cost of construction.

1012.2.1.1 (NEW)-EB-BAJNAI-BCAC.doc

Committee Action Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The proposal was approved as Group A occupancies can have a potential of many occupants who are typically unfamiliar with the building. This clarifies that the sprinklers be located not only within the Group A occupancy but also protect all portions of the building below to the nearest level of exit discharge to protect occupants during evacuation. This proposal is consistent with the IBC. This addresses situations such as a Group A occupancy being added to a roof.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Steve Orlowski, National Association of Home Builders (NAHB) and Tim Ryan, International Association of Building Officials (IABO), request Disapproval.

Commenter's Reason: We disagree with the committee's action to now require the installation of a suppression system in all areas and levels between the new assembly occupancy and the level of discharge in existing buildings. The existing building code has always taken into consideration that there are a large number of existing buildings that do not meet the current building code requirements and that to bring these buildings into compliance would be cost prohibitive and would ultimately leave many of these buildings that could be rehabilitated to be left unused, vacant and become unusable and not properly maintained. For existing buildings that are occupied, to require all levels between the new assembly and the level of discharge to be equipped with a fire suppression system, not only would be a huge financial burden on the building owner, it would require displacing tenants and business from areas that would be unaffected by a change in occupancy somewhere in the building that is outside the work area. Under the current requirements of the IEBC, the assembly is already required to be sprinklered and the means of egress must be separate from the remainder of the building, which provides protection for the occupants evacuating the structure without compromising the minimum standard for life safety and fire prevention in existing buildings.

EB57-13

Final Action: AS AM AMPC____ D

EB59-13
1012.5.1

Proposed Change as Submitted

Proponent: Gene Boecker, Code Consultants, Inc., representing self

Revise as follows:

1012.5.1 Height and area for change to higher hazard category. When a change of occupancy classification is made to a higher hazard category as shown in Table 1012.5, heights and areas of buildings and structures shall comply with the requirements of Chapter 5 of the *International Building Code* for the new occupancy classification.

Exceptions:

1. In other than Groups H, F-1 and S-1, in lieu of fire walls, use of fire barriers having a fire-resistance rating of not less than that specified in Table 706.4 of the *International Building Code*, constructed in accordance with Section 707 of the *International Building Code*, shall be permitted to meet area limitations required for the new occupancy in buildings protected throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 of the *International Fire Code*.
2. Regardless of height, for high-rise buildings, the type of construction reduction specified in Section 403.2.1 of the *International Building Code* is permitted. This shall include the reduction for columns. The high rise building is required to be equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 of the *International Building Code*.

Reason: When the International Building Code changed to disallow the reduction of ratings on columns for high-rise buildings, it created a problem for existing buildings which had previously used the allowed reduction. This provision in the IEBC does not recognize those previously complying buildings. To meet the requirements as currently written, any change in occupancy from an office to a retail area would require a complete upgrade in the fire-resistance rating for all the columns in the entire building. This is excessive for small changes in occupancy and often impractical.

The revised language makes it clear that if the building is protected throughout with an automatic fire sprinkler system, designed to meet NFPA 13 (not 13R), then the column ratings can be what was allowed prior to the code change to the IBC. Additions will need to meet the requirements for new construction, but a change in occupancy of this type should not require the entire building to fall into non-compliance when it was fully compliant when it was built as little as five years ago.

Cost Impact: This code change proposal will not increase the cost of construction.

1012.5.1-EB-BOECKER.doc

Committee Action Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The proposal was felt to be a reasonable approach that would not require high rise buildings to upgrade their construction type due to more restrictive requirements in Section 403. These restrictions have only been in the IBC in more recent code editions. A building could only use this exception where it is equipped throughout with an automatic sprinkler system.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jonathan Siu, City of Seattle Department of Planning & Development, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

1012.5.1 Height and area for change to higher hazard category. When a change of occupancy classification is made to a higher hazard category as shown in Table 1012.5, heights and areas of buildings and structures shall comply with the requirements of Chapter 5 of the *International Building Code* for the new occupancy classification.

Exceptions:

1. In other than Groups H, F-1 and S-1, in lieu of fire walls, use of fire barriers having a fire-resistance rating of not less than that specified in Table 706.4 of the *International Building Code*, constructed in accordance with Section 707 of the *International Building Code*, shall be permitted to meet area limitations required for the new occupancy in buildings protected throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 of the *International Fire Code*.

2. ~~Regardless of height, for~~ For high-rise buildings constructed in compliance with a previously-issued permit, the type of construction reduction specified in Section 403.2.1 of the *International Building Code* is permitted. This shall include the reduction for columns. The high rise building is required to be equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 of the *International Building Code*.

Commenter's Reason: While we agree with the intent of the code change, there are two issues in this proposed code change that when considered in conjunction with each other may lead to unintended consequences for new high rise buildings, unless addressed as we have proposed in this Public Comment. The first issue is related to the phrase, "Regardless of height," which appears to be intended to address the "super high-rise" buildings greater than 420 feet in height. The second issue is related to the definition of "existing building" in the IEBC.

For new construction, the IBC limits the reduction of type of construction to buildings not greater than 420 feet in height (IBC Section 403.2.1.1, Item 1). In his reason statement, the proponent discusses the problem created "for existing buildings which had previously used the allowed reduction." It is clear he is addressing buildings which have already been constructed, and we agree with that perspective—it would be impractical to add fireproofing in an existing super high-rise building. The difficulty with the proposal arises due to the definition of "existing building" in the IEBC:

"EXISTING BUILDING. A building erected prior to the date of adoption of the appropriate code, or one for which a legal building permit has been issued." [emphasis added]

With this definition, a designer can get a permit issued to build a new super high-rise building, then come back later and apply for a change of occupancy and reduce the fire protection, without having actually built the building. This is not an entirely hypothetical situation. In Seattle, we issued building permits for a 600-plus foot tall office building several years ago. In the recent economic downturn, the owner mothballed the project. Within the last year, the owner applied for revisions to the original permit, to change the upper portion of the building to hotel. This would clearly be a change of occupancy classification to a higher hazard category in IEBC Table 1012.5 (Relative Hazard category 4 for B occupancies, 2 for R-1 occupancies). Yet, even though no construction has started, if the proposed change were in place, the architect could reduce the fire protection on the columns.

We believe the focus, as implied in the reason statement, ought to be on buildings that have already been constructed and were in compliance with a previous edition of the code, but are now non-conforming because the current code is different. To keep this focus, we have proposed to:

1. Delete the phrase "regardless of height." This phrase is unnecessary, as what remains will apply to all high-rise buildings.
2. Limit the application of the proposed exception to buildings that have been actually been built in accordance with a previous building permit, and therefore, presumably constructed in compliance with the applicable codes in effect at the time of construction.

We believe these changes will keep the focus on existing non-conforming buildings, and address the issue of the combination of the super high-rise provisions and the IEBC definition as discussed above.

As a note, this proposed code change would not change how projects that include changes to existing fire-resistance protection are regulated, since those projects would be subject to the provisions in the IEBC dealing with alterations.

EB59-13

Final Action: AS AM AMPC____ D

EB63-13
602.1.1 (New), 702.1.1 (New), 1202.2.1 (New), Chapter 16

Proposed Change as Submitted

Proponent: Rebecca Morley, National Center for Healthy Housing

Add new text as follows:

SECTION 602
BUILDING ELEMENTS AND MATERIALS

602.1 Existing building materials. Materials already in use in a building in compliance with requirements or approvals in effect at the time of their erection or installation shall be permitted to remain in use unless determined by the *code official* to render the building or structure unsafe or *dangerous* as defined in Chapter 2.

602.1.1 Disturbance of existing painted surfaces. In any Group E, I-4, R-2, R-3, R-4 occupancies completed prior to 1978, where repairs disturb painted surfaces, the work shall comply with the information distribution, certification and work practice requirements of 40 CFR 745 for renovations.

> **Exception:** Where documentation is provided from an approved test in accordance with 40 CFR 745.82(a)(1) or (2) that proves that the disturbed paint contains lead levels below specified levels, the work is not required to comply with this section.

SECTION 702
BUILDING ELEMENTS AND MATERIALS

702.1 Interior finishes. All newly installed interior wall and ceiling finishes shall comply with Chapter 8 of the *International Building Code*.

702.1.1 Disturbance of existing painted surfaces. In any Group E, I-4, R-2, R-3, R-4 occupancies completed prior to 1978, where alterations disturb painted surfaces, the work shall comply with the information distribution, certification and work practice requirements of 40 CFR 745 for renovations.

> **Exception:** Where documentation is provided from an approved test in accordance with 40 CFR 745.82(a)(1) or (2) that proves that the disturbed paint contains lead levels below specified levels, the work is not required to comply with this section.

SECTION 1202
REPAIRS

1202.1 General. Repairs to any portion of an *historic building* or structure shall be permitted with original or like materials and original methods of construction, subject to the provisions of this chapter. Hazardous materials, such as asbestos and lead-based paint, shall not be used where the code for new construction would not permit their use in buildings of similar occupancy, purpose and location.

1202.2.1 Disturbance of existing painted surfaces. In any Group E, I-4, R-2, R-3, R-4 occupancies, where repairs disturb painted surfaces, the work shall comply with the information distribution, certification and work practice requirements of 40 CFR 745 for renovations.

> **Exception:** Where documentation is provided from an approved test in accordance with 40 CFR 745.82(a)(1) or (2) that proves that the disturbed paint contains lead levels below specified levels, the work is not required to comply with this section.

Add the following standard to Chapter 16:

EPA U.S. Environmental Protection Agency

40 CFR 745 - July 1, 2012 Lead-Based Paint Poisoning Prevention in Certain Residential Structures

Reason: The purpose of this proposed code language is to incorporate protection from lead-based paint into the Code's requirements. These requirements are already law in every state through the Environmental Protection Agency's Renovation Repair and Painting Rule, which governs work with paint that may contain lead-based paint in order to prevent childhood lead poisoning. These regulations have been in effect since April 2010, and have been adopted by 12 states.

Renovation of painted surfaces is a significant sources of lead dust that poisons children. The dangers associated with lead poisoning are well-known: serious health effects, detrimental effects on cognitive and behavioral development, with serious personal and social consequences that may persist throughout their lifetime.

Multiple studies have demonstrated that lead dust is the major source of lead poisoning for young children. There is no safe level of lead exposure for children; lead affects intelligence even at very low levels.[1,2,5,8,9] Indeed, the rate of IQ loss per 1 microgram of lead per deciliter of blood (µg/dL) is greatest at lead levels below 10 µg/dL. As a child's BLL increases from 1 to 10 µg/dL, experts estimate a child may lose anywhere from 3.9 to 7.4 IQ points, but from 10 to 30 µg/dL the decrement is 2.5 to 3.0 IQ points. Low-level chronic exposure may have an even greater effect on IQ than a single instance of very high BLL.[10]

Research indicates that a five-point negative shift in IQ at the population level would increase the number of children with an "extremely low" IQ by 57%, substantially increasing the cost of special education programs.[3] Considering the costs to the special education system alone, one study conservatively estimated that it costs $38,000 over three years to educate a child with lead poisoning.[11] Low-level exposure to lead has also been linked to factors other than IQ that can further impact educational outcomes. EBLLs are associated with Attention Deficit Hyperactivity Disorder (ADHD) and antisocial behavior, which in turn increase the likelihood of conduct disorder, criminal activity, and drug abuse.[1,4] Each 1 µg/dL reduction in the average preschool blood lead level saves $13.4 billion from the direct and indirect costs of crime.[1]

Several recent studies have explored the specific effects of lead on educational outcomes. These studies show a strong relationship between slightly elevated blood lead levels in young children and decreased scores on end-of-grade tests in elementary school. While similar educational effects were documented for higher blood levels decades ago,[12] the recent studies confirm that the connection between blood lead and poor educational outcomes remains true for blood levels as low as 3-4 µg/dL. A more recent study of 57,000 North Carolina children found that children with a BLL as low as 4 µg/dL at three years of age were significantly more likely to be classified as learning-disabled than children with a BLL of 1 µg/dL.[6]

The consequences of lead exposure are clear. This code change proposal seeks to reduce the risk.

The additions to Sections 602, 702, and 1202 add health-protective requirements to protect children from lead poisoning by preventing the dispersal of lead before, during, and after work performed on a pre-1978 home. The information distribution, certification, and lead safe practices requirements are already in effect in federal and state regulation.

This change would only affect structures likely to contain lead-based paint: pre-1978 homes. As noted under the exception, the requirement is waived if paint testing proves that the paint is not lead-based paint. A rebuttable presumption of lead's presence allows the builder to demonstrate that lead is not present and obtain exemption from the requirements. EPA-approved tests include lead-based paint inspection or risk assessment, test kit used by a certified renovator, and collection of a lead-based paint chips for laboratory analysis.

The EPA 40 CFR 745 standard is available at http://www.gpo.gov/fdsys/pkg/CFR-2012-title40-vol32/xml/CFR-2012-title40-vol32-part745.xml.

Assembly Action **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jane Malone, National Center for Healthy Housing, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

SECTION 602
BUILDING ELEMENTS AND MATERIALS

602.1 Existing building materials. Materials already in use in a building in compliance with requirements or approvals in effect at the time of their erection or installation shall be permitted to remain in use unless determined by the *code official* to render the building or structure unsafe or *dangerous* as defined in Chapter 2.

602.1.1 Disturbance of existing painted surfaces. In any Group E day care, Group I-4 child day care, R-2, R-3, R-4 occupancies completed prior to 1978, where repairs disturb painted surfaces, the work shall ~~comply with the information distribution, certification and work practice requirements of 40 CFR 745 for renovations.~~ leave behind no visible dust, debris or residue .

Exception: Where documentation is provided from an approved test in accordance with 40 CFR 745.82(a) ~~(1) or (2) that proves~~ that the disturbed paint contains lead levels below specified levels, the work is not required to comply with this section.

SECTION 702
BUILDING ELEMENTS AND MATERIALS

702.1 Interior finishes. All newly installed interior wall and ceiling finishes shall comply with Chapter 8 of the *International Building Code*.

702.1.1 Disturbance of existing painted surfaces. In any Group E day care, Group I-4 child day care, R-2, R-3, R-4 occupancies completed prior to 1978, where alterations disturb painted surfaces, the work shall ~~comply with the information distribution, certification and work practice requirements of 40 CFR 745 for renovations.~~ leave behind no visible dust, debris or residue .

Exception: Where documentation is provided from an approved test in accordance with 40 CFR 745.82(a) ~~(1) or (2) that proves~~ that the disturbed paint contains lead levels below specified levels, the work is not required to comply with this section.

SECTION 1202
REPAIRS

1202.1 General. Repairs to any portion of an *historic building* or structure shall be permitted with original or like materials and original methods of construction, subject to the provisions of this chapter. Hazardous materials, such as asbestos and lead-based paint, shall not be used where the code for new construction would not permit their use in buildings of similar occupancy, purpose and location.

1202.2.1 Disturbance of existing painted surfaces. In any <u>Group E day care, Group </u>I-4<u> child day care, </u>R-2, R-3, R-4 occupancies completed prior to 1978, where repairs disturb painted surfaces, the work shall ~~comply with the information distribution, certification and work practice requirements of 40 CFR 745 for renovations~~<u> leave behind no visible dust, debris or residue .</u>

> **Exception:** Where documentation is provided from an approved test in accordance with 40 CFR 745.82(a)~~ (1) or (2) that proves~~ that the disturbed paint contains lead levels below specified levels, the work is not required to comply with this section.

Add the following standard to Chapter 16:

EPA U.S. Environmental Protection Agency

40 CFR 745 - July 1, 2012 Lead-Based Paint Poisoning Prevention in Certain Residential Structures

Commenter's Reason: Based on the Committee decision, we have reduced this code change from a requirement for full compliance with the federal regulation to the essential but simple performance standard that will protect the occupant's and worker's children from exposure to harmful lead. It is consistent with the federal regulation in that clean-up is required at the end of renovation work. This requirement can be enforced by the code official with a visual inspection: no testing or special information is needed.

We have also clarified the Group I and E occupancies.

The exemption applies if the project meets one of these standards at 40 CFR 745.82(a):
(1) a written determination has been made by a certified inspector or risk assessor that the components affected by the renovation are free of paint or other surface coatings that contain lead;
(2) a certified renovator, using an EPA recognized test kit, has tested each component affected by the renovation and determined that the components are free of paint or other surface coatings that contain lead;
(3) a certified renovator has collected a paint chip sample from each painted component affected by the renovation and a laboratory recognized by EPA has determined that the samples are free of paint or other surface coatings that contain lead.

