> Review the recommendations issued by NIST in its report entitled "Final Report on the Collapse of the World Trade Center Towers", issued September 2005, for applicability to the building environment as regulated by the I-Codes. To evaluate the necessity of developing code changes in response to the NIST report.

The current provisions for minimum bond strength were added to the code via G68-06/97. The following is the committees reason for inclusion:

Committee Reason: Although the data which provides technical support was not provided within the proposal, this does go along with the NIST recommendations and should provide better safety in high-rise buildings. Using the greater bond strengths will increase the probability that the protection will stay in place and will reduce the likelihood of being dislodged. These factors should provide for a longer time of safety. Placing the requirements in the high-rise provisions of Chapter 4 instead of within Chapter 7 makes sense because they are only applicable to high-rises and will be more likely to be found within that section. The committee did agree with the different bond strength requirements based upon the thought the taller buildings are at a higher risk and that items such as the vibration of tall buildings will affect the long term performance. Based on testimony which was provided, the cost impact of this requirement was considered as being relatively small. The higher density products which are currently available will generally meet these requirements. The modifications included a revision of the terminology "spray applied" to "sprayed" to be consistent with the action of FS156-06/07 and to create a more global point of reference for building height by moving footnote a to the main title of the first column.

In submitting a public comment to G69-07/08 last cycle to remove the minimimum and retain the 150 psf in Chapter 17, CTC noted that the current provisions for minimum bond strength were the results of G68-06/07 last cycle. As noted in the reason statement for the code change, it notes "The purpose of this proposal is to increase the required adhesions of Spray Applied Fire Resistant Materials (SFRM)." The proposal further sites Recommendation 6 of the NIST WTC report which calls for improvement of the in-place performance of SFRM. NIST Recommendation 6 reads as follows:

NIST recommends the development of criteria, test methods, and standards: (1) for the in-service performance of sprayed fire-resistive materials (SFRM, also commonly referred to as fireproofing or insulation) used to protect structural components; and (2) to ensure that these materials, as-installed, conform to conditions in tests used to establish the fire resistance rating of components, assemblies, and systems.

The CTC notes that the prior to the approval of the increased bond strength in Table 403.15 that the code mandated cohesive/adhesive bond strength, regardless of height, was 150 psf in Section 1704.10.5. In fact, this section has remained unchanged and was not coordinated with the new provisions in Table 403.15.

Based on input received by the CTC, the CTC position remains that the bond strength should not be increased as a function of height. As noted in the NIST recommendation, the concern is one of in-service performance of the SFRM which means the material must remain in place to perform its intended function, regardless of height. This is an inspection related issue, one for which the CTC submitted code change S39-06/07 to improve the inspection provisions, including:

Increased number of sampling locations

Specific sampling for columns, beams, joists and trusses

Physical and visual tests for: substrates; thickness; density, bond strength

S39-06/07 was approved and the provisions will be incorporated in the 2009 edition of the IBC.

There is no credible technical evidence or documented experience to indicate that the increased minimum bond strength requirements specified in the subject text and Table improve the long term durability of sprayed fire –resistive materials (SFRM) in high-rise buildings or improve the chances of SFRM to be in place when it is needed (in the event of a fire). The single proven effect of these increased bond provisions is to dramatically increase the SFRM installed cost by up to 250%. SFRM minimum bond strength of 150 psf (Section 1704.12.6), in conjunction with inspections and field tests, specified in Section 1704.12, are adequate to ensure SFRM is in place after completion of the construction phase. Regular inspections and timely repairs are needed to ensure SFRM in-place condition over the life of the building, regardless of the bond strength of SFRM.

A survey of the commercially available SFRM products in terms of their bond strength and density, conducted by the American Iron and Steel Institute (AISI) in 2007 clearly indicates that the provisions in Section 403.2.4 and Table 403.2.4 are specifically calibrated and targeted to ban standard-density SFRM products from the high-rise market – i.e., these provisions create an artificial commercial barrier, but do not address any measurable risks or safety concerns tied to any meaningful bond strength values (in terms of SFRM in-place durability).

The current provisions in Section 403.2.4and Table 403.2.4 resulted from proposal G68-06/07 (and further slightly modified by proposal G68-07/08), based on misleading technical information and flawed cost impact analysis provided in the proposal and relevant testimonies during the public hearings:

G68-06/07 reason statement suggested "building sway" as a "known" "initiating event" for SFRM dislodgement. Testimony during the public hearings also suggested building vibration as a possible cause for SFRM dislodgement. To date, no evidence has been found to document either of these claims.

G68-06/07 reason statement noted that "The purpose of this proposal is to increase the required adhesions of Spray Applied Fire Resistant Materials (SFRM)", seeking to achieve the improvements called for in Recommendation 6 of NIST WTC Report. Testimonies during the hearings further suggested that proposal G68-06/07 is somehow based on NIST WTC Investigation and its recommendations. In fact, NIST Recommendation 6 reads as follows:

"NIST recommends the development of criteria, test methods, and standards: (1) for the in-service performance of sprayed fire-resistive materials (SFRM, also commonly referred to as fireproofing insulation) used to protect structural components; and (2) to ensure that these materials, as-installed, conform to conditions in tests used to establish the fire resistance rating of components, assemblies, and systems."

There is nothing in Recommendation 6, or in any other part of the NIST WTC Investigation Report, to justify the immediate need to arbitrarily increase the SFRM bond strength. Nothing in the published NIST report suggested that the SFRM bond strength was inadequate for any of the intended purposes. The compiled records actually indicated that WTC towers endured numerous fires prior to 9/11 with minimal or no structural damage. Nothing in the NIST Report suggested that any existing SFRM product with higher bond strength and/or higher density would have performed better, or would have changed the sequence or the outcome of events.

G68-06/07 proposal noted that "Many tall buildings already utilize these higher strength materials". However, in 2006, there was only one high-rise building known to utilize medium-density SFRM throughout the building (the reconstructed WTC 7), and the owner did it for understandable reasons In fact, the absence of long-term nation-wide experience with the "throughout" application of medium-density and high-density SFRM in high-rise buildings should be a cause for concern – due to the lack of long term data to support their use.

G68-06/07 offered flawed cost impact analysis stating that the associated cost increase will be only marginal. In fact, credible estimates for real projects indicated very significant cost increase for installed medium-density and high-density SFRM. Independent estimates by government agencies (reported in G69-07/08) indicated that minimum bond strength requirement of 430 psf increases the SFRM cost by over 50%, while the requirement of 1000 psf increases SFRM cost by about 170%. Other independent estimates in the 2007 AISI report show similar cost increases: by over 50% for medium-density SFRM, and by over 230% for high-density SFRM. These increases cannot be characterized as "marginal" or "relatively small". The cost impact of Table 403..2.4 provisions needs to be fully considered, and society's fire protection resources need to be effectively allocated in a meaningful way.

Several testimonies during the public hearing exploited the notion of standard-density SFRM dislodgement under its own weight for no apparent reason or due to the lack of bond strength. In fact, SFRM dislodgement are almost always linked to very specific reasons that are irrelevant to bond strength – over the building lifetime, the overwhelming majority of documented dislodgement cases are caused by direct contact/impact removals of SFRM associated with human activities such as construction, demolition, remodeling, testing, structural inspections, maintenance operations, electrical/mechanical installations, and also, associated with equipment failures, such as water leaks, improper elevator operations, and similar reasons. The information compiled in WTC Investigation Report NCSTAR 1-6A clearly illustrates typical cases, e.g.:

"Section 3.7 with photographs in Figures 3-5 through 3-10 states that, "There were many instances where SFRM had obviously been dislodged in the process of installing utilities. In some cases hardware was attached directly to the lower chords and SFRM was dislodged. These damaged areas should have been repaired when the various trades had completed their work". Section 3.7 also states that "the overall views of the trusses showed that regions of missing insulation were minor in extent when compared with the total area of applied SFRM".

Figure A-36 points to SFRM damage on trusses due to "tenant construction work" or "works over the years in the ceiling" by the Port Authority.

Figure A-37 points to SFRM damage on trusses "during demolition after tenants move out" as "ductwork, partitions, hangers, etc. are removed".

Figure A-38 points to SFRM "damaged by installation of new construction".

Figure A-39 points to SFRM "disturbed by remodeling operations"

Figure A-49 points to SFRM re-occurring "extensive damage" in the elevator shafts caused by "the slack condition in compensating cables, especially on shuttle cars, causing a chafing condition against finished spray-on fireproofing on structural steel within hoistways".

Figure A-56 and A-57 (excerpts from LERA reports dated 1993 and 1995) point to SFRM damage in elevator shafts due to "rubbing of the hoist cable against the face of column", or "due to testing purposes". In one instance, the LERA reports also point to the installation of bracket as the cause for missing fireproofing.

The entire compilation of maintenance and inspections documents in the published reports of NIST WTC Investigation does not contain a single case of SFRM dislodgement linked to the lack of SFRM bond strength, despite the fact that all structural steel and steel joists in WTC towers was primed (SFRM application over primed and/or painted steel is known to reduce bond strength).

Similar causes of SFRM dislodgement, irrelevant to bond strength, were reported in the 2007 AISI report of building architects and construction contractors to evaluate their use of SFRM and their experiences with it. This survey is more relevant to the initial construction and/or major renovation phases in buildings' lifetime, and identifies intentional removal of SFRM by construction trades as the primary cause of SFRM dislodgement.

In summary, the two leading causes of SFRM dislodgement during construction and maintenance of buildings are:

Primary cause - intentional removal of SFRM associated with human activities, such as construction, renovation, electrical/mechanical installations, testing, inspections, maintenance operations, etc. This type of SFRM dislodgement is completely irrelevant to SFRM bond strength. Only inspections and timely repairs could address intentional removal of SFRM.

Secondary cause - unintentional/accidental removal of SFRM associated with human activities and equipment failures. While the use of higher-density SFRM products could slightly reduce dislodgements associated with some accidental abuses, such as light abrasive actions and light impacts, existing medium-density and high-density SFRM products are still by far incapable to substantially reduce dislodgements or address all common causes of accidental removals (e.g. water leaks, repeated and stronger abrasive actions and impacts, etc). Concealment of SFRM-protected steel elements in protective envelopes (e.g. gypsum board) or behind suspended ceilings is the most effective way in avoiding accidental dislodgement due to most accidental impacts and abrasions. Again, only inspections and timely repairs could adequately address unintentional/accidental removal of SFRM.

Analysis of Proposed Change G68-06/07 to the 2006 Edition of IBC", by Farid Alfawakhiri, Ph.D., American Iron and Steel Institute, January 2007.

Carino et al, NIST NCSTAR 1- 6A, "Federal Building and Fire Safety Investigation of the World Trade Center Disaster: Passive Fire Protection", National Institute of Standards and Technology, September 2005 (available at http://wtc.nist.gov/).

Perry - In their approval of the new SFRM requirements during the 2006/2007 cycle, the Fire Safety Committee specifically noted that neither technical substantiation nor cost data had been provided to the committee. Last cycle (2007/2008), cost information was provided to the committee, clearly indicating that costs are far beyond the moderate 'incremental' increases alluded to by proponents last cycle. The Fire Safety Committee voted to maintain the increased SFRM bond strength provisions, "based on a lack of technical substantiation to take them out".

This committee is on record that they had no technical substantiation when they added this requirement to the code, yet they now will not remove the provisions unless they receive technical substantiation?

There is no evidence that arbitrarily tripling (from 150 psf to 430 psf) the bond strength of SFRM will provide any additional degree of safety in 75' tall buildings, and no evidence that increasing the bond strength by a factor of 7 (from 150 psf to 1000 psf) will provide any additional degree of safety in buildings >420' in height.

The extent of the cost impacts calculated by both GSA and the steel industry make it clear that the first response to this provision, if it remains, will be to look for alternatives. There has been no explanation from those touting the need for increasing SFRM bond strength for how a gypsum-board encased column (which can achieve the required hourly ratings) would compare to columns with any of the various types of SFRM.

Cost Impact: Heilstedt - The code change proposal will not increase the cost of construction.
Perry - The code change proposal will not increase the cost of construction. This change will decrease the cost of construction.

ICCFILENAME: HEILSTEDT-G6-403.2.4.doc

Public Hearing Results

Committee Action: Disapproved

Committee Reason: The committee's disapproval is based on the lack of substantiating data to show that bond strength failure is not an issue for SFRM. Further, this action provides for consistency with the committees action on G42-09/10.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Lawrence G. Perry, AIA, representing Building Owners and Managers Association (BOMA) International, requests Approval as Submitted.

Commenter's Reason: This code change should be approved for the following reasons:

1. This significant, costly change was made without any evidence that it will increase either building performance or life safety, with a misleading industry statement about the 'minimal' cost impact.
2. The CTC rationale to the original code change provides a lengthy explanation of the history of this issue, and the lack of technical substantiation.

Final Action: AS AM AMPC____ D

G43-09/10

403.3.3 (New), Table 508.2.5

Proposed Change as Submitted

Proponent: Wayne R. Jewell, CBO, City of Southfield, representing self

1. Add new text as follows:

403.3.3 **Fire Pump Room.** Fire pumps shall be located in rooms protected in accordance with Section 913.2.1.

2. Revise Table as follows:

TABLE 508.2.5
INCIDENTAL ACCOSSORY OCCUPANCIES

ROOM OR AREA	SEPARATION AND/OR PROTECTION
Furnace room where any piece of equipment is over 400,000 Btu per hour input	1 hour or provide automatic fire-extinguishing system
Rooms with boilers where the largest piece of equipment is over 15 psi and 10 horsepower	1 hour or provide automatic fire-extinguishing system
Refrigerant machinery room	1 hour or provide automatic sprinkler system
Hydrogen cut-off rooms, not classified as Group H	1-hour in Group B, F, M, S and U occupancies. 2-hour in Group A, E, I and R occupancies.
Incinerator rooms	2 hours and automatic sprinkler system
Paint shops, not classified as Group H, located in occupancies other than Group F	2 hours; or 1 hour and provide automatic fire-extinguishing system
Laboratories and vocational shops, not classified as Group H, located in Group E or I-2 occupancies	1 hour or provide automatic fire-extinguishing system
Laundry rooms over 100 square feet	1 hour or provide automatic fire-extinguishing system
Group I-3 cells equipped with padded surfaces	1 hour
Group I-2 waste and linen collection rooms	1 hour
Waste and linen collection rooms over 100 square feet	1 hour or provide automatic fire-extinguishing system
Stationary storage battery systems having a liquid electrolyte capacity of more than 50 gallons or a lithium-ion capacity of 1,000 pound used for facility standby power, emergency power or uninterrupted power supplies	1-hour in Group B, F, M, S and U occupancies. 2-hour in Group A, E, I and R occupancies
~~Rooms containing fire pumps in nonhigh-rise buildings~~	~~2 hours; or 1 hour and provide automatic sprinkler system throughout the building~~
~~Rooms containing fire pumps in high-rise buildings~~	~~2 hours~~

For SI: 1 square foot = 0.0929 m^2, 1 pound per square inch (psi) = 6.9 kPa, 1 British thermal unit (Btu) per hour = 0.293 watts, 1 horsepower = 746 watts, 1 gallon = 3.785 L.

Reason: Adding Section 403.3.3 provides a proper link to the protection requirements found in Section 913.2.1 added during the last cycle for a fire pump room in a high-rise building. Revising Table 508.2.5 in striking the two lines removes the confusion that could occur since all options under Section 508 are not required to use the provisions of the table, yet fire pumps can occur in the multiple types of buildings permitted under Section 508 and these protection provisions are required under all instances.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: JEWELL-G1-403.3.3 NEW

Public Hearing Results

Committee Action: Approval as Submitted

Committee Reason: The change relocates the requirements to the appropriate location in the code and removes redundant language.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jason Thompson, National Concrete Masonry Association (NCMA), representing Masonry Alliance for Codes and Standards (MACS), requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

403.3.3 Fire pump room. Fire pumps shall be located in rooms protected in accordance with Section 913.2.1.

TABLE 508.2.5
INCIDENTAL ACCESSORY OCCUPANCIES

ROOM OR AREA	SEPARATION AND/OR PROTECTION
Furnace room where any piece of equipment is over 400,000 Btu per hour input	1 hour or provide automatic fire-extinguishing system
Rooms with boilers where the larges piece of equipment is over 15 psi and 10 horsepower	1 hour or provide automatic fire-extinguishing system
Refrigerant machinery room	1 hour or provide automatic sprinkler system
Hydrogen cut-off rooms, not classified as Group H	1-hour in Group B, F, M, S, and U occupancies. 2-hour in Group A, E, I and R occupancies
Incinerator rooms	2 hours and automatic sprinkler system
Paint shops, not classified as Group H, located in occupancies other than Group F	2 hours; or 1 hour and provide automatic fire-extinguishing system
Laboratories and vocational shops, not classified as Group H, located in Group E or I-2 occupancies	1 hour or provide automatic fire-extinguishing system
Laundry rooms over 100 square feet	1 hour or provide automatic fire-extinguishing system
Group I-3 cells equipped with padded rooms	1 hour
Group I-2 waste and linen collection rooms	1 hour
Waste and linen collection rooms over 100 square feet	1 hour or provide automatic fire-extinguishing system
Stationary storage battery system having a liquid electrolyte capacity of more than 50 gallons or a lithium-ion capacity of 1,000 pound used for facility standby power, emergency power or uninterrupted power supplies	1-hour in Group B, F, M, S, and U occupancies. 2-hour in Group A, E, I and R occupancies
<u>Rooms containing fire pumps in buildings other than high-rise buildings</u>	<u>2 hours; or 1 hour and provide automatic sprinkler system throughout the building</u>
<u>Rooms containing fire pumps in high-rise buildings</u>	<u>2 hours</u>

For SI: 1 square foot = 0.0929m^2, 1 pound per square inch (psi) = 6.9 kPa, 1 British thermal unit (Btu) per hour = 0.293 watts, 1 horsepower = 746 watts, 1 gallon = 3.785 L.

Commenter's Reason: We agree with the proponent's addition of the new Section 403.3.3 Fire Pump Room which we believe will make the code more user friendly and provide for better enforcement of the requirements for fire pump rooms which are covered by Section 913.2.1. However, we do not agree with the proponent's deletion of the two entries at the end of Table 508.2.5 Incidental Accessory Occupancies addressing fire pumps in both high-rise and nonhigh-rise buildings.

The proponent indicates in his Reason statement that the reason for deleting the two lines in Table 508.2.5 is to remove the confusion that could occur since all options under Section 508 are not required to use the provisions of the table. We disagree with the proponent's statement in that regard. In our opinion, it is very clear that Section 508.2.5 Separation of Incidental Accessory Occupancies which references Table 508.2.5 Incidental Accessory Occupancies is applicable for all buildings under all cases for buildings of mixed use and occupancy, whether they use the nonseparated occupancy option in Section 508.3 or the separated occupancies option in Section 508.4. Specific incidental accessory occupancies listed in Table 508.2.5 are required to be separated and/or protected as specified regardless of the main occupancy or the other occupancies in the building. Thus, we have reinstated the two lines and made an editorial correction to the one entry by deleting the term "nonhigh-rise buildings" and substituting the term "buildings other than high-rise buildings" to be consistent with the terminology in Section 913.2.1.

Again, we believe these two lines in Table 508.2.5 make the code more user friendly and enforceable by providing specific guidance to the protection and/or separation of fire pump rooms in any buildings where they are installed which is consistent with the requirements in Section 913.2.1. Therefore, we believe the Class A voting members should approve this Public Comment for approval as modified of Code Change G43-09/10.

Final Action: AS AM AMPC____ D

G44-09/10, Part I
403.4.5, 403.4.8.1, 708.14.1, Chapter 35

Proposed Change as Submitted

Proponent: Gary Lewis, Chair, ICC Ad Hoc Committee on Terrorism-Resistant Buildings

Part I - IBC

1. Add new text as follows:

403.4.5 Video surveillance system. A video surveillance system installed in accordance with NFPA 731, shall be installed in each elevator lobby provided in accordance with Section 708.14.1 and at every fifth floor of each required stairway and connected to an approved, constantly attended station. The surveillance system shall not be required to provide positive visual recognition of individual persons.

(Renumber subsequent sections.)

2. Revise as follows

403.4.8.1 Emergency power loads. The following are classified as emergency power loads:

1. **Exit signs and *means of egress* illumination required by Chapter 10;**
2. **Elevator car lighting;**
3. **Emergency voice/alarm communications systems;**
4. **Automatic fire detection systems;**
5. **Video surveillance systems;**

~~5.~~6. **Fire alarm** systems; and
~~6.~~7. Electrically powered fire pumps.

708.14.1 Elevator lobby. An enclosed elevator lobby shall be provided at each floor where an elevator shaft enclosure connects more than three stories. The lobby enclosure shall separate the elevator shaft enclosure doors from each floor by fire partitions. In addition to the requirements of Section 709 for fire partitions, doors protecting openings in the elevator lobby enclosure walls shall also comply with Section 715.4.3 as required for corridor walls and penetrations of the elevator lobby enclosure by ducts and air transfer openings shall be protected as required for corridors in accordance with Section 716.5.4.1. Elevator lobbies shall have at least one means of egress complying with Chapter 10 and other provisions within this code. In high-rise buildings the elevator lobby shall be provided with a video surveillance system installed in accordance with NFPA 731.

Exceptions:

1. through 7. *(No change to exceptions)*

3. Add new standard to Chapter 35 as follows:

NFPA

731-2008 The Standard for the Installation of Electronic Premises Security Systems

Reason: This proposal adds new requirements to the code for high-rise buildings. The purpose of this change is to increase the ability of firefighters, and other emergency responders, to develop a clear picture of conditions throughout the building which will enable them to better manage evacuation, fire suppression and other emergency response activities. The purpose is also to enhance the safety of emergency responders by enabling them to maintain better situational awareness.

The National Institute of Standards and Technology's (NIST) report on the World Trade Center (WTC) tragedy amply documented the tactical and informational difficulties experienced by emergency responders and occupants during the WTC event. Similar difficulties occur in much smaller events and they place lives at risk.

The Code already requires many systems which enhance emergency responder and occupant awareness. Their use can be improved and they can be further supplemented. Recommendation 23 of the WTC Report specifically calls for:

> The establishment and implementation of detailed procedures and methods for gathering, processing, and delivering critical information through integration of relevant voice, video, graphical and written data to enhance situational awareness of all emergency responders.

This proposal seeks to improve responder awareness of conditions in the building to assist in management of an incident and improve the existing fire command center to enhance its value. Awareness is improved by requiring control center monitoring of video surveillance in stairway shafts and elevator lobbies. With the introduction of dedicated fire service elevators and occupant egress elevators into the IBC, the necessity of monitoring the status of the elevator lobbies becomes even more significant.

There will be those opponents that will claim that that the amount of information generated by the video monitoring in a large building will cause "information overload". They will question the ability of the staff in the fire command center to observe all of the required video feeds at once. In response to this, please be aware that there is commercial off-the-shelf "intelligent software" that is available such that the staff of the fire command center need not observe all of these feeds; the software is "event driven" and will select information that is pertinent and display just this information. This software is currently available off-the-shelf from companies such as Johnson Control and Honeywell. The Port Authority of New York and New Jersey is currently installing a system to monitor the perimeter of the Newark airport by the use of *ONE* video screen. Clearly the perimeter of this airport is substantially larger than the portions of the building that are required to be monitored as a result of this code change. By requiring these video feeds, the situational awareness of the staff in the fire command center is substantially increased. While researching the availability of this software, we were informed by Mr. Alan Reiss the building manager of the World Trade Center, that he was unaware of the magnitude of the event on September 11, 2001. In fact, he commented that the people at home watching the television had a better situational awareness than he did because of the lack of information available at the fire command center. This has to be changed and this proposal will change it.

Bottom line, the video monitoring system will provide fire and emergency responders' immediate information on the life safety condition and status of the areas noted. Having such ability will exceed any expense incurred for the installation of the video monitoring system - the expense is minor to the benefit of the system. (Note: Regardless of this requirement, electronic data access systems can be installed for a reasonable cost in most buildings today). A video monitoring system will provide fire and emergency responders with accurate and up to date information on the condition and activities of the given areas for emergency responders to make tactical decisions under emergency conditions. With that said, the TRB committee encourages consideration and support for this proposal.

Bibliography: National Institute of Standards & Technology, Final Report of the National Construction safety Team on the Collapses of the World Trade Center Towers. United States Government Printing Office: Washington, D.C. September 2005.

Referenced Standards
National Fire Protection Association Standard 731, the Standard for the Installation of Electronic Premises Security Systems

Cost Impact: The code change proposal will not increase the cost of construction. These proposed amendments will increase the cost of construction, but, the increase will be modest when viewed as a percentage of total construction costs.

Analysis: Review of the proposed new standard indicated that, in the opinion of ICC staff, the standard did comply with ICC standards criteria.

ICCFILENAME: LEWIS-G3-403.12.1.doc

Public Hearing Results

Part I - IBC

Committee Action: Disapproved

Committee Reason: The committee disapproved the proposal for a variety of reasons. The application to all high-rise buildings regardless of height was judged excessive. Providing surveillance every 5 floors did not provide very much situational awareness as intended by the proposal. Because there were so many exceptions for elevator lobbies, the effectiveness in those areas was uncertain. The occupant evacuation elevator requirements would provide communications in elevator lobbies, this system should be connected to the proposed system. There would be costs to installing such systems, especially as it relates to providing emergency power connections. The proponent should have provided more detailed cost impact information. Reference to the standard, while appropriate, was clear that the facial recognition was not required under the IBC provisions, but not for the reference contained in the IFC.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Gary Lewis, City of Summit, representing ICC Ad Hoc Committee on Terrorism Resistant Buildings, requests Approval as Modified by this Public Comment.

Replace proposal as follows:

403.4.5 Video surveillance systems. In buildings greater than 420 feet in height, a video surveillance system installed in accordance with NFPA 731 shall be installed. Video cameras shall be provided at every fifth floor in each required stairwell. The surveillance system shall not be required to provide positive visual recognition of individual persons.

(Renumber subsequent sections)

403.4.8.1 Emergency power loads. The following are classified as emergency power loads:

1. Exit signs and *means of egress* illumination required by Chapter 10;
2. Elevator car lighting;
3. Emergency voice/alarm communications systems;
4. Automatic fire detection systems;
5. Video surveillance systems required by this code;

~~5.~~ 6. Fire alarm systems;
~~6.~~ 7. Electrically powered fire pumps.

SECTION 3008
OCCUPANT EVACUATION ELEVATORS

3008.13 Two-way communication and video surveillance system. A two-way communication system and a video surveillance system shall be provided in each occupant elevator lobby for the purpose of initiating communication with the fire command center or an alternative location *approved* by the fire department.

3008.13.1 Design and installation. The two-way communication system shall include audible and visible signals and shall be designed and installed in accordance with the requirements of ICC 117.1.

3008.13.2 Instructions. Instructions for the use of the two-way communication system along with the location of the station shall be permanently located adjacent to each station. Signage shall comply with the ICC A117.1 requirements for visual characters.

3008.13.3 Video surveillance. Each elevator lobby shall be provided with a video surveillance system installed in accordance with NFPA 731. The surveillance system shall not be required to provide positive visual recognition of individual persons.

NFPA
731-2008 The Standard for the Installation of Electronic Premises Security Systems

Commenter's Reason: This proposal was disapproved by the Committee in Baltimore by a vote of 6-5. The Ad Hoc Committee continues to believe that emergency responders and incident commanders require enhanced situational awareness to properly manage evacuation, suppression and related emergency response activities.

Recommendation #23 of the National Institute of Standards and Technology (NIST) Final Report of the World Trade Center Disaster specifically calls for the "*establishment and implementation of detailed procedures and methods for gathering, processing and delivering critical information through integration of relevant voice, video, graphical and written data to enhance the situational awareness of all emergency responders*."

The disapproval from the Committee was based primarily on several issues raised at the hearing, and not an objection to the concept. The Ad Hoc Committee has revised this proposal twice in response to guidance from the General Committee and objectors, and has now further modified the language to meet all technical objections.

In response to comments by the Code Technology Committee, BOMA and a General Committee member, we have reduced the scope of the provision for stairway monitoring exclusively to apply to 'super' high-rise buildings in excess of 420' in height instead of all high-rise buildings pursuant to the Committee's stated reasons. The language of this modification also addresses the Committee's stated concern about elevator lobby exceptions.

In response to the cost issue, this public comment reduces the number of devices dramatically, by deleting the provision to provide surveillance at all elevator lobbies…..surveillance would only be mandated at every fifth floor in required stairwells and in occupant egress elevator lobbies, if provided. Remember, occupant egress elevators remain optional in the IBC. If utilized, the Ad Hoc Committee is convinced that incident commanders need real-time surveillance to understand whether building occupants are utilizing or waiting for elevator service. If such elevators are not provided, the cameras would not be required in those locations.

In response to earlier CTC objections, we have removed the requirement that the video signal be sent to a 'constantly attended location', in deference to those buildings that may not have 24-hour manned security. Instead, the provision would mandate the *capability* for monitoring all required video surveillance in the fire command center.

The issue of cost was raised some estimates indicate an overall 'system' cost at about $3,000 per device. That figure represents all associated costs, including the hardware, software, wiring, labor, general conditions, etc. While the Ad Hoc Committee believes this cost to be inflated. A 45-story building without egress elevators would require 27 devices under this proposal, with an attendant maximum cost of $81,000. By comparison, that equates to less than $0.10 per square foot on a typical 20,000 square foot per floor building, or less that one-tenth of one per-cent of the project construction cost.

In summary, NIST and the ICC's fire service members have attested that video monitoring of real-time building conditions are essential to timely and effective command decisions during an incident. The Ad Hoc Committee has refined this proposal and has focused the scope sufficiently such that all reasonable concerns have been met and the Committee petitions the membership for approval as modified herein.

Bibliography: National Institute of Standards and Technology, Final Report of the National Construction Safety Team on the Collapse of the World Trade Center Towers, United States Government Printing Office: Washington, D.C., September, 2005. Also, see wtc.nist.gov.

Referenced Standards:

Cost Impact: The proposed amendments represent a minor increase in the cost of construction for certain iconic structures.

TRB Funding Disclosure: Since the inception of the Ad Hoc-TRB Committee, the ICC has fully funded the travel expenses of the Committee Chair to present the code proposals developed by the Ad Hoc Committee. Given the current economic condition, the ICC is not able to fully fund travel expenses by the Committee Chair to present the TRB proposals to you. The National Institute of Standards and Technology, a federal agency in the U.S. Department of Commerce, through a grant to the National Institute of Building Sciences, has agreed to fund the TRB Chair's travel expense *deficit*….whatever amount ICC does *not* fund….with full disclosure to the ICC. NIST has not ever, nor would, play *any* role in the deliberations of the TRB Committee in our development of code change proposals. This is entirely consistent with ICC CP#28.

Public Comment 2:

Gary Lewis, City of Summit, representing ICC Ad Hoc Committee on Terrorism Resistant Buildings, requests Approval as Modified by this Public Comment.

Replace proposal as follows:

3007.6 Elevator system monitoring. The fire service access elevator shall be continuously monitored at the fire command center by a standard emergency service interface system meeting the requirements of NFPA 72. Each fire service access elevator lobby shall be provided with a video surveillance system installed in accordance with NFPA 731. The surveillance system shall not be required to provide positive visual recognition of individual persons.

NFPA
731-2008 The Standard for the Installation of Electronic Premises Security Systems

Commenter's Reason: Concerns expressed in Baltimore regarding the provisions for video surveillance included thresholds, cost and some confusion regarding the original proposed reference to elevator lobbies in Chapter 7, which contains certain exceptions. This public comment seeks to address all of those stated concerns and reasons for disapproval. The IBC General Committee issued a split 6-5 decision in favor of disapproval in Baltimore.

Recommendation #23 of the National Institute of Standards and Technology (NIST) Final Report of the World Trade Center Disaster specifically calls for the "*establishment and implementation of detailed procedures and methods for gathering, processing and delivering critical information through integration of relevant voice, video, graphical and written data to enhance the situational awareness of all emergency responders*."

The original G44-09/10 would have required video surveillance in *all* elevator lobbies of *all* high-rise buildings, which the Committee found excessive. The ICC Ad Hoc Committee on Terrorism Resistant Buildings reconsidered the matter and further refined the scope of lobby surveillance to the two critical needs: 1] occupant evacuation elevators if provided (see G44-09/10 TRB Public Comment #1), and 2] fire service access elevators.

Occupant evacuation elevators are an option, but the 2009 IBC now includes a first-ever provision that 'hardened' fire service access elevators be provided in all buildings greater than 120' in height. These elevators can and will be used for the transport of emergency responders and potentially building occupants in cases of emergency. Requiring video monitoring of the lobby spaces for such elevators will allow incident commanders to transmit real-time information about building conditions and occupant status to ascending responders, and will also serve as redundant protection to those responders in addition to the required communication systems.

Reference to the elevator lobby in Section 3007.6 as opposed to lobbies generally in Chapter 7 eliminates any application confusion from the original proposal.

Bibliography: National Institute of Standards and Technology, *Final Report of the National Construction Safety Team on the Collapse of the World Trade Center Towers*, United States Government Printing Office: Washington, D.C., September, 2005. Also, see wtc.nist.gov.

Referenced Standards:

National Fire Protection Association Standard 731, *Standard for the Installation of Electronic Premises Security Systems*

Cost Impact: This proposal does represent a minor increase in the cost of construction, but a portion of the cost is already absorbed in currently-required provision for continuous emergency system interface per NFPA 72, the balance representing less than two-tenths of one per cent of the project budget, a small price to pay for enhanced emergency responder and occupant life safety.

TRB Funding Disclosure: Since the inception of the Ad Hoc-TRB Committee, the ICC has fully funded the travel expenses of the Committee Chair to present the code proposals developed by the Ad Hoc Committee. Given the current economic condition, the ICC is not able to fully fund travel expenses by the Committee Chair to present the TRB proposals to you. The National Institute of Standards and Technology, a federal agency in the U.S. Department of Commerce, through a grant to the National Institute of Building Sciences, has agreed to fund the TRB Chair's travel expense *deficit*….whatever amount ICC does *not* fund….with full disclosure to the ICC. NIST has not ever, nor would, play *any* role in the deliberations of the TRB Committee in our development of code change proposals. This is entirely consistent with ICC CP#28.

Final Action: AS AM AMPC____ D

G44-09/10 Part II
IFC 508.1.5 (IBC [F] 911.1.5)

Proposed Change as Submitted

Proponent: Gary Lewis, Chair, representing ICC Ad Hoc Committee on Terrorism-Resistant Buildings

Revise as follows:

508.1.5 (IBC [F] 911.1.5) Required features. The fire-command center shall comply with NFPA 72 and shall contain the following features:

1. The emergency voice/alarm communication system control unit.
2. The fire department communications system.
3. Fire detection and alarm system annunciator.
4. Annunciator unit visually indicating the location of the elevators and whether they are operational.
5. Status indicators and controls for air handling systems.
6. The fire-fighter's control panel required by Section 909.16 for smoke control systems installed in the building.
7. Controls for unlocking stairway doors simultaneously.
8. Sprinkler valve and water-flow detector display panels.
9. Emergency and standby power status indicators.
10. A telephone for fire department use with controlled access to the public telephone system.
11. Fire pump status indicators.
12. Schematic building plans indicating the typical floor plan and detailing the building core, means of egress, fire protection systems, firefighting equipment and fire department access and the location of fire walls, fire barriers, fire partitions, smoke barriers and smoke partitions.
13. Work table.
14. Generator supervision devices, manual start and transfer features.
15. Public address system, where specifically required by other sections of this code.
16. Elevator fire recall switch in accordance with ASME A17.1.
17. Elevator emergency or standby power selector switch(es), where emergency or standby power is provided.
18. Video monitoring for video surveillance system required by this code.

Reason: This proposal adds new requirements to the code for high-rise buildings. The purpose of this change is to increase the ability of firefighters, and other emergency responders, to develop a clear picture of conditions throughout the building which will enable them to better manage evacuation, fire suppression and other emergency response activities. The purpose is also to enhance the safety of emergency responders by enabling them to maintain better situational awareness.

The National Institute of Standards and Technology's (NIST) report on the World Trade Center (WTC) tragedy amply documented the tactical and informational difficulties experienced by emergency responders and occupants during the WTC event. Similar difficulties occur in much smaller events and they place lives at risk.

The Code already requires many systems which enhance emergency responder and occupant awareness. Their use can be improved and they can be further supplemented. Recommendation 23 of the WTC Report specifically calls for:

> The establishment and implementation of detailed procedures and methods for gathering, processing, and delivering critical information through integration of relevant voice, video, graphical and written data to enhance situational awareness of all emergency responders.

This proposal seeks to improve responder awareness of conditions in the building to assist in management of an incident and improve the existing fire command center to enhance its value. Awareness is improved by requiring control center monitoring of video surveillance in stairway shafts and elevator lobbies. With the introduction of dedicated fire service elevators and occupant egress elevators into the IBC, the necessity of monitoring the status of the elevator lobbies becomes even more significant.

There will be those opponents that will claim that that the amount of information generated by the video monitoring in a large building will cause "information overload". They will question the ability of the staff in the fire command center to observe all of the required video feeds at once. In response to this, please be aware that there is commercial off-the-shelf "intelligent software" that is available such that the staff of the fire command center need not observe all of these feeds; the software is "event driven" and will select information that is pertinent and display just this information. This software is currently available off-the-shelf from companies such as Johnson Control and Honeywell. The Port Authority of New York and New Jersey is currently installing a system to monitor the perimeter of the Newark airport by the use of *ONE* video screen. Clearly the perimeter of this airport is substantially larger than the portions of the building that are required to be monitored as a result of this code change. By requiring these video feeds, the situational awareness of the staff in the fire command center is substantially increased. While researching the availability of this software, we were informed by Mr. Alan Reiss the building manager of the World Trade Center, that he was unaware of the magnitude of the event on September 11, 2001. In fact, he commented that the people at home watching the television had a better situational awareness than he did because of the lack of information available at the fire command center. This has to be changed and this proposal will change it.

Bottom line, the video monitoring system will provide fire and emergency responders' immediate information on the life safety condition and status of the areas noted. Having such ability will exceed any expense incurred for the installation of the video monitoring system - the expense is minor to the benefit of the system. (Note: Regardless of this requirement, electronic data access systems can be installed for a reasonable cost in most buildings today). A video monitoring system will provide fire and emergency responders with accurate and up to date information on the condition and activities of the given areas for emergency responders to make tactical decisions under emergency conditions. With that said, the TRB committee encourages consideration and support for this proposal.

Bibliography: National Institute of Standards & Technology, Final Report of the National Construction safety Team on the Collapses of the World Trade Center Towers. United States Government Printing Office: Washington, D.C. September 2005.

Referenced Standards
National Fire Protection Association Standard 731, the Standard for the Installation of Electronic Premises Security Systems

Cost Impact: The code change proposal will not increase the cost of construction. These proposed amendments will increase the cost of construction, but, the increase will be modest when viewed as a percentage of total construction costs.

Analysis: A review of the standard proposed for inclusion in the code, NFPA 731, for compliance with ICC criteria for referenced standards given in Section 3.6 of Council Policy #CP 28 will be posted on the ICC website on or before September 24, 2009.

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Gary Lewis, City of Summit, representing ICC Ad Hoc Committee on Terrorism Resistant Buildings, requests Approval as Modified by this Public Comment.

Modify as follows:

508.1.5 (IBC [F] 911.1.5) Required features. The fire command center shall comply with NFPA 72 and shall contain the following features:

1. The emergency voice/alarm communications system control unit.
2. The fire department communications system.
3. Fire detection and alarm system annunciator.
4. Annunciator unit visually indicating the location of the elevators and whether they are operational.
5. Status indicators and controls for air handling systems.
6. The fire-fighters control panel required by Section 909.16 for smoke control systems installed in the building.
7. Controls for unlocking stairway doors simultaneously.
8. Sprinkler valve and water-flow detector display panels.
9. Emergency and standby power status indicators.
10. A telephone for fire department use with controlled access to the public telephone system.
11. Fire pump status indicators.
12. Schematic building plans indicating the typical floor plan and detailing the building core, means of egress, fire protection systems, firefighting equipment and fire department access and the location of fire walls, fire barriers, fire partitions, smoke barriers and smoke partitions.
13. Work table
14. Generator supervision devices, manual start and transfer features.
15. Public address system, where specifically required by other sections of this code.
16. Elevator fire recall switch in accordance with ASME A17.1.
17. Elevator emergency or standby power selector switch(es), where emergency or standby power is provided.
18. <u>Capability for</u> video monitoring for video surveillance system required by this code.

Commenter's Reason: See Commenter's reason for Part I, Public Comment 1

Final Action: AS AM AMPC____ D

G46-09/10
403.5.2, 3008.4

Proposed Change as Submitted

Proponent: Rick Thornberry, PE, The Code Consortium, Inc., representing: California Fire Safety Advisory Council (CFSAC); Bill Ziegert, representing Smoke Guard, Inc.

1. Revise as follows:

403.5.2 Additional exit stairway. For buildings other than Group R-2 that are more than 420 feet (128 000 mm) in building height, one additional exit stairway meeting the requirements of Sections 1009 and 1022 shall be provided in addition to the minimum number of exits required by Section 1021.1. The total width of any combination of remaining exit stairways with one exit stairway removed shall not be less than the total width required by Section 1005.1. Scissor stairs shall not be considered the additional exit stairway required by this section.

> ~~**Exception:** An additional exit stairway shall not be required to be installed in buildings having elevators used for occupant self-evacuation in accordance with Section 3008.~~

2. Delete without substitution:

~~**3008.4 Additional exit stairway.** Where an additional means of egress is required in accordance with Section 403.5.2, an additional exit stairway shall not be required to be installed in buildings having elevators used for occupant self-evacuation in accordance with this section.~~

Reason:

Thornberry: We are proposing to delete the Exception to Section 403.5.2 as well as Section 3008.4 which allow the use of occupant evacuation elevators in lieu of the additional exit stairway where required by Section 403.5.2 for super high-rise buildings (buildings greater than 420 ft in height). We believe this technology is too new and unproven to allow it to substitute for a required means of egress. This position is also consistent with Section 1003.7 Elevators, Escalators and Moving Walks which prohibits elevators from being used as a component of a required means of egress. Until such time as occupant evacuation elevators (which are allowed to be used on a voluntary basis without reducing the required means of egress) have proven to be safe, reliable, and effective, this exception should be deleted from the code.

Ziegert: When the concept of Occupant Evacuation Elevators was proposed during the Palm Springs hearings in 2008, while many committee members were in favor of such a concept, the change was Disapproved primarily because it sought a tradeoff of reducing exit stair capacity (width). The proponent brought this change back to the Minneapolis Final Action hearings with substantial modifications and replaced the reduction in exit stair width with this alternate tradeoff to reduce the third stair in High Rise buildings over 420 feet (a different form of tradeoff but still a reduction in exit capacity). Justification for this tradeoff of exit capacity was never sufficiently provided, particularly when one recognizes that the elevator occupant evacuation system will only be operational until the Fire Service arrives (typically in 10 minutes or less from the first alarm). At this time Phase 1 Elevator Recall will normally be implemented which will immediately terminate the use of elevators for occupant evacuation. Following that, occupants needing to use stairs for evacuation in these very tall buildings would be limited to only the two stair systems, rather than the three stair systems the code currently mandates.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: THORNBERRY-G6-403.5.2

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The purpose of the third stairway is to allow for the fire service to take one stairway out of service for fire department activities. The third stairway is in excess to the required means of egress. Therefore, allowing for the option of occupant evacuation elevators in place of the third stairway will not reduce the required means of egress. The occupant evacuation elevator is future technology that is supported by NIST and the World Trade Center report. The tradeoff is an incentive to get effective technology into high rise buildings that will significantly reduce the time needed for evacuation of high rise buildings. This is especially important when a full building evacuation is deemed necessary. It is a significant improvement for persons with disability to allow for self-evacuation with the general population as well as to allow for them to evacuate with their mobility devices.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Rick Thornberry, PE, The Code Consortium, Inc., representing California Fire Safety Advisory Council (CFSAC), requests Approval as Submitted.

Commenter's Reason: We believe that the IBC Means of Egress Code Development Committee recommendation for disapproval of this code change proposal should be overturned and the code change voted for approval. A two-thirds majority vote will be necessary to achieve an approval recommendation by the Class A voting members so it is very important that all Class A voting members carefully listen to the arguments and consider the importance of this very significant code change.

The main reason the Committee recommended disapproval was on the basis of their Committee Statement that said: "Allowing for the option of occupant evacuation elevators in place of the third stairway will not reduce the required means of egress." However, the purpose of the required third stairway in these super high-rise buildings (greater than 420 feet in height) is to assure that the minimum required exit capacity will be available in the building once the fire department arrives and takes over one of the three exit stairways for their use in gaining access to the fire floor and performing their firefighting and search and rescue operations. Thus, the code presumes that the minimum required capacity for exiting will still be provided in the building. However, if the occupant evacuation elevators are allowed to substitute for the third required exit stairway, then once the fire department arrives and takes over one of the two remaining stairways, 50% of the exit capacity will be lost since the required exit width will be reduced because of the actions of the fire department. The assumption being made by the Committee is that the occupant evacuation elevators will make up the difference due to the loss of one of the two stairways being taken over by the fire department. But are they reliable enough at this time to allow such a trade-off?

It should be noted that this is a new technology to the United States which has yet to be proven. In fact, the criteria for occupant evacuation elevators are still being developed by the ASME Committee responsible for developing the elevator requirements. It should also be noted that IBC Section 3008.3 Operation states that the occupant evacuation elevators can only be used in the normal elevator operating mode prior to Phase I Emergency Recall Operation. So it only takes one smoke detector located in any elevator lobby to terminate the elevator use when that detector is activated and automatically recalls all elevators served by that lobby. Furthermore, once the fire department arrives, they will normally recall all elevators under their Phase I Manual Recall Operation. So there will be very little time available for the occupant evacuation elevators to be utilized in the early stages of a fire emergency.

Another concern we have with the reliability of these elevator systems is in regard to potential water damage which could cause malfunctioning operations of the elevators. IBC Section 3008.10 Water Protection simply requires an "approved method" to prevent automatic sprinkler system water from infiltrating into the hoistway enclosure. An approved method is specified since there is no simple resolution to this requirement that can be met in a cost-effective manner at this time. Furthermore, the water infiltration limitations only deal with automatic sprinkler system discharge water and not with firefighting hose streams which will be used during firefighting activities by the responding fire department. The water from firefighting hose streams can often be significantly greater than the automatic sprinkler system discharge water.

Another argument stated was that this code change will eliminate an incentive to utilize occupant evacuation elevators in these very tall buildings. However, this code change does not eliminate the option to install occupant evacuation elevators. It only eliminates the trade-off. If these occupant evacuation elevators are so critical to occupant evacuation, then it follows that building owners will install them in any case in order to minimize their liability and provide enhanced fire and life safety to the building occupants.