Final Action: AS AM AMPC____ D

F6-13
202 (IBC [F] 202)

Proposed Change as Submitted

Proponent: Elley Klausbruckner representing Klausbruckner & Associates Inc (ek@klausbruckner.com)

Revise as follows:

SECTION 202 (IBC [F] 202)
GENERAL DEFINITIONS

FLAMMABLE SOLID. A solid, other than a blasting agent or *explosive*, that is capable of causing fire through friction, absorption of moisture, spontaneous chemical change or retained heat from manufacturing or processing, or which has an ignition temperature below 212°F (100°C) or which burns so vigorously and persistently when ignited as to create a serious hazard. A chemical shall be considered a flammable solid as determined in accordance with the test method of CPSC 16 CFR Part 1500.44, if it ignites and burns with a self-sustained flame at a rate greater than ~~0.1~~ 0.0866 inch (~~2.5 mm~~ 2.2 mm) per second along its major axis.

Reason: The definition proposed is in line with GHS [Globally Harmonized System] which is now adopted by OSHA. When an MSDS is prepared today, a material classified as “Flammable Solids” is typically based on this definition and not the previous definition [existing language in the Fire Code]. For additional details please see http://www.osha.gov/dsg/hazcom/ghs.html.

Cost Impact: The code change proposal will not increase the cost of construction.

202-FLAMMABLE SOLID-F-KLAUSBRUCKNER

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: The disapproval was based on the committee’s judgment that the code change could be the beginning of a trend toward acceptance of OSHA definitions which are much different than IFC definitions and are focused on worker and work-place safety only.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Elley Klausbruckner, representing Klausbruckner & Associates Inc., requests Approval as Submitted.

Commenter’s Reason: The issue that this code change is attempting to resolve has nothing to do with trends but is a practical one. Chemicals are classified by using data in the Materials Safety Data Sheet [MSDS]. Unlike flammable/combustible liquids, where locations are provided data entry of flashpoint and boiling point, data on combustibility of a dust, as well as method of testing, is typically not found on an MSDS. The MSDS will simply indicate “Combustible Dust” in the MSDS. The MSDS typically follows the definitions of OSHA as well as GHS. Therefore the person classifying the material [whether it be an AHJ or an industry] cannot determine for certain whether the dust is combustible based on the definitions in the fire code. Whether an individual classifies a material as Combustible Dust or not, based on the statement in an MSDS, it will subject that person classifying the product to liability.

Given that the definitions between OSHA and the Fire Code are close [self-sustained flame at a rate greater than 0.1 <u>0.0866</u> inch (2.5 mm <u>2.2 mm</u>) per second] this would be a minor adjustment in definitions.

F6-13

Final Action: AS AM AMPC____ D

F13-13
308.1.6.3 (New), 202 (New)

Proposed Change as Submitted

Proponent: Anthony C. Apfelbeck, City of Altamonte Springs Building/Fire Safety Division, representing self (ACApfelbeck@Altamonte.org)

Add new text as follows:

308.1.6.3 Sky lanterns. No person shall release or cause to be released an untethered sky lantern.

Add new definition as follows:

SECTION 202
GENERAL DEFINITIONS

SKY LANTERN. An unmanned device with a combustible fuel source that incorporates an open flame in order to make the device airborne.

Reason: Sky lanterns contain an open flame used to heat the air inside the device to make it airborne. Once airborne, these devices are subject to winds and other atmospheric conditions so that the location of the landfall is completely unknown and uncontrolled by the user. Obviously, uncontrolled open flame devices descending out of the sky have the significant potential to start wildfires and structural fires.

Cost Impact: This code change will not increase the cost of construction

308.1.6.3 (NEW)-F-APFELBECK

Committee Action Hearing Results

Committee Action: **Approved as Modified**

Modify the proposal as follows:

SKY LANTERN. An unmanned device with a ~~combustible~~ fuel source that incorporates an open flame in order to make the device airborne.

(Portions of the proposal not shown remain unchanged.)

Committee Reason: The committee approved the code change based on the proponent's reason statement that untethered flaming sky effects pose an uncontrollable ignition hazard. The modification recognizes that the fuel package may not be limited to combustible fuel but could include flammable fuels as well.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

SKY LANTERN. An unmanned device ~~with a fuel source~~ that incorporates an open flame in order to make the device airborne.

(Portions of the proposal not shown remain unchanged.)

Commenter's Reason: This proposal is submitted by the ICC Fire Code Action Committee (FCAC). This ICC committee was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portions thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the Fire-CAC has held 6 open meetings and numerous Regional Work Group and Task Group meetings and conference calls which included members of the committees as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the FAC website at: http://www.iccsafe.org/cs/CAC/Pages/default.aspx.

It is not necessary to describe that sky lanterns have a fuel source; the open flame describes the device, and the hazard, appropriately without reference to a fuel source.

F13-13

Final Action: AS AM AMPC____ D

F16-13
315.3.2

Proposed Change as Submitted

Proponent: Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azumiamia@yahoo.com)

Revise as follows:

315.3.2 Means of egress. Combustible materials shall not be stored in exits, <u>corridors</u> or enclosures for stairways and ramps.

Reason: The code presently does not address storage of combustible materials in exit access corridors. The code prohibits storage in the exit, but says nothing about the corridor. This will provide the inspector with a tool to regulate the storage of combustible materials in a corridor.

Cost Impact: The code change will not increase the cost of construction.

315.3.2-F-ZUBIA-FCAC

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: The disapproval was based on the committee's judgment that the provisions of current Section 1020 adequately cover the issue. It was also unclear as to what "storage" could be interpreted to be, such as one piece of furniture, or a single file cabinet. It was also noted that corridors are not required by the code and are not subject to the same stringent requirements as an exit would be.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jeffrey M. Shapiro, P.E., International Code Consultants, representing self, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

315.3.2 Means of egress. Combustible materials shall not be stored in exits<u>,</u> ~~corridors or~~ enclosures for stairways<u>, enclosures for</u> ~~and~~ ramps<u>, or any exit access for 10 or more occupants</u>.

Commenter's Reason: Disapproval of this item will allow a significant hole to remain in the IFC that is a direct contributor to past multiple-fatality fires. The committee statement, which indicates that Section 1020 adequately addresses this issue, is incorrect. Section 1020 only deals with exits, not exit access, which is a different part of the 3-part means of egress used by the IFC and IBC. The focus of this proposal is storage in an exit access (not an exit), which currently has no storage limitations.

The committee statement also complained about a lack of clarity associated with the term "stored," but this term is already in the existing code text. It was the intent of the original proposal to simply continue use of the existing term, and this comment maintains that approach.

This issue originated as a result of rolled carpet, padding and adhesive being stored in the corridor of a hotel where ICC was holding committee meetings. The hotel was being remodeled. Fire code officials who were present at the meeting were concerned about the risk that this storage created, and we looked for a code section that could be cited to ask management to remove these materials from the exit access corridor. To our surprise, we couldn't come up with any clear requirement in the IFC to address the issue (although many of us were sure that there was one).

It is understood that the committee had some heartburn with the original proposal targeting “corridors,” because technically corridors aren’t required to be provided. So, this comment takes a different approach. The basis of applying this provision to exit accesses serving 10 or more occupants is an attempt to find a “reasonable” threshold for the requirement while avoiding a specific limitation to corridors. IFC Table 1015.1 was used as a guide. It establishes a threshold at or above which two or more exits or exit access doorways must be provided for most occupancies, indicating that an increased level of safety is warranted for the means of egress.

F16-13
Final Action: AS AM AMPC____ D

F17-13

315.3.5 (New), 903.3.1.1.1 (IBC [F] 903.3.1.1.1)

Proposed Change as Submitted

Proponent: Adolf Zubia, Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azubiamia@yahoo.com)

Add new text as follows:

315.3.5 Rooms and areas exempted from automatic sprinkler system requirements. Storage shall not be permitted in any room or area where automatic sprinklers have been omitted in accordance with Section 903.3.1.1.1.

Revise as follows:

903.3.1.1.1 (IBC [F] 903.3.1.1.1) Exempt locations. Automatic sprinklers shall not be required in the following rooms or areas where such rooms or areas are protected with an approved automatic fire detection system in accordance with Section 907.2 that will respond to visible or invisible particles of combustion. Sprinklers shall not be omitted from any room merely because it is damp, of fire-resistance-rated construction or contains electrical equipment. Storage shall not be permitted in any room or area omitting automatic sprinklers.

Reason: These exceptions in the IBC go beyond the requirements of NFPA 13 by inserting a heat detection system. Storage needs to be specifically addressed by this section as this exemption can be interpreted to allow storage in an unsprinklered room. Sprinkler systems adjacent to these rooms are not mandated to increase design criteria to accommodate this unsprinklered space. Fires in unsprinklered rooms with unknown or unpermitted storage could overcome the sprinkler system.

This proposal is submitted by the ICC Fire Code Action Committee (FCAC). This ICC committee was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portions thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the Fire-CAC has held 6 open meetings and numerous Regional Work Group and Task Group meetings and conference calls which included members of the committees as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the FAC website at: http://www.iccsafe.org/cs/CAC/Pages/default.aspx.

Cost Impact: This code change will not increase the cost of construction

315.3.5 (NEW)-F-ZUBIA-FCAC

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: The disapproval was based on the committee's judgment that the code change would lead to inconsistent enforcement due to the use of the subjective term "storage" and since sprinklers could be omitted from "storage" rooms storing materials such as those that are incompatible with water [903.3.1.1.1(2)] or materials that are noncombustible [903.3.1.1.1(4)]. Such determinations should be left to the fire code official and the design professional.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jeffrey M. Hugo, CBO, representing National Fire Sprinkler Association, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

315.3.5 Rooms and areas exempted from automatic sprinkler system requirements. Combustible storage shall not be permitted in any room or area where automatic sprinklers have been omitted in accordance with Section 903.3.1.1.1.

903.3.1.1.1 (IBC [F] 903.3.1.1.1) Exempt locations. Automatic sprinklers shall not be required in the following rooms or areas where such rooms or areas are protected with an approved automatic fire detection system in accordance with Section 907.2 that will respond to visible or invisible particles of combustion. Sprinklers shall not be omitted from any room merely because it is damp, of fire-resistance-rated construction or contains electrical equipment. Combustible storage shall not be permitted in any room or area omitting automatic sprinklers.

Commenter's Reason: Combustible storage in a room where sprinklers are exempt (in a fully sprinklered building) could permit a fire to grow and not be contained to the room of origin thus jeopardizing the surrounding automatic sprinkler system.

The size of the rooms or areas exempt from sprinklers in Section 903.3.1.1.1 is not defined or limited. A building could be fully sprinklered, use all the automatic sprinkler system tradeoffs and have an unlimited exempt area with combustible storage. This section gives the designer and code official authority to have sprinklers exempted, and a direct prohibition on what else can be in that room or area.

F17-13

Final Action: AS AM AMPC____ D

F20-13
319 (New), 202 (New)

Proposed Change as Submitted

Proponent: Anthony C. Apfelbeck, City of Altamonte Springs Building/Fire Safety Division, representing self (ACApfelbeck@Altamonte.org)

Add new text as follows:

SECTION 319
WILDLAND-URBAN INTERFACE AREAS

319.1 General. Buildings, structures or premises within wildland-urban interface areas shall comply with the *International Wildland-Urban Interface Code.*

SECTION 202
GENERAL DEFINITIONS

WILDLAND-URBAN INTERFACE AREA. That geographical area where structures and other human development meets or intermingles with wildland or vegetative fuels.

Reason: This code change:

1. Provides a definition for a "Wildland-Urban Interface Area" in the IFC Section 202 extracted from the definition in the IWUIC.
2. Provides a direct referral to the "Wildland-Urban Interface Code" in a new Section 319 within the IFC.

This code change will integrate the designation of a "Wildland-Urban Interface Area" and the reference International Wildland-Urban Interface Code as an integral part of the IFC. Rather than forcing a local jurisdiction to adopt the IWUIC separately, the IWUIC will be adopted as a reference when the IFC is adopted. The reason for this is two fold:

1. The base IFC should contain Wildland-Urban Interface requirements as an integral part of the document due to the expanding prevalence of these types of hazards that are confronted by the fire official. Users should not be forced to adopt a second document to be able to utilize the IWUIC and effectively address these types of conditions. Wildland-urban interface fire prevention is no different from the other base fire prevention requirements of the IFC and should be included as part of the model fire prevention code.
2. Adding the direct reference to the IWUIC into the IFC will not burden any jurisdiction with the requirement of the document unless there is an actual "Wildland-Urban Interface Area" within the jurisdiction. If there is a "Wildland-Urban Interface Area" within the jurisdiction, then the code should be specifying that the WUIA needs to be protected appropriately and set the standard of protection.

Cost Impact: This code change proposal will increase the cost of construction. Some WUIA that are not currently protected with a code, but should be protected, will end up with protection under this code change.

319 (NEW)-F-APFELBECK

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: The disapproval was based on the committee's judgment that the applicability of the IWUIC would be better located in Chapter 1, Section 102 similar to the applicability statements for the IBC and the IRC.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Marcelo M. Hirschler, (GBH International), requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

~~SECTION 319~~
~~WILDLAND-URBAN INTERFACE AREAS~~

~~**319.1 General.** Buildings, structures or premises within wildland-urban interface areas shall comply with the *International Wildland-Urban Interface Code.*~~

102.6 Application of wildland-urban interface code. After a jurisdiction has designated an area as a wildland-urban interface area, the design and construction of new structures within that wildland-urban interface area shall comply with the International Wildland-Urban Interface Code and any *alterations*, additions, changes in use or changes in structures required by this code, which are within wildland-urban interface areas and are within the scope of the International Wildland-Urban Interface Code, shall be made in accordance therewith.

(Renumber following sections.)

SECTION 202
GENERAL DEFINITIONS

WILDLAND-URBAN INTERFACE AREA. That geographical area where structures and other human development meets or intermingles with wildland or vegetative fuels.

Commenter's Reason: The technical committee was not in opposition to the necessary link but just to the location. This comment places the link in the section recommended by the committee. Note that the language states that the application only starts **after** the jurisdiction has designated an area as a WUI area. In that way, areas that have not been designated as WUI areas by the jurisdiction will not be required to comply with the IWUIC code.

F20-13
Final Action: AS AM AMPC____ D

F23-13
403.3

Proposed Change as Submitted

Proponent: Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azubiamia@yahoo.com)

Revise as follows:

403.3 Crowd managers. Trained crowd managers shall be provided for ~~facilities or~~ events where more than ~~1,000~~ 250 or more persons congregate. The minimum number of crowd managers shall be established at a ratio of one crowd manager to every 250 persons. ~~Where *approved* by the *fire code official*, the ratio of crowd managers shall be permitted to be reduced where the facility is equipped throughout with an *approved automatic sprinkler system* or based upon the nature of the event.~~

Exceptions:

1. Where approved, the number of crowd managers shall be permitted to be reduced by up to 50 percent where the fire and life safety protection provided and the nature of the event warrant a reduction.
2. Gatherings exclusively for religious worship with an occupant load not exceeding 1,000.

Reason: This proposal is submitted by the ICC Fire Code Action Committee (FCAC). This ICC committee was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portions thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the Fire-CAC has held 6 open meetings and numerous Regional Work Group and Task Group meetings and conference calls which included members of the committees as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the FAC website at: http://www.iccsafe.org/cs/CAC/Pages/default.aspx.

The current code has no requirement for crowd managers until the occupant load in a public assembly reaches 1,000, then the code requires five trained crowd managers for an occupant load of 1001. This is illogical, especially since one of the events that generated this requirement, the Station Nightclub Fire, had an occupant load of less than 500. Smaller venues sometimes place the public at greater risk than large ones for many reasons, including the fact that larger facilities have greater requirements for other fire protection features. NFPA 1 and NFPA 101 require crowd managers in all public assemblies (except churches), so approving this code change will bring the two regulations closer to conformity.