Furthermore, the performance based design option can be used to determine how occupant evacuation elevators can be integrated with an exit system in these super high-rise buildings in a cost-effective yet safe and reliable manner. But such a trade-off should not be contained in the prescriptive code requirements for these super high-rise buildings.

Let's get some experience with the voluntary use of occupant evacuation elevators in this country that don't substitute for any of the required exit capacity before we begin to allow such trade-offs. In essence, the trade-off is a de facto substitution of an elevator system for a required means of egress which is clearly prohibited by Section 1003.7 which states: "Elevators, escalators, and moving walks shall not be used as a component of a required means of egress from any other part of the building.

It was also noted that these occupant evacuation elevators would be a significant improvement for persons with disabilities to allow for self-evacuation with the general population. We can't argue with that statement but we can point out that the International Building Code (IBC) currently provides for occupant evacuation of persons with disabilities via elevators in accordance with Section 1007.2.1 Elevators Required which is part of the requirements for the accessible means of egress.

In conclusion, now is not the time to allow for a trade-off of the required means of egress capacity for the use of occupant evacuation elevators in super high-rise buildings. Therefore, we strongly urge the Class A voting members to overturn the Committee's recommendation for disapproval and subsequently vote for approval as submitted of this code change proposal to delete the trade-off.

Final Action: AS AM AMPC____ D

G48-09/10

403.6.1, 3007.1, 3007.1.1 (New)

Proposed Change as Submitted

Proponent: Dave Frable, representing U.S. General Services Administration

Revise as follows:

403.6.1 Fire service access elevator. In buildings with an occupied floor more than 120 feet (36 576 mm) above the lowest level of fire department vehicle access, a minimum of ~~one~~ two elevators having a minimum 3,500 pounds (1588 kilograms) capacity serving every floor within the subject building shall be provided to serve as a fire service access elevator ~~shall be provided~~ in accordance with Section 3007.

> **Exception:** One elevator having a minimum capacity of 4,000 pounds (1814 kilograms) shall be permitted instead of 2 elevators of 3,500 pounds (1588 kilograms) capacity.

3007.1 General. Where required by Section 403.6.1, every floor of the building shall be served by ~~a~~ fire service access ~~elevator~~ elevators. Except as modified in ~~this section, the~~ Sections 3007.1 through 3007.7, fire service access ~~elevator~~ elevators shall be installed in accordance with this chapter and ASME A17.1/CSA B44.

Reason: Last Code Development Cycle, a code change was submitted to require a minimum of 3 fire service elevators. The subject proposal was disapproved by the Code Committee based on concerns that requiring a minimum of 3 fire service access elevators would have an adverse impact on a small footprint high-rise building and that requiring a minimum of 3 fire service access elevators seemed excessive. The intent of this code change is to provide a compromise that addresses the minimum number of fire service access elevators that are required in a building based on the size and capacity of the elevator and not strictly the number of elevators. The proposed text also allows for design flexibility as well as providing minimum requirements for the size and capacity of the fire service access elevators by correlating with Section 3002.4

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: FRABLE-G6-403.6.1

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The option of three elevators in G49-09/10 is preferred to one or two elevators with a higher capacity car as proposed in this item. If the trade-off is capacity vs. number of elevators the fire service would prefer more elevators to allow for different elevators to be used for different purposes. Whether fire service elevators need to be also sized for stretchers can be addressed in G157-09/10.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Dave Frable, representing U.S. General Services Administration, requests Approval as Submitted.

Commenter's Reason: The intent of this code change is to address that the minimum number of fire service access elevators be based on size and capacity of the elevator and not strictly on the minimum number of elevators. In addition, it ensures that each fire service access elevator serves every floor of the building and that at least 1 fire service elevator car be of sufficient size to accommodate a 24 inch by 84 inch stretcher.

The Code Committee states in their reason statement that the option of three elevators in G49-09/10 is preferred to providing only two elevators with a higher capacity car as proposed. The Committee further states that if the trade-off is capacity vs. number of elevators the fire service would prefer to have available more elevators to allow for different elevators to be used for different purposes and to ensure an elevator car is available for fire department use.

It is our opinion, requiring a minimum of 3 fire service elevators for every building of 10 stories or more is not reasonable for all building designs and occupancy classifications. We strongly believe that without taking into consideration elevator capacity, a typical 10 story commercial office building having a small floor plate will lead to unintended architectural design consequences since each fire service elevator lobby will be required to have direct access to an exit stair. For example, a small floor plate building with two passenger elevator cars in one shaft and one service car/freight elevator car in another shaft would need both elevator lobbies providing direct access to the exit stairs while still meeting the exit remoteness requirements in the Code.

Typically in new commercial office buildings of this height, passenger elevator cars can range from a small 2,500 pound capacity elevator car, to a medium 3,500 pound capacity car, to larger 4,000 pound capacity elevator car. Therefore, the size of the available space within each car can range from 28 sq ft per car, 36 square feet per car, and to 41 sq ft per car, respectively. The premise of this code change is the larger the space within the elevator car the less number of trips and number of elevator cars the fire department may need to make to the staging floor on the upper floors of the building.

The subject exception is similar to what the City of San Francisco has required since 2007 for elevators for fire fighter use to be installed in buildings greater than 20 stories in height. One of the paragraphs within the San Francisco Fire Code states that "Where required, a minimum of one 4500 lb. capacity elevator or two 2500 lb. capacity elevators shall be provided for use as firefighter elevators but are not intended to be for exclusive use of the fire department." Therefore, it appears the City of San Francisco also believes that a minimum of one (1) fire service access is adequate if it is of sufficient size and capacity. However, 4,500 pound capacity elevator cars are typically only installed in hospitals and not commercial office buildings whereas 4,000 pound capacity cars are available in commercial office buildings.

It should also be noted that 2,500 pound capacity elevator cars can no longer accommodate the subject new stretcher dimensions and to our knowledge, a 3,500 pound capacity car can only accommodate the new stretcher dimensions if it is modified to a side door configuration opening. Whereas, the 4,000 pound elevator car will be able to accommodate the new stretcher dimensions without any door modifications.

We believe this revision will allow for maximum design flexibility as well as providing minimum requirements for the size and capacity of the fire service access elevators by correlating with Section 3002.4 and will improve the use of fire service access elevators across the country.

Lastly, it should be noted that a similar code change was submitted to the NFPA TC on Building Systems during the NFPA Code Development ROP phase and was approved.

Public Comment 2:

Dave Frable, representing U.S. General Services Administration, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

403.6.1 Fire service access elevator. In buildings with an occupied floor more than 120 feet (36 576 mm) above the lowest level of fire department vehicle access, a minimum of two elevators having a minimum 3,500 pounds (1588 kilograms) capacity serving every floor within the subject building shall be provided to serve as a fire service access elevator in accordance with Section 3007.

> ~~**Exception:** One elevator having a minimum capacity of 4,000 pounds (1814 kilograms) shall be permitted instead of 2 elevators of 3,500 pounds (1588 kilograms) capacity.~~

(Portions of proposal not shown remain unchanged)

Commenter's Reason: The intent of this code change is to address that the minimum number of fire service access elevators be based on size and capacity of the elevator and not strictly on the minimum number of elevators. In addition, it ensures that each fire service access elevator serves every floor of the building and that at least 1 fire service elevator car be of sufficient size to accommodate a 24 inch by 84 inch stretcher.

The Code Committee states in their reason statement that the option of three elevators in G49-09/10 is preferred to providing only two elevators with a higher capacity car as proposed. The Committee further state that if the trade-off is capacity vs. number of elevators the fire service would prefer to have available more elevators to allow for different elevators to be used for different purposes and to ensure an elevator car is available for fire department use.

It is our opinion, requiring a minimum of 3 fire service elevators for every building of 10 stories or more is not reasonable for all building designs and occupancy classifications. We strongly believe that without taking into consideration elevator capacity, a typical 10 story commercial office building having a small floor plate will lead to unintended architectural design consequences since each fire service elevator lobby will be required to have direct access to an exit stair. For example, a small floor plate building with two passenger elevator cars in one shaft and one service car/freight elevator car in another shaft would need both elevator lobbies providing direct access to the exit stairs while still meeting the exit remoteness requirements in the Code.

Typically in new commercial office buildings of this height, passenger elevator cars can range from a small 2,500 pound capacity elevator car, to a medium 3,500 pound capacity car, to larger 4,000 pound capacity elevator car. Therefore, the size of the available space within each car can range from 28 sq ft per car, 36 square feet per car, and to 41 sq ft per car, respectively. The premise of this code change is the larger the space within the elevator car the less number of trips and number of elevator cars the fire department may need to make to the staging floor on the upper floors of the building.

It should be noted that 2,500 pound capacity elevator cars can no longer accommodate the subject new stretcher dimensions and to our knowledge, a 3,500 pound capacity car can only accommodate the new stretcher dimensions if it is modified to a side door configuration opening. Whereas, the 4,000 pound elevator car will be able to accommodate the new stretcher dimensions without any door modifications.

We believe this revision will allow for maximum design flexibility as well as providing minimum requirements for the size and capacity of the fire service access elevators by correlating with Section 3002.4 and will improve the use of fire service access elevators across the country.

Lastly, it should be noted that a similar code change was submitted to the NFPA TC on Building Systems during the NFPA Code Development ROP phase and was approved.

Public Comment 3:

Lee J. Kranz, City of Bellevue, representing Washington Association of Building Officials Technical Code Development Committee, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

403.6.1 Fire service access elevator. In buildings with an occupied floor more than 120 feet (36 576 mm) above the lowest level of fire department vehicle access, a minimum of two elevators, each having a minimum 3,500 pounds (1588 kilograms) capacity serving every floor within the subject building, shall be provided to serve as a fire service access elevators in accordance with Section 3007.

> ~~**Exception:** One elevator having a minimum capacity of 4,000 pounds (1814 kilograms) shall be permitted instead of 2 elevators of 3,500 pounds (1588 kilograms) capacity.~~

(Portions of proposal not shown remain unchanged)

Commenter's Reason: Washington Association of Building Official's Technical Code Development Committee (WABO-TCDC) agrees that more fire service access elevators (FSAE) in high-rise buildings greater than 120' in height will improve fire fighter and occupant safety by providing the ability to move suppression equipment and personnel to the fire location expediently. We believe that the economic impacts of increasing the number of FSAE from 1 to 2 (a 100% increase) is justified to provide improved safety for fire fighters and the public. WABO-TCDC recommends disapproval of proposal G-49 that requires an increase from 1 to 3 FSAE and supports the moderate increase provided in proposal G-48, as modified by this public statement. The exception to allow a single 4,000 lb. elevator instead two 3,500 lb. elevators was deleted to insure that at least 2 FSAE elevators would be installed so that if 1 were shut down there would be at least 1 available.

Final Action: AS AM AMPC____ D

G49-09/10
403.6.1

Proposed Change as Submitted

Proponent: Brian Black, BDBlack Codes, Inc., representing National Elevator Industry, Inc. (NEII), Sean DeCrane, representing International Association of Fire Fighters (IAFF), Jack Murphy, representing Fire Safety Directors of Greater New York (FSDAGNY)

Revise as follows:

403.6.1 Fire service access elevator. In buildings with an occupied floor more than 120 feet (36 576 mm) above the lowest level of fire department vehicle access, a minimum of ~~one~~ <u>three</u> fire service access elevator<u>s, or all elevators, whichever is less,</u> shall be provided in accordance with Section 3007.

Reason: The proponents performed a survey of firefighters from across the country to explore the sufficiency of this current code requirement. Thirty-five responses were received from cities such as Charlotte, Orlando, San Francisco, Houston, Los Angeles, Fort Worth, Boston and Pittsburgh, all indicating that the number of elevators used for firefighting operations varies from 2 to 6. (Only one respondent, a suburban bedroom community indicated one elevator is sufficient for firefighting.) Firefighters experienced in high rise operations stated that the Fire Service must be able to count on **at least two** elevators at all times. They are necessary for 1) transporting firefighters to and from the staging area, usually located two floors below the fire floor; 2) moving firefighters to other floors for the purpose of search and rescue, fire extension, recon; hauling of equipment such as spare cylinders, exhaust fans, etc; and, 3) transporting those with disabilities to the building lobby.

Past experience during fires of this type (high-rise), is that on many occasions elevators are not available due to shut downs for various reasons, including problems in operation, routine maintenance, modernization programs, EMS operations in the building prior to firefighter arrival and other reasons. Without this change there will be a high chance that there will not be a Fire Service Access Elevator available for the firefighters' to perform their critical firefighting and life-saving rescue duties.

Cost Impact: This code change will increase the cost of construction.

ICCFILENAME: BLACK-G5-403.6.1

Public Hearing Results

Committee Action: **Approval as Submitted**

Committee Reason: Redundancy in the number of elevators available for fire department use is critical for effective fire fighting operations in buildings tall enough to need Fire Service Access elevators. Elevators size can be addressed in G157-09/10. While there are some issues of additional cost, small foot-print buildings are addressed in the additional language of "or all elevators, whichever is less."

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Paul K. Heilstedt, PE, Hon. AIA, Chair, representing ICC Code Technology Committee (CTC), requests Approval as Modified by this Public Comment.

Modified proposal as follows:

403.6.1 Fire service access elevator. In buildings with an occupied floor more than 120 feet (36 576 mm) above the lowest level of fire department vehicle access, a minimum of ~~three~~ <u>two</u> fire service access elevators, or all elevators, whichever is less, shall be provided in accordance with Section 3007. <u>Each fire service access elevator shall have a minimum capacity of 3500 pounds.</u>

Commenter's Reason: There were two code changes proposed to add elevator car size requirements for fire service elevators, namely:

G48: This code change proposed either two elevators (each 3500 pounds) or a single larger elevator (4000 pounds). This code change was disapproved.

G49: This code change proposed three fire service elevators but did not mandate a size. As such the typical size of 2500 pounds would be permitted. This code change was approved.

This public comment is a compromise between G48 which proposed 2 elevators and allowed an exception for 1 provided it could accommodate fire service needs such as a stretcher and this proposed change which requires 3. This comment further mandates a minimum size of 3500 pounds which is consistent with demands for fire service access and stretcher accommodation. There is no technical justification to require 3 fire service elevators.

Public Comment 2:

Dave Frable, representing U.S. General Services Administration, requests Disapproval.

Commenter's Reason: The proponents have stated that the intent of this code change is to increase the minimum number of fire service access elevators from 1 to 3 elevators based on 35 responses from a survey of firefighters who indicated that the number of elevators they used during an event ranged from 2 to 6. However, it should be noted that the survey did not indicate the size of the elevators used by the firefighters. Typically in commercial office buildings, elevator cars can range from 2,500 pound capacity elevator cars to 3,500 pound capacity elevator cars and the size of the available space within each car can range from 28 sq ft per car to 41 sq ft per car respectively. Therefore, in our opinion, the size of the car does matter and it is possible that the firefighters that responded to the survey and stated they utilized multiple elevators were using 2500 pound capacity cars.

In addition, we also believe that requiring all of the elevators in small floor plate building to be fire service access elevators will cause major unintended design consequences when trying to meet the requirement for providing direct access from the subject enclosed fire service access elevator lobbies to an exit stair. For example, a small foot-print building with two passenger elevators in one elevator lobby and a two service car elevators in another lobby would need to be designed such that the exit stairs where remote and still had direct access to each of the elevator lobbies.

We also feel that the proponent's statement that "past experience during fires of this type (high-rise), is that on many occasions elevators are not available due to shut downs for various reasons" is based on the older technology elevators and not elevators using state-of-the-art technology which the subject fire service access elevators will have incorporated into them. Based on our discussions with elevator industry representatives, elevators using today's technology are more reliable and require less maintenance that elevators in the past.

However, the most compelling reason for disapprove of this code change is that as currently written the subject proposal will not meet the intent stated in proponents reason statement. The proponents have stated that "without this change there will be a high chance that there will not be a fire service access elevator available for the firefighters' to perform their critical firefighting and life-saving rescue duties". However, even if one agrees with this statement; based on the requirements in 3007.1, only one (1) of the three (3) designated fire service access elevators will be required to serve every floor and therefore all three (3) designated fire service elevators may not serve every floor, and may lead to confusion during fire department operations as well as unintended consequences.

Lastly, it should be noted that a similar code change was submitted to the NFPA TC on Building Systems during the NFPA Code development ROP phase and was disapproved.

Public Comment 3:

Lee J. Kranz, City of Bellevue, representing Washington Association of Building Officials Technical Code Development Committee, requests Disapproval.

Commenter's Reason: Washington Association of Building Official's Technical Code Development Committee (WABO-TCDC) believes the proposed requirement to provide 3 fire service access elevators (FSAE) in high-rise buildings greater than 120' in height is excessive. This change could increase the cost of construction to the point where it may become economically unrealistic for many high-rise projects to proceed.

WABO-TCDC agrees that additional FSAE in high-rise buildings would improve fire fighter safety and the ability to move suppression equipment and personnel to the fire location expediently but the economic impacts of increasing the number from 1 to 3 (a 200% increase) is not justified. Requiring 3 FSAE would also have an adverse impact on small footprint high-rise buildings.

WABO-TCDC suggests disapproval of G-49 and supports a moderate increase provided in proposal G-48, as modified by our public statement.

Public Comment 4:

Michael Perrino, representing Code Consultants, Inc., requests Disapproval.

Commenter's Reason: This code change requires a single fire department elevator in buildings up to 120 feet. At that threshold the minimum number jumps to three. No justification was put forth for requiring a 200 percent increase in the number of elevators once an imaginary line in the sky is crossed.

While there may be validity to the need for increased fire fighter access, the code has generally addressed such needs through progressively increasing requirements. Should there be a threshold where two elevators are required? Then another where three are required?

This argument was never fully explained at the hearings. Without justification for the sudden jump in requirements (from one to three) there should be a review of what the proper thresholds may be and whether a progressive increase is a more appropriate method to address this issue.

Public Comment 5:

Lawrence G. Perry, AIA, representing Building Owners and Managers Association (BOMA) International, requests Disapproval.

Commenter's Reason: This code change proposal should be Disapproved for the following reasons:

1. There is inadequate technical justification to mandate three fire service access elevators, particularly in all buildings >120' in height.
2. The current, brand new provisions in the 2009 code require at least one fire service access elevator. While not required, the vast majority of designs would chose to also make this elevator the required ambulance stretcher elevator, since access to each floor of the building must be provided by each type.
3. The current provisions were specifically crafted to allow the use of either the 'general public' elevator lobby or a separate lobby to serve as the required fire service access lobby. By mandating multiple elevators, the size of the required lobby increases significantly, and the likelihood of a design choosing to use a separate lobby is significantly reduced. Combining this with the potential for very tall buildings to also use occupant evacuation elevators, their efficiency would be significantly impacted by multiple fire service access elevators and conflicting lobby uses.

4. A lot of the testimony provided in support of this change made it sound as if elevators are not ever used, and could not ever be used, by the fire service if not for the newly-added fire service access elevator provisions. This is contrary to current ongoing practice in virtually all major jurisdictions.

Final Action: AS AM AMPC____ D

G50-09/10
404.6

Proposed Change as Submitted

Proponent: Michael Perrino, representing Code Consultants, Inc.

Delete and substitute as follows:

404.6 Enclosure of atriums. Atrium spaces shall be separated from adjacent spaces by a 1-hour fire barrier constructed in accordance with Section 707 or a horizontal assembly constructed in accordance with Section 712, or both.

Exceptions:

~~1. A glass wall forming a smoke partition where automatic sprinklers are spaced 6 feet (1829 mm) or less along both sides of the separation wall, or on the room side only if there is not a walkway on the atrium side, and between 4 inches and 12 inches (102mmand 305 mm) away from the glass and designed so that the entire surface of the glass is wet upon activation of the sprinkler system without obstruction. The glass shall be installed in a gasketed frame so that the framing system deflects without breaking (loading) the glass before the sprinkler system operates.~~

1. A glass wall and doors forming a smoke partition in accordance with Section 711, constructed of a tempered, wired or laminated glass wall and doors, complying with all of the following:
   1.1. Automatic sprinklers are spaced 6 feet (1829 mm) or less along both sides of the separation wall and doors, or on the room side only if there is not a walkway on the atrium side, and between 4 inches and 12 inches (102 mm and 305 mm) away from the glass. When activated the sprinkler system shall completely wet the entire surface of the glass.
   1.2. The glass shall be in a gasketed frame and installed in a manner that the framing system will deflect without breaking (loading) the glass before the sprinklers operate.
   1.3. Obstructions shall not be installed between the sprinklers and the glass wall or doors.
2. A glass-block wall assembly in accordance with Section 2110 and having a 3/4-hour fire protection rating.
3. The adjacent spaces of any three *floors* of the atrium shall not be required to be separated from the atrium where such spaces are accounted for in the design of the smoke control system.

Reason: The change brings to the atrium section the allowance for doors to be protected in the same manner as is permitted for walls and doors separating a pedestrian walkway from a building by Section 3104.5, exception 1. The allowances are almost identical as currently written, the only difference being the specific allowance for doors to be installed in the glass walls separating buildings, but not in glass walls separating atrium spaces.

Cost Impact: The code change proposal will not increase the cost of construction. The proposal will decrease the cost of construction.

ICCFILENAME: PERRINO-G2-404.5

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee liked the proposed reformatting of the provisions because it provided clarity to the existing requirements; however the change included some technical flaws. Therefore the committee felt that G51-09/10 better addressed the issue.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Don Davies, Salt Lake City Corporation, representing Utah Chapter, requests Approval as Submitted.

Commenter's Reason: This provision is far superior to G51. The current Ex.1 to I.B.C. Section 404.6 describes a smoke partition with glazing in gasketed frames. The proponent understood the concept that the separation was intended only to control smoke and need not be a fire barrier as is currently required in the code. Requiring a ¾ hour door next to a nonrated wall was always a difficult position to defend. Simply referring to Section 711 addresses the concern that the door be tested to meet the smoke and draft control requirements of U.L. 1784. This is a well thought out change which should have occurred years ago.

Final Action: AS AM AMPC____ D

G51-09/10
404.6

Proposed Change as Submitted

Proponent: Clay Aler, PE, representing Koffel Associates

Revise as follows:

404.6 Enclosure of atriums. Atrium spaces shall be separated from adjacent spaces by a 1-hour *fire barrier* constructed in accordance with Section 707 or a *horizontal assembly* constructed in accordance with Section 712, or both.

Exceptions:

1. A glass wall forming a smoke partition where automatic sprinklers are spaced 6 feet (1829 mm) or less along both sides of the separation wall, or on the room side only if there is not a walkway on the atrium side, and between 4 inches and 12 inches (102 mm and 305 mm) away from the glass and designed so that the entire surface of the glass is wet upon activation of the sprinkler system without obstruction. The glass <u>wall</u> shall be installed in a gasketed frame so that the framing system deflects without breaking (loading) the glass before the sprinkler system operates. <u>Self-closing glass doors shall be permitted in the glass wall.</u>
2. A glass-block wall assembly in accordance with Section 2110 and having a 3/4-hour *fire protection rating*.
3. The adjacent spaces of any three floors of the atrium shall not be required to be separated from the atrium where such spaces are accounted for in the design of the smoke control system.