The formatting change to place the potential reduction in the number of crowd managers in an exception is editorial; the exception was also changed to limit the reduction to half of the required number of crowd managers. Recent events have again emphasized that fire is not the only reason people will need to quickly exit a facility, so reducing the number strictly on the basis of a sprinkler system may be problematic. The exception for places of worship with occupant loads up to 1,000 recognizes the fact that people who are in these places of assembly normally have a greater awareness of their surroundings, and are more familiar with egress routes because they attend the church on a more regular basis than those at performances, who tend to be more transient.

Cost Impact: This code change will not increase the cost of construction

403.3-F-ZUBIA-FCAC

Committee Action Hearing Results

Committee Action: **Approved as Modified**

Modify the proposal as follows:

403.3 Crowd managers. Trained crowd managers shall be provided for occupancies or events where more than 250 or more persons congregate. The minimum number of crowd managers shall be established at a ratio of one crowd manager to every 250 persons.

Exceptions:

1. Where approved, the number of crowd managers shall be permitted to be reduced by up to 50 percent where the fire

and life safety protection provided and the nature of the event warrant a reduction.
2. Gatherings exclusively for religious worship with an occupant load not exceeding 1,000.

Committee Reason: The committee approved the code change based on the proponent's reason statement. The modification makes it clear that the provisions apply to both indoor and outdoor venues.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Dave Frable, representing U.S. General Services Administration, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

403.3 Crowd managers. Trained crowd managers shall be provided for assembly occupancies ~~or events~~ where more than 250 or more persons congregate. The minimum number of crowd managers shall be established at a ratio of one crowd manager to every 250 persons.

Exceptions:

1. Where approved, the number of crowd managers shall be permitted to be reduced by up to 50 percent where the fire and life safety protection provided and the nature of the event warrant a reduction.
2. Gatherings exclusively for religious worship with an occupant load not exceeding 1,000.

Commenter's Reason: In the original reason statement the proponent states that the code change revisions were based on code text in NFPA 1 and NFPA 101 for assembly occupancies. The proponent further states that his intent was to have the requirements in the IFC and IBC consistent with the requirements in NFPA 1 and NFPA 101. However, the scope of the current code text appears to be much broader than the scope in NFPA 1 and NFPA 101 and now appears to be inconsistent with the requirements in NFPA 1 and NFPA 101. Therefore, we have revised the current code text to only require crowd managers for assembly occupancies and have deleted the text "or events" since this requirement would also apply to any event held outdoors where more than 250 person would congregate. For example, this would require outdoor wedding receptions as well as office picnics held in parks having more than 250 persons in attendance to require a crowd manager. We do not believe that the intent of the requirements for crowd managers that resulted from the Station Nightclub fire were to be applied to outdoor events such as those stated in the above examples. Last but not least, the fact that trying to enforce this requirement for all outdoor events of this size will be very difficult for the local code authority.

Public Comment 2:

Tim Ryan, representing The International Association of Building Officials, requests Disapproval.

Commenter's Reason: This proposal is overly restrictive in that such events as high school sporting events, large restaurants, wedding receptions, Bar Mitzvah's, etc., would be required to have a crowd manager. No data has been submitted that would indicate such events require trained crowd managers to increase the level of safety. The proponent identified one event, the Station Night Club fire, as the main supporting evidence for this requirement. It is questionable if the problems associated with the Station Night Club were the lack of codes or the lack of enforcement due to overcrowding.

F23-13
Final Action: AS AM AMPC____ D

F24-13
403.3.1

Proposed Change as Submitted

Proponent: Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azubiamia@yahoo.com)

Add new text as follows:

403.3.1 Training. Training for crowd managers shall be approved.

403.3.2 Duties. The duties of crowd managers shall include, but not be limited to:

1. Conduct an inspection of the area of responsibility and identify and address any egress barriers.
2. Conduct an inspection of the area of responsibility to identify and mitigate any fire hazards.
3. Verify compliance with all permit conditions, including those governing pyrotechnics and other special effects.
4. Direct and assist the event attendees in evacuation during an emergency.
5. Assist emergency response personnel where ~~if~~ requested.
6. Other duties required by the fire code official.
7. Other duties as specified in the fire safety plan

Reason: The Code requires "trained crowd managers", but doesn't provide any guidance or describe what that training should include. This has been an ongoing issue for enforcement personnel. This change is intended to address that void.

This proposal is submitted by the ICC Fire Code Action Committee (FCAC). This ICC committee was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portions thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the Fire-CAC has held 6 open meetings and numerous Regional Work Group and Task Group meetings and conference calls which included members of the committees as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the FAC website at: http://www.iccsafe.org/cs/CAC/Pages/default.aspx.

Cost Impact: This code change will not increase the cost of construction

403.3-F-ZUBIA-FCAC

Committee Action Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The committee agreed with the proponent that the code change provides needed specific guidance in the duties for crowd managers in support of the changes made in code change F23-13.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Tim Ryan, representing The International Association of Building Officials, requests Disapproval.

Commenter's Reason: The proponent's reasoning statement indicated that this change was submitted to provide guidance for or describe what training should be included for crowd managers. The proposed change does not achieve the proponent's intent. The change only identifies duties but does not identify training or certification other than it has to be "approved" which is left to the enforcement official to decide. This creates inefficiencies between jurisdictions and is a very arbitrary requirement.

Proposed Change as Submitted

Proponent: Carl Baldassarra, P.E., FSFPE, Chair, ICC Code Technology Committee (cbaldassarra@RJAGroup.com)

Revise as follows:

404.3.2 Fire safety plans. Fire safety plans shall include the following:

1. The procedure for reporting a fire or other emergency.
2. The life safety strategy and procedures for notifying, relocating or evacuating occupants, including occupants who need assistance.
3. Site plans indicating the following:
   3.1. The occupancy assembly point.
   3.2. The locations of fire hydrants.
   3.3. The normal routes of fire department vehicle access.
4. Floor plans identifying the locations of the following:
   4.1. Exits.
   4.2. Primary evacuation routes.
   4.3. Secondary evacuation routes.
   4.4. Accessible egress routes.
   4.5. Areas of refuge.
   4.6 Refuge areas
   4.7 ~~4.6~~. Exterior areas for assisted rescue.
   4.8 ~~4.7~~. Manual fire alarm boxes.
   4.9 ~~4.8~~. Portable fire extinguishers.
   4.10 ~~4.9~~. Occupant-use hose stations.
   4.11 ~~4.10~~. Fire alarm annunciators and controls.
5. A list of major fire hazards associated with the normal use and occupancy of the premises, including maintenance and housekeeping procedures.
6. Identification and assignment of personnel responsible for maintenance of systems and equipment installed to prevent or control fires.
7. Identification and assignment of personnel responsible for maintenance, housekeeping and controlling fuel hazard sources.

TABLE 405.2
FIRE AND EVACUATION DRILL
FREQUENCY AND PARTICIPATION

GROUP OR OCCUPANCY	FREQUENCY	PARTICIPATION
Group A	Quarterly	Employees
Group B [c]	Annually	Employees
Group E	Monthly[a]	All occupants
Group F	Annually	Employees
Group I	Quarterly on each shift [a]	Employees[b]
Group R-1	Quarterly on each shift	Employees
Group R-2 [d]	Four annually	All occupants
Group R-4	Quarterly on each shift [a]	Employees[b]
High-rise buildings	Annually	Employees

a. The frequency shall be allowed to be modified in accordance with Sections 408.3.2, 408.5.6 and 408.10.6.
b. Fire and evacuation drills in residential care assisted living facilities shall include complete evacuation of the premises in accordance with

Section 408.10.5. Where occupants receive habilitation or rehabilitation training, fire prevention and fire safety practices shall be included as part of the training program.

c. Group B buildings having an occupant load of 500 or more persons or more than 100 persons above or below the lowest level of exit discharge.

d. Applicable to Group R-2 college and university buildings in accordance with Section 408.3.

408.5.1.1 Fire evacuation plan. The fire evacuation plan required by Section 404 shall include a description of special staff actions. Plans shall include the following in addition to the requirements of Section 404.

1. In Group I-1 Condition 2 occupancies, procedures for evacuation through a refuge area in an adjacent smoke compartment and then to an exterior assembly point.

408.5.1.2 Fire safety plans. A copy of the plan shall be maintained at the facility at all times. Plans shall include the following in addition to the requirements of Section 404:

1. Location and number of any residents sleeping rooms.
2. Location of any special locking or egress control arrangements.

408.5.3 Resident training. Residents capable of assisting in their own evacuation shall be trained in the proper actions to take in the event of a fire. In Group I-1 Condition 2 occupancies training shall include evacuation through an adjacent smoke compartment and then to an exterior assembly point. The training shall include actions to take if the primary escape route is blocked. Where the resident is given rehabilitation or habilitation training, training in fire prevention and actions to take in the event of a fire shall be a part of the rehabilitation training program. Residents shall be trained to assist each other in case of fire to the extent their physical and mental abilities permit them to do so without additional personal risk.

408.5.5 Resident participation. Emergency evacuation drills shall involve the actual evacuation of residents to a selected assembly point and shall provide residents with experience in exiting through all required exits. All required exits shall be used during emergency evacuation drills.

408.5.6 Emergency evacuation drill deferral. In severe climates, the *fire code official* shall have the authority to modify the emergency evacuation drill frequency specified in Section 405.2.

408.10.1.1 Fire safety plans. A copy of the plan shall be maintained at the facility at all times. Plans shall include the following in addition to the requirements of Section 404:

1. Location and number of any residents sleeping rooms.
2. Location of any special locking or egress control arrangements.

408.10.5 Resident participation. Emergency evacuation drills shall involve the actual evacuation of residents to a selected assembly point and shall provide residents with experience in exiting through all required exits. All required exits shall be used during emergency evacuation drills.

> **Exception:** Actual exiting from emergency escape and rescue windows shall not be required. Opening the emergency escape and rescue window and signaling for help shall be an acceptable alternative.

408.10.6 Emergency evacuation drill deferral. In severe climates, the *fire code official* shall have the authority to modify the emergency evacuation drill frequency specified in Section 405.2.

Reason: The intent of this proposal is to clarify the requirements for Group I-1 and R-4 assembly points. It also clarifies the implementation of smoke compartments in the new Group I-1 Condition 2 as was approved for the 2015 IBC in the G 31-12. Finally it proposes severe climate flexibility for fire drill frequency.

The proposed change clarifies that Group I-1 Condition 2 “smoke compartment” refuge areas, as required in the G 31-12 Section 420, can be used as a temporary “refuge area” during evacuation prior to complete building evacuation..

The proposed code change allows for severe climate deferrals, similar to current Group E deferrals that are already allowed. This takes into consideration the possible danger to seniors inhabiting these occupancies, when they are required to go outside during fire drills when possible inclement weather is occurring. The proposal allows the fire code official to modify drill frequency. The provision is left as a general provision purposely due to the variations of severe climate throughout the country, whether it be hot or cold, winter or summer or from storms. It leaves up to local discretion, the opportunity to allow modifications. (This is reflected in the additional section references in Note a to Table 405.2.) The modifications in actual practice may also include still conducting the drill, while not requiring residents to actually go outside during the drill at certain times of the year. The residents would still be trained to go outside to the outdoor assembly point during a real emergency situation.

The assembly point aspects of the proposed change are more clerical. The revisions are proposed essentially from the current wording in Group E clarifying that an assembly point is outdoors coinciding with the building evacuation concepts of both Group I-1 and R-4 irrelevant of the "Condition."

These changes are stand alone but have been coordinated with the Ad Hoc committee proposed IFC changes for Group I-2 so as not to conflict with those proposed changes. These changes have also been coordinated with the separate CTC proposed IFC changes for the Table 405.2 for fire and safety evacuation drills for both Groups I-1 and R-4.

The ICC Board established the ICC Code Technology Committee (CTC) as the venue to discuss contemporary code issues in a committee setting which provides the necessary time and flexibility to allow for full participation and input by any interested party. The code issues are assigned to the CTC by the ICC Board as "areas of study". Information on the CTC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CTC effort can be downloaded from the following website: http://www.iccsafe.org/cs/CTC/Pages/default.aspx. Since its inception in April/2005, the CTC has held twenty five meetings - all open to the public.

Cost Impact: None

404.3.2-F-BALDASSARRA-CTC

Committee Action Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The committee approved the code change based on the proponent's reason statement that it clarifies the text and provides the fire code official with flexibility in requiring drills during inclement weather.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Carl Baldassarra, P.E., FSFPE, Chair, ICC Code Technology Committee and Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee, request Approval as Modified by this Public Comment.

Modify the proposal as follows:

404.3.2 Fire safety plans. Fire safety plans shall include the following:

1. The procedure for reporting a fire or other emergency.
2. The life safety strategy and procedures for notifying, relocating or evacuating occupants, including occupants who need assistance.
3. Site plans indicating the following:
   - 3.1. The occupancy assembly point.
   - 3.2. The locations of fire hydrants.
   - 3.3. The normal routes of fire department vehicle access.
4. Floor plans identifying the locations of the following:
   - 4.1. Exits.
   - 4.2. Primary evacuation routes.
   - 4.3. Secondary evacuation routes.
   - 4.4. Accessible egress routes.
     - 4.4.1 ~~4.5~~. Areas of refuge.
     - 4.4.2 ~~4.7~~. Exterior areas for assisted rescue.
   - 4.5 ~~4.6~~ Refuge areas associated with smoke barriers and horizontal exits
   - 4.6 ~~4.8~~. Manual fire alarm boxes.
   - 4.7 ~~4.9~~. Portable fire extinguishers.
   - 4.8 ~~4.10~~ Occupant-use hose stations.

4.9 ~~4.11~~. Fire alarm annunciators and controls.
5. A list of major fire hazards associated with the normal use and occupancy of the premises, including maintenance and housekeeping procedures.
6. Identification and assignment of personnel responsible for maintenance of systems and equipment installed to prevent or control fires.
7. Identification and assignment of personnel responsible for maintenance, housekeeping and controlling fuel hazard sources.

(Portions of proposal not shown remain unchanged.)

Reason: There was concern that the three terms, “areas of refuge”, “exterior area for assisted rescue” and “refuge area”, may be confused. However, all three are necessary information for the fire safety plan. The relocation will eliminate confusion and clarify the distinction between the elements that can be found in a building.

This proposal is co-sponsored by the ICC Fire Code Action Committee (FCAC). This ICC committee was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portions thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the Fire-CAC has held 6 open meetings and numerous Regional Work Group and Task Group meetings and conference calls which included members of the committees as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the FAC website at: http://www.iccsafe.org/cs/CAC/Pages/default.aspx.

F30-13

Final Action: AS AM AMPC____ D

F39-13
503.2.2

Proposed Change as Submitted

Proponent: Carl D. Wren, P.E., Austin Fire Department, representing self (carl.wren@austintexas.gov)

Revise as follows:

503.2.2 Authority. The fire code official shall have the authority to require <u>or permit</u> an increase <u>or a decrease</u> in the minimum access widths where ~~they are inadequate for fire or rescue operations~~ <u>necessary to meet the public safety objectives of the jurisdiction.</u>

Reason: Fire departments respond to many types of emergency situations and the jurisdictions they serve may have traffic safety criteria that have an impact on the design of access roadways used by emergency response vehicles. It would also seem to be a wise course of action for the fire service and ICC to acknowledge and, when it is possible, to assist in developing methods of improving the safety of the public by helping to prevent injuries and deaths from hazards other than fire.

Cost Impact: This code change will not increase the cost of construction

503.2.2 -F-WREN

Committee Action Hearing Results

Committee Action: **Approved as Modified**

Modify the proposal as follows:

503.2.2 Authority. The fire code official shall have the authority to require or permit ~~an increase or a decrease in the minimum~~ <u>modifications to the required</u> access widths where <u>they are inadequate for fire or rescue operations or where</u> necessary to meet the public safety objectives of the jurisdiction.

Committee Reason: The committee agreed with the proponent that the code change provides the fire code official with greater flexibility to accommodate variables and changes in hazard associated with fire apparatus access roads. The modification clarifies that the authorized modification may be to increase or to decrease the width.

Assembly Action: **Disapproved**

Individual Consideration Agenda

This code change proposal is on the agenda for individual consideration because the proposal received a successful assembly action of Disapproved.