Reason: Where glass walls are used as an atrium enclosure, it is typical to include glass doors in the glass walls to maintain material continuity. The current code text makes no reference to whether glass doors are permitted as part of the atrium enclosure. The proposed revised text will make it clear that glass doors are permitted in glass walls, so long as the glass doors are sprinkler protected in a manner consistent with that provided for the glass wall.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: ALER-G1-404.5.doc

Public Hearing Results

Committee Action: **Approval as Submitted**

Committee Reason: The proposal provides a clear answer to the question of whether doors are allowed in the glass wall forming the separation between an atrium and adjoining spaces.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Clay Aler, representing Koffel Associates, Inc., requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

404.6 Enclosure of atriums. Atrium spaces shall be separated from adjacent spaces by a 1-hour fire barrier constructed in accordance with Section 707 or a horizontal assembly constructed in accordance with Section 712, or both.

Exceptions:

<u>1.</u> <u>A fire barrier is not required where</u> a glass wall forming a smoke partition ~~where~~ <u>is provided. The glass wall shall comply</u> ~~complying~~ with all of the following:

1.1 Automatic sprinklers are <u>provided</u> ~~spaced 6 feet (1829 mm) or less~~ along both sides of the separation wall <u>and doors</u>, or on the room side only if there is not a walkway on the atrium side. <u>The sprinklers shall be located</u> ~~and~~ between 4 inches and 12 inches (102 mm and 305 mm) away from the glass <u>and at intervals along the glass not exceeding 6 feet (1829 mm)</u>. <u>The sprinkler system shall be designed so that the entire surface of the glass is wet upon activation of the sprinkler system without obstruction</u>;

1.2 The glass wall shall be installed in a gasketed frame ~~so~~ <u>in a manner</u> that the framing system deflects without breaking (loading) the glass before the sprinkler system operates; <u>and</u>

~~1.3~~ ~~Self-closing or automatic-closing~~ <u>Where</u> glass doors ~~shall be permitted~~ <u>are provided</u> in the glass wall, <u>they shall be either self-closing or automatic closing.</u>

2\. A <u>fire barrier is not required where a</u> glass-block wall assembly, ~~in accordance~~ <u>complying</u> with Section 2110 and having a 3/4-hour *fire protection rating,* <u>is provided</u>.

<u>3.</u> <u>A fire barrier is not required between the atrium and</u> the <u>adjoining</u> ~~adjacent~~ spaces of any three floors of the atrium ~~shall not be required to be separated from the atrium where~~ <u>provided</u> such spaces are accounted for in the design of the smoke control system.

Commenter's Reason: The modification to proposal G51-09/10 addresses two issues. First it addresses the Committee's comment to rewrite the approved proposal, specifically item #1 of that proposal, to be in a format more consistent with proposal G50-09/10. In preparing the Exception #1 into its three subparts, it became clear that all three exceptions were unclear because of their format and, in some cases, lack of a complete sentence. The additional revisions to Exception 1 as well as the revisions to Exceptions 2 and 3 are intended to be purely editorial in order to provide the limits and requirements of the exceptions in clear language.

Public Comment 2:

Ali M. Fattah, City of San Diego, Development Services Department, representing San Diego Area Chapter of ICC, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

404.6 Enclosure of atriums. Atrium spaces shall be separated from adjacent spaces by a 1-hour *fire barrier* constructed in accordance with Section 707 or a *horizontal assembly* constructed in accordance with Section 712, or both.

Exceptions:

1. A glass wall forming a smoke partition where automatic sprinklers are spaced 6 feet (1829 mm) or less along both sides of the separation wall, or on the room side only if there is not a walkway on the atrium side, and between 4 inches and 12 inches (102 mm and 305 mm) away from the glass and designed so that the entire surface of the glass is wet upon activation of the sprinkler system without obstruction. The glass wall shall be installed in a gasketed frame so that the framing system deflects without breaking (loading) the glass before the sprinkler system operates. Self-closing glass doors shall be permitted in the glass wall <u>and shall be provided with smoke and draft control and shall comply with the air leakage rates in Section 715.4.3.1.</u>
2. A glass-block wall assembly in accordance with Section 2110 and having a 3/4-hour fire protection rating.
3. The adjacent spaces of any three floors of the atrium shall not be required to be separated from the atrium where such spaces are accounted for in the design of the smoke control system.

Commenter's Reason: This public comment adds more clarification that the glazed door requires smoke and draft control as is required for the glass wall that is required to be gasketed. It makes no sense to have a self closing glass door in a glass wall assembly that is constructed to prevent the passage of smoke. Sprinkler protection on the glass cools the glass so that it does not fracture due to fire but does not prevent the migration of smoke from the atrium into adjoining spaces that are required to be separated.

Public Comment 3:

Michael Perrino, representing Code Consultants, Inc., requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

404.6 Enclosure of atriums. Atrium spaces shall be separated from adjacent spaces by a 1-hour *fire barrier* constructed in accordance with Section 707 or a *horizontal assembly* constructed in accordance with Section 712, or both.

Exceptions:

1. A glass wall forming a smoke partition~~, where~~ complying with all of the following:
   - 1.1 Automatic sprinklers are spaced 6 feet (1829 mm) or less along both sides of the separation wall and doors, or on the room side only if there is not a walkway on the atrium side, and between 4 inches and 12 inches (102 mm and 305 mm) away from the glass. The sprinkler system shall be designed so that the entire surface of the glass is wet upon activation of the sprinkler system without obstruction;
   - 1.2 The glass wall shall be installed in a gasketed frame ~~so~~ in a manner that the framing system deflects without breaking (loading) the glass before the sprinkler system operates; and
   - 1.3 Self-closing or automatic-closing glass doors shall be permitted in the glass wall.
2. A glass-block wall assembly in accordance with Section 2110 and having a 3/4-hour fire protection rating.
3. The adjacent spaces of any three floors of the atrium shall not be required to be separated from the atrium where such spaces are accounted for in the design of the smoke control system.

Commenter's Reason: The committee liked the proposed reformatting of the provisions in proposal G50-09/10, because it provided clarity to the existing requirements. However, the committee felt that G51-09/10 better addressed the question of whether doors are allowed in the glass wall forming the separation between an atrium and adjoining spaces.

This Public Comment incorporates the formatting of G50 with the technical elements of G51, to address all of the committee's comments on this section.

Public Comment 4:

Don Davis, Salt Lake City Corporation, representing Utah Chapter, requests Disapproval.

Commenter's Reason: Code change G50 correctly addresses the type of door which should occur at the separation of the atrium and adjoining spaces by requiring that the door meet the requirements of a smoke and draft control assembly, as required in U.L. 1784. This proposal allows glass pivoting doors with no mention of how smoke control will occur at that location. The adjoining sidelights and glazed walls are currently required to be in gasketed frames, as opposed to butt glazing which would allow smoke migration. While the door need not be required to be ¾-hour rated, allowing a door without smoke gasketing defeats the purpose of separating the surrounding areas from the atrium.

Final Action: AS AM AMPC____ D

G52-09/10
404.6 (New), 1022.1(IFC [B] 1022.1)

Proposed Change as Submitted

Proponent: David S. Collins, FAIA, The Preview Group, Inc., representing The American Institute of Architects

1. Add new text as follows:

404.6 Exit Stairway. Up to 50 percent of the exits required by Section 1021 shall be permitted to be located within an atrium without enclosure required by Section 1022, provided:

1. The stairway discharges to the floor of the atrium;
2. The floor of the atrium is at the level of exit discharge and conforms with Section 1027.1; and
3. The footprint of the stairway when measured horizontally within the perimeter of the atrium floor opening shall not equal more than 25 percent of the area of the atrium on a per floor basis.

(Renumber subsequent sections)

2. Revise as follows:

1022.1 (IFC [B] 1022.1) Enclosures required. Interior exit stairways and interior exit ramps shall be enclosed with fire barriers constructed in accordance with Section 707 or horizontal assemblies constructed in accordance with Section

712, or both. Exit enclosures shall have a fire-resistance rating of not less than 2 hours where connecting four stories or more and not less than 1 hour where connecting less than four stories. The number of stories connected by the exit enclosure shall include any basements but not any mezzanines. Exit enclosures shall have a fire-resistance rating not less than the floor assembly penetrated, but need not exceed 2 hours. Exit enclosures shall lead directly to the exterior of the building or shall be extended to the exterior of the building with an exit passageway conforming to the requirements of Section 1023, except as permitted in Section 1027.1. An exit enclosure shall not be used for any purpose other than means of egress.

Exceptions:

1. In all occupancies, other than Group H and I occupancies, a stairway is not required to be enclosed when the stairway serves an occupant load of less than 10 and the stairway complies with either Item 1.1 or 1.2. In all cases, the maximum number of connecting open stories shall not exceed two.
   1.1. The stairway is open to not more than one story above its level of exit discharge; or
   1.2. The stairway is open to not more than one story below its level of exit discharge.

<u>2.</u> <u>Exit stairways in atriums conforming to Section 404.6 are not required to be enclosed.</u>

~~2~~<u>3.</u> Exits in buildings of Group A-5 where all portions of the means of egress are essentially open to the outside need not be enclosed.

~~3~~<u>4.</u> Stairways serving and contained within a single residential dwelling unit or sleeping unit in Group R-1, R-2 or R-3 occupancies are not required to be enclosed.

~~4~~ <u>5.</u> Stairways in open parking structures that serve only the parking structure are not required to be enclosed.

~~5~~<u>6.</u> Stairways in Group I-3 occupancies, as provided for in Section 408.3.8, are not required to be enclosed.

~~6~~<u>7.</u> Means of egress stairways as required by Sections 410.5.3 and 1015.6.1 are not required to be enclosed.

~~7~~<u>8.</u> Means of egress stairways from balconies, galleries or press boxes as provided for in Section 1028.5.1 are not required to be enclosed.

Reason: The atrium enclosure provides adequate protection for occupants of the building by providing fire suppression, smoke removal systems and provides additional features that a stair enclosure lacks; the ability to observe the environment in which the stair is located. It would be a simple matter to glance down into the atrium prior to mounting the stairs to see if there are problems associated with the environment, making the decision to use the atrium stair much simpler than a stair whose environment is unknown beyond the one visible flight of stairs.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: COLLINS-G4-404.6.doc

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The proposal sets no limit on the number of stories or travel distance. In tall buildings the atrium could potentially fill up with smoke enough that some upper floors would have the use of the exit stairway jeopardized. It is not clear how this revision will coordinate with the committee's approval of E5-09/10 for open exit access stairways and open exit stairways.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

David S. Collins, The Preview Group, Inc., representing The American Institute of Architects, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

404.6 Exit stairway. Up to 50 percent of the exits required by Section 1021 shall be permitted to be located within an atrium without enclosure required by Section 1022, provided:

1. The stairway <u>or ramp</u> discharges to the floor of the atrium;
2. The floor of the atrium is at the level of exit discharge and conforms with Section 1027.1; and
3. The footprint of the stairway <u>or ramp</u> when measured horizontally within the perimeter of the atrium floor opening shall not equal more than 25 percent of the area of the atrium on a per floor basis.

(Portions of proposal not shown remain unchanged)

Commenter's Reason: The committee rejected this code change for three reasons:

1. *The proposal sets no limit on the number of stories or travel distance.*
   Travel distance is determined by the distance within the occupied space to the exit. With this change, the stair within the atrium would become the exit and the travel distance would be measured to it. An atrium is required to have significant features that provide a safe environment even when it may be involved in an event that would compromise this stair. 50% of the required stairs from any floor would not be permitted to be in the atrium, allowing alternate paths should the atrium stair be compromised.

2. *In tall buildings the atrium could potentially fill up with smoke enough that some upper floors would have the use of the exit stairway jeopardized.*
   It is possible for any exit to become compromised due to any number of circumstances, however a very tall atrium is required to have a smoke removal system capable of maintaining a viable environment at the highest occupied floor within the atrium enclosure. The smoke layer is designed to be at least 6' above the highest occupied floor when using the exhaust method for design (Section 909.8.1).
3. *It is not clear how this revision will coordinate with the committee's approval of E5-09/10 for open exit access stairways and open exit stairways.*
   In a separate comment I have submitted a change to E5-09/10 to incorporate the use of an atrium as an exit as part of Section 1022.2 when it conforms with Section 404.
   Atriums have proven to not create serious problems for building occupants. Because atriums are typically a significant part of the building configuration when they are incorporated into a building, use of an atrium as a part of the building exiting system will improve occupant awareness of at least the option to use the atrium stair as an exit in an emergency.

Final Action: AS AM AMPC____ D

G54-09/10
406.1 (New), 406.2 (New), 406.2.1, 406.3.1, 406.3.2

Proposed Change as Submitted

Proponent: Donald R. Monahan, PE, Walker Parking Consultants, representing the National Parking Association and the Automated & Mechanical Parking Association

1. Add new text as follows:

SECTION 406
MOTOR-VEHICLE-RELATED OCCUPANCIES

406.1 General. Motor –vehicle related occupancies shall comply with Sections 406.1 through 406.8 and other applicable provisions of this code, the *International Fire Code* and *International Mechanical Code.*

406.2 Definitions. The following words and terms shall, for the purposes of this chapter and as used elsewhere in this code, have the meanings shown herein.

PARKING GARAGE. A building, structure, or portion thereof used for the parking, storage, or both, of motor vehicles less than 6500 lbs empty curb weight.

PARKING GARAGE, OPEN. A parking garage that meets the requirements of Section 406.3.

PARKING GARAGE, ENCLOSED. Any parking garage that is not an open parking garage.

PARKING GARAGE, RAMP TYPE. A parking garage that utilizes sloped floors for vertical vehicle circulation.

PARKING GARAGE, ASSISTED MECHANICAL TYPE. A parking garage that uses lifts or other mechanical devices to transport vehicles to the upper or lower floors of a parking garage, where the vehicles are then parked by an attendant.

PARKING GARAGE. AUTOMATED MECHANICAL TYPE. A parking garage that utilizes computer-controlled machines to store and retrieve vehicles, without drivers, in multi-level storage bays.

(Renumber subsequent sections)

2. Delete without substitution as follows:

406.2 Parking garage

~~**406.2.1 Classification.** Parking garages shall be classified as either open, as defined in Section 406.3, or enclosed and shall meet the appropriate criteria in Section 406.4. Also see Section 509 for special provisions for parking garages.~~

(Renumber subsequent sections)

3. Revise as follows:

406.3 Open parking garages.

406.3.1 Scope. Except where specific provisions are made in Sections 406.3.2 through ~~406.3.13~~ 406.3.12, other requirements of this code shall apply.

4. Delete text as follows:

~~**406.3.2 Definitions.** The following words and terms shall, for the purposes of this chapter and as used elsewhere in this code, have the meanings shown herein.~~

~~**MECHANICAL-ACCESS OPEN PARKING GARAGES.** *Open parking garages* employing parking machines, lifts, elevators or other mechanical devices for vehicles moving from and to street level and in which public occupancy is prohibited above the street level.~~

~~**OPEN PARKING GARAGE.** A structure or portion of a structure with the openings as described in Section 406.3.3.1 on two or more sides that is used for the parking or storage of private motor vehicles as described in Section 406.3.4.~~

~~**RAMP-ACCESS OPEN PARKING GARAGES.** *Open parking garages* employing a series of continuously rising floors or a series of interconnecting ramps between floors permitting the movement of vehicles under their own power from and to the street level.~~

(Renumber subsequent sections)

Reason: Section 406 applies to parking garages in general. Therefore, the different types of parking garages should be defined in this section. Listing the definitions under Section 406.3 is inappropriate as that section is a special subset of parking garages that only applies to Open Parking Garages. In particular, it is necessary to define the different types of mechanical access garages, as some types of mechanical access garages use freight elevators to lift a vehicle to another floor where it is then parked by an attendant. Therefore, ventilation of vehicle emissions is important for that type of garage. However, automated, mechanical access parking garages are finding their way into the U.S. market from Europe and Asia. These garages use computer-controlled machines to store and retrieve vehicles without the vehicle engine running and without human intervention. The vehicles are stored in an unoccupied, enclosed storage vault. Therefore, the life safety provisions inside that unoccupied storage vault are considerably different than in an occupied space. Only access by maintenance personnel and firefighter personnel is required in the storage vault. Ventilation of vehicle emissions is not required. These garages are not defined in the current building code. Further, up to double the number of vehicles can be accommodated in automated mechanical garages so they represent "Green" design in addition to the reduction in vehicle emissions that make this type of garage greener than traditional garages.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: MONAHAN-G4-406.2.1

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The organization issues were resolved by approval of Item G53-09/10. The committee was uncertain that the revised definitions contained in this proposal were necessary or provided clear application to the rest of the section. In addition there was concern regarding adding a vehicle weight limit to the definition of a parking garage. The committee was concerned regarding its enforceability or that it was even necessary.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Stephen Thomas, Colorado Code Consulting, LLC, representing Automated Mechanical Parking Association (AMPA), requests Approval as Modified by this Public Comment.

Replace the proposal as follows:

~~**406.3.2**~~ **406.2 Definitions**. The following words and terms shall, for the purposes of this chapter and as used elsewhere in this code, have the meanings shown herein.

~~**MECHANICAL-ACCESS OPEN PARKING GARAGES.** Open parking garages employing parking machines, lifts, elevators or other mechanical devices for vehicles moving from and to street level and in which public occupancy is prohibited above the street level.~~

ASSISTED MECHANICAL PARKING GARAGE. A parking garage that uses lifts or other mechanical devices to transport vehicles to the upper or lower floors of a parking garage, where the vehicles are then parked by an attendant, and in which public occupancy is prohibited within the storage area.

AUTOMATED MECHANICAL PARKING GARAGE. A parking garage that utilizes computer-controlled machines to store and retrieve vehicles in multi-level storage bays without drivers or attendants, and in which public occupancy is prohibited within the storage bay levels.

OPEN PARKING GARAGE. A structure or portion of a structure with the openings as described in Section 406.3.3.1 on two or more sides that is used for the parking or storage of private motor vehicles as described in Section 406.3.4.

RAMP-ACCESS OPEN PARKING GARAGES. Open parking garages employing a series of continuously rising floors or a series of interconnecting ramps between floors permitting the movement of vehicles under their own power from and to the street level.

Commenter's Reason: This proposal is intended to introduce the concept of automated mechanical parking garages into the code. The first part of the change relocates the definitions in Section 406 to the front of the section in 406.2. This is consistent with code change G53-09/10 which was approved by the General Committee. The second portion of the change splits the definition of "Mechanical Access Open Parking Garages" into two different categories. The first is a garage that used attendants to park the vehicle and the second where a computer-controlled machine parks the vehicle. These types of garages are beginning to make their entry into the United States. Local code officials would prefer to accommodate these types of structures into the IBC.

This proposal is the first of two that introduce this concept into the code. Automated and mechanical parking alternatives have, over the years, become more and more in demand in the US as land becomes less available (and more expensive) and cars more plentiful. While a newly emerging industry in the US, in other parts of the world it has been established for almost half a century. Additional information on these types of parking garages can be found at www.ampapark.org

Final Action: AS AM AMPC____ D

G60-09/10
406.3.3.1.1 (New)

Proposed Change as Submitted

Proponent: Daniel E. Nichols, P.E., representing New York State Division of Code Enforcement and Administration

Add new text as follows:

406.3.3.1.1 Openings below grade. Where openings below grade provide required natural ventilation, the outside horizontal clear space measured perpendicular to the opening shall be one and one-half times the depth of the opening. The depth of the opening shall be measured from the average adjoining ground level to the bottom of the opening.

Reason: One of the main differences between open parking garages and enclosed garages is the ability of the openness on one or two walls to provide adequate natural ventilation. IBC Section 406.3.1.1 clearly states in the section that the openness is for natural ventilation purposes. This is supported by the IMC being completely silent on any requirements for ventilation in an open parking garage.

Open parking garages are generally separated from a surrounding structure due to limitations of fire separation distance (10 feet). However, fire separation distance isn't needed from grades and retaining walls. A condition has been experienced where an open parking garage has been built into a steep grade, and the openings are provided. In one case, a retaining wall is 5 feet away from the exterior wall of the open parking garage and the vertical distance from the lowest level of the open parking garage to the top of the wall is approximately 50 feet.

IBC Section 1203 has requirements for the use of below ground openings being used for natural ventilation. This proposal uses the exact language in Section 1203 to provide recognized design standards for below ground openings.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: NICHOLS-G1-406.3.3.1.1.doc

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee found the text confusing and it would seem to require a below grade area that would have to be wider at the bottom than at the top of the opening at grade. There was debate whether the 1 - 1/2 factor was appropriate.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Daniel E. Nichols, P.E., representing New York State Division of Code Enforcement and Administration, requests Approval as Modified by this Public Comment.

Replace the proposal as follows

<u>**406.3.3.1.1 Openings below grade.** Where openings below grade provide required natural ventilation, the outside horizontal clear space shall be one and one-half times the depth of the opening. The width of the horizontal clear space shall be maintained from grade down to the bottom of the lowest required opening.</u>

Commenter's Reason: The committee was concerned on how multiple levels would be measured and that they intended objective was not reflected in the original proposal. This public comment addresses the issue by basing the measurement point on the depth of the lowest required opening. The one and one-half is based on the requirement of openings below grade for providing natural ventilation for operable windows in occupied spaces.

Final Action: AS AM AMPC____ D

G64-09/10, PART I

IBC 406.7 (New), IFC 2303.2

NOTES: PART II DID NOT RECEIVE A PUBLIC COMMENT AND IS ON THE CONSENT AGENDA. PART II IS REPRODUCED FOR INFORMATIONAL PURPOSES ONLY FOLLOWING <u>ALL</u> OF PART I.

Proposed Change as Submitted

Proponent: Donald R. Monahan, PE, Walker Parking Consultants, representing the National Parking Association and the Automated & Mechanical Parking Association

PART I – IBC GENERAL

1. Add a new section as follows:

<u>**406.7 Parking garages, automated mechanical type.**</u>

<u>**406.7.1 General.** Automated mechanical type parking garages shall comply with Sections 406.7.1 through 406.7.3.</u>

<u>**406.7.2 Construction.** The storage vault enclosure is classified as a high-bay storage warehouse for motor vehicles, and shall meet the requirements of Chapter 23 of the *International Fire Code*.</u>

<u>**406.7.3 Storage Racks.** The storage racks shall consist of non-combustible construction. Steel storage racks shall designed in accordance with Section 2208.</u>

Reason: (IBC) Automated, mechanical-access parking garages are finding their way into the U.S. market from Europe and Asia. These facilities utilize computer-controlled machines and lifts to store and retrieve vehicles on a platform without the engine running and without human intervention in an unoccupied, high-bay storage vault. They have unique fire and life safety issues and as such need a separate code section to define the code requirements for these unique facilities.

References: *Parking Structure Fires* by the Parking Consultants Council of the National Parking Association, Washington, DC, December 2008

Cost Impact: None

ICCFILENAME: MONAHAN-G5-406.7 NEW (Pt II F2-2303.2)

Public Hearing Results

PART I- IBC GENERAL

Committee Action: **Disapproved**

Committee Reason: The committee felt that standards for automated garages eventually need to be in the code, however this proposal needs further refinement. Among the issues identified by the committee that need to be clarified are: How would sprinklers be provided; Should there be different criteria if these are in open versus enclosed garages; Egress and accessibility need to be addressed; While there may be limited occupant load, the occupancy is still a storage facility for cars, therefore a Group S occupancy. Clear provisions on structural requirements would need to be added.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Stephen Thomas, Colorado Code Consulting, LLC, representing Automated Mechanical Parking Association (AMPA), requests Approval as Modified by this Public Comment for Part I.

Modify the proposal as follows:

406.7 <u>Automated mechanical</u> parking garages~~, automated mechanical type~~.