F42-13
503.4.1

Proposed Change as Submitted

Proponent: Carl D. Wren, P.E., Austin Fire Department, representing self (carl.wren@austintexas.gov)

Revise as follows:

503.4.1 Traffic calming devices. ~~Traffic calming devices shall be prohibited unless approved by the fire code official.~~ <u>The fire code official and the jurisdiction's traffic engineer shall work collaboratively to plan, design, and install traffic calming devices. Approved traffic calming devices shall be designed to provide for adequate emergency vehicle access in addition to mitigating unsafe traffic conditions identified by the traffic engineer.</u>

Reason: Fire departments respond to many types of emergency situations and the jurisdictions they serve may have traffic safety criteria that have an impact on the design of access roadways used by emergency response vehicles. The design of traffic calming features has been changing over the years as traffic engineers better understand measures that can change how people drive their vehicles. Since data available from the Centers for Disease Control indicate that annual traffic fatalities involving pedestrians likely exceed fire deaths in the United States (see http://www.edc.gov/motorvehiclesafety/pedestrian_safety/factsheet.html), it would also seem to be a wise course of action for the fire service and ICC to encourage collaboration with traffic engineers and, when it is possible, to assist in developing methods of improving the safety of the public by helping to prevent injuries and deaths from hazards other than fire.

Cost Impact: This code change will not increase the cost of construction

503.4.1-F-WREN

Committee Action Hearing Results

Committee Action: **Approved as Modified**

Modify the proposal as follows:

503.4.1 Traffic calming devices. <u>Traffic calming devices in fire vehicle access routes shall only be permitted where necessary to mitigate unsafe traffic conditions that have been identified and documented by a registered design professional specializing in traffic engineering.</u> The fire code official <u>is authorized to approve such traffic calming devices provided that, in the opinion of the fire code official, adequate emergency vehicle access is maintained.</u> ~~and the jurisdiction's traffic engineer shall work collaboratively to plan, design, and install traffic calming devices. Approved traffic calming devices shall be designed to provide for adequate emergency vehicle access in addition to mitigating unsafe traffic conditions identified by the traffic engineer.~~

Committee Reason: The committee approved the code change because it lets the fire code official know that he is not operating alone, that there are other parties with an interest in traffic calming devices that need to have input and provides broader opportunities for cooperation. The modification uses the proper terminology for design professionals as is used elsewhere in the code and the revised wording provides the fire code official more flexibility than the original proposal for addressing the various types of traffic calming devices that may be proposed.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Tim Ryan, representing City of Overland Park, KS, requests Disapproval.

Commenter's Reason: Traffic calming design is used specifically for traffic safety particularly in residential neighborhoods. This level of safety usually is addressed by traffic engineers who use other standards such as AWPA and National Highway Patrol standards. Concerns should be addressed to those organizations to deal with traffic design.

F42-13
Final Action: AS AM AMPC____ D

F45-13
507.4, Chapter 80

Proposed Change as Submitted

Proponent: Bob D. Morgan, P.E., Fort Worth, TX Fire Department representing Fire Advisory Board to North Central Texas Council of Governments

Revise as follows:

507.4 Water supply test date and information. The water supply test used for hydraulic calculation of fire protection systems shall be conducted in accordance with NFPA 291 and within one year of sprinkler plan submittal, or as otherwise approved by the fire code official. The fire code official shall be notified prior to the water supply test. Water supply tests shall be witnessed by the fire code official, as required ~~or approved documentation of the test shall be provided to the fire code official prior to final approval of the water supply system~~. The exact location of the static/residual hydrant and the flow hydrant shall be indicated on the design drawings. All fire protection plan submittals shall be accompanied by waterflow test report information, or as otherwise approved by the fire code official. At a minimum, the waterflow test report shall indicate the documented fluctuation of the water supply system in question, in accordance with the water supply operator or authority, for an entire year. The fire protection designer shall then design the fire protection system including this fluctuation information, in accordance with the applicable referenced NFPA standard.

Add new standard to Chapter 80 as follows:

NFPA

291-13 *Recommended Practice for Fire Flow Testing and Marking of Hydrants* 507.4

Reason: Water supply system fluctuation is regularly ignored in fire protection design. Often times, a sprinkler system is designed based on a fire hydrant flow test that only represents one point in time throughout the year when water supply systems may fluctuate up to 50 psi in some areas or more, based on summer vs. winter demands of the systems. This information is critical to ensure that such fire protection systems are designed to account for this potential fluctuation.

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: A review of the standard proposed for inclusion in the code, NFPA 291-13, with regard to the ICC criteria for referenced standards (Section 3.6 of CP#28), will be posted on the ICC website on or before April 1, 2013.

507.4-F-MORGAN

Committee Action Hearing Results

For staff analysis of the content of NFPA 291-13 relative to CP#28, Section 3.6, please visit:
http://www.iccsafe.org/cs/codes/Documents/2012-2014Cycle/Proposed-B/ProposedStandards.pdf

Committee Action: **Disapproved**

Committee Reason: The committee's disapproval was based on the fact that the code change belongs in Chapter 9 since its focus is on fire protection system calculations rather than on fire protection water supply. Also, gathering an entire year of test data can be problematic in areas of the country where testing can only be done for 4 or 5 months out of the year due to weather extremes.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Bob D. Morgan, P.E., Fort Worth Fire Dept., representing Fire Advisory Board to North Central Texas Council of Governments, requests Approval as Modified by this Public Comment.

Replace the proposal as follows:

903.3.5 Water supplies. Water supplies for *automatic sprinkler systems* shall comply with this section and the standards referenced in Section 903.3.1. The potable water supply shall be protected against backflow in accordance with the requirements of this section and the *International Plumbing Code*. <u>For connections to public waterworks systems, the water supply test used for design of fire protection systems shall be adjusted to account for seasonal and daily pressure fluctuations based on information from the water supply authority and as approved by the fire code official.</u>

Commenter's Reason: This public comment replaces the original proposal by relocating the new wording to Chapter 9, as per the committee's reason statement for Disapproval. There is no longer a proposed change to Section 507.4, but rather to Section 903.3.5. Also, such information on pressure fluctuation is not only necessary to ensure that the minimum required pressure will be available for the fire sprinkler system, but also, to ensure that high pressures do not exceed boundaries of the sprinkler system. If the water pressure on a sprinkler system exceeds 100 psi, changes in the hanging methods are required. Also, if a fire pump is provided, it might be possible to exceed 175 psi, which is typically considered the maximum working pressure for a sprinkler system. These are just additional reasons for why it is critical to account for pressure fluctuations in the water supply. Obviously, fire flows can be affected by this, as well as other water-based fire protection systems, such as standpipes, which require a minimum 100 psi at the roof of high-rise buildings, and such may not be available due to pressure fluctuations. That is why the original proposal was made to water supply tests in general, in addition to the fact, that one would usually acquire that information at the time of water supply testing. However, the above public comment relocates the change to the applicable section of 903 to satisfy the committee's request. With regards to gathering of data, the above code change simply requires that pressure fluctuations be addressed as per the water supply authority, i.e. to the extent that such information is available, and further allows the fire code official to accept otherwise.

F45-13
Final Action: AS AM AMPC____ D

F54-13
604.1.2 (New) (IBC [F] 2702.1.2), Chapter 80

Proposed Change as Submitted

Proponent: John Williams, CBO, Chair, ICC Ad Hoc Committee on Health Care (john.williams@doh.wa.gov)

Add new text as follows:

604.1.1(IBC [F] 2702.1.1) Stationary generators. Stationary emergency and standby power generators required by this code shall be *listed* in accordance with UL 2200

604.1.2 (IBC [F] 2702.1.2) Group I-2 Occupancies. In Group I-2 occupancies, where an essential electrical system is located in flood hazard areas established in Section 1612.3 of the *International Building Code*, the system shall be located and installed in accordance with ASCE 24.

Add new standard to Chapter 80 as follows:

ASCE 24-05	Flood Resistant Design and Construction	604.1.2

Reason: This proposal is submitted by the ICC Ad Hoc Committee for Healthcare (AHC). The AHC was established by the ICC Board of Directors to evaluate and assess contemporary code issues relating to hospitals and ambulatory healthcare facilities. The AHC is composed of building code officials, fire code officials, hospital facility engineers, and state healthcare enforcement representatives. The goals of the committee are to ensure that the ICC family of codes appropriately addresses the fire and life safety concerns of a highly specialized and rapidly evolving healthcare delivery system. This process is part of a joint effort between ICC and the American Society for Healthcare Engineering, a subsidiary of the American Hospital Association, to eliminate duplication and conflicts in healthcare regulation. Since its inception in April, 2011, the AHC has held 5 open meetings and over 80 workgroup calls which included members of the AHC as well as any interested party to discuss and debate the proposed changes. All meeting materials and reports are posted on the AHC website at: http://www.iccsafe.org/cs/AHC/Pages/default.aspx.

There is no way to get to the requirements or limitations regarding generator placement for healthcare facilities that are in the standard if the code text for the specific code section does not take you there.

The Adhoc committee on healthcare identified this coordination oversight as it has been identified in healthcare facilities and that generators are being installed in areas subject to flooding, and although they were designed to meet the structural loads for the flooding, they would operationally fail.

There is no cost impact for these requirements because the compliance with ASCE 24 is required for these facilities; specific reference to ASCE for coordination of requirements applicable to healthcare facilities that require emergency or standby power systems per federal, state and licensing agency requirements and references. Also, both this section and this proposal are not intended to be retroactive in application. The AHC has a separate code change that would require facilities to do a risk assessment of existing installations.

It is an installation construction requirement that is not specifically addressed in the code; emergency and standby power by generators is necessary for life safety and preservation for healthcare and for other occupancies and uses as specified in 2702.

Note that G80-12 added requirements for essential electrical systems in I-2 occupancies. This is simply a continuation of that concept. This proposal is furthering the reliability of the essential electrical systems when they will be needed most by specifically referencing to ASCE 24. The additional language referencing Section 1612.3 is similar to that used in Section 3001.2 for elevators.

Cost impact: The code change proposal should not increase the cost of construction because compliance is already required by facility licensure requirements.

Analysis: The standard proposed for inclusion in the code, ASCE 24-05, is currently referenced in the IBC. An update in the year edition of that standard will be accomplished by an administrative standards update code change to be heard by the ADM Code Development Committee.

604.1.2 (NEW)-F-WILLIAMS-ADHOC

Committee Action Hearing Results

For staff analysis of the content of ASCE/SEI 24-05 relative to CP#28, Section 3.6, please visit:
http://www.iccsafe.org/cs/codes/Documents/2012-2014Cycle/Proposed-B/ProposedStandards.pdf

Committee Action: **Approved as Modified**

Modify the proposal as follows:

604.1.2 (IBC [F] 2702.1.2) Group I-2 Occupancies. In Group I-2 occupancies, in new construction or where the building is substantially damaged, where an essential electrical system is located in flood hazard areas established in Section 1612.3 of the *International Building Code*, the system shall be located and installed in accordance with ASCE 24.

(Portions of proposal not shown remain unchanged.)

Committee Reason: The committee approved the code change based on the proponent's reason statement and agreed that the proposal provides for important protection for critical systems. The modification clarifies that the applicability of the section would be to existing buildings only when they sustain substantial damage such as from the recent east coast hurricane.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

John Williams, CBO, Chair, ICC Ad Hoc Committee on Health Care, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

604.1.2 (IBC [F] 2702.1.2) Group I-2 Occupancies. In Group I-2 occupancies~~, in new construction or where the building is substantially damaged~~, where an essential electrical system is located in flood hazard areas established in Section 1612.3 of the *International Building Code*, and where new or replacement essential electrical system generators are installed, the system shall be located and installed in accordance with ASCE 24.

(Portions of proposal not shown remain unchanged.)

Commenter's Reason: The Adhoc committee recommends that generators be protected from floods sooner than when a building is substantially damaged. However, the Adhoc committee did not feel that generators should have to be protected if a flood plane was revised and no alterations were planned at that time. This modification will work with the hospital hazard vulnerability analysis and risk assessments. We believe that this proposal would require modifications when a substantial change is contemplated the trigger being the generator.

F54-13
Final Action: AS AM AMPC____ D

F55-13
604.2.14.1.3 (IBC [F] 403.4.8.2) (New)

Proposed Change as Submitted

Proponent: Robert J Davidson, Davidson Code Concepts, LLC, representing self (rjd@davidsoncodeconcepts.com)

Add new text as follows:

604.2.14.1 (IBC [F] 403.4.8.1) Standby power. A standby power system shall be provided. Where the standby system is a generator set inside a building, the system shall be located in a separate room enclosed with 2-hour fire barriers constructed in accordance with Section 707 of the International Building Code or horizontal assemblies constructed in accordance with Section 711 of the International Building Code, or both. System supervision with manual start and transfer features shall be provided at the fire command center.

604.2.14.1.1 Fuel supply. (No change to current text.)

604.2.14.1.2 Capacity. (No change to current text.)

<u>**604.2.14.1.3 (IBC [F] 403.4.8.2) Fuel line piping protection**: Fuel lines supplying a generator set inside a building shall be separated from areas of the building other than the room the generator is located in by fire barriers or by an approved piping protective system that have a fire-resistance rating of not less than 2 hours. Where gypsum wallboard is used, joints on the piping side of the enclosure are not required to be taped. Access openings into the enclosure shall be protected by approved fire protection-rated assemblies.</u>

(Renumber subsequent sections)

Reason: Currently IFC Section 604.2.14.1 and IBC Section [F] 403.4.8.1 require the generator to be protected from a fire within the occupancy by enclosure with 2 hour fire-resistance rated construction.

However, for diesel fueled generators it is common to supply the generators with a day tank and resupply the day tank via remote fuel oil tanks and the fuel line piping from those remote tanks to the generator can be exposed to the fire the generator has been protected against. Loss of the fuel line due to fire exposure has the same impact as loss of the generator itself from fire exposure. The wording only refers to "fuel lines' to also provide protection in those cases where a gaseous fuel supply is approved for use.

This proposal calls for fire-resistance protection of those portions of the fuel line piping that are located outside of the fire-resistance rated room the generator is located in. A portion of the new language was taken from IBC Section [F]415.10.6.4 where protection of HPM supply piping is provided for.

Cost Impact: The code change proposal will increase the cost of construction.

604.2.14.1.3 (NEW)-F-DAVIDSON

Committee Action Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee's disapproval was based on its concern that rather than simply requiring a 2-hour fire-resistance-rated assembly, the proposal specifies methods and materials that may or not be consistent with a 2-hour rated assembly. The committee also felt that there was inadequate justification for the change and noted that sprinkler protection was not credited in reducing the hazard of fire exposure cited in the reason statement.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Robert J Davidson, Davidson Code Concepts, LLC, representing self, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

604.2.14.1.3 (IBC [F] 403.4.8.2) Fuel line piping protection: Fuel lines supplying a generator set inside a building shall be separated from areas of the building other than the room the generator is located in ~~by fire barriers or by~~ an approved ~~piping protective system~~ method or assembly that ~~have~~ has a fire-resistance rating of not less than 2 hours~~. Where gypsum wallboard is used, joints on the piping side of the enclosure are not required to be taped. Access openings into the enclosure shall be protected by approved fire protection-rated assemblies.~~ Where the building is protected throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.3.1.2 the required fire-resistance rating may be reduced to 1 hour.

Commenter's Reason: In response to the committee concerns the specific methods have been deleted to instead refer to a generic requirement of protection with "an approved method or assembly". In recognition of the committee discussion this modified wording provides for acceptance of a wider base of solutions.

Recognition for sprinkler protection has been added with a reduction of the 2 hour protection to 1 hour when the building is protected throughout by an automatic sprinkler system in response to committee concerns.

Though there was one committee member that did not see the need for the protection, there were several members that agreed with the concept, but not the language that was initially proposed.

F55-13

Final Action: AS AM AMPC____ D

F57-13

604.3 (New) [IBC [F] 2702.3 (New)]; Chapter 80 (IBC Chapter 35)

Proposed Change as Submitted

Proponent: Bob Eugene, representing Underwriters Laboratories (Robert.Eugene@ul.com)

Add new text as follows:

604.3 (IBC [F] 2702.3) Critical circuits. Cables used for survivability of critical circuits shall be listed in accordance with UL 2196. Electrical circuit protective systems shall be installed in accordance with their listing requirements.