406.7.1 General. Automated mechanical type parking garages shall comply with Sections 406.7.2 through 406.7.3.

406.7.2 Construction. The storage vault enclosure ~~is classified as a high-bay storage warehouse storage for motor vehicles, and~~ shall meet the requirements of Chapter 23 of the *International Fire Code*.

406.7.3 Storage Racks. The storage racks shall consist of non-combustible construction. Steel storage racks shall designed in accordance with Section 2208.

Commenter's Reason: This proposal is intended to introduce the concept of automated mechanical parking garages into the code. The jurisdictions that have reviewed these structures in the United States have required them to comply with the high-piled storage requirements of the IFC. The committee agreed that standards for automated garages need to be in the code. They had concerns about different aspects of the change. By requiring the storage vault to comply with Chapter 23 of the IFC, the fire protection requirements will be answered and generally the buildings will be required to be sprinklered or provided with draft curtains and smoke and heat vents. The committee also questioned whether the criteria should apply to both open and enclosed facilities. The proposed language does not differentiate between the two. It is designed for enclosed facilities and can be applied to open structures. An open structure would provide a safer condition from a fire and smoke standpoint, but the design would comply with an enclosed structure requirements. We believe that the egress and accessibility requirements are already handled in the code. There is no need to add specific requirements into the code for these types of buildings. The committee agreed that these buildings are classified as a Group S occupancy and therefore, all of the requirements for that use group would need to be met.

These types of garages are beginning to make their entry into the United States. Local code officials are would prefer to accommodate these types of structures into the IBC. This proposal is the second of two that introduce this concept into the code. Automated and mechanical parking alternatives have, over the years, become more and more in demand in the US as land becomes less available (and more expensive) and cars more plentiful. While a newly emerging industry in the US, in other parts of the world it has been established for almost half a century. Additional information on these types of parking garages can be found at www.ampapark.org

Final Action: AS AM AMPC____ D

NOTE: PART II REPRODUCED FOR INFORMATIONAL PURPOSES ONLY – SEE ABOVE

G64-09/10, PART II – IFC

Revise text as follows:

2303.2 Class I commodities. Class I commodities are essentially noncombustible products on wooden or nonexpanded polyethylene solid deck pallets, in ordinary corrugated cartons with or without single-thickness dividers, or in ordinary paper wrappings with or without pallets. Class I commodities are allowed to contain a limited amount of Group A plastics in accordance with Section 2303.7.4. Examples of Class I commodities include, but are not limited to, the following:

Alcoholic beverages not exceeding 20-percent alcohol
Appliances noncombustible, electrical
Cement in bags
Ceramics
Dairy products in nonwax-coated containers (excluding bottles)
Dry insecticides
Foods in noncombustible containers
Fresh fruits and vegetables in nonplastic trays or containers
Frozen foods
Glass
Glycol in metal cans
Gypsum board
Inert materials, bagged
Insulation, noncombustible
Motor vehicles less than 6500 pounds empty curb weight
Noncombustible liquids in plastic containers having less than a 5-gallon (19 L) capacity
Noncombustible metal products

Reason (IFC): Automated, mechanical-access parking garages are finding their way into the U.S. market from Europe and Asia. These facilities utilize computer-controlled machines and lifts to store and retrieve vehicles without the engine running and without human intervention in an unoccupied, high-bay storage vault. They have unique fire and life safety issues that are similar to high piled storage of commodities covered by Chapter 23 of the IFC and therefore should be included in this Chapter. The reference below indicates that the amount of combustibles in a typical passenger vehicle is less than 5 pounds per sf, which then classifies passenger vehicles as low hazard in accordance with NIST standards and qualifies as a Class I commodity in this section.

References: *Parking Structure Fires* by the Parking Consultants Council of the National Parking Association, Washington, DC, December 2008

Cost Impact: None

PART II- IFC

Committee Action: **Disapproved**

Committee Reason: The committee questioned the selection of the 6500 pound limit for the vehicles. Many common vehicles exceed that weight. The committee also felt there was not sufficient justification provided for listing these as a Class I commodity based on the fuel load present. Proponent should reconsider the classification.

Assembly Action: **None**

G70-09/10
[F] 410.6

Proposed Change as Submitted

Proponent: Bill Conner, representing American Society of Theatre Consultants

Revise as follows:

[F] 410.6 Automatic sprinkler system. Stages and associated dressing rooms, performer lounges, shops, storerooms and technical production areas located within and adjoining a stage shall be equipped with an automatic ~~fire-extinguishing~~ sprinkler system in accordance with ~~Chapter 9~~ Section 903.3.1.1. ~~Sprinklers shall be installed under the roof and gridiron and under all catwalks and galleries over the stage. Sprinklers shall be installed in dressing rooms, performer lounges, shops and storerooms accessory to such stages.~~

Exceptions:

1. Sprinklers are not required under stage areas less than 4 feet (1219 mm) in clear height that are utilized exclusively for storage of tables and chairs, provided the concealed space is separated from the adjacent spaces by not less than 5/8-inch (15.9 mm) Type X gypsum board.

2. Sprinklers are not required for stages 1,000 square feet (93 m2) or less in area and 50 feet (15 240 mm) or less in height where curtains, scenery or other combustible hangings are not retractable vertically. Combustible hangings shall be limited to a single main curtain, borders, legs and a single backdrop.
3. Sprinklers are not required within portable orchestra enclosures on stages.

Reason: Update language to be consistent with other parts of the code. This also provides a specific reference to Section 903.3.1.1 which contains the reference to the NFPA 13 requirements. The NFPA standard provides adequate information regarding the placement of sprinklers in the backstage and other technical production areas, and such language is not needed in the code.

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: There is an MOE code change proposal that contains a definition of technical production areas.

ICCFILENAME: CONNER-G1-410.6

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The proposal was disapproved as it was felt it would eliminate sprinklers in critical areas such as gridirons.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Joe Pierce, Dallas Fire Department, representing Joint Fire Service Review Committee, requests Approval as Modified by this Public Comment.

Replace the proposal as follows:

[F] 410.6 (IFC 914.6.1) Automatic sprinkler system. Stages shall be equipped with an automatic ~~fire-extinguishing~~ sprinkler system in accordance with ~~Chapter 9~~ Section 903.3.1.1. Sprinklers shall be installed under the roof and gridiron and under all catwalks and galleries over the stage. Sprinklers shall be installed in dressing rooms, performer lounges, shops and storerooms accessory to such stages.

(Remaining text remains unchanged.)

Commenter's Reason: This Public Comment essentially retains the original text in Section 410.6 except for the reference to Chapter 9. The code change proposed to revise the vague Chapter 9 reference with a specific reference to Section 903.3.1.1.

This Public Comment intends to approve the proposed reference to Section 903.3.1.1, rather than a reference to Chapter 9. Section 903.3.1.1 is the correct reference for the sprinkler system design as this will refer to NFPA 13. Both NFPA 13R and NFPA 13D are inappropriate design standards for a fire sprinkler system over a stage. The change also maintains the update to consistent language referring to an automatic sprinkler system rather than a fire-extinguishing system.

Final Action: AS AM AMPC____ D

G80-09/10
419.9 (New)

Proposed Change as Submitted

Proponent: Tom Rubottom City of Westminster, Colorado representing the Colorado Chapter of ICC

Add new text as follows:

419.9 Plumbing facilities. The nonresidential area of the live/work unit shall be provided with minimum plumbing facilities as specified by Chapter 29, based on the function of the nonresidential area.

Reason: The current code requirements do not require toilet facilities for the work area of a live/work unit. Live/work units are classified as Group R-2 occupancies. The only toilet facilities now required are those for the dwelling unit which could be located on the upper floors and therefore there would be no requirements for any plumbing fixtures on the main level work area. The toilet room in the dwelling unit will not be accessible to the same standards as required for an accessible public toilet room in business and commercial occupancies. This code change would add language to make sure the work area would have the same minimum plumbing facilities (both for number of fixtures and for meeting accessibility requirements) as a typical commercial project.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: RUBOTTOM-G2-419.1

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The intent of the live/work provisions is small business oriented. The proposal is too far reaching for the limited size of live/work units. A valid concern is that the toilets required for the work area can be accessed from the work area.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Tim Pate representing Colorado Chapter of ICC, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

419.9 Plumbing facilities. The nonresidential area of the live/work unit shall be provided with minimum plumbing facilities as specified by Chapter 29, based on the function of the nonresidential area. <u>Where the nonresidential area of the live/work unit is required to be accessible by Section 1103.2.13, the plumbing fixtures specified by Chapter 29 shall be accessible.</u>

Commenter's Reason: This public comment and modification will address the concerns of the General Committee that the original proposal was too far reaching for the limited sizes of live work units and that the live work provisions are small business oriented.

The live/work provisions allow the total square footage to be 3,000 and up to 50% of that can be the work area. In reality since the total square footage allowed for the work portion of a live work unit is 1,500 square feet only one bathroom would be required in almost every situation and you would rarely require a drinking fountain.

Section 2902.2 exception 2 only requires one bathroom when total occupant load (employees and customers) is 15 or less and Section 2902.2 exception 3 only requires one bathroom when occupant load is 50 or less. Therefore if a work portion is business you would have a maximum area of 1,500 square feet which would be an occupant load of 15 and if work area is mercantile you would have an occupant load of 50. In either case you would only be required to have one bathroom. If you had a coffee shop or food service you would need two bathrooms when square footage exceeded 195 square feet (assuming two employees and 15 square feet per occupant for seating).

Footnote f of Table 2902.1 says that you do not need drinking fountain when the occupant load is 15 or less and IPC section 4 says that you do not need drinking fountain in restaurant that serves water. Therefore in most cases you would not need a drinking fountain.

Table 2902.1 does require a service sink in all occupancies. This is always a challenge in the typical small commercial spaces and most AHJ's use proper discretion when enforcing this provision based on the type of use. One would make the case that a typical laundry sink that is in the living portion of the live/work unit could suffice. I believe that most Health Departments would require some sort of service sink anyway.

The live/work provisions allow up to 5 non residential workers and it does not make sense to not require bathrooms for the workers so that they would have to travel through the private living space to get to a bathroom not to mention the accessible route requirements.

A final item to keep in mind is that if the work area is an office and is less than 10% of total square footage it is not classified as live/work.

As can be seen having Section 419 refer to Chapter 29 for plumbing fixture requirements it will be rare to ever require more than one bathroom or even to require a drinking fountain. It does not make sense to treat this business use any differently than someone building under the IBC. The live/work provision already refer to ventilation provisions out of IMC and structural, means of egress, and accessibility provisions out of IBC. It should also refer to the plumbing fixture requirements.

Final Action: AS AM AMPC____ D

2. Delete without substitution as follows:

~~**509.5 Groups R-1 and R-2 buildings of Type IIIA construction.** The height limitation for buildings of Type IIIA construction in Groups R-1 and R-2 shall be increased to six stories and 75 feet (22 860 mm) where the first floor assembly above the basement has a fire-resistance rating of not less than 3 hours and the floor area is subdivided by 2-hour fire-resistance-rated fire walls into areas of not more than 3,000 square feet (279 m^2).~~

~~**509.6 Groups R-1 and R-2 buildings of Type IIA construction.** The height limitation for buildings of Type IIA construction in Groups R-1 and R-2 shall be increased to nine stories and 100 feet (30 480 mm) where the building is separated by not less than 50 feet (15 240 mm) from any other building on the lot and from lot lines, the exits are segregated in an area enclosed by a 2-hour fire-resistance-rated fire wall and the first floor assembly has a fire-resistance rating of not less than 1$^1/_2$ hours.~~

3. Revise as follows:

705.11 Parapets. Parapets shall be provided on *exterior walls* of buildings.

Exceptions:

1. through 4. *(Exceptions not shown remain unchanged)*
5. In Group~~s R-2 and~~ R-3 where the entire building is provided with a Class C roof covering, the exterior wall shall be permitted to terminate at the underside of the roof sheathing or deck in Type III, IV and V construction, provided:
   5.1. The roof sheathing or deck is constructed of *approved* noncombustible materials or of *fire-retardant-treated wood* for a distance of 4 feet (1220 mm); or
   5.2. The roof is protected with 0.625-inch (16 mm) Type X gypsum board directly beneath the underside of the roof sheathing or deck, supported by a minimum of nominal 2-inch (51 mm) ledgers attached to the sides of the roof framing members for a minimum distance of 4 feet (1220 mm).
6. *(Exceptions not shown remain unchanged)*

4. Add new text as follows:

<u>**707.3.10 Separation of dwelling units and sleeping units.** The fire-resistance rating of the separation between individual dwelling units and sleeping units, and between dwelling units and sleeping units and other spaces in the building shall comply with Table 707.3.9.</u>

<u>**Exception:** In Group R-3 occupancies, walls separating dwelling units in the same building, walls separating sleeping units in the same building, and walls separating dwelling units or sleeping units in the same building shall be a fire-resistance-rating in accordance with Section 709.3.</u>

5. Revise as follows:

709.3 Fire-resistance rating. Fire partitions shall have a fire-resistance rating of not less than 1 hour.

Exception~~s~~:

~~1.~~ Corridor walls permitted to have a ½ hour fire-resistance rating by Table 1018.1.

~~2. Dwelling unit and sleeping unit separations in buildings of Type IIB, IIIB and VB construction shall have fire-resistance ratings of not less than ½ hour in buildings equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1.~~

709.4 Continuity. Fire partitions shall extend from the top of the foundation or floor/ceiling assembly below to the underside of the floor or roof sheathing, slab or deck above or to the fire-resistance-rated floor/ceiling or roof/ceiling assembly above, and shall be securely attached thereto. If the partitions are not continuous to the sheathing, deck or slab, and where constructed of combustible construction, the space between the ceiling and the sheathing, deck or slab above shall be fireblocked or draftstopped in accordance with Sections 717.2 and 717.3 at the partition line. The supporting construction shall be protected to afford the required fire-resistance rating of the wall supported, except for walls separating tenant spaces in covered mall buildings, ~~walls separating dwelling units,~~ ~~walls separating sleeping units~~ and corridor walls in buildings of Type IIB, IIIB and VB construction.

Exceptions:

1. through 4. *(Exceptions not shown remain unchanged)*
~~5. Fireblocking or draftstopping is not required at the partition line in Group R-2 buildings that do not exceed four stories above grade plane, provided the attic space is subdivided by draftstopping into areas not exceeding 3,000 square feet (279 m^2) or above every two dwelling units, whichever is smaller.~~
5.~~6.~~ *(Exceptions not shown remain unchanged)*

717.3.2 Groups ~~R-1, R-2~~, R-3 and R-4. Draftstopping shall be provided in floor/ceiling spaces ~~in Group R-1 buildings, in Group R-2 buildings with three or more dwelling units,~~ in Group R-3 buildings with two dwelling units and in Group R-4 buildings. Draftstopping shall be located above and in line with the dwelling unit and sleeping unit separations.

Exceptions:

1. Draftstopping is not required in buildings equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1.
2. Draftstopping is not required in buildings equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.2, provided that automatic sprinklers are also installed in the combustible concealed spaces.

6. Delete without substitution as follows:

~~**717.4.2 Groups R-1 and R-2.** Draftstopping shall be provided in *attics*, mansards, overhangs or other concealed roof spaces of Group R-2 buildings with three or more *dwelling units* and in all Group R-1 buildings. Draftstopping shall be installed above, and in line with, *sleeping unit* and *dwelling unit* separation walls that do not extend to the underside of the roof sheathing above.~~

~~**Exceptions:**~~

~~1. Where *corridor* walls provide a *sleeping unit* or *dwelling unit* separation, draftstopping shall only be required above one of the *corridor* walls.~~
~~2. Draftstopping is not required in buildings equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1.~~
~~3. In occupancies in Group R-2 that do not exceed four *stories above grade plane*, the *attic* space shall be subdivided by draftstops into areas not exceeding 3,000 square feet (279 m^2) or above every two *dwelling units*, whichever is smaller.~~
~~4. Draftstopping is not required in buildings equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.2, provided that automatic sprinklers are also installed in the combustible concealed spaces.~~

Reason: Though the loss of life from fires affecting Group I-1, R-1 and R-2 occupancies is not high the amount of property damage continues to remain high. To reduce this loss this proposal modifies the requirements for Group I-1, R-1and R-2 occupancies to require that all buildings constructed for these occupancies shall be constructed of non-combustible construction and the fire rated separations between sleeping and dwelling units shall be a minimum of 2-hour fire resistance rating. The removal of combustible materials from the building construction and the increase in the fire resistance provides a much higher degree of protection to property in the event of a fire. In addition, when occupants in these types of buildings are sleeping they are less likely to be aware of conditions around them. Fires occurring during these times pose a high risk to the occupants. This increase in the fire resistance provides a higher degree of protection to sleeping occupants in reducing the spread of fire.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: Thompson-G4-419

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee disapproved the proposed change because it appeared by be addressing concerns of property protection and not life safety of the occupants of such buildings. Fire statistics cited were concentrating on buildings under construction, not those completed with required systems in place and occupied by residents. The committee concluded that the safeguards are adequate to continue to allow Group R occupancies to be located in buildings of combustible construction.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jason Thompson, National Concrete Masonry Alliance (NCMA), representing, Masonry Alliance for Codes and Standards (MACS), requests Approval as Submitted.

Commenter's Reason: The IBC General Code Development Committee's statement contained in their Committee Reason indicated that they recommended disapproval of this Code Change because it was more focused on addressing property protection rather than the life safety of the occupants of the Group I-1, R-1, and R-2 occupancy buildings addressed in this Code Change. They also stated that the fire statistics cited during the hearings concentrated more on buildings under construction rather than those completed with required systems in place and occupied by residents. So the Committee concluded that the safeguards were adequate to continue to allow Group R occupancies in buildings of combustible construction.

We have submitted this Public Comment because we disagree with the Committee's reasons for recommending disapproval of this Code Change Proposal. We are asking the Class A voting members to overturn that recommendation for disapproval and then approve this Public Comment as submitted for Code Change G81-09/10.

It is interesting to note that in the Committee Reason the Committee expressed its concerns that the information provided by us at the hearings was mainly about property loss and not threats to the life safety of the occupants. But that was precisely our point. Section 101.3 Intent of Part 1 – Scope and Application of the IBC clearly states that: "The purpose of this code is to establish the minimum requirements to safeguard the public health, safety and general welfare through… safety to life and property from fire…" Thus, property protection is clearly part of the purpose of the IBC. And it is especially important where property losses affect the overall general welfare of the public which could be seriously harmed by the loss of a significant amount of the housing stock in this country due to fire. As we all know, there is already a shortage of affordable housing in this country, so it should be incumbent upon the IBC to provide a sufficient level of fire and life safety for residential occupancies to minimize property losses to those occupancies that result in the significant loss of available housing units or future housing units due to fires that occur during construction. If this Code Change is approved, it will, in effect, prohibit the construction of Group R occupancy buildings to a height of five stories and 75 feet using one of the nonrated types of construction, i.e. Type IIB and IIIB, with the installation of an NFPA 13 sprinkler system. However, currently Table 503 of the IBC with an NFPA 13R automatic sprinkler system height increase will allow Group R occupancy buildings to be constructed as high as four stories and 60 feet in Types IIB and IIIB construction. These allowable building heights are greater than allowed for any other occupancy classification regulated by the code for these types of construction. Clearly, this does not make any sense since Group R occupancies contain people who are staying overnight sleeping and are thus more vulnerable to fires occurring during the night.

Furthermore, we have researched the last several years of large loss fires reported by the National Fire Protection Association (NFPA) and have discovered a very alarming and disturbing trend in such fires involving three and four story Group R occupancies. It should be noted that NFPA defines a large loss fire as any fire resulting in at least $5 million in property damage. In 2007 residential fires qualifying as large loss fires represented 11% of the number of large loss fires reported and 2% of the total loss with a reported loss for residential fires of $78.5 million. In 2008 residential fires represented 17% of the large loss fires reported to the NFPA which resulted in 7.2% of the total loss with a reported loss of $170.5 million for residential occupancies. Several of these fires involved residential occupancies protected with NFPA 13R sprinkler systems where the attics are allowed to remain unsprinklered, even though they are often constructed of combustible materials in these three and four story buildings as currently allowed by Table 503 of the IBC. And several of these fires occurred in buildings under construction which were to be sprinklered in accordance with NFPA 13R but burned down before the sprinkler system could be installed in an operational mode. Thus, a significant quantity of residential dwelling units and/or apartments have been lost in recent years in buildings allowed to be up to four stories in height of unprotected construction such as Type IIB and IIIB construction.

We should also point out that requiring these Group I-1 and R occupancies to be constructed of noncombustible construction with 2-hour fire-resistant separations between adjacent dwelling units and sleeping units will greatly improve the effectiveness of the NFPA 13R sprinkler systems allowed to be used in these buildings up to four stories in height. Such buildings will have a significantly higher degree of compartmentation and will not contain combustible concealed spaces such as attics which are not required to sprinklered per NFPA 13R. But if the attics are constructed of noncombustible materials, then there is a significantly less likelihood that a fire starting in or spreading into the attic would cause any significant property damage. This, in turn, will result in reduced insurance costs and make the cost of living in residential occupancies more affordable. This will also better assure a stable and sustainable housing stock that is less likely to be lost in significant fires since the fire will in all probability be contained to the unit of origin.

It should be noted that we have performed cost comparison studies throughout various regions of the country to demonstrate that this type of construction is cost effective not only in the short term but also in the long term, as compared to more traditional wood frame construction for such residential type occupancies. So approving this Code Change as submitted will greatly increase the general public welfare and achieve significant reductions in the overall property losses associated with residential type occupancies due to fire. This can all be accomplished without any significant increase in the cost of construction of these residential type occupancies. Therefore, we respectfully request the Class A voting members overturn the Committee's recommendation for disapproval and approve this Public Comment.

Final Action: AS AM AMPC____ D

G83-09/10
424 (New), Chapter 35

Proposed Change as Submitted

Proponent: Edward L. Repic, Architectural Refuse Solutions, LLC, representing self

Add new text as follows:

SECTION 424
RUBBISH CHUTES, RUBBISH COMPACTORS & LAUNDRY CHUTES

424.1 General. Rubbish and laundry chutes and rubbish compactors shall comply with the provisions of Section 424.1 through 424.7 and other applicable provisions of this code. Rubbish and laundry chutes shall comply with Sections 5.1 and 5.2 of NFPA-82, Rubbish compactors shall comply with Chapter 7 of NFPA-82.

424.2 Chute diameter. Chutes shall have a diameter of not less than 24 inches (610 mm). The diameter of the chute shall be maintained for the entire length of the chute,

424.3 Chute materials. The chute shall be constructed of aluminized steel, stainless steel, or galvanized steel of not less than 16 gage, (0.060 inches). The use of thinner materials shall be prohibited.

424.4 Vent. Chutes shall be provided with a vent of the same diameter of the chute. The vent shall extend through the roof. Reduced diameter vents shall be prohibited.

> **Exception.** Subject to the approval of the building official, where the building configuration constrains the continuation of a round vent, a round-to-rectangular transition shall be used above the highest intake allowing the use of a rectangular vent of equivalent, clear cross-sectional area of the round chute being vented. The rectangular vent may either extend to the top of the vent, or where allowed by the building configuration, the vent shall transition from rectangular-to-round before penetrating the roof to create the vent.

424.5 Shaft enclosure at rubbish and laundry chutes. The shaft enclosure containing a rubbish or laundry chute shall comply with Sections 424.5.1 through 424.5.3.

424.5.1 Single sided construction. The chute shaft enclosure shall be of a listed construction that can be fully assembled in accordance with its approved design, including all required drywall taping when required by the design, from one side after the chute has been installed, regardless of the presence of bearing walls supporting floor framing.

424.5.2 Identical floor and wall ratings. A chute shaft enclosure shall provide the required fire protection rating over its entire length. Fire ratings shall not be lower at floor, ceiling or roof framing intersections.

424.5.3 Extend shaft enclosure to roof. The shaft enclosure shall extend to the underside of the roof. Structural framing members supporting the roof shall be outside of the chute shaft enclosure and shall not be permitted inside the shaft enclosure.

424.6 Electric interlocks. Where used, electric interlocks shall be normally engaged. They shall disengage at the door which is signaled to be open. In the event of loss of power, all interlocks shall be in the engaged position.

424.6.1 Safety switch. Electric interlock safety switch shall be provided in the discharge room to permit maintenance of the chute or chute accessories.

424.6.2 Interconnection. Electric interlocks where used with a rubbish compactor shall be interconnected to the power pack of the rubbish compactor to go off line in the event of an alarm notification from the compactor. Such required notifications shall include: container away, emergency shutoff engaged, pressure overload, motor overheating

424.7. Rubbish compactors. Rubbish compactor provisions included in Section 424.6.2 shall apply to all apartment style compactors.

<u>**424.6.1 Power Pack**. Power packs for apartment-style rubbish compactors shall be UL approved.</u>

2. Add new standards to Chapter 35 as follows:

NFPA
<u>82-2004 Gravity Waste or Linen Chutes</u>

Reason: This submittal is part of four such proposals submitted as independent documents with the intent of adequately addressing Trash Chutes (which can include "recycling" chutes that simply redirect parts of the trash waste stream to locations other than a landfill) and Linen (or Laundry) Chutes. These proposals individually address Life Safety, Sprinkler Placement, Accessibility in new and existing facilities, and actual Chute Construction and a related component to Rubbish Chutes: Compactors. Codes generally address the shaft enclosure but ignore the actual chute being enclosed or the compactor it is feeding.

To quote from an authoritative source:

> *"Internationally, code officials recognize the need for a modern, up-to-date building code addressing the design and installation of building systems through requirements emphasizing performance. <u>The International Building Code®,</u> in this 2009 edition, is designed to meet these needs through model code regulations that safeguard the public health and safety in all communities, large and small. This comprehensive building code establishes minimum regulations for building systems using prescriptive and performance-related provisions. It is founded on broad-based principles that make possible the use of new materials and new building designs."*

The following information seeks to address the design and installation of a two specific building systems, Rubbish & Laundry Chutes and Rubbish Compactors, to enhance the comprehensive aspects of this code in the full spirit of this quoted material from the Preface of your document. As manufacturers of Chutes and Compactors, with distributors throughout the United States, we see the problems a lack of minimum regulation creates on a daily basis for design professionals. Without regulation design professionals resort to the talent they know best: Design. The problem lies in the fact that they undertake that design function without the benefit of knowing what the industry has learned over the last 90 or so years.

This is not to say that guidelines do not exist. In fact, they do. However, the NFPA-82 document is not a referenced standard to this Code. We are not qualified to recommend the adoption of that entire document as the document addresses items other than chutes and compactors (incinerators, for instance) that are beyond our areas of expertise. We can, however, comment upon and even improve upon the basics included in NFPA-82.

We recommend the addition of certain portions of NFPA-82, namely:
Sections: 5.1 General.
5.2 Gravity Waste or Linen Chutes
Chapter 7 Waste Compactors
(Please note that the words "waste" and "linen" in NFPA-82 correspond to the words "rubbish" and "laundry" in the IBC)
These sections cover several chute-related topics: Design, materials, intakes, discharges, offsets, and vents

Per the "Editor's Note" in section 424.1 These sections should be augmented in two ways:
First, we recommend the addition of certain provisions to NFPA-82 already presented/reasoned under separate proposals and obliquely referenced in Section 424.1, namely:
The Accessibility features outlined in our proposal for
1103.1, 1103.1.1 (new), 1103.1.2 (new);
The Latching and Closing features outlined in our proposal for
708.3.1 (new), 708.3.1.1 (new), 708.3.1.2 (new), 708.3.1.3 (new), 708.13.1, 708.13.3, 715.4.1 Exception (new), 715.4.2, 715.4.8, 715.4.8.1, and 715.4.8.3

Secondly, we recommend other modifications outlined in provisions 424.2 through 424.7. Our reasons for these are as follows:

424.2: Diameter lays the foundation for a common problem in chute design: vent diameter which becomes the subject of the paragraph that follows: 424.3.

424.3: Addresses a problem created by some industry participants who publicly claim adherence to the provisions of NFPA-82 and falsely advertise their material thickness as 16 gage material while actually using 18 gage material. The problem most commonly occurs in Spiral Chute construction. Lighter gage material is used on the premise that 18 gage material is stronger than non-spiraled 16 gage material. This is probably true, but the reasoning is, nonetheless, fallacious. At issue are the burn-through properties of the materials. Physical strength of the material is meaningless beyond the ability of the chute to be supported as chutes convey waste materials; they do not "hold" anything. Again, the issues are Life Safety and Fire Prevention, not Structural Strength.

424.4: Presented are an option (the rectangular-equivalent concept) to permit chutes and their enclosing walls to be installed without structural interference. The importance of venting cannot be over estimated as it provides rapid relief of steam buildup in the event of sprinkler activation during a fire. This prevents the intake doors from being blown open, thereby exposing other smoke protection zones from becoming engaged in the fire.

424.5 and subparagraphs: The proposed additions are designed to overcome common mistakes that most commonly, but not exclusively, occur in wood frame structures. The single side construction concept is crucial as most fire wall designs require full fire taping on both sides of the wall. It is impossible to properly install all required fire taping on the inside surface of a chute enclosure because the chute is in place, as is the chute intake door. Wood framing also commonly creates problems with fire ratings at wall and floor intersection as well as at roof framing interferences.

424.6 and sub paragraphs: Electric interlocks are an extremely popular chute accessory that permits all doors to lock when one door is opened to avoid rubbish from above falling on a depositor below if two or more people are depositing waste at the same time. This is a pretty common occurrence as people tend to throw out their garbage after feeding times, causing back-ups at the intake doors. Some interlocks are manufactured in such a way that they actually energize a downward moving locking mechanism to engage when a door is opened. Said another way the interlocks are held in a retracted position by a spring and then forced down to close all the doors not in use. The problem is that these doors are not protected by the electric interlocks when power drops as it does in a fire emergency. Other manufacturers utilize a common power source ... gravity ... to engage their interlocks and retract a single interlock when the system is activated for a deposit at a specific location. In the power loss scenario, these interlocks are engaged and act as a back up system that protects the firewall penetration from unnecessary exposure in the event of the latch failure scenario described in an another proposal submitted as part of this whole chute discussion. The provisions of Section 424.6.2 is designed to provide protection to maintenance personnel in the event of compactor trouble and during the correction of that trouble.

424.7 and sub paragraph: Rubbish compactor provisions establishes the need to interconnect the electric interlock system and this common piece of equipment for the protection of both the equipment and the personnel involved. The UL standardization is a simple protective feature for building owners, residents, and maintenance personnel.

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: A review of the standard proposed for inclusion in the code, NFPA 82, for compliance with ICC criteria for referenced standards given in Section 3.6 of Council Policy #CP 28 will be posted on the ICC website on or before September 24, 2009.

ICCFILENAME: REPIC-G1-424 New

Public Hearing Results

Note: The following analysis was not in the Code Change monograph but was published on the ICC website at http://www.iccsafe.org/cs/codes/Documents/2009-10cycle/ProposedChanges/Standards-Analysis.pdf :

Analysis: Review of the proposed new standard indicated that, in the opinion of ICC staff, the standard did comply with ICC standards criteria. . The standard is currently referenced in the IMC code change referenced the 2004 edition, however the 2009 was reviewed anticipating a modification request from the proponent.

Committee Action: Disapproved

Committee Reason: Without the modification that was offered by the proponent, the change would conflict with provisions approved by the Fire Safety Committee for inclusion in Chapter 7. The provisions regarding electrical interlocks are unclear regarding where the interlocks are to be provided.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Edward L. Repic, Architectural Refuse Solutions, LLC, requests Approval as Modified by this Public Comment.

Replace the proposal as follows:

715.4.8.3 Smoke-activated doors. Automatic-closing doors installed in the following locations shall be automatic-closing by the actuation of smoke detectors installed in accordance with Section 907.3 or by loss of power to the smoke detector or hold-open device. Doors that are automatic-closing by smoke detection shall not have more than a 10-second delay before the door starts to close after the smoke detector is actuated:

(Items 1 through 7 - No changed in the text.)

8. Doors installed in ~~refuse and laundry chutes and~~ <u>chute intake</u> access <u>rooms</u> and termination rooms in accordance with Section 708.13.

(Items 9 through 11 – no change in the text.)

708.13.3 Refuse and laundry chute access rooms. *(No change in the text).*

<u>**708.13.3.1 Chute intake doors.** Chute intake doors installed in refuse and laundry chutes shall comply with the following:</u>

1. <u>The chute intake doors shall be automatic closing by the actuation of an approved automatic heat detector installed in the chute above the highest intake door and complying with the follo;</u>
   - <u>1.1. The approved automatic heat detector shall be heat responsive to a maximum temperature of 135° F. (57° C.); and</u>
   - <u>1.2. The heat detector shall be connected to the building's fire alarm control units where a fire alarm systems is required by Section 907.2. Detectors shall, upon actuation, perform the intended function and activate the alarm notification appliances or activate a visible and audible supervisory signal at a constantly attended location.</u>
2. <u>The chute intake doors shall be connected to an electronic interlock system complying with the following:</u>
   - <u>2.1. The interlock system shall be normally engaged when the intake doors are in a closed position;</u>
   - <u>2.2. The interlock system shall be provided with a manually controlled safety switch in the termination room;</u>
   - <u>2.3. When a refuse compactor is utilized in conjunction with a refuse chute, the manually controlled safety switch shall be interconnected with the automatic alarm circuits of the refuse compactor that initiate compactor shutdown; and</u>
   - <u>2.4. The interlock system components shall be labeled as appropriate for such systems. The interlock system shall utilize a Class 2, low-voltage circuit in accordance with NFPA 70.</u>

Commenter's Reason: *TRASH & LINEN CHUTES ARE ONLY INSTALLED IN BUILDINGS WHERE PEOPLE SLEEP*. Few things are more disorienting than being awakened by a fire alarm and exiting through a darkened, smoke-filled corridor. While Codes do a good job of addressing chute enclosures, the chute itself is almost completely ignored. As chute manufacturers, Life Safety Enhancement of a chute installation for the protection of its end users has become our core value. Nothing in this proposal will sell a single chute for us or anyone else. This proposal introduces applications of chute products and accessories common to all chute manufacturers. These applications are a compilation of the best information we have gained from our experiences and interactions with architects, builders, and fire marshals from across the entire country representing hundreds of installations.

FIRST, SOME CHUTE BACKGROUND IS IN ORDER:

Codes primarily discuss "fire doors" in terms of man doors. However, chute intakes are fire doors that have very different characteristics, functions and life safety impacts than man doors. This proposal begins with the intent of addressing those issues by differentiating between these two types of fire rated doors. Further, this proposal addresses the functional realities of the impact the provisions of Section 715.4.8.3 have on the safety of building maintenance personnel.

While both are fire doors, Chute Intake Doors must be differentiated from Man Doors for at least four major reasons ... each of which can have a critical impact on Life Safety:

1: Chute intake doors are part of a conveyance system (the vertical chute itself) that intersects every single fire containment zone through which that vertical chute passes. We have installed chutes in 60-story buildings. Except at stairwells, man doors simply separate one fire containment zone from another on the same floor.

2: Additionally, chute intake doors are subjected to far more use than most man-type fire doors. The labeled corridor door with a hold open device is closed infrequently ... maybe as little as once a year when it's inspected by a fire marshal. Labeled chute intake doors on each floor of a building with 20 units per floor can be used 20 times a day ... more than 7,000 times per year. In hospital environments we have doors utilized more than three times that often. The need for reliability under high use conditions is crucial, even in the absence of good maintenance because chute doors, like all fire doors, have as their primary purpose, the protection of a fire wall penetration.

3: Further, because refuse chutes use bottom hinged doors with vertical latches at the top of the door panel that extend into the door frame ... a *major* difference in hinge and latch positions from man doors ... the potential for failure during a fire emergency, especially in the presence of poor maintenance, is very high. Labeled chute intake doors can actually fall open, permitting fire to spread up the chute to the next poorly maintained door. There are many documented incidents of trash or laundry room (termination room) fires spreading up a poorly maintained chute five, ten or more stories and doing millions of dollars worth of property damage at incredible distances from the initial blaze location.

4: Finally, because chutes are gravity-driven conveyances, falling debris can reach incredible speeds: up to and including terminal velocity. This combination of mass and speed can create a clear and present danger to those responsible for chute or refuse compactor maintenance under a chute. The most common maintenance action is the replacement of full containers (usually attached to refuse compactors) with empty containers. Unless the intake doors are deactivated during these container changes, anyone dropping something down the chute can seriously endanger maintenance personnel. The use of the word "anyone" is accurate and appropriate when you consider that refuse chutes in residential buildings are typically designated as "General Access Chutes"... chutes open to the public ... by the provisions of NFPA 82 (the standard for waste and linen chutes which was adopted in November 2009 as part of this code).

SECONDLY, LET US LOOK AT THE PARTICULARS OF THIS PROPOSAL:

Section 715.4.8.3, Item 8: is modified to limit its application to Man Doors associated with the access rooms and termination rooms.

Section 708.13 provides requirements of trash and laundry chutes as a specific type of shafts. The new proposal contained in the public comment creates a new subsection within Section 708.13 to provide specific requirements for the small doors – or hatches – that provide access to the chutes. The intent of the provisions of the new 708.13.3.1 is as follows:

Sec. 708.13.3.1: Beginning text specifies what the following standards apply to.

Item #1. This Section directs that a heat detector instead of a smoke detector to address the fact that the environment of the chute interior is filled with dust and vapor that can negatively affect the performance of a smoke detector which is an ion-detection device. The substitution under these conditions is discussed in Section 907.2.3, Exception 2.3. The installation of a detector in the chute is found in NFPA 82 and is recommended because a fire in the chute can be very difficult to detect.

Item #1.1: This provision for the activating temperature of the heat detector is to insure that its alarm precedes the activation of the sprinkler system at which occurs at about 165° F. (73.8° C.). This provides an earlier warning and may also prevent or minimize the water damage common to sprinkler system activations.

Item #1.2: This provision serves two purposes: 1: Augmentation of the early warning mentioned above, and 2: rapid identification of the location of the fire. Chutes are not usually the first place people look for a fire.

Item 2 specifically requires an interlock system for the chute access doors and specifies how such system should operate and be built. It recognizes the fact that a component known in the chute industry as an "Electric Interlock" is required to meet the automatic-closing provisions of 715.4.8.3. All chute manufacturers offer electric interlocks as optional equipment for a different purpose. This information is necessary because no one in the chute industry actually installs electric interlocks as standard equipment.

To Clarify: Electric Interlocks (EI's) were designed by the chute industry as a safety feature to protect someone depositing waste or linen into a chute from being hit by materials being dropped from above. Electric interlocks typically include a latch bolt that is supplementary to the primary latch. In refuse chutes the primary latch is mounted in the top of the door panel and extends into the frame above. It is held in its extended position by a spring. In laundry chutes, which utilize side hinged doors, the primary latch extends into the door frame at the side of the door. In both door types, the latch bolt of the electric interlock is mounted in a box above the frame and extends down into the top of the door panel. It is activated by an electric solenoid. The solenoids are interconnected from floor-to-floor so that when one interlock is activated at the intake door of a given floor ... the remaining intake doors remain locked until the door in use signals it is closed. The act of closing activates a switch which resets the system. The system is controlled from a panel in the termination room that includes a manual, on-off safety switch

Item 2.1: Recognizes that gravity is a dependable, low-cost, power source that can be counted upon to hold the interlock system's latch bolts in place. This means that the solenoid is used to raise the activated latch bolt. It also means that in the event of a power loss (as can occur in a fire emergency when normal house power drops out as the emergency generator shunts into action) the interlock's latch bolt is in its latched position. This allows the interlock system to act as a reliable back-up for the primary latch bolt.

To Clarify: This redundancy is valuable because under certain circumstances, the intake door's closer can be disabled ... it actually loses its hydraulic fluid and the cylinder cover melts (at about 350°) ... and the spring holding the primary latch up loses its tension (at about 600°). In tandem, these events can result in the intake door falling open *during a fire.* We have actually demonstrated this under UL fire test conditions. We have also made a related proposal to the ICC (with UL's encouragement and assistance) that received committee approval last November. That proposal requires chute intakes doors, which, as fire doors must be self-closing and self-latching, to *remain* closed and to *remain* latched. The required electric interlock system with normally engaged interlocks provides a simple, safe and effective redundancy to the primary latch.

Item 2.2: Recognizes that the maintenance personnel in the termination room are at risk of injury from falling debris. It further recognizes that the addition of a manual control ... a simple ON-OFF switch ... is all that is needed to protect those people from unnecessary injury.

Item 2.3: Recognizes that refuse compactors are common to trash discharge (termination) rooms. It also recognizes that refuse compactors are commonly equipped with multiple, automatic alarm circuits (shut-off features) that protect maintenance employees from accidental compactor activation during servicing activities, i.e., access door open; container full; and/or motor overload.

To Clarify: The extension of two wires from the compactor's power pack to the automatic shut off switch for the Electric Interlocks is all that is necessary to deactivate the intake doors during any one of these compactor alarm events as a means of protecting employees from falling debris during servicing activities. This provision also reduces the potential for fire when a compactor has been filled, but not serviced. We have seen trash backed up as high as six stories in a chute. We have also seen buildings destroyed when kids decide to drop a lighted cigarette into backed-up chutes as a "joke".

Item 2.4: Establishes a safety standard for the electric interlock circuit in that it is low-voltage (typically 12 or 24 volt), installed in conformance with the provisions of the National Electrical Code (NEC), and provided with tested product components for the safety of the end users. The low voltage condition also provides: 1: ease of installation (conduit is not required for Class 2 circuits); 2: lower electrical operating costs; and 3: protection for the end user or repair personnel from accidental electrocution.

In terms of component labeling, we believe that UL 508 which addresses "Industrial Control Equipment" and, more specifically to that category, "Definite Purpose Controllers" might be a good reference. In the instance of electric interlocks, the definite purpose is Life Safety. The electric interlock is an assembly of several listed components mounted in a box on the top frame of an individual door, which has been assembled to UL 508 manufacturing criteria. The interlock assembly becomes part of a "system" when connected to other components assembled to UL 508 criteria whether they are door interlocks on other floors, heat or smoke detectors, or refuse compactor control panels, or any combination thereof, designed to close the doors for the protection of users and/or maintenance personnel.

Analysis: The standard, UL 508, is already a referenced standard in the *International Mechanical Code* and *International Residential Code*.

Final Action: AS AM AMPC____ D

G83-Revised 3/2.doc

G85-09/10
503.1, Table 503, 507.1

Proposed Change as Submitted

Proponent: Rick Thornberry, PE, The Code Consortium, Inc., representing self.

Revise as follows:

503.1 General. The building height and area shall not exceed the limits specified in Table 503 based on the type of construction as determined by Section 602 and the occupancies as determined by Section 302 except as modified ~~hereafter~~ <u>by Sections 503.1.1 through 503.1.5 and Sections 504, 506.2 and 506.3</u>. Each portion of a building separated by one or more fire walls complying with Section 706 shall be considered to be a separate building.

503.1.1 Special industrial occupancies. Buildings and structures designed to house special industrial processes that require large areas and unusual building heights to accommodate craneways or special machinery and equipment, including, among others, rolling mills; structural metal fabrication shops and foundries; or the production and distribution of electric, gas or steam power, shall be exempt from the building height and area limitations of Table 503.

503.1.2 Buildings on same lot. Two or more buildings on the same lot shall be regulated as separate buildings or shall be considered as portions of one building if the building height of each building and the aggregate building area of the buildings are within the limitations of Table 503 as modified by Section 504 and 506. The provisions of this code applicable to the aggregate building shall be applicable to each building.

503.1.3 Type I construction. Buildings of Type I construction permitted to be of unlimited tabular building heights and areas are not subject to the special requirements that allow unlimited area buildings in Section 507 or unlimited building height in Sections 503.1.1 and 504.3 or increased building heights and areas for other types of construction.

503.1.4 Unlimited area buildings. The area of buildings complying with Section 507 shall not be limited by Table 503.
503.1.5 Special provisions. The height and area of buildings complying with Section 509, as applicable, shall not be limited by Table 503.

TABLE 503
ALLOWABLE BUILDING HEIGHTS AND AREAS[a]
(Portions of Table not shown remain unchanged)

For SI: 1 foot = 304.8 mm, 1 square foot = 0.0929 m^2
A = building area per story. S= stories above grade plane, UL = Unlimited, NP = Not permitted.

~~a.~~ ~~See the following sections for general exceptions to Table 503:~~
~~1.~~ ~~Section 504.2, Allowable building height and story increase due to automatic sprinkler system installation.~~
~~2.~~ ~~Section 506.2, Allowable building area increase due to street frontage.~~
~~3.~~ ~~Section 506.3, Allowable building area increase due to automatic sprinkler system installation.~~
~~4.~~ ~~Section 507, Unlimited area buildings.~~
~~b.~~ a. For open parking structures, see Section 406.3.
~~c.~~ b. For private garages, see Section 406.1.
~~d.~~ c. See Section 415.5 for limitations.

507.1 General. The area of buildings of the occupancies and configurations specified herein shall not be limited by Table 503.

Reason: This code change proposal is editorial. Basically, it deletes Footnote a from Table 503 and incorporates it into the text of the code. We believe that code requirements are better addressed in the body of the code rather than as footnotes to a table unless the footnotes are very specific to the table and not general in nature. However, Footnote a is somewhat broad and can be better handled, in our opinion, by relocating the text to Section 503.1 and making a clarification to Section 507.1. And in order to make Section 503.1 more comprehensive regarding how Table 503 is intended to regulate the allowable building heights and areas, we have incorporated new Subsection 503.1.4 addressing unlimited area buildings regulated by Section 507 and Subsection 503.1.5 Special Provisions regulating heights and areas of buildings complying with Section 509. Thus, the user of the code can find all he or she needs to know regarding the determination of building height and area limitations based on the application of Table 503 and the cases where modifications and/or exceptions are made to that table in accordance with the applicable provisions of the sections referenced in Section 503.1 including its subsections.

The proposed revision to Section 507.1 merely correlates with the revisions made to Section 503.1 to indicate that the building area is not limited by Table 503 for these unlimited area buildings.

In conclusion, we believe that these editorial revisions will provide for better code interpretation, application, and enforcement.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: Thornberry-G1-503

Public Hearing Results

Committee Action: Disapproved

Committee Reason: The committee disapproved the proposal, preferring the existing format of footnotes which quantify and limit the application of Table 503. The phrasing of Section 503.1 was awkward and unclear. Section 503.1.5 is misleading regarding the interaction of Table 503 and Section 509.1

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Rick Thornberry, PE, The Code Consortium, Inc., representing self, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

503.1 General. The building height and area shall not exceed the limits specified in Table 503 based on the type of construction as determined by Section 602 and the occupancies as determined by Section 302 except as modified by Sections 503.1.1 through 5.3.1.~~5~~3, ~~and Sections~~ 504~~, 506.2~~ and 506~~.3~~. Each portion of a building separated by one or more fire walls complying with Section 706 shall be considered to be a separate building.