(Renumber subsequent sections)

Add new standard to Chapter 80 (IBC Chapter 35) as follows:

UL

2196-2001 Tests for Fire Resistive Cables, with revisions through December 7, 2003...604.3 (2703.2)

Reason: UL 2196 is the ANSI approved standard for tests of fire resistive cables. NFPA 20 (fire pumps) and NFPA 72 (fire alarm) include selective survivability requirements to assure integrity of certain critical circuits. NFPA 70 does not specify the applicable standard within the mandatory provisions of the code, but recognizes electrical circuit protective systems as an alternate to listed cables. An electrical circuit protective system is a field assembly of components that must be installed according to the listing requirements and manufacturer's instructions in order to maintain the listing for the system. There are more than two dozen electrical circuit protective systems listed in the UL Fire Resistance Directory.

Cost Impact: The code change proposal may or may not increase the cost of construction. Such systems are already commonly installed.

604.3 (NEW)-F-EUGENE

Committee Action Hearing Results

For staff analysis of the content of UL2196-2001 relative to CP#28, Section 3.6, please visit:
http://www.iccsafe.org/cs/codes/Documents/2012-2014Cycle/Proposed-B/ProposedStandards.pdf

Committee Action: **Approved as Modified**

Modify the proposal as follows:

604.3 (IBC [F] 2702.3) Critical circuits. Cables used for survivability of required critical circuits shall be listed in accordance with UL 2196. Electrical circuit protective systems shall be installed in accordance with their listing requirements.

(Portions of the proposal not shown remain unchanged.)

Committee Reason: The committee agreed with the proponent's reason statement that the code change
Brings needed clarity regarding critical circuits and provides correlation with similar language used in many referenced standards, including NFPA 20, 70 and 72. Though the committee expressed some concern that the term "critical circuits" is not defined, it was pointed out that the phrase is widely used and described throughout nationally recognized standards and industry practices. The modification clarifies that the requirement only applies to required critical circuits.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Bob Eugene, representing UL LLC, requests Approval as Modified by Public Comment.

Further modify the proposal as follows:

UL	**Underwriters Laboratories**	
Standard Reference Number	**Title**	**Referenced in Code Section Number**
2196-2001	Tests for Fire Resistive Cables, with revisions through ~~December 7, 2003~~ March 2012	604.3 (2703.2)

(Portions of proposal not shown remain unchanged)

Commenter's Reason: This proposal was originally submitted with the Group A proposals, but held over for the Group B proposals. The revisions to the standard, including ANSI approval, occurred after the original submittal and should be included in the 2015 edition of the codes.

Analysis: The edition of UL2196 that was submitted for review by the IFC Committee included the revisions through March, 2012. For the staff analysis of the content of this standard, please visit: http://www.iccsafe.org/cs/codes/Documents/2012-2014Cycle/Proposed-B/ProposedStandards.pdf

Public Comment 2:

Marcelo M. Hirschler, (GBH International), requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

SECTION 202
GENERAL DEFINITIONS

Add new definition as follows:

CRITICAL CIRCUIT. A **c**ircuit that requires continuous operation to ensure safety of the structure and occupants.

(Portions of proposal not shown remain unchanged.)

Commenter's Reason: During the proposal stage an issue was raised by the committee that the term "critical circuit" is not defined. This proposed definition is based on the definitions in section 645.2 and 708.2 of the National Electrical Code (NFPA 70), which read as shown below. Article 645 deals with Information Technology Equipment and article 708 deals with Critical Operations Power Systems.

> **645.2: Critical Operations Data System.** An information technology equipment system that requires continuous operation for reasons of public safety, emergency management, national security, or business continuity.
>
> **708.2: Critical Operations Power Systems (COPS).** Power systems for facilities or parts of facilities that require continuous operation for the reasons of public safety, emergency management, national security, or business continuity.

The National Electrical Code also states, in article 725 that:

> **Circuit Integrity (CI) Cable.** Cable(s) used for remote control, signaling, or power-limited systems that supply critical circuits to ensure survivability for continued circuit operation for a specified time under fire conditions.
>
> **Circuit Integrity (CI) Cable or Electrical Circuit Protective System.** Cables used for survivability of critical circuits shall be listed as circuit integrity (CI) cable. Cables specified in 725.154(A), (B), (D)(1), and (E), and used for circuit integrity, shall have the additional classification using the suffix "-CI". Cables that are part of a listed electrical circuit protective system shall be considered to meet the requirements of survivability.

Informational Note: One method of defining *circuit integrity* is by establishing a minimum 2-hour fire resistance rating when tested in accordance with UL 2196-2002, *Standard for Tests of Fire Resistive Cables*.

The same concept is shown in several articles, including 760, 770 and 800.

F57-13

Final Action: AS AM AMPC____ D

F59-13, Part I

604 (IBC [F] 2702) among others; 907.5.2.2.5 (IBC [F] 907.5.2.2.5); IMC [F] 513.11, [F]513.11.1 (New); IWUIC 404.10.3; IEBC 805.4.5

Proposed Change as Submitted

Proponent: Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azubiamia@yahoo.com)

THIS IS A 2 PART CODE CHANGE. PART I WILL BE HEARD BY THE IFC COMMITTEE AND PART II WILL BE HEARD BY THE IEBC COMMITTEE AS TWO SEPARATE CODE CHANGES. SEE THE TENTATIVE HEARING ORDER FOR THOSE COMMITTEES.

PART I – INTERNATIONAL FIRE CODE

EMERGENCY VOICE/ALARM COMMUNICATION SYSTEMS

NOTE: *The normal convention for portraying code changes to duplicated texts is by showing the parallel section numbers (e.g., "**907.5.2 (IBC [F] 907.5.2)**" or "**1011.6.3 (IFC [B] 1011.6.3**"). In this code change, however, for improved clarity, duplicate texts are shown for each code in this part.*

Revise the IBC as follows:

[F] 402.7.3 Emergency ~~Standby~~ power. *Covered mall buildings* greater than 50,000 square feet (4645 m2) in area and *open mall buildings* greater than 50,000 square feet (4645 m2) within the established perimeter line shall be provided with ~~standby~~ emergency power ~~systems~~ that is ~~are~~ capable of operating the *emergency voice/alarm communication system* in accordance with Section 2702.

[F] 907.5.2.2.5 Emergency power. Emergency voice/alarm communications systems shall be provided with ~~an *approved*~~ emergency power ~~source~~ in accordance with Section 2702. The system shall be capable of powering the required load for a duration of not less than 24 hours, as required in NFPA 72.

[F] ~~2702.2.1 Group A occupancies.~~ ~~Emergency power shall be provided for emergency voice/alarm communication systems in Group A occupancies in accordance with Section 907.5.2.2.4.~~

[F] ~~2702.2.14 Covered and open mall buildings.~~ ~~Standby power shall be provided for voice/alarm communication systems in *covered and open mall buildings* in accordance with Section 402.7.3.~~

[F] 2702.2.1 Emergency voice/alarm communication systems. Emergency power shall be provided for emergency voice/alarm communication systems as required in Section 907.5.2.2.5. The system shall be capable of powering the required load for a duration of not less than 24 hours, as required in NFPA 72.

Revise the IFC as follows:

~~**604.2.1 Group A occupancies.** Emergency power shall be provided for emergency voice/alarm communication systems in Group A occupancies in accordance with Section 907.2.1.1.~~

~~**604.2.13 Covered and open mall buildings.** Covered mall buildings exceeding 50,000 square feet (4645 m2) and open mall buildings exceeding 50,000 square feet (4645 m2) within the established perimeter line shall be provided with standby power systems that are capable of operating the emergency voice/alarm communication system.~~

604.2.1 Emergency voice/alarm communication systems. Emergency power shall be provided for emergency voice/alarm communication systems as required in Section 907.5.2.2.5. 5. The system shall be capable of powering the required load for a duration of not less than 24 hours, as required in NFPA 72.

907.5.2.2.5 Emergency power. Emergency voice/alarm communications systems shall be provided with ~~an *approved*~~ emergency power ~~source~~ in accordance with Section 604. The system shall be capable of powering the required load for a duration of not less than 24 hours, as required in NFPA 72.

SMOKE CONTROL SYSTEMS

NOTE: *The normal convention for portraying code changes to duplicated texts is by showing the parallel section numbers (e.g., "**907.5.2 (IBC [F] 907.5.2)**" or "**1011.6.3 (IFC [B] 1011.6.3**"). In this code change, however, for improved clarity, duplicate texts are shown for each code in this part.*

Revise the IBC as follows:

[F] 404.7 Standby power. Equipment required to provide smoke control shall be provided with standby power in accordance with ~~connected to a standby power system in accordance with~~ Section 909.11.

[F] 909.11 Standby power ~~Power systems.~~ ~~The~~ ~~s~~Smoke control systems shall be provided with standby power in accordance with Section 2702. ~~shall be supplied with two sources of power. Primary power shall be from the normal building power systems. Secondary power shall be from an approved standby source complying with Chapter 27 of this code.~~

[F] 909.11.1 Equipment room. The standby power source and its transfer switches shall be in a room separate from the normal power transformers and switch gears and ventilated directly to and from the exterior. The room shall be enclosed with not less than 1-hour *fire barriers* constructed in accordance with Section 707 or *horizontal assemblies* constructed in accordance with Section 711, or both. ~~The transfer to full standby power shall be automatic and within 60 seconds of failure of the primary power.~~

909.20.6.2 Standby power. Mechanical vestibule and *stair* shaft ventilation systems and automatic fire detection systems shall be provided with ~~powered by an *approved*~~ standby power in accordance with Section 2702. ~~system conforming to Section 403.4.8 and Chapter 27.~~

909.21.5 Standby power. The pressurization system shall be provided with standby power in accordance with Section 2702. ~~from the same source as other required emergency systems for the building.~~

[F] 2702.2.2 Smoke control systems. Standby power shall be provided for smoke control systems as required in ~~in accordance with~~ Sections 404.7, 909.11, 909.20.6.2, and 909.21.5.

[F] ~~2702.2.20 Smokeproof enclosures.~~ ~~Standby power shall be provided for smokeproof enclosures as required by~~ in ~~Section 909.20.6.2.~~

Revise the IFC as follows:

604.2.2 Smoke control systems. Standby power shall be provided for smoke control systems as required in ~~in accordance with~~ Section 909.11.

909.11 Standby power ~~Power systems.~~ ~~The~~ ~~s~~Smoke control systems shall be provided with standby power in accordance with Section 2702. ~~shall be supplied with two sources of power. Primary power shall be from the normal building power systems. Secondary power shall be from an approved standby source complying with Chapter 27 of this code.~~

909.11.1 Equipment room. The standby power source and its transfer switches shall be in a room separate from the normal power transformers and switch gears and ventilated directly to and from the exterior. The room shall be enclosed with not less than 1-hour *fire barriers* constructed in accordance with Section 707 or *horizontal assemblies* constructed in accordance with Section 711, or both. ~~The transfer to full standby power shall be automatic and within 60 seconds of failure of the primary power.~~

Revise the IMC as follows:

[F] 513.11 Power systems. ~~The s~~Smoke control system shall be supplied with standby power in accordance with Section 2702 of the International Building Code. ~~two sources of power. Primary power shall be the normal building power systems. Secondary power shall be from an *approved* standby source complying with Chapter 27 of the *International Building Code*.~~

[F] 513.11.1 Equipment room. The standby power source and its transfer switches shall be in a room separate from the normal power transformers and switch gear and ventilated directly to and from the exterior. The room shall be enclosed with not less than 1-hour fire-resistance rated fire barriers constructed in accordance with Section 707 of the *International Building Code* or horizontal assemblies constructed in accordance with Section 711 of the *International Building Code*, or both. Power distribution from the two sources shall be by independent routes. ~~Transfer to full standby power shall be automatic and within 60 seconds of failure of the primary power. The systems shall comply with NFPA 70.~~

EXIT SIGNS

NOTE: *The normal convention for portraying code changes to duplicated texts is by showing the parallel section numbers (e.g., "**907.5.2 (IBC [F] 907.5.2)**" or "**1011.6.3 (IFC [B] 1011.6.3**"). In this code change, however, for improved clarity, duplicate texts are shown for each code in this part.*

Revise the IBC as follows:

[F] 2702.2.3 Exit signs. Emergency power shall be provided for *exit* signs as required in ~~in accordance with~~ Section 1011.6.3. The system shall be capable of powering the required load for a duration of not less than 90 minutes.

Revise the IFC as follows:

604.2.3 Exit signs. Emergency power shall be provided for *exit* signs as required in ~~in accordance with~~ Section 1011.6.3. The system shall be capable of powering the required load for a duration of not less than 90 minutes.

MEANS OF EGRESS ILLUMINATION

NOTE: *The normal convention for portraying code changes to duplicated texts is by showing the parallel section numbers (e.g., "**907.5.2 (IBC [F] 907.5.2)**" or "**1011.6.3 (IFC [B] 1011.6.3**"). In this code change, however, for improved clarity, duplicate texts are shown for each code in this part.*

Revise the IBC as follows:

[F] 2702.2.4 Means of egress illumination. Emergency power shall be provided for *means of egress* illumination as required in ~~in accordance with~~ Section 1006.3. The system shall be capable of powering the required load for a duration of not less than 90 minutes.

Revise the IFC as follows:

604.2.4 Means of egress illumination. Emergency power shall be provided for *means of egress* illumination in accordance with Sections 1006.3 and 1104.5.1.

1104.5.1 Emergency power duration and installation. Emergency power for means of egress illumination shall be provided in accordance with Section 604. In other than Group I-2, ~~the~~ emergency power ~~system shall provide power~~ shall be provided for not less than 60 minutes. ~~and consist of storage batteries, unit equipment or an on-site generator.~~ In Group I-2, ~~the~~ emergency power ~~system shall provide power~~ shall be provided for not less than 90 minutes. ~~and consist of storage batteries, unit equipment or an on-site generator. The installation of the emergency power system shall be in accordance with Section 604.~~

ELEVATORS AND PLATFORM LIFTS

***NOTE:** The normal convention for portraying code changes to duplicated texts is by showing the parallel section numbers (e.g., "**907.5.2 (IBC [F] 907.5.2)**" or "**1011.6.3 (IFC [B] 1011.6.3**"). In this code change, however, for improved clarity, duplicate texts are shown for each code in this part.*

Revise the IBC as follows:

[F] 2702.2.5 Elevators and platform lifts. Standby power shall be provided for elevators and platform lifts as required in Sections 1007.4, 1007.5, 3003.1, 3007.9 and 3008.9.

[F] ~~**2702.2.5 Accessible means of egress elevators.** Standby power shall be provided for elevators that are part of an *accessible means of egress* in accordance with Section 1007.4.~~

[F] ~~**2702.2.6 Accessible means of egress platform lifts.** Standby power in accordance with this section or ASME A 18.1 shall be provided for platform lifts that are part of an *accessible means of egress* in accordance with Section 1007.5.~~

[F] ~~**2702.2.19 Elevators.** Standby power for elevators shall be provided as set forth in Sections 3003.1, 3007.9 and 3008.9.~~

Revise the IFC as follows:

~~**604.2.5 Accessible means of egress elevators.** Standby power shall be provided for elevators that are part of an accessible *means of egress* in accordance with Section 1007.4.~~

~~**604.2.6 Accessible means of egress platform lifts.** Standby power in accordance with this section or ASME A18.1 shall be provided for platform lifts that are part of an accessible *means of egress* in accordance with Section 1007.5.~~

604.2.18 Elevators and platform lifts. Standby power shall be provided for elevators and platform lifts as required in Sections 607.2, 1007.4, and 1007.5.

Relocate IFC sections and renumber the remaining sections.

607.2 Standby power. ~~**604.2.18 Elevators.**~~ In buildings and structures where standby power is required or furnished to operate an elevator, standby power shall be provided in accordance with Section 604. ~~the o~~Operation of the system shall be in accordance with Sections ~~604.2.18.1 through 604.2.18.4~~ 607.2.1 through 607.2.4.

607.2.1 ~~**604.2.18.1**~~ **Manual transfer.** (No change to current text.)

607.2.2 ~~**604.2.18.2**~~ **One elevator.** (No change to current text.)

607.2.3 ~~**604.2.18.3**~~ **Two or more elevators.** (No change to current text.)

607.2.4 ~~**604.2.18.4**~~ **Machine room ventilation.** (No change to current text.)