503.1.1 Special industrial occupancies. (*No change in text.)*

~~**503.1.4**~~ **<u>503.1.2</u> Unlimited area buildings.** The area of buildings complying with Section 507 shall not be limited by Table 503.

~~**503.1.5**~~ **<u>503.1.3</u> Special provisions.** The height ~~and area~~ of buildings complying with Section 509<u>.5 or Section 509.6</u>~~, as applicable,~~ shall not be limited by Table 503.

~~**503.1.2**~~ **<u>503.1.4</u> Buildings on same lot.** Two or more buildings on the same lot shall be regulated as separate buildings or shall be considered as portions of one building if the building height of each building and the aggregate building area of the buildings are within the limitations of Table 503 as modified by Section 504 and 506. The provisions of this code applicable to the aggregate building shall be applicable to each building.

~~**503.1.3**~~ **<u>503.1.5</u> Type I construction.** Buildings of Type I construction permitted to be of unlimited tabular building heights and areas are not subject to the special requirements that allow unlimited area buildings in Section 507 or unlimited building height in Sections 503.1.1 and 504.3 or increased building heights and areas for other types of construction.

(Portions of proposal not shown remain unchanged)

Commenter's Reason: We believe that the revisions proposed in this Public Comment to revise our original code change proposal G85-09/10 respond to some of the IBC General Committee's concerns expressed during the hearings when the Committee recommended disapproval. The revisions clarify any direct references to the sections in Chapter 5 that modify Table 503 for height and area. This will eliminate regulation by the footnotes in Table 503 and instead rely directly upon the code text for those sections that are intended to modify Table 503 for determining the maximum allowable building height and area.

Final Action: AS AM AMPC____ D

G86-09/10

503.1.4 (New)

<u>Proposed Change as Submitted</u>

Proponent: Sarah A. Rice, C.B.O., representing self

Add new text as follows:

<u>503.1.4 Occupancies on roofs.</u> <u>Open-air roofs occupied by an occupancy different than the primary occupancy of the building shall not be required to be taken into account when determining the minimum type of construction for the building when the means of egress system from the open-air roof complies with Chapter 10.</u>

> **<u>Exception:</u>** <u>Open-air roofs of buildings of Groups A, B, E, F-2, I, M, R and S-2 occupancies shall not be occupied by Group S-1, F-1 or H occupancies.</u>

Reason: Occupied roof gardens, pool levels and similar uses are literally classified as Group A-3 occupancies but the hazard they present to the building is minimal. So this change proposes that even though their occupancy is Group A-3 (assembly) for determining the minimum level of means of egress from that level, the building not be penalized for their location.

Should a fire incident occur, the very openness of the space will provide venting of any smoke or hot gases that may be generated, in other words it will offer the perfect smoke control system.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: RICE-G6-503.1.4.doc

<u>Public Hearing Results</u>

Committee Action: **Disapproved**

Committee Reason: The proposal is written too broadly and would have a greater impact than the issues discussed by the proponent. At the same time the proposal doesn't really resolve the issues raised. Chapter 9 requires floors below an assembly occupancy to be sprinkler protected, such would not be guaranteed by this proposal. Reference to the means of egress requirements is redundant. This might be more acceptable if it specifically addressed the height and area issues and didn't try to redefine an occupancy.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Sarah A. Rice, CBO, The Preview Group, representing self, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

503.1.4 Occupancies on roofs. Open-air roofs ~~occupied by~~ classified as a Group A-3 occupancy ~~an occupancy different than the primary occupancy of the building~~ shall not be required to be taken into account when determining the minimum type of construction for the building when the means of egress system complies with Chapter 10 from the open-air roof to the public way, and the building is equipped with an automatic sprinkler system in accordance with Section 903.1.1 or 903.1.2 ~~complies with Chapter 10~~.

> ~~**Exception:** Open-air roofs of buildings of Groups A, B, E, F-2, I, M, R and S-2 occupancies shall not be occupied by Group S-1, F-1 or H occupancies.~~

Commenter's Reason: The Committee Reason stated that "The proposal is written too broadly" and that "Chapter 9 requires floors below an assembly occupancy to be sprinkler protected." In response to these concerns the scope of the original proposal has been modified so to only address the occupancy which initially prompted the code change, open-air roofs with roof gardens, patios, swimming pools, and other similar functions – Group A-3 occupancies.

The hazards typically associated with open-air assembly spaces are those that are related to the means of egress from such spaces. Thus this provision would require that the means of egress from the open-air roof must comply with Chapter 10 for the Group A-3 occupancy, regardless of the occupancy(s) in the rest of the building, and that it be maintained from the roof to the public way. In addition the building on top of which these open-air assembly spaces would be located is required to be sprinklered.

Final Action: AS AM AMPC____ D

G87-09/10
503.1.4 (New)

Proposed Change as Submitted

Proponent: Ken Kraus, Los Angeles Fire Department

Add new text as follows:

503.1.4 Occupancy location. An occupancy shall not be located above the story or height limit set forth in Table 503. Where Section 504.2 allows modifications to limits of Table 503, occupancies shall not located above the additional story or increased height limit.

Reason: This proposed addition to the Code is intended to clearly disallow the occupancy of roof areas and stories above the height and story limits prescribed in Table 503 and Section 504.2.

As written, the code can be misapplied if areas above the floor level of the highest story allowed (roof and floor surfaces) are considered part of the highest story allowed for occupant use.

This is due to misinterpretation of the definition of Story which states, in part "The portion of a building included between the upper surface of a floor and the upper surface of the floor or roof next above".

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: KRAUS-G1-503.1.4

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee felt this proposal was the opposite extreme from G86-09/10 and was too restrictive. The committee would like to see something in the middle ground between the two code changes.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jason Thompson, representing National Concrete Masonry Alliance (NCMA), Masonry Alliance for Codes and Standards (MACS), requests Approval as Modified by this Public Comment.

Replace the proposal as follows:

503.1.4 Allowable height of occupancies. No occupancy shall be located above the maximum allowable building height for that occupancy as determined by Table 503 for the type of construction of the building including any height increases allowed by Sections 504.2, 509.5 and 509.6.

Commenter's Reason: We are submitting this Public Comment because we agree with the proponent's intent to limit the height of occupancies in buildings based upon the building's type of construction and the maximum allowable heights allowed for that type of construction for the occupancy that would be located therein. However, we believe that the requirement can be better stated as indicated by the substitute language for the proposed new Section 503.1.4 Allowable Height of Occupancies. We believe the revised text makes it clear that no occupancy is allowed to be located above the maximum allowable building height which includes both number of story limits and height limits in feet above grade plane for the specific occupancy as determined using Table 503 for the type of construction of the building with any allowable height increases included based on the height increases in Sections 504.2, 509.5 and 509.6.

We believe this is totally consistent with the intent of the code for regulating the allowable height and area of buildings containing various occupancies. This is reinforced by requirements in Section 508.2.3 Allowable Building Height and Area which applies to accessory occupancies. In fact, this section would limit the accessory occupancy height to that of the tabular values in Table 503 without any increases allowed in accordance with Section 504. Of course, this is a more specific requirement so it would take precedence over the more general requirement in this new Section 503.1.4.

Section 508.3.2 Allowable Building Area and Height applies to the nonseparated occupancies option for mixed use and occupancy buildings. It states "The allowable building area and height of the building or portion thereof shall be based on the most restrictive allowances for the occupancy groups under consideration for the type of construction of the building in accordance with Section 503.1."

And, finally, Section 508.4.3 Allowable Height which applies to the separated occupancies option for mixed use in occupancy buildings states: "Each separated occupancy shall comply with the building height limitations based on the type of construction of the building in accordance with Section 503.1." It also has an Exception for the special provisions permitted by Section 509 which include Sections 509.5 and 509.6 noted in the proposed new Section 503.1.4.

But common sense should also apply since the allowable building height based on Table 503 with any increases allowed is determined by not only the type of construction of the building but also by the occupancy of the building. This certainly implies that no occupancy should be located to a height greater than that allowed by Table 503 (with any appropriate increases allowed for the building height) based on the building's type of construction. This proposed new section simply states the obvious and correlates with the other requirements in the code for those sections previously noted above. Therefore, we encourage the Class A voting members to overturn the Committee recommendation for disapproval and approve this Code Change Proposal as modified by this Public Comment.

Final Action: AS AM AMPC____ D

G89-09/10
Table 503

Proposed Change as Submitted

Proponent: Jason Thompson, National Concrete Masonry Association, representing the Masonry Alliance for Codes and Standards

Revise as follows:

TABLE 503
ALLOWABLE HEIGHT AND BUILDING AREAS[a]

GROUP		TYPE OF CONSTRUCTION								
		TYPE I		TYPE II		TYPE III		TYPE IV	TYPE V	
	HEIGHT (feet)	A	B	A	B	A	B	HT	A	B
		UL	160	65	55	65	55	65	50	40
		STORIES (S) AREA (A)								
R-1	S	UL	11	4	~~4~~ 3	4	~~4~~ 3	4	3	2
	A	UL	UL	24,000	16,000	24,000	16,000	20,500	12,000	7,000
R-2	S	UL	11	4	~~4~~ 3	4	~~4~~ 3	4	3	2
	A	UL	UL	24,000	16,000	24,000	16,000	20,500	12,000	7,000
R-4	S	UL	11	4	~~4~~ 3	4	~~4~~ 3	4	3	2
	A	UL	UL	24,000	16,000	24,000	16,000	20,500	12,000	7,000

(Portions of table and footnotes not shown remain unchanged.)

Reason: One area of concern identified for study by the ICC Code Technology Committee's Height and Area Study Group was 4 and 5 story buildings of non-fire-resistance-rated types of construction. The table below shows the occupancies in the 2006 International Building Code (IBC) where that condition existed for sprinklered buildings of Types IIB and IIIB construction. In addition, the table shows the sprinklered height allowances for these occupancies in the legacy codes.

Type IIB and Type IIIB Construction
Story Comparison (w/ NFPA 13 Sprinkler System)

	SBC	NBC	UBC	2006 IBC
B	5	4	2	**5**
F-2	4	4	2	**4**
M	5	3	2	**5**
S-1	4	3	2	**4**
S-2	4	4	2	**5**
R* (NFPA 13)	5	4	4	**5**
R* (NFPA 13R)	4	4	3	**4**

* - Applies for R-1, R-2 and R-4 Use Groups

The Study Group noted that for Use Group B, M, S-1, and R buildings of Type IIB and Type IIIB construction, the allowance for 4 or 5 stories in the IBC was premised on the story heights allowed in the SBCCI Standard Building Code (SBC). In all these instances, the SBC sprinklered height allowance for those Use Groups was based on a multiple story sprinkler increase. For example, for Use Group R, the SBC allowed 2 stories for unsprinklered construction and 5 stories for sprinklered construction. This exceeded the consistent one story sprinkler height increase incorporated in the IBC height and area provisions. Based on this review, the Study Group identified two anomalies from what was permitted by the legacy codes. First, the story height allowance for S-2 use groups was not based on any of the legacy code allowances. Second, for Use Groups B, M, S-1, and R in Types IIB and IIIB construction, the IBC story height allowance for unsprinklered buildings exceeded what was allowed by any of the legacy codes. For example, the largest height allowed for an unsprinklered Type IIB construction apartment building (Group R-2 occupancy) in any of the legacy codes was the BOCA National Building Code (NBC) allowance for 3 stories. Currently, the IBC allows 4 stories for this condition. Rather than modify the sprinkler increase in the IBC, the Study Group suggested the following recommended story heights for Table 503:

Unsprinklered 2006 IBC Table 503 Values (Revised)

Use Group	IIB	IIIB
B	3	3
M	2	2
S-1	2	2
S-2	3	3
R*	3	3

* - Applies for R-1, R-2 and R-4 Use Groups

In essence, these reductions would eliminate the anomalies created by the multi-story SBC sprinkler increase and drop the IBC values back to the next least restrictive legacy code (in these cases, the NBC). It should be noted that during the ICC Final Action Hearings in Minneapolis for the last code cycle, all of the code changes submitted by the Study Group to reduce the allowable story heights were approved by the ICC Class A voting members with a greater than two-thirds majority vote except for one. That one was Code Change G118-07/08 which is identical to this code change proposal. Although the voting members were able to overturn the Committee's recommendation for disapproval, the code change was subsequently disapproved because the two-thirds (67%) majority vote could not be achieved. The final vote was 243 in favor and 163 opposed (60%). Since a significant majority of the Class A voters wanted to see that code change approved, the change is being resubmitted for reconsideration by the IBC General Committee.

Although the proposal will reduce the allowable height of Group R buildings of Types IIB and IIIB construction by one story, the maximum area (total of all stories) of the tallest building that will then be permitted will generally still be considerably greater than that permitted by any of the legacy codes (see table below). For example, consider a residential building (Group R occupancy) of Type IIB construction, which does not have an NFPA 13 sprinkler system, with a height of 3 stories; the tallest permitted by any of the legacy codes. If less than 20 feet of open space is provided around the building, the IBC permits the total area of all three stories to be 108% greater than the largest total area permitted by the legacy codes. If the width of the open space is increased to 40 feet, the IBC's total area allowed is still 27% greater than the largest area allowed by any of the legacy codes. If an NFPA 13 sprinkler system is provided in a Group R residential building of Type IIB construction, the height of the building can be increased to four stories. If the building has less than 20 feet of open space, the maximum area allowed by the IBC is 50% greater than the largest area allowed by any of the legacy codes. Although allowable heights are proposed to be reduced, the foregoing illustrates that residential buildings will still be able to have total areas that are comparable to or greater than that permitted by the largest areas allowed by any of the legacy codes.

It should be noted that this proposal has no impact on residential buildings equipped with NFPA 13R or NFPA 13D sprinklers since they are not currently allowed to use the height increase for sprinklers.

Occupancy Group	Type of Construction	NFPA 13 Sprinklers – Yes/No	Width of Open Space (ft.)[a, b]	Ratio of IBC Maximum Building Area to the Largest Maximum Building Area Permitted by Legacy Codes				
				Number of Stories				
				1	2	3	4	5
R-1 R-2 R-4	IIB	No	< 20	1.33	1.33	2.08	NPLC	NP
			40	1.17	1.17	1.27	NPLC	NP
		Yes	< 20	1.78	1.67	2.00	1.50	1.20
			40	1.39	1.39	1.67	1.25	1.00
	IIIB	No	< 20	1.33	1.33	2.08	NPLC	NP
			40	1.17	1.17	1.27	NPLC	NP
		Yes	< 20	1.78	1.67	2.00	1.50	1.20
			40	1.39	1.39	1.67	1.25	1.00

NPLC means not permitted by any of the legacy codes, but permitted by the IBC.
NP means not permitted by any of the legacy codes or the IBC.

If this code change is approved, building heights represented by shaded cells will not be permitted by the IBC.
a. Width of open space around 100% of building perimeter.
b. 40 feet was used because the ICBO Uniform Building Code (UBC) required a minimum 40 feet of open space on all sides of the building in order to qualify for a 100% area increase; the maximum permitted by that code. The NBC and SBC permitted maximum open space increases of 150% and 100%, respectively, at 30 feet.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: Thompson-G2-T503

Public Hearing Results

Committee Action: Disapproved

Committee Reason: The proponent did not provide technical information justifying the reduction of allowable height for these occupancies. The information that was provided was about property loss, not threats to life safety of the occupants.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jason Thompson, National Concrete Masonry Alliance (NCMA), representing Masonry Alliance for Codes and Standards (MACS), requests Approval as Submitted.

Commenter's Reason: We are submitting this Public Comment to our Code Change G89-09/10 requests Approval as submitted because we believe the ICC Class A voting members should have the opportunity to once again vote on this very important issue regarding the reduction by one story of the story height limits in Table 503 for Group R occupancies in buildings of Types IIB and IIIB construction. Approval of this Public Comment will also close the last chapter in the ICC Code Technology Committee's Height and Area Study Group's efforts to revise the height and area requirements of the International Building Code (IBC). The Group R occupancies are the only occupancy classification that did not achieve the two-thirds majority vote needed to approve the series of Code Changes submitted by the Study Group to reduce the allowable story heights for buildings of Types IIB and IIIB construction.

As noted in our Reason Statement for this Code Change, the vote taken during the last ICC Final Action Hearing to overturn the IBC General Code Development Committee's recommendation for disapproval fell slightly short of the two-thirds majority needed by a vote of 243 in favor to 163 opposed for a 60% majority vote. Clearly, this is a significant majority but not enough to achieve that necessary to be successful at the ICC Final Action Hearings. Once again, the IBC General Code Development Committee has recommended this Code Change for disapproval but on a much closer vote of 7 to 5. Thus, we believe the Class A voting members should have this one last chance to complete the ICC Code Technology Committee's Height and Area Study Group Code Change packet to make the building height limits in Table 503 more consistent in relationship to the relative hazards of the other occupancy classifications for the 2012 edition of the IBC. This will be our only opportunity to accomplish such a revision until the next 3 year code cycle for the 2015 edition.

Contrary to the Committee's Reason Statement that no technical information was provided to justify the proposed reduction in the allowable height for these Group R occupancies, we believe that our Reason Statement contains substantial technical justification.

Furthermore, we have researched the last several years of large loss fires reported by the National Fire Protection Association (NFPA) and have discovered a very alarming and disturbing trend in such fires involving three and four story Group R occupancies. It should be noted that NFPA defines a large loss fire as any fire resulting in at least $5 million in property damage. In 2007 residential fires qualifying as large loss fires represented 11% of the number of large-loss fires reported and 2% of the total loss with a reported loss for residential fires of $78.5 million. In 2008 residential fires represented 17% of the large loss fires reported to the NFPA which resulted in 7.2% of the total loss with a reported loss of $170.5 million for residential occupancies. Several of these fires involved residential occupancies protected with NFPA 13R sprinkler systems where the attics are allowed to remain unsprinklered, even though they are often constructed of combustible materials in these three and four story buildings as allowed by Table 503 of the IBC. And several of these fires occurred in buildings under construction which were to be sprinklered in accordance with NFPA 13R but burned down before the sprinkler system could be installed in an operational mode. Thus, a significant quantity of residential dwelling units and/or apartments have been lost in recent years in buildings allowed to be four stories in height of unprotected construction such as Type IIB and IIIB construction.

By reducing the allowable story heights for these types of construction from four stories to three stories, it would only be possible to utilize an NFPA 13R sprinkler system to allow the buildings to be increased in height to four stories. However, buildings greater than four stories in height would be required to be protected with an automatic sprinkler system designed in accordance with NFPA 13 which mandates protection of combustible attic spaces with sprinklers. This would significantly reduce the likelihood of a large-loss fire occurring in these buildings should the fire get into the attic space.

It is interesting to note that in the Committee Statement the Committee expressed its concerns that the information provided by us at the hearings was mainly about property loss and not threats to the life safety of the occupants. But that was precisely our point. Section 101.3 Intent of Part 1 – Scope and Application of the IBC clearly states that: "The purpose of this code is to establish the minimum requirements to safeguard the public health, safety and general welfare through… safety to life and property from fire…" Thus, property protection is clearly part of the purpose of the IBC. And it is especially important where property losses affect the overall general welfare of the public which could be seriously harmed by the loss of a significant amount of the housing stock in this country due to fire. As we all know, there is already a shortage of affordable housing in this country, so it should be incumbent upon the IBC to provide a sufficient level of fire and life safety for residential occupancies to minimize property losses to those occupancies that result in the significant loss of available housing units or future housing units due to fires that occur during construction. If this Code Change is approved, it will, in effect, prohibit the construction of Group R occupancy buildings to a height of five stories and 75 feet using one of the nonrated types of construction, i.e. Type IIB and IIIB, with the installation of an NFPA 13 sprinkler system. However, currently Table 503 of the IBC with an NFPA 13R automatic sprinkler system height increase will allow Group R occupancy buildings to be constructed as high as four stories and 60 feet in Types IIB and IIIB construction. These allowable building heights are greater than allowed for any other occupancy classification regulated by the code for these types of construction. Clearly, this does not make any sense since Group R occupancies contain people who are staying overnight sleeping and are thus more vulnerable to fires occurring during the night.

It should also be pointed out that there is another anomaly in Chapter 5 as it relates to determining the maximum allowable building area based on automatic sprinkler system protection being provided. Exception 2 to Section 506.4.1 Area Determination allows a four story Group R occupancy building protected with an automatic sprinkler system designed in accordance with NFPA 13R to have its maximum building area determined by multiplying the allowable area per story as determined by Section 506.1 by the number of stories above grade plane. That means that the allowable building area could be four times that allowed for a single story building. This should be compared to the maximum building area allowed for all other occupancy buildings sprinklered in accordance with NFPA 13 which by Item 2 of Section 506.4.1 are only allowed to be three times that allowed for the single story building area for any building three or more stories in height above grade plane. Thus, a Group R occupancy sprinklered with an NFPA 13R sprinkler system (which is not a true property protection system) is allowed to have a greater total building area than a Group R occupancy building, or any other occupancy building for that matter, protected with an NFPA 13R sprinkler system which is both a life safety and a property protection system. So there is less of an incentive to install an NFPA 13 sprinkler system in Group R buildings that are four stories in height.

We intend to provide the Class A voting members at the ICC Final Action Hearings in Dallas with a more detailed analysis of the large loss fire statistics for Group R residential occupancies to support this Code Change Proposal from a property loss/loss of housing stock perspective which we believe is significant and which we believe this Code Change will help to mitigate. Therefore, we urge the Class A voting members to overturn the Committee's recommendation for disapproval and vote for approval as submitted of this Code Change G89-09/10.

Final Action: AS AM AMPC____ D

G90-09/10
Table 503

Proposed Change as Submitted

Proponent: A. Hal Key, PE, Mesa, AZ Fire Department

Revise as follows:

TABLE 503
ALLOWABLE BUILDING HEIGHTS AND AREAS[a]
Building height limitations shown in feet above grade plane. Story limitations shown as stories above grade plane.
Building area limitations shown in square feet, as determined by the definition of "Area, building," per story

		TYPES OF CONSTRUCTION								
		TYPE I		TYPE II		TYPE III		TYPE IV	TYPE V	
		A	B	A	B	A	B	HT	A	B
	Height(feet)	UL	160	65	55	65	55	65	50	40
GROUP	STORIE(S) AREA (A)									
S-1[e]	S A	UL UL	11 48,000	4 26,000	2 17,500	3 26,000	2 17,500	4 25,500	3 14,000	1 9,000

For SI: 1 foot = 304.8 mm, 1 square foot = 0.0929m2.
A = building area per story, S = stories above grade plane, UL = Unlimited, NP = Not permitted.

a. See the following sections for general exceptions to Table 503:
   1. Section 504.2, Allowable building height and story increase due to automatic sprinkler system installation.
   2. Section 506.2, Allowable building area increase due to street frontage.
   3. Section 506.3, Allowable building area increase due to automatic sprinkler system installation.
   4. Section 507, Unlimited area buildings.
b. For open parking structures, see Section 406.3.
c. For private garages, see Section 406.1.
d. See Section 415.5 for limitations.
<u>e. For aircraft hangars, see Section 412.2.</u>

(Portions of table not shown remain unchanged)

Reason: During the last cycle, changes were made to Section 412.2 classifying aircraft hangars by the NFPA 409 classifications to determine the fire suppression requirements. These changes created area limitations that a user of the Building Code may not find without going to Section 412.2. The addition of footnote "e" sends the user of the Building Code to this section similarly to other footnotes found in this table.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: KEY-G1-TABLE 503.doc

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: Committee felt the added reference was not needed because designers and building officials would find the aircraft use special provisions without the assist of this footnote. Committee members expressed concern of starting another laundry list of references.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

A. Hal Key, PE, representing self, requests Approval as Submitted.

Commenter's Reason: The committee disapproved this proposal for the following reason: "Committee felt the added reference was not needed because designers and building officials would find the aircraft use special provisions without the assist of this footnote. Committee members expressed concern of starting another laundry list of references." I disagree with the committee's statement. There already is list with footnotes b and c for Group S-2 occupancies and footnote d for Group H occupancies. This pointer to Chapter 4 is necessary so the designer knows to also look in Chapter 4 for area requirements contained there. Without this footnote, the designer may use only the area limits from Table 503 without realizing that Section 412.2 also limits the area of an aircraft hangar based on its classification as an aircraft hangar and the type of fire protection system installed in that hangar. In fact, none of the S-1 area limitations in Table 503 apply to an aircraft hangar. All the area limitations are now contained in Section 412.2. Note that all aircraft hangars are now S-1 occupancies with the 2009 Edition of the IBC. There are no longer aircraft hangars that are S-2 occupancies. The designer could be severely misled on the area limitations listed in Table 503 for just an S-1 occupancy.