HORIZONTAL SLIDING DOORS

***NOTE:** The normal convention for portraying code changes to duplicated texts is by showing the parallel section numbers (e.g., "**907.5.2 (IBC [F] 907.5.2)**" or "**1011.6.3 (IFC [B] 1011.6.3**"). In this code change, however, for improved clarity, duplicate texts are shown for each code in this part.*

Revise the IBC as follows:

[F] 2702.2.7 Horizontal sliding doors. Standby power shall be provided for horizontal sliding doors as required in ~~in accordance with~~ Section 1008.1.4.3. The standby power supply shall have a capacity to operate a minimum of 50 closing cycles of the door.

Revise the IFC as follows:

604.2.7 Horizontal sliding doors. Standby power shall be provided for horizontal sliding doors as required in ~~in accordance with~~ Section 1008.1.4.3. The standby power supply shall have a capacity to operate a minimum of 50 closing cycles of the door.

MEMBRANE STRUCTURES

NOTE: *The normal convention for portraying code changes to duplicated texts is by showing the parallel section numbers (e.g., "**907.5.2 (IBC [F] 907.5.2)**" or "**1011.6.3 (IFC [B] 1011.6.3**"). In this code change, however, for improved clarity, duplicate texts are shown for each code in this part.*

Revise the IBC as follows:

[F] 2702.2.9 Membrane structures. Standby power shall be provided for auxiliary inflation systems in permanent membrane structures as required in ~~in accordance with~~ Section 3102.8.2. Standby power shall be provided for a duration of not less than four hours. Auxiliary inflation systems in temporary air-supported and air-inflated membrane structures shall be provided in accordance with Section 3103.10.4 of ~~Emergency power shall be provided for *exit* signs in temporary tents and membrane structures in accordance with~~ the *International Fire Code*.

Revise the IFC as follows:

604.2.9 Membrane structures. ~~Emergency power shall be provided for *exit* signs in temporary tents and membrane structures in accordance with Section 3103.12.6.1.~~
Standby power shall be provided for auxiliary inflation systems in permanent membrane structures in accordance with Section 2702 of the *International Building Code*. Auxiliary inflation systems shall be provided in temporary air-supported and air-inflated membrane structures in accordance with Section 3103.10.4.

3103.10.4 Auxiliary inflation systems ~~power~~. Places of public assembly for more than 200 persons shall be furnished with an auxiliary inflation system capable of powering a blower with the capacity to maintain full inflation pressure with normal leakage in accordance with Section 3103.10.3 for a minimum duration of four hours. The auxiliary inflation system can be either a fully automatic auxiliary engine-generator set ~~capable of powering one blower continuously for 4 hours,~~ or a supplementary blower powered by an internal combustion engine which shall be automatic in operation. The system shall be capable of automatically operating the required blowers at full power within 60 seconds of a commercial power failure.

SEMICONDUCTOR FABRICATION FACILITIES

NOTE: *The normal convention for portraying code changes to duplicated texts is by showing the parallel section numbers (e.g., "**907.5.2 (IBC [F] 907.5.2)**" or "**1011.6.3 (IFC [B] 1011.6.3**"). In this code change, however, for improved clarity, duplicate texts are shown for each code in this part.*

Revise the IBC as follows:

[F] 415.10.10 Emergency power system. An emergency power system shall be provided in Group H-5 occupancies in accordance with Section 2702. ~~where required in Section 415.10.10.1.~~ The emergency power system shall ~~be designed to~~ supply power automatically to ~~required~~ the electrical systems specified in Section 415.10.10.1 when the normal electrical supply system is interrupted.

[F] 415.10.10.1 Required electrical systems. Emergency power shall be provided for electrically operated equipment and connected control circuits for the following systems:

1. through 6. (No change to current text.)
7. Manual <u>and automatic</u> *fire alarm* systems.
8. through 11. (No change to current text.)

[F] 2702.2.8 Semiconductor fabrication facilities. Emergency power shall be provided for semiconductor fabrication facilities <u>as required in</u> ~~in accordance with~~ Section 415.10.10.

Revise the IFC as follows:

604.2.8 Semiconductor fabrication facilities. Emergency power shall be provided for semiconductor fabrication facilities <u>as required in</u> ~~in accordance with~~ Section 2703.15.

2703.15 Emergency power system. An emergency power system shall be provided in Group H-5 occupancies <u>in accordance with</u> ~~where required by~~ Section 604. The emergency power system shall ~~be designed to~~ supply power automatically to ~~required~~ <u>the</u> electrical systems <u>specified in Section 2703.15.1</u> when the normal supply system is interrupted.

HAZARDOUS MATERIALS

NOTE: *The normal convention for portraying code changes to duplicated texts is by showing the parallel section numbers (e.g., "**907.5.2 (IBC [F] 907.5.2)**" or "**1011.6.3 (IFC [B] 1011.6.3**"). In this code change, however, for improved clarity, duplicate texts are shown for each code in this part.*

Revise the IBC as follows:

[F] 414.5.3 Emergency or standby power. Where mechanical *ventilation*, treatment systems, temperature control, alarm, detection or other electrically operated systems are required by the *International Fire Code* or this code, such systems shall be provided with ~~an~~ emergency or standby power ~~system~~ in accordance with <u>Section 2702</u> ~~Chapter 27~~.~~**Exceptions:** 1.~~

[F] <u>414.5.3.1 Exempt applications</u>. Emergency or standby power are not required for ~~the following storage areas: 1.1. M~~ <u>m</u>echanical ventilation <u>systems provided</u> *for:*

1. <u>S</u>~~s~~<u>torage</u> of Class IB and Class IC flammable and combustible liquids in closed containers not exceeding 6.5 gallons (25 L) capacity.
   ~~1.2~~<u>1.1.</u> Storage ~~areas for~~ <u>of</u> Class 1 and 2 oxidizers.
   ~~1.3~~<u>1.2</u>. Storage ~~areas for~~ <u>of</u> Class II, III, IV and V organic peroxides.
   ~~1.4~~<u>1.3.</u> Storage~~, use and handling areas for~~ <u>of</u> asphyxiant, irritant and radioactive gases.
   ~~1.5. For storage, use and handling areas for highly toxic or toxic materials, see Sections 6004.2.2.8 and 6004.3.4.2 of the *International Fire Code*.~~

[F] <u>414.5.3.2 Fail-safe engineered systems.</u> <u>Standby power for mechanical ventilation, treatment systems and temperature control systems shall not be required where an *approved* fail-safe engineered system is installed.</u>

[F] 421.8 Standby power. Mechanical *ventilation* and gas detection systems shall be ~~connected to a~~ <u>provided with</u> standby power ~~system~~ in accordance with <u>Section 2702.</u> ~~Chapter 27.~~

[F] 2702.2.10 Hazardous materials. Emergency or standby power shall be provided in occupancies with hazardous materials <u>as required in</u> ~~in accordance with~~ Section<u>s</u> 414.5.3 <u>and 421.8 and the *International Fire Code*</u>.

Revise the IFC as follows:

604.2.10 Hazardous materials. Emergency ~~or standby~~ power shall be provided in occupancies with hazardous materials as required in the following ~~in accordance with~~ sections ~~5004.7 and 5005.1.5.~~:

Hazardous materials – 5001.3.3.10
Highly toxic and toxic gases - 6004.2.2.8, 6004.3.4.2
Organic peroxides - 6204.1.11

5004.7 Standby or emergency power. Where mechanical ventilation, treatment systems, temperature control, alarm, detection or other electrically operated systems are required, such systems shall be provided with ~~an~~ emergency or standby power ~~system~~ in accordance with ~~NFPA 70 and~~ Section 604.

~~Exceptions~~:

5004.7.1 Exempt applications. Standby or emergency power is not required for ~~M~~mechanical ventilation systems provided for:

1. Storage of Class IB and Class IC flammable and *combustible liquids* in closed containers not exceeding 61/2 gallons (25 L) capacity.
2. Storage ~~areas for~~ of Class 1 and 2 oxidizers.
3. Storage ~~areas for~~ of Class II, III, IV and V organic peroxides.
4. Storage ~~areas for~~ of asphyxiant, irritant and radioactive gases.
5. ~~For storage areas for highly toxic or toxic materials, see Sections 6004.2.2.8 and 6004.3.4.2.~~

5004.7.2 Fail-safe engineered systems. ~~6.~~ Standby power for mechanical ventilation, treatment systems and temperature control systems shall not be required where an *approved* fail-safe engineered system is installed.

5005.1.5 Standby or emergency power. Where mechanical ventilation, treatment systems, temperature control, manual alarm, detection or other electrically operated systems are required in this code, such systems shall be provided with ~~an~~ emergency or standby power ~~system~~ in accordance with ~~NFPA 70 and~~ Section 604.

~~Exceptions:~~ ~~1.~~

5005.1.5.1 Exempt applications. Standby power for mechanical ventilation, treatment systems and temperature control systems shall not be required where an *approved* fail-safe engineered system is installed.

2. ~~Systems for highly toxic or toxic gases shall be provided with emergency power in accordance with Sections 6004.2.2.8 and 6004.3.4.2.~~

6004.2.2.8 Emergency power. Emergency power shall be provided for the following systems in accordance with the Section 604~~. and NFPA 70 shall be provided in lieu of standby power where any of the following systems are required~~:

1. through 7. *(No change to current text.)*

6004.2.2.8.1 Fail-safe engineered systems. **~~Exception:~~** Emergency power ~~is~~ shall not be required for mechanical exhaust ventilation, treatment systems and temperature control systems where *approved* fail-safe engineered systems are installed.

6204.1.11 Standby power. Standby power ~~in accordance with Section 604 shall be provided for storage areas of Class I and unclassified detonable organic peroxide.~~ shall be provided in accordance with

Section 604 for the following systems used to protect Class I and unclassified detonable organic peroxide:

1. through 7. *(No change to current text.)*

6204.1.11.1 Fail-safe engineered systems. ~~**Exception:**~~ Standby power shall not be required for mechanical exhaust ventilation, treatment systems and temperature control systems where *approved* fail-safe engineered systems are installed.

HIGH RISE BUILDINGS

NOTE: *The normal convention for portraying code changes to duplicated texts is by showing the parallel section numbers (e.g., "**907.5.2 (IBC [F] 907.5.2)**" or "**1011.6.3 (IFC [B] 1011.6.3**"). In this code change, however, for improved clarity, duplicate texts are shown for each code in this part.*

Revise the IBC as follows:

[F] 403.4.8 Standby and emergency power. A standby power system complying with Section 2702 ~~Chapter 27~~ and Section 3003 shall be provided for the standby power loads specified in 403.4.8.2. An emergency power system complying with Section 2702 shall be provided for the emergency power loads specified in Section 403.4.8.3.~~Where elevators are provided in a *high-rise building* for *accessible means of egress*, fire service access or occupant self-evacuation, the standby power system shall also comply with Sections 1007.4, 3007 or 3008, as applicable.~~

[F] 403.4.8.1 Equipment room. ~~**Special requirements for standby power systems.**~~ If the standby or emergency power system includes ~~is~~ a generator set inside a building, the system shall be located in a separate room enclosed with 2-hour *fire barriers* constructed in accordance with Section 707 or *horizontal assemblies* constructed in accordance with Section 711, or both. System supervision with manual start and transfer features shall be provided at the *fire command center*.

[F] 403.4.8.2 Standby power loads. The following are classified as standby power loads:

1. Power and lighting for the *fire command center* required by Section 403.4.6;
2. *Ventilation* and automatic fire detection equipment for *smokeproof enclosures*; and
3. Elevators.
4. Where elevators are provided in a *high-rise building* for *accessible means of egress*, fire service access or occupant self-evacuation, the standby power system shall also comply with Sections 1007.4, 3007 or 3008, as applicable.

[F] ~~**403.4.9 Emergency power systems.** An emergency power system complying with Chapter 27 shall be provided for emergency power loads specified in Section 403.4.9.1.~~

[F] ~~**403.4.9.1**~~ **403.4.8.3 Emergency power loads.** The following are classified as emergency power loads:

1. Exit signs and *means of egress* illumination required by Chapter 10;
2. Elevator car lighting;
3. *Emergency voice/alarm communications systems*;
4. Automatic fire detection systems;
5. *Fire alarm* systems; and
6. Electrically powered fire pumps.

[F] 2702.2.15 High-rise buildings. Emergency and standby power systems shall be provided in high-rise buildings as required in ~~in accordance with~~ Section~~s~~ 403.4.8~~ and 403.4.9~~.

Revise the IFC as follows:

604.2.14 High-rise buildings. Standby power and emergency power ~~, light and emergency systems in high-rise buildings~~ shall be provided as required in Section 403 of the International Building Code, and shall be in accordance with Section 604. ~~comply with the requirements of Sections 604.2.14.1 through 604.2.14.3.~~

~~**604.2.14.1 Standby power.** A standby power system shall be provided. Where the standby system is a generator set inside a building, the system shall be located in a separate room enclosed with 2-hour *fire barriers* constructed in accordance with Section 707 of the *International Building Code* or *horizontal assemblies* constructed in accordance with Section 711 of the *International Building Code*, or both. System supervision with manual start and transfer features shall be provided at the *fire command center*.~~

~~**604.2.14.1.1 Fuel supply.** An on-premises fuel supply, sufficient for not less than 2-hour full-demand operation of the system, shall be provided.~~
~~**Exception:** When *approved*, the system shall be allowed to be supplied by natural gas pipelines.~~

~~**604.2.14.1.2 Capacity.** The standby system shall have a capacity and rating that supplies all equipment required to be operational at the same time. The generating capacity is not required to be sized to operate all of the connected electrical equipment simultaneously.~~

~~**604.2.14.1.3 Connected facilities.** Power and lighting facilities for the *fire command center* and elevators specified in Sections 403.4.8.2 and 403.6 of the *International Building Code*, as applicable, shall be transferable to the standby source. Standby power shall be provided for at least one elevator to serve all floors and be transferable to any elevator.~~

~~**604.2.14.2 Separate circuits and luminaires.** Separate lighting circuits and luminaires shall be required to provide sufficient light with an intensity of not less than 1 footcandle (11 lux) measured at floor level in all *means of egress corridors*, *stairways*, smokeproof enclosures, elevator cars and lobbies, and other areas that are clearly a part of the escape route.~~

~~**604.2.14.2.1 Other circuits.** Circuits supplying lighting for the *fire command center* and mechanical equipment rooms shall be transferable to the standby source.~~

~~**604.2.14.3 Emergency systems.** *Exit* signs, *exit* illumination as required by Chapter 10, electrically powered fire pumps required to maintain pressure, and elevator car lighting are classified as emergency systems and shall operate within 10 seconds of failure of the normal power supply and shall be capable of being transferred to the standby source.~~

> ~~**Exception:** *Exit* sign, *exit* and *means of egress* illumination are permitted to be powered by a standby source in buildings of Group F and S occupancies.~~

UNDERGROUND BUILDINGS

NOTE: *The normal convention for portraying code changes to duplicated texts is by showing the parallel section numbers (e.g., "**907.5.2 (IBC [F] 907.5.2)**" or "**1011.6.3 (IFC [B] 1011.6.3**"). In this code change, however, for improved clarity, duplicate texts are shown for each code in this part.*

Revise the IBC as follows:

[F] 405.8 Standby and emergency power. A standby power system complying with Section 2702 ~~Chapter 27~~ shall be provided for the standby power loads specified in Section 405.8.1. An emergency power system complying with Section 2702 shall be provided for the emergency power loads specified in Section 405.8.2.

[F] 405.8.1 Standby power loads. The following loads are classified as standby power loads:

1. Smoke control system.
2. *Ventilation* and automatic fire detection equipment for *smokeproof enclosures.*
3. Fire pumps.
4. ~~Standby power shall be provided for e~~Elevators, as required in ~~in accordance with~~ Section 3003.

[F] ~~405.8.2 Pick-up time.~~ ~~The standby power system shall pick up its connected loads within 60 seconds of failure of the normal power supply.~~

[F] ~~405.9 Emergency power.~~ ~~An emergency power system complying with Chapter 27 shall be provided for emergency power loads specified in Section 405.9.1.~~

[F] ~~405.9.1~~ 405.8.2 Emergency power loads. The following loads are classified as emergency power loads:

1. through 5. *(No change to current text.)*

[F] 2702.2.16 Underground buildings. Emergency and standby power shall be provided in underground buildings as required in ~~in accordance with~~ Sections 405~~.8 and 405.9~~.

Revise the IFC as follows:

604.2.15 Underground buildings. Emergency and standby power ~~systems~~ shall be provided in underground buildings ~~covered~~ as required in ~~Chapter 4~~ Section 405 of the *International Building Code* ~~shall comply with Sections 604.2.15.1 and 604.2.15.2.~~ and shall be in accordance with Section 604.

~~**604.2.15.1 Standby power.** A standby power system complying with this section and NFPA 70 shall be provided for standby power loads as specified in Section 604.2.15.1.1.~~

~~**604.2.15.1.1 Standby power loads.** The following loads are classified as standby power loads:~~

1. ~~Smoke control system.~~
2. ~~Ventilation and automatic fire detection equipment for smokeproof enclosures.~~
3. ~~Fire pumps.~~
4. ~~Standby power shall be provided for elevators in accordance with Section 3003 of the *International Building Code*.~~

~~**604.2.15.1.2 Pickup time.** The standby power system shall pick up its connected loads within 60 seconds of failure of the normal power supply.~~

~~**604.2.15.2 Emergency power.** An emergency power system complying with this code and NFPA 70 shall be provided for emergency power loads as specified in Section 604.2.15.2.1.~~

~~**604.2.15.2.1 Emergency power loads.** The following loads are classified as emergency power loads:~~

1. ~~Emergency voice/alarm communication systems.~~
2. ~~Fire alarm systems.~~
3. ~~Automatic fire detection systems.~~
4. ~~Elevator car lighting.~~
5. ~~*Means of egress* lighting and *exit* sign illumination as required by Chapter 10.~~

GROUP I-3 OCCUPANCY DOOR LOCKS

NOTE: *The normal convention for portraying code changes to duplicated texts is by showing the parallel section numbers (e.g., "**907.5.2 (IBC [F] 907.5.2)**" or "**1011.6.3 (IFC [B] 1011.6.3**"). In this code change, however, for improved clarity, duplicate texts are shown for each code in this part. See Part XX for this subject in the IEBC.*

Revise the IBC as follows:

[F] 408.4.2 Power-operated doors and locks. Power-operated sliding doors or power-operated locks for swinging doors shall be operable by a manual release mechanism at
the door<u>. Emergency power shall be provided for the doors and locks in accordance with Section 2702.</u>
~~and either emergency power or a remote mechanical operating release shall be provided.~~

Exception<u>s</u>:

1. Emergency power is not required in facilities with 10 or fewer locks complying with the exception to Section 408.4.1.
2. <u>Emergency power is not required when remote mechanical operating releases are provided.</u>

[F] 2702.2.17 Group I-3 occupancies. Emergency power shall be provided for <u>power operated</u> doors <u>and locks</u> in Group I-3 occupancies <u>as required in</u> ~~in accordance with~~ Section 408.4.2.

Revise the IFC as follows:

604.2.16 Group I-3 occupancies. Power-operated sliding doors or power-operated locks for swinging doors shall be operable by a manual release mechanism at
the door<u>. Emergency power shall be provided for the doors and locks in accordance with Section 604.</u>
~~and either emergency power or a remote mechanical operating release shall be provided.~~

Exception<u>s</u>:

1. Emergency power is not required in facilities with 10 or fewer locks complying with the exception to Section 408.4.1.
2. <u>Emergency power is not required when remote mechanical operating releases are provided.</u>

AIRPORT TRAFFIC CONTROL TOWERS

NOTE: *The normal convention for portraying code changes to duplicated texts is by showing the parallel section numbers (e.g., "**907.5.2 (IBC [F] 907.5.2)**" or "**1011.6.3 (IFC [B] 1011.6.3**"). In this code change, however, for improved clarity, duplicate texts are shown for each code in this part.*

Revise the IBC as follows:

~~**[F] 2702.2.18 Airport traffic control towers.** Standby power shall be provided in airport traffic control towers in accordance with Section 412.3.4.~~

~~**[F] 412.3.4 Standby power.** A standby power system that conforms to Chapter 27 shall be provided in airport traffic control towers more than 65 feet (19 812 mm) in height.~~
~~Power shall be provided to the following equipment:~~

1. ~~Pressurization equipment, mechanical equipment and lighting.~~
2. ~~Elevator operating equipment.~~
3. ~~*Fire alarm* and smoke detection systems.~~

Revise the IFC as follows:

~~**604.2.17 Airport traffic control towers.** A standby power system shall be provided in airport traffic control towers more than 65 feet (19 812 mm) in height. Power shall be provided to the following equipment:~~

1. ~~Pressurization equipment, mechanical equipment and lighting.~~
2. ~~Elevator operating equipment.~~
3. ~~Fire alarm and smoke detection systems.~~

SMOKE ALARMS

NOTE: *The normal convention for portraying code changes to duplicated texts is by showing the parallel section numbers (e.g., "**907.5.2 (IBC [F] 907.5.2)**" or "**1011.6.3 (IFC [B] 1011.6.3**"). In this code change, however, for improved clarity, duplicate texts are shown for each code in this part.*

Revise the IBC as follows:

[F] 907.2.11.4 Power source. In new construction, required smoke alarms shall receive their primary power from the building wiring where such wiring is served from a commercial source and shall be equipped with a battery backup. Smoke alarms with integral strobes that are not equipped with battery backup shall be connected to an emergency electrical system<u> in accordance with Section 2702</u>. Smoke alarms shall emit a signal when the batteries are low. Wiring shall be permanent and without a disconnecting switch other than as required for overcurrent protection.

> **Exception:** Smoke alarms are not required to be equipped with battery backup where they are connected to an emergency electrical system <u>that complies with Section 2702.</u>

Revise the IFC as follows:

907.2.11.4 Power source. In new construction, required smoke alarms shall receive their primary power from the building wiring where such wiring is served from a commercial source and shall be equipped with a battery backup. Smoke alarms with integral strobes that are not equipped with battery back-up shall be connected to an emergency electrical system <u>in accordance with Section 604</u>. Smoke alarms shall emit a signal when the batteries are low. Wiring shall be permanent and without a disconnecting switch other than as required for overcurrent protection.

> **Exception:** Smoke alarms are not required to be equipped with battery backup where they are connected to an emergency electrical system <u>that complies with Section 604.</u>

EMERGENCY ALARM SYSTEMS

NOTE: *The normal convention for portraying code changes to duplicated texts is by showing the parallel section numbers (e.g., "**907.5.2 (IBC [F] 907.5.2)**" or "**1011.6.3 (IFC [B] 1011.6.3**"). In this code change, however, for improved clarity, duplicate texts are shown for each code in this part.*

Revise the IBC as follows:

[F] <u>**414.7.4 Emergency alarm systems.** *Emergency alarm systems* shall be provided with emergency power in accordance with Section 2702.</u>

[F] <u>**2702.2.21 Emergency alarm systems.** Emergency power shall be provided for emergency alarm systems as required by Section 414.7.4.</u>

Revise the IFC as follows:

604.2.19 Emergency alarm systems. Emergency power shall be provided for emergency alarm systems as required by Section 414 of the International Building Code.

EMERGENCY RESPONDER RADIO COVERAGE SYSTEMS

NOTE: *The normal convention for portraying code changes to duplicated texts is by showing the parallel section numbers (e.g., "**907.5.2 (IBC [F] 907.5.2)**" or "**1011.6.3 (IFC [B] 1011.6.3**"). In this code change, however, for improved clarity, duplicate texts are shown for each code in this part.*

Add a new Section 2702.2.21 to the IBC as follows:

[F] 2702.2.21 Emergency responder radio coverage systems. Standby power shall be provided for emergency responder radio coverage systems required in Section 915 and the *International Fire Code*. The standby power supply shall be capable of operating the emergency responder radio coverage system for a duration of not less than 24 hours.

Revise the IFC as follows:

510.4.2.3 Standby power. ~~Secondary power.~~ Emergency responder radio coverage systems shall be provided with ~~an *approved* secondary source of~~ standby power in accordance with Section 604. The ~~secondary~~ standby power supply shall be capable of operating the emergency responder radio coverage system for a ~~period of at least~~ duration of not less than 24 hours. ~~When primary power is lost, the power supply to the emergency responder radio coverage system shall automatically transfer to the secondary power supply.~~

604.2.19 Emergency responder radio coverage systems. Standby power shall be provided for emergency responder radio coverage systems as required in Section 510.4.2.3. The standby power supply shall be capable of operating the emergency responder radio coverage system for a duration of not less than 24 hours.

FLARING SYSTEMS FOR MECHANICAL REFRIGERATION

Revise the IFC as follows:

606.12.5 Flaring systems. Flaring systems for incineration of flammable refrigerants shall be designed to incinerate the entire discharge. The products of refrigerant incineration shall not pose health or environmental hazards. Incineration shall be automatic upon initiation of discharge, shall be designed to prevent blowback and shall not expose structures or materials to threat of fire. Standby fuel, such as LP gas, and standby power shall have the capacity to operate for one and one-half the required time for complete incineration of refrigerant in the system. Standby electrical power, where required to complete the incineration process, shall be in accordance with Section 604.

WATER SUPPLY POWER

Revise the IWUIC as follows:

404.10.3 Standby power. Standby power shall be provided to pumps, controllers and related electrical equipment so that ~~S~~stationary water supply facilities within the *wildland-urban interface area* that are dependent on electrical power can provide the required ~~to meet adequate~~ water supply. The standby power system shall be ~~demands shall provide standby power systems~~ in accordance with Section 2702 ~~Chapter 27~~ of the *International Building Code*~~,~~ and Section 604 of the *International Fire Code.* ~~and NFPA 70 to ensure that an uninterrupted water supply is maintained.~~ The standby power source shall be capable of providing power for a minimum of two hours.

Exceptions: *(No change to current text.)*

Reason: This proposal is submitted by the ICC Fire Code Action Committee (FCAC). This ICC committee was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portions thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the Fire-CAC has held 6 open meetings and numerous Regional Work Group and Task Group meetings and conference calls which included members of the committees as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the FAC website at: http://www.iccsafe.org/cs/CAC/Pages/default.aspx.
This proposal is part of a comprehensive rewrite of the I-Codes emergency and standby power requirements. Some edits are made to provide consistency in how standby power is referenced in the codes.

Part I - INTERNATIONAL FIRE CODE

Emergency voice/alarm communication systems: Emergency voice/alarm communication systems are required to include an emergency power source in IBC/IFC Section 907.5.2.2.5. A reference to these systems has been added to IBC 2702.2 and IFC 604.2. With the addition of this requirement it is no longer necessary to indicate that these systems are required in covered malls and Group A occupancies, which are just two of the many occupancies and building types that require emergency voice/alarm communication systems.
All reference in the IFC and IBC to emergency voice/alarm communication systems requires them to be provided with a source of emergency power, except for IBC Section 402.7.3. This oversight was corrected.

Smoke control systems: Smoke control systems are required to include a standby power source in IBC/IFC Section 909.11. In addition the IBC requires standby power to be provided for smoke control systems or components of the systems in Sections 404.7, 909.20.6.2, and 909.21.5. A reference to these section have been added to IBC 2702.2.
By referencing section 909.20.6.2 in Section 2702.2.2, it is no longer necessary to include Section 2702.2.20 smokeproof enclosure reference.
IBC/IFC 909.11and IMC 513.11 were rather lengthy and included requirements for standby power equipment rooms. These were broken off and put in Section 909.11.1 and 513.11.1. The reference to automatically transferring to standby power within 60 seconds is included in a separate code proposal for Sections 2702.1 and 604.1, and does not need to be repeated here.

Exit signs: The proposal updates references to emergency power requirements by including the appropriate IFC and IBC code sections that specify requirements for emergency power supply and operation of Exit Signs.

Means of egress illumination: Details on system components in 1006.3.1 have been eliminated because these are covered in the revised IFC Section 604.1 and IBC Section 2702.1 requirements. The last part of IFC Section 1006.3 was renumbered 1006.3.1 to match the format used in the equivalent IBC requirements.

Elevators and platform lifts: In IBC Section 2702.2 and IFC Section 604.2, references to three types of elevators or platform lifts were consolidated into a single reference to elevators and platform lifts.
Requirements for the specific rating of the standby systems required in 3007.9 and 3008.9 were removed since they are covered under another comprehensive rewrite of IBC Section 2702.1 and IFC Section 604.1.
Elevator requirements in IFC Section 604.2.18 were relocated to IFC Section 607, which covers similar elevator requirements.

Horizontal sliding doors: The requirement for the standby power supply to have a capacity to operate a minimum of 50 opening and closing cycles of the door is based on requirements in NFPA 80, Section 9.4.2.2.2.

Membrane structures: The IBC and IFC require auxiliary inflation systems to be provided for air-supported and air-inflated membrane structures. (The IBC covers permanent membrane structures and the IFC covers temporary membrane structures). The differences are that permanent air-inflated membrane structures include standby power as covered by Section 2702 of the IBC. Temporary air-inflated membrane structures are required to include an automatic engine-generator set or a blower powered by an internal combustion engine to serve as an auxiliary inflation system in the event of a commercial power failure. These are not required to be permanently installed.

Semiconductor fabrication facilities: Automatic fire alarm systems are required to be provided with emergency power, which is consistent with NFPA 72.

Hazardous materials: Reference in Section 2702 of the IBC for emergency power for pyrophoric materials to be provided in accordance with the IFC was removed since backup power is not required in IFC Chapter 64.
IBC Section 414.5.3 and IFC Section 5004.7 were reformatted with no substantive changes to the systems that do not require emergency or standby power and fail-safe engineered systems.
In IBC Section 414.5.3 the requirements to provide emergency power for ventilation systems required by the IBC (or this code) were removed. This eliminates the need to provide emergency power for normal building ventilation systems as required by Section 1203. In looking at the hazardous material related systems that require a secondary power source, they all fall under the definition of emergency power system as included in NFPA 110. Therefore reference to standby power was removed from this section.
References for emergency power were added to Sections 53, 54, 55, 57, 61 and 63 since these sections include requirements for system that require emergency power per Section 5001.3.3.10.

High rise buildings: The scope of IFC Section 604 covers emergency and standby power system, and yet sections 604.2.14.1 through 604.2.14.3 either duplicated requirements in revised Section 604.1, (covered under a separate proposal), or covered electrical system components that are not part of the standby or emergency power system. These requirements were eliminated. If the desire is to include these systems in the IFC they should be placed in a more appropriate location.

Underground buildings: Sections 604.2.15.1 through 604.2.15.2.1 duplicate some, but not all of the IBC requirements for underground buildings, and were therefore eliminated. If the desire is to include these details in the IFC they should be added in their entirety.

Group I-3 occupancy door locks: The proposal updates references to emergency power requirements by including the appropriate IFC and IFC code sections that specify requirements for emergency power supply and operation of power-operated door locks.

Airport traffic control towers: There is no reason to call out emergency and standby power requirements for aircraft traffic control towers. These requirements are specified for the types of electrical systems that will be provided, such as exit signs, egress illumination, elevators, smoke control, etc. In addition there is an error in some of the criteria since emergency power is required for fire alarm and smoke detection equipment and lighting of the means of egress. If the desire is to include a list of all possible emergency and standby power loads that can be included in these towers that can be done.

Smoke alarms: The proposal updates references to emergency power requirements by including the appropriate IFC and IBC code sections that specify requirements for emergency power supply and operation of Smoke Alarms.

Emergency alarms systems: Emergency power for emergency alarm systems is not currently required in either the IBC or the IFC, but it should be, based on the proposed definition of emergency power system.

Emergency responder radio coverage systems: Reference to standby power for emergency responder radio coverage systems was inadvertently left out of IBC Section 2702 and IFC Section 604.

Flaring systems for mechanical refrigeration: The proposal updates references to emergency power requirements by including the appropriate IFC code sections that specify requirements for emergency power supply and operation of flaring systems for mechanical refrigeration.

Clothes dryer exhaust systems: The proposal updates IMC references to stand-by power requirements by including the appropriate IBC code sections that specify requirements for stand-by power supply and operation of clothes dryer exhaust systems.

Water supply power: The proposal updates IWUI references to stand-by power requirements for pumps, controllers and related electrical equipment so that stationary water supply facilities within the *wildland-urban interface* by including the appropriate IFC and IBC code sections that specify requirements for stand-by power supply and operation of specified water supply equipment.

Cost Impact: This code change will increase the cost of construction

604.2.1(NEW)-F-ZUBIA-FCAC

Committee Action Hearing Results

PART I – IFC
Committee Action: Approved as Modified

Modify the proposal as follows:

HIGH-RISE BUILDINGS

IBC [F] 403.4.8.1 Equipment room. If the standby or emergency power system includes a generator set inside a building, the system shall be located in a separate room enclosed with 2-hour *fire barriers* constructed in accordance with Section 707 or *horizontal assemblies* constructed in accordance with Section 711, or both. System supervision with manual start and transfer features shall be provided at the *fire command center*.

> <u>**Exception:** In Group I-2 Condition 2, manual start and transfer features for the critical branch of the emergency power are not required to be provided at the fire command center.</u>

(Portions of the proposal not shown remain unchanged.)

Committee Reason: The committee approved the code change based on the proponent's reason statement and agreed that the proposal accomplishes much needed revisions and clarifications to the emergency and standby power system requirements. The modification leaves the control of critical circuits in the hands of the hospital engineers.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

[F] 414.5.3 Emergency or standby power. Where required by the International Fire Code or this code mechanical *ventilation*, treatment systems, temperature control, alarm, detection or other electrically operated systems ~~are required by the *International Fire Code* or this code, such systems~~ shall be provided with an emergency or standby power system in accordance with Section 2702.

(Portions of proposal not shown remain unchanged.)

Commenter's Reason: This proposal is submitted by the ICC Fire Code Action Committee (FCAC). This ICC committee was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portions thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the Fire-CAC has held 6 open meetings and numerous Regional Work Group and Task Group meetings and conference calls which included members of the committees as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the FAC website at: http://www.iccsafe.org/cs/CAC/Pages/default.aspx.

This public comment clarifies that mechanical ventilation, treatment systems, temperature control, alarm, detection or other electrically operated systems are only to be provided with an emergency or standby power system where required by the IFC or elsewhere in the IBC.

F59-13, Part I

Final Action: AS AM AMPC____ D

F59-13, Part II

604 (IBC [F] 2702) among others; 907.5.2.2.5 (IBC [F] 907.5.2.2.5); IMC [F] 513.11, [F]513.11.1 (New); IWUIC 404.10.3; IEBC 805.4.5

Proposed Change as Submitted

Proponent: Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azubiamia@yahoo.com)

THIS IS A 2 PART CODE CHANGE. PART I WILL BE HEARD BY THE IFC COMMITTEE AND PART II WILL BE HEARD BY THE IEBC COMMITTEE AS TWO SEPARATE CODE CHANGES. SEE THE TENTATIVE HEARING ORDER FOR THOSE COMMITTEES.

PART II - INTERNATIONAL EXISTING BUILDING CODE

GROUP I-3 OCCUPANCY DOOR LOCKS

Revise the IEBC as follows:

IEBC 805.4.5 Emergency power source in Group I-3. Power-operated sliding doors or power-operated locks for swinging doors shall be operable by a manual release mechanism at the door. Emergency power shall be provided for the doors and locks in accordance with Section 2702 of the International Building Code.

Exceptions:

1. Emergency power is not required in facilities with 10 or fewer locks complying with the exception to Section 408.4.1.
2. Emergency power is not required where remote mechanical operating releases are provided.

~~Work areas in buildings of Group I-3 occupancy having remote power unlocking capability for more than 10 locks shall be provided with an emergency power source for such locks. Power shall be arranged to operate automatically upon failure of normal power within 10 seconds and for a duration of not less than 1 hour.~~

Reason: This proposal is submitted by the ICC Fire Code Action Committee (FCAC). This ICC committee was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portions thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the Fire-CAC has held 6 open meetings and numerous Regional Work Group and Task Group meetings and conference calls which included members of the committees as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the FAC website at: http://www.iccsafe.org/cs/CAC/Pages/default.aspx.
This proposal is part of a comprehensive rewrite of the I-Codes emergency and standby power requirements. Some edits are made to provide consistency in how standby power is referenced in the codes.

Part II - INTERNATIONAL EXISTING BUILDING CODE

Group I-3 occupancy door locks in the IEBC: The IEBC format was revised to more closely correlate with the IBC and IFC.

Cost Impact: This code change will increase the cost of construction

604.2.1(NEW)-F-ZUBIA-FCAC

Committee Action Hearing Results

PART II – IEBC
This code change was heard by the IEBC code development committee.

Committee Action: **Disapproved**

Committee Reason: This proposal was disapproved primarily related to concerns with references to sections not found in the IEBC. Specifically, exception 1 references Section 408.4.1 which is not found in the IEBC.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

IEBC 805.4.5 Emergency power source in Group I-3. Power-operated sliding doors or power-operated locks for swinging doors shall be operable by a manual release mechanism at the door. Emergency power shall be provided for the doors and locks in accordance with Section 2702 of the International Building Code.

Exceptions:

1. Emergency power is not required in facilities with 10 or fewer locks complying with the exception to Section 408.4.1 <u>of the International Building code.</u>
2. Emergency power is not required where remote mechanical operating releases are provided.

Commenter's Reason: This proposal is submitted by the ICC Fire Code Action Committee (FCAC). This ICC committee was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portions thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the Fire-CAC has held 6 open meetings and numerous Regional Work Group and Task Group meetings and conference calls which included members of the committees as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the FAC website at: http://www.iccsafe.org/cs/CAC/Pages/default.aspx.

The original proposal for F59, Part II was correctly disapproved because reference to the IBC was not included in Exception 1. This has been corrected in this public comment, which accomplishes the following:

1. Correlates the requirements for how emergency and standby power throughout the family of I-Codes so they are treated in a consistent manner.
2. Correlates the requirements for providing emergency power for power operated sliding doors or power operated locks for swinging doors with the requirements in IBC section 408.4.2, which was revised as part of proposal F59-13.

F59-13, Part II
Final Action: AS AM AMPC____ D

F62-13
605.11, 605.11.3, 605.11.3.2, 605.11.3.3

Proposed Change as Submitted

Proponent: Adolf Zubia. Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee (azubiamia@yahoo.com)

Revise as follows:

605.11 Solar photovoltaic power systems. Solar photovoltaic power systems shall be installed in accordance with Sections 605.11.1 through 605.11.4, the *International Building Code* and NFPA 70.

> ~~**Exception:** Detached, nonhabitable Group U structures including, but not limited to, parking shade structures, carports, solar trellises and similar structures shall not be subject to the requirements of this section.~~

605.11.3 Access and pathways. Roof access, pathways, and spacing requirements shall be provided in accordance with Sections 605.11.3.1 through 605.11.3.3.3.

> ~~**Exceptions:**~~
>
> 1. ~~Residential structures shall be designed so that each photovoltaic array is no greater than 150 feet (45 720 mm) by 150 feet (45 720 mm) in either axis.~~
> 2. ~~Panels/modules shall be permitted to be located up to the roof ridge where an alternative ventilation method approved by the fire chief has been provided or where the fire chief has determined vertical ventilation techniques will not be employed.~~
>
> **Exception:** Detached, nonhabitable Group U structures including, but not limited to, parking shade structures, carports, solar trellises and similar structures.

605.11.3.2 ~~Residential~~ Solar photovoltaic systems for one- and two-family dwellings. ~~Access to residential~~ Solar photovoltaic systems for one- and two-family dwellings shall ~~be provided in accordance~~ comply with Sections 605.11.3.2.1 through 605.11.3.2.~~4~~5.

605.11.3.2.1 Size of solar photovoltaic array. Each photovoltaic array shall be limited to 150 feet (45 720 mm) by 150 feet (45 720 mm). Multiple arrays shall be separated by a 3-foot-wide (914 mm) clear access pathway.

605.11.3.2.~~1~~2 ~~Residential buildings with hip~~ Hip roof layouts. Panels~~/~~ and modules installed on ~~residential buildings~~ one- and two-family dwellings with hip roof layouts shall be located in a manner that provides a 3-foot-wide (914 mm) clear access pathway from the eave to the ridge on each roof slope where panels~~/~~ and modules are located. The access pathway shall be located at a structurally strong location on the building capable of supporting the live load of fire fighters accessing the roof.

> **Exception:** These requirements shall not apply to roofs with slopes of two units vertical in 12 units horizontal (2:12) or less.

605.11.3.2.~~2~~3 ~~Residential buildings with a s~~Single ridge roofs. Panels~~/~~ and modules installed on ~~residential buildings~~ one- and two-family dwellings with a single ridge shall be located in a manner that provides two, 3-foot-wide (914 mm) access pathways from the eave to the ridge on each roof slope where panels~~/~~ and modules are located.

Exception: This requirement shall not apply to roofs with slopes of two units vertical in 12 units horizontal (2:12) or less.

605.11.3.2.~~3~~4 ~~Residential buildings with r~~Roofs with hips and valleys. Panels~~/~~ and modules installed on ~~residential buildings~~ one- and two-family dwellings with roof hips and valleys shall be located no closer than 18 inches (457 mm) to a hip or a valley where panels/modules are to be placed on both sides of a hip or valley. Where panels are to be located on only one side of a hip or valley that is of equal length, the panels shall be permitted to be placed directly adjacent to the hip or valley.

Exception: These requirements shall not apply to roofs with slopes of two units vertical in 12 units horizontal (2:12) or less.

605.11.3.2.~~4~~5 ~~Residential building~~ Allowance for smoke ventilation operations. Panels~~/~~ and modules installed on ~~residential buildings~~ one- and two-family dwellings shall be located no ~~higher~~ less than 3 feet (914 mm) ~~below~~ from the ridge in order to allow for fire department smoke ventilation operations.

Exception: Panels and modules shall be permitted to be located up to the roof ridge where an alternative ventilation method approved by the fire chief has been provided or where the fire chief has determined vertical ventilation techniques will not be employed.

605.11.3.3 Other than ~~residential buildings~~ one- and two-family dwellings. Access to systems for occupancies other than one- and two-family dwellings shall be provided in accordance with Sections 605.11.3.3.1 through 605.11.3.3.3.

Exception: Where it is determined by the fire code official that the roof configuration is similar to that of a one- or two-family dwelling, the residential access and ventilation requirements in Sections 605.11.3.2.1 through 605.11.3.2.4 shall be permitted to be used.

605.11.3.3.1 Access. There shall be a minimum 6-foot-wide (1829 mm) clear perimeter around the edges of the roof.

Exception: Where either axis of the building is 250 feet (76 200 mm) or less, ~~there~~ the clear perimeter around the edges of the roof shall be permitted to be reduced to a minimum 4-foot-wide (1290 mm) ~~clear perimeter around the edges of the roof~~.

Reason: This proposal is submitted by the ICC Fire Code Action Committee (FCAC). This ICC committee was established by the ICC Board of Directors to pursue opportunities to improve and enhance assigned International Codes or portions thereof. This includes both the technical aspects of the codes as well as the code content in terms of scope and application of referenced standards. Since its inception in July, 2011, the Fire-CAC has held 6 open meetings and numerous Regional Work Group and Task Group meetings and conference calls which included members of the committees as well as any interested party to discuss and debate the proposed changes. Related documentation and reports are posted on the FAC website at: http://www.iccsafe.org/cs/CAC/Pages/default.aspx.

This proposal is primarily an editorial clarification to Section 605.11.3. There is only one section which contains new text, it is Section 605.11.3.2.1. The sections and their revisions are noted below:

605.11 Exc:	This exception eliminates all requirements for solar PV systems located on Group U structures. This exception inadvertently eliminates the requirements for listing of components, marking and location of disconnects. This exception is relocated to Section 605.11.3 so that it only eliminates the requirements for access and pathways which will then retain the listing and marking requirements.
605.11.3 Exc 1:	This exception is actually a requirement; it is not an exception. Therefore, the exception is deleted and the text has been relocated to Section 605.11.3.2.1.
605.11.3 Exc 2:	This is an exception based on the need for the ability to vertically ventilate smoke through the roof. Section 605.11.3.2.5 (renumbered from 605.11.3.2.4) deals with smoke ventilation. The exception is intended to apply to a specific set of requirements regarding smoke ventilation. If the exception is left in this section, it exempts these systems from all of the requirements in this entire section. Therefore this exception has been relocated to Section 605.11.3.2.5.
605.11.3.2:	The title of this section is revised to correlate with the text of the section. The text only applies to one- and two-family dwellings so the term “residential” is removed from the title.

Also, the section is revised by deleting the reference to 'access' since the subsections deal with more than access, and additional access requirements are found in 605.11.3.1.
605.11.3.2.1: This section originates from 605.11.3 Exception 1. It is relocated to the section which applies to dwellings and is inserted as a requirement.

Additionally, the 2nd sentence is added as a new requirement. The current requirements limit the size of each PV array but provide no guidance as to the required separation between multiple PV arrays. This requirement fills that void by requiring a 3 foot separation between PV arrays. The 3 foot distance is the same spacing requirement found around PV arrays to the edge of roof or to the ridge of the roof, and provides for access around the arrays.

605.11.3.2.2: Renumbered from 605.11.3.2.1. The text is revised to correlate with the previous sections regarding one- and two-family dwellings.
605.11.3.2.3: Renumbered from 605.11.3.2.2. The text is revised to correlate with the previous sections regarding one- and two-family dwellings.
605.11.3.2.4: Renumbered from 605.11.3.2.3. The text is revised to correlate with the previous sections regarding one- and two-family dwellings.
605.11.3.2.5: Renumbered from 605.11.3.2.4. The text is revised to correlate with the previous sections regarding one- and two-family dwellings.

Additionally, the exception is added which was previously located in Section 605.11.3. This exception is based on the need for the ability to vertically ventilate smoke through the roof, and Section 605.11.3.2.5 deals with smoke ventilation.

605.11.3.3: The text is revised to correlate with the previous revisions regarding one- and two-family dwellings.
605.11.3.3.1: This exception is reworded into an actual exception which states that the required clearance is allowed to be reduced to 4', rather than requiring a clearance of 4'.

Cost Impact: This code change will not increase the cost of construction

605.11 #2-F-ZUBIA-FCAC

Committee Action Hearing Results

Committee Action: Approved as Submitted

Committee Reason: The committee agreed with the proponent's reason statement that the proposal is a needed editorial clean-up and minor technical improvement to the PV section that represents a collaborative effort of the fire service and the major subject stakeholders and results in a more logical presentation of the requirements.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Adolf Zubia, Chairman IAFC Fire and Life Safety Section, representing ICC Fire Code Action Committee, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

605.11 Solar photovoltaic power systems. Solar photovoltaic power systems shall be installed in accordance with Sections 605.11.1 through 605.11.3 ~~605.11.4~~, the *International Building Code* and NFPA 70.

605.11.1 ~~**605.11.3**~~ **Access and pathways.** Roof access, pathways, and spacing requirements shall be provided in accordance with Sections 605.11.1.1 through 605.11.1.3.3 ~~605.11.3.1 through 605.11.3.3.3~~.

Exceptions:

1. Detached, nonhabitable Group U structures including, but not limited to, parking shade structures, carports, solar trellises and similar structures.
2. Roof access, pathways, and spacing requirements need not be provided where the fire chief has determined rooftop operations will not be employed.

__**605.11.1.1**__ ~~**605.11.3.1**~~ **Roof access points.** Roof access points shall be located in areas that do not require the placement of ground ladders over openings such as windows or doors, and located at strong points of building construction in locations where the access point does not conflict with overhead obstructions such as tree limbs, wires, or signs.

__**605.11.1.2**__ ~~**605.11.3.2**~~ **Solar photovoltaic systems for Group R-3 buildings.** Solar photovoltaic systems for Group R-3 buildings shall comply with Sections 605.11.3.2.1 through 605.11.3.2.4.

> **Exception:** These requirements shall not apply to structures designed and constructed in accordance with the International Residential Code.

__**605.11.1.2.1**__ ~~**605.11.3.2.1**~~ **Size of solar photovoltaic array.** Each photovoltaic array shall be limited to 150 feet (45 720 mm) by 150 feet (45 720 mm). Multiple arrays shall be separated by a 3-foot-wide (914 mm) clear access pathway.

__**605.11.1.2.2**__ ~~**605.11.3.2.2**~~ **Hip roof layouts.** Panels and modules installed on __Group R-3 buildings__ ~~one- and two-family dwellings~~ with hip roof layouts shall be located in a manner that provides a 3-foot-wide (914 mm) clear access pathway from the eave to the ridge on each roof slope where panels and modules are located. The access pathway shall be located at a location on the building capable of supporting the live load of fire fighters accessing the roof.

> **Exception:** These requirements shall not apply to roofs with slopes of two units vertical in 12 units horizontal (2:12) or less.