Aircraft hangars are one of those occupancies that are not built very often and as a result most designers will go to the IBC and research this occupancy and not find all the references to it without some help. This proposal is intended to assist both the "once and a while" aircraft hangar designer and the code official in locating the requirements for this special occupancy.

Public Comment 2:

David S. Collins, FAIA, The Preview Group, Inc., representing The American Institute of Architects, requests Approval as Modified by this Public Comment.

Replace the proposal as follows:

TABLE 503
ALLOWABLE BUILDING HEIGHTS AND AREAS[a, b]
Building height limitations shown in feet above grade plane. Story limitations shown as stories above grade plane.
Building area limitations shown in square feet, as determined by the definition of "Area, building," per story
(Remove all footnotes from body of table)

a. See the following sections for general exceptions to Table 503:
 1. Section 504.2, Allowable building height and story increase due to automatic sprinkler system installation.
 2. Section 506.2, Allowable building area increase due to street frontage.
 3. Section 506.3, Allowable building area increase due to automatic sprinkler system installation.
 4. Section 507, Unlimited area buildings.

b. ~~For open parking structures, see Section 406.3.~~ See Chapter 4 for specific exceptions to the allowable height and areas in Chapter 5.

~~c. For private garages, see Section 406.1.~~

~~d. See Section 415.5 for limitations.~~

Commenter's Reason: This code change was intended to add a reference note sending the code user to the criteria for aircraft hangers that had been added to the code and placed in Chapter 4. The concern expressed by the committee in rejecting this proposed change was that a list of various conditions would be created. They are right, but lacking a general reference to Chapter 4 exceptions to height and area, the code user would not know that such exceptions exist or that they are exceptions in the first place. This change will send the code user to Chapter 4 for all special occupancy conditions.

Final Action: AS AM AMPC____ D

G91-09/10
504.2

Proposed Change as Submitted

Proponent: Jason Thompson, National Concrete Masonry Association, representing the Masonry Alliance for Codes and Standards

Revise as follows:

504.2 Automatic sprinkler system increase. Where a building is equipped throughout with an approved automatic sprinkler system in accordance with Section 903.3.1.1, the value specified in Table 503 for maximum height is increased by 20 feet (6096 mm) and the maximum number of stories is increased by one story. These increases are permitted in addition to the area increase in accordance with Sections 506.2 and 506.3. ~~For Group R buildings equipped throughout with an approved automatic sprinkler system in accordance with Section 903.3.1.2, the value specified in Table 503 for maximum height is increased by 20 feet (6096 mm) and the maximum number of stories is increased by one story, but shall not exceed four stories or 60 feet (19 288 mm), respectively.~~

Exceptions:

1. Buildings, or portions of buildings, classified as a Group I-2 occupancy of Type IIB, III, IV or V construction.
2. Buildings, or portions of buildings, classified as a Group H-1, H-2, H-3 or H-5 occupancy.
3. *Fire-resistance rating* substitution in accordance with Table 601, Note d.

Reason: This code change proposes to eliminate the special allowances given for Group R occupancy buildings that are protected with an NFPA 13R automatic sprinkler system as specified in Section 903.3.1.2. Currently, Section 504.2 will allow an increase in the building height of one story and 20 feet where an NFPA 13R sprinkler system is provided, as long as the building does not exceed a total height of four stories or 60 feet. Furthermore, Section 506.4 allows an area increase for the installation of an NFPA 13R sprinkler system for Group R buildings that are greater than three stories in height. It is not appropriate to provide for both an allowance of an area increase and height increase for the types of construction. Where an NFPA 13R sprinkler system is installed the net result in the overall level of safety is a lessening of the passive built-in fire resistance that would be required if one of the NFPA 13R reductions (area or height) were not permitted.

NFPA 13R sprinkler systems primarily provide for life safety in buildings. They were developed for that purpose as clearly stated in Section 1.2 of the 2002 edition of the standard. It is interesting to note the Annex A discussion of the purpose of NFPA 13R which states: “Various levels of sprinkler protection are available to provide life safety and property protection. This standard is designed to provide a high, but not absolute, level of life safety and a lesser level of property protection. Greater protection to both life and property could be achieved by sprinklering all areas in accordance with NFPA 13… it should be recognized that the omission of sprinklers from certain areas could result in the development of untenable conditions in adjacent spaces. Where evacuation times could be delayed, additional sprinkler protection and other fire protection features, such as detection and compartmentation, could be necessary.” That statement says it all about an NFPA 13R sprinkler system.

The intent of the IBC as expressed in Section 101.3 Intent is as follows: “The purpose of this code is to establish the minimum requirements to safeguard the public health, safety, and general welfare… and safety to life and property from fire and other hazards attributed to the built environment and to provide safety to fire fighters and emergency responders during emergency operations.” Allowing the use of an NFPA 13R sprinkler system to increase the size of a building is counter to the intent and purpose of the IBC. Types of construction are designed to limit the height and area of buildings based on the occupancy and the degree of built-in fire-resistive protection and use of combustible or noncombustible construction materials. Buildings are allowed to get larger in area and taller in height with more fire-resistance built in and the reduced use of combustible construction for the building’s structural elements. Therefore, property protection is a primary outcome of the types of construction used. Of course, type of construction also plays a role in life safety, especially in multi-story buildings, and has an impact on fire fighter safety as well. But an NFPA 13R sprinkler system is basically a partial sprinkler system because the standard does not require sprinklers in many concealed combustible areas including attics. So why should a building protected with an NFPA 13R sprinkler system be given the same credit for a building with more complete protection based on NFPA 13 sprinkler system?

Within the last few years there have been many fires involving buildings protected with NFPA 13R sprinkler systems which have burned to the ground. In most of those cases, the fire was able to get into the unprotected combustible attic space and spread throughout the building and then burn downward, overpowering the sprinkler system. It is not logical to allow increases in height and area for sprinkler systems that can not reduce the risk of a building being burned to the ground.

There have been several code changes in the recent two cycles to eliminate this height increase for NFPA 13R sprinkler systems. Though not previously approved the Masonry Alliance for Codes and Standards (MACS) still agrees with the previous proponents’ supporting statements on why this reduction is not warranted. The issues have been clearly stated and adequate reasons given to support this particular code change proposal. Therefore, we respectfully request the Committee approve this code change proposal as submitted for the reasons stated.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: Thompson-G6-504.2

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: Fire statistics do not support the reduction of the allowance. There is no data that the fire loss experience is different for three story versus four story building. The NFPA 13R systems are adequate. While there are fires in attics, they rarely result in loss of the building.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Jason Thompson, National Concrete Masonry Association (NCMA), representing the Masonry Alliance for Codes and Standards (AMCS), requests Approval as Submitted.

Commenter's Reason: We believe that the large-loss fire statistics compiled by the National Fire Protection Association (NFPA) clearly show a trend in Group R residential occupancies constructed three or four stories in height and protected with NFPA 13R sprinkler systems. The indication that we've been able to conclude from our analysis of the NFPA large-loss fire data for losses greater than $5 million in property damage seems to indicate that fires in Group R occupancies protected with NFPA 13R sprinkler systems are more likely to result in a large loss fire if the fire originates in the attic space or is able to get into the attic space before the sprinkler system below can control it. We intend to provide a detailed analysis of the NFPA large loss fire statistics compiled over the last several years for Group R residential occupancies to support this conclusion which will be made available at the ICC Final Action Hearings for the Class A voting members to review prior to the vote on this Code Change Proposal. We believe that the fire data alone will support this Code Change Proposal which eliminates the allowable height increase of one story and 20 feet for Group R occupancies protected with an NFPA 13R sprinkler system.

We are also concerned that the NFPA 13R sprinkler system is actually being used to "double dip" by allowing both a height increase, as indicated in this section we are trying to revise, as well as an area increase. The area increase is allowed for four story Group R occupancy buildings protected with NFPA 13R sprinkler systems in accordance with Exception 2 to Section 506.4.1 Area Determination. This Exception will allow such a four story building to have a total building area determined by multiplying the number of stories (four) by the allowable area per floor. This, in essence, is an area increase since the total building area allowed for all other occupancies and for all other buildings protected with an NFPA 13 sprinkler system is based on a maximum of three times the area allowed for a single story for buildings three or more stories in height. Thus, a four story building under Item 2 of Section 506.4.1 would only be allowed to have a total building area equal to three times that of a single floor area.

It is interesting to note that this height increase allowance would actually only be used under the current IBC for Group R occupancies of Types VA and VB construction. Type VB construction would be allowed to be increased in building height of two stories/40 feet to three stories/60 feet and a Type VA construction building would be allowed to be increased in the building height from three stories/50 feet to four stories/60 feet where an NFPA 13R sprinkler system is provided. In terms of allowable building height, this would make a Type VA building comparable to a Type IIA or IIIA building when protected with an NFPA 13R sprinkler system. We don't believe that is a reasonable allowance for Type VA construction using a primarily life safety sprinkler system to achieve the increased allowable building height.

We also ask the question: "Is it reasonable to allow a Type VB construction building of a Group R occupancy to be three stories/60 feet in height?" These buildings would have no requirement for fire-resistance ratings of the bearing walls and columns and, of course, would be allowed to have attics unprotected with sprinklers. In essence, this equates a Type VB construction building of a Group R occupancy to a Type VA construction building of the same occupancy classification with the installation of an NFPA 13R sprinkler system. Again, we do not believe this is a reasonable allowance for a life safety type sprinkler system which is being equated to providing 1-hour fire-resistive protection for the structural elements supporting the building.

In conclusion, we believe we have adequately substantiated why the Committee recommendation for disapproval of this Code Change Proposal should be overturned by the Class A voting members at the ICC Final Action Hearings so this Code Change can then be Approval as Submitted to eliminate the allowable building height increase for Group R occupancies protected with an NFPA 13R sprinkler system.

Public Comment 2:

Jason Thompson, National Concrete Masonry Association (NCMA), representing the Masonry Alliance for Codes and Standards (AMCS), requests Approval as Modified by this Public Comment.

Replace the proposal as follows:

504.2 Automatic sprinkler system increase. Where a building is equipped throughout with an approved automatic sprinkler system in accordance with Section 903.3.1.1, the value specified in Table 503 for maximum height is increased by 20 feet (6096 mm) and the maximum number of stories is increased by one story. These increases are permitted in addition to the area increase in accordance with the Sections 506.2 and 506.3. For Group R buildings <u>of Type VA</u> construction equipped throughout with an approved automatic sprinkler system in accordance with Section 903.3.1.2, the value specified in Table 503 for maximum height is increased by 20 feet (6096 mm) and the maximum number of stories is increased by one story, but shall not exceed four stories or 60 feet (19 288 mm), respectively.

Exceptions:

1. Buildings, or portions of buildings, classified as a Group I-2 occupancy of Type IIB, III, IV or V construction.
2. Buildings, or portions of buildings, classified as a Group H-1, H-2, H-3 or H-5 occupancy.
3. *Fire-resistance rating* substitution in accordance with Table 601, Note d.

Commenter's Reason: This Public Comment is being submitted to offer a compromise to the Class A voting members regarding the sprinkler trade-off for a building height increase of one story and 20 feet to a maximum height of four stories and 60 feet for Group R buildings protected with an NFPA 13R sprinkler system.

The revisions in this Public Comment will limit the application of this automatic sprinkler system trade-off for an NFPA 13R sprinkler system to allow the increased one story and 20 feet in building height to Group R occupancy buildings of Type VA construction only. So, in other words, an NFPA 13R sprinkler system could not be used in a Group R occupancy building of Type VB construction to get an increase in building height. It should be noted that only Type V construction buildings can currently take advantage of this building height increase for an NFPA 13R sprinkler system since it is limited to a maximum building height of four stories and 60 feet. All the other building construction types for Group R occupancies allow a maximum story height of four stories and at least 55 feet without considering any sprinkler increases.

Does this appear to be a reasonable compromise? We believe that it is not as desirable as eliminating the building height increase altogether for NFPA 13R sprinkler systems, but it at least would not allow the trade-off to be used in a type of construction that does not provide for any fire-resistive protection for the building's structural elements. Thus, approval of this Public Comment that revises Section 504.2 would not allow a Group R occupancy building of Type VB construction to have its building height increased from two stories/40 feet to three stories/60 feet. Without this modification, the code is basically equating an NFPA 13R sprinkler system to 1-hour fire-resistive protection of the building structural elements that carry the loads of the building to ground. This would appear reasonable given the fact that an NFPA 13R sprinkler system, as indicated in our Reason Statement, is not primarily a property protection system, but rather a life safety protection system. We believe this is especially important given the fact that attics are not required to be sprinklered in an NFPA 13R sprinkler system. Therefore, if a fire gets out of control in a Type VB construction building protected with an NFPA 13R sprinkler system, it is very likely that it will burn to the ground, resulting in a total loss.

This could conceivably have an impact on firefighter safety as well since, as noted previously, the vertical bearing elements of the building would not have any fire-resistive protection so a concealed fire could cause premature structural collapse of the building while the fire department was still inside trying to make an internal attack to control and eventually extinguish the fire. Certainly this would be a detriment to the public welfare with a loss of all of the dwelling units which would render many people temporarily homeless. So we would much more prefer to see the NFPA 13R sprinkler system height increase trade-off allowed for Type VA buildings, if it is to be allowed at all, since these buildings provide a minimum 1-hour fire-resistive protection throughout including all structural bearing elements. This will certainly provide for greater property protection, as well as enhance firefighter safety and improve public welfare by minimizing the chance that the building would be totally destroyed by a fire that is able to overcome the NFPA 13R sprinkler system.

In conclusion, we urge the Class A voting members to consider this Public Comment as a reasonable compromise for allowing the NFPA 13R sprinkler trade-off for increased building height in Group R occupancy buildings to remain in the IBC should the Class A members concur with this Public Comment. Although our choice would be for this Code Change Proposal to be approved, we believe this to be an acceptable compromise. However, in order for this Public Comment to be approved as revised for Code Change G91-09/10, it will be necessary for the Class A voting members to overturn the Committee's recommendation for disapproval. Then a two-thirds majority vote would still be required to approve this Code Change as modified by this Public Comment.

Final Action: AS AM AMPC____ D

G92-09/10
504.2, 506.3

Proposed Change as Submitted

Proponent: Robert J Davidson, Code Consultant, Alan Shuman, President, representing the National Association of State Fire Marshals (NASFM)

Revise as follows:

504.2 Automatic sprinkler system increase. Where a building is equipped throughout with an approved automatic sprinkler system in accordance with Section 903.3.1.1, the value specified in Table 503 for maximum height is increased by 20 feet (6096 mm) and the maximum number of stories is increased by one. These increases are permitted in addition to the area increase in accordance with Section~~s~~ 506.2 ~~and 506.3~~. For Group R buildings equipped throughout with an approved automatic sprinkler system in accordance with Section 903.3.1.2, the value specified in Table 503 for maximum height is increased by 20 feet (6096 mm) and the maximum number of stories is increased by one, but shall not exceed 60 feet (18 288 mm) or four stories, respectively.

Exception~~s:~~ The use of an automatic sprinkler system to increase building heights shall not be permitted for the following conditions:

1. Buildings, or portions of buildings, classified as a Group I-2 occupancy of Type IIB, III, IV or V construction.
2. Buildings, or portions of buildings, classified as a Group H-1, H-2, H-3 or H-5 occupancy.
3. ~~Fire-resistance rating substitution~~ Buildings where an automatic sprinkler system is substituted for fire-resistance rated construction in accordance with Table 601, Note d.
4. Buildings where an automatic sprinkler system is used to increase the building height or number of stories accordance with Section 506.3.

506.3 Automatic sprinkler system increase. Where a building is equipped throughout with an approved automatic sprinkler system in accordance with Section 903.3.1.1, the area limitation in Table 503 is permitted to be increased by an additional 200 percent (I_s = 2) for buildings with more than one story above grade plane and an additional 300 percent (I_s = 3) for buildings with no more than one story above grade plane. ~~These increases are permitted in addition to the height and story increases in accordance with Section 504.2.~~

Exception: The use of an automatic sprinkler system to increase the building area limitation ~~increases~~ shall not be permitted for the following conditions:

1. ~~The automatic sprinkler system increase shall not apply to Buildings with an occupancy in Group H-1~~. Buildings classified as a Group H-1 occupancy.
2. ~~The automatic sprinkler system increase shall not apply to the building area of an occupancy in Group H-2 or H-3~~. Buildings, or portions of buildings, classified as either a Group H-2 or H-3 occupancy. For buildings containing such occupancies, the allowable area shall be determined in accordance with Section 508.4.2, with the sprinkler system increase applicable only to the portions of the building not classified as Group H-2 or H-3.
3. Buildings where an automatic sprinkler system is substituted for fire-resistance rated construction ~~Fire-resistance rating substitution~~ in accordance with Table 601, Note d.
4. Buildings where an automatic sprinkler system is used to increase the building height or number of stories in accordance with Section 504.2.

Reason: In reviewing this comment we ask that you keep in mind that when the IBC was created, there was a policy decision made that when merging the three legacy codes into one, any conflict between legacy code provisions would default to the lesser requirement. This reportedly was done to avoid adoption problems for jurisdictions when moving to the IBC from a legacy code, i.e., if the new code was more restrictive there could be opposition to adoption. The concept of balance is constantly bandied about when examining specific code provisions in that when looking at the code as a whole, one requirement balances out the other. This concept is spoken of specifically when dealing with automatic sprinkler system trade offs. If we accept the fact that the three separate legacy codes were balanced, i.e., they had some requirements less restrictive than the same topic in another legacy code but they had other topics that were more restrictive, what happened when we merged the three codes? We went through and took the lowest requirement from each code without taking the more restrictive. What happened to the balancing effect that each legacy code had developed over the years? It does not exist in the IBC.

Another way to look at this issue is that in many jurisdictions the building code is the minimum standard to apply, in some it is the minimum and the maximum standard, (mini-max code). In any jurisdiction that previously applied one of the legacy codes, at the time they had a legacy code effective, the current IBC provisions would be less than that applicable code permitted. In other words, application of many of the provisions in the

IBC would be illegal. It is for that reason we seek to reduce the size of some of the buildings permitted to be built under the IBC to start to bring balance back to the code.

Those of us that have been proposing to modify some of the height and area requirements have been asked by opponents why we are so focused on this issue, what is so wrong with the height and areas. To be honest, we are not focused on this one issue. We have been active in many areas of the code we felt need clarification or tightening of requirements. But our specific interest in the height and area is because of the cumulative effect of the process we describe in the first two paragraphs of this reasoning statement.

We not only get bigger buildings under the IBC as compared to various legacy codes, we get them with less protective features and a reduced ability to withstand attack by fire. In much of the country Type 1A construction required 4 hour protection. Now it only requires 3 hour protection. So the buildings are bigger and when attacked by fire they may come down quicker.

The size of the buildings directly relates to how much area a responding fire department must deal with and possibly how much area must be searched. No one checked with the fire service to see if their manning levels could handle the increased size allowance coupled with the reduction in protection features. Take a look at the legacy codes and compared the restrictions on communicating floor levels with what the IBC allows now. So not only are the buildings bigger with reduced fire resistance requirements, we now allow the smoke and heat to travel to more of the building.

The answer we get on this topic is that the buildings in question will have an automatic fire suppression system and that takes care of all of your concerns. Though we are strong believers in the installation of automatic sprinkler systems and we would like to eventually see them installed in all buildings and structures, we also believe in striking a balance. Being safe means not relying on a single method of protection, or in this case a single protective system.

This position is supported by the recent NFPA report, "U.S. Experience with Sprinklers and Other Automatic Fire Extinguishing Equipment", http://www.nfpa.org/assets/files//PDF/OSsprinklers.pdf . Though overall sprinklers operate in 95% of all reported structure fires and are effective 96% of that time, resulting in a combined overall effectiveness of 91%. The actual percentage changes based upon occupancy with warehouses at the 78% level.

They are out of service for maintenance, construction, (tenant improvements), unintentional human error. There is also a vulnerability factor- besides seismic, we have experience where systems were taken out by vehicle crash or explosion. In instances of improper design/use or arson, the system can be overcome. Most sprinkler systems as designed don't extinguish the fire, they only control it and there can be tremendous smoke generation and spread (particularly smoldering or shielded fires, etc). In fact, sprinklers drive the smoke lower and impede visibility, building size becomes more of an issue to both rescue (panic) and firefighting.

To balance this out we seek buildings to have increased fire-resistive design and they get larger. The larger the building the more time the fire service needs to deal with rescue and fire extinguishment. The more time the fire service needs to be in the building during adverse conditions, the better protected the building needs to be.

This proposal seeks to strike a balance. An increase would still be permitted based upon the presence of the automatic sprinkler protection, but a choice would have to be made to take either an area increase or a height increase, not both.

This proposal does not stop larger buildings from being constructed, what it does is change the trigger for the use of non-combustible versus combustible types of construction and changes the trigger of when protected types of construction would be required and at what fire resistance rating to building a larger building.

As already stressed fire departments suffer through wave after wave of cut backs in staff, equipment and fire stations, this issue increases in importance every day.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: DAVIDSON-SHUMAN-G4-504.2.doc

Public Hearing Results

Committee Action: Disapproved

Committee Reason: The proponent provided no new data or information to provide technical justification for this change. The committee felt that the issues of height and area have been more than adequately reviewed both during the original drafting of the code and through the subsequent studies of the CTC. This proposal provided no information that distinguished it from past proposals that were disapproved in the past code development cycles.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Robert J Davidson, Davidson Code Concepts, LLC, representing self, requests Approval as Submitted.

Commenter's Reason: The committee disapproved the proposal by a narrow vote with the following reason statement:

The proponent provided no new data or information to provide technical justification for this change. The committee felt that the issues of height and area have been more than adequately reviewed both during the original drafting of the code and through the subsequent studies of the CTC. This proposal provided no information that distinguished it from past proposals that were disapproved in the past code development cycles.

That is an incorrect assessment by some of the committee members. New information is included below and new testimony was provided. It is disingenuous of some committee members to refer to "subsequent studies of the CTC". Everyone that followed that process knows that CTC recommended a change, a big change concerning height and area. The problem is the majority of the ICC membership did not agree with the change that was proposed. This proposal is an alternate recommendation and deserves equal consideration, not simply brushed off because another group already looked at the issue.

As fire departments across the nation continue to suffer layoffs and cutbacks of staff responsible for firefighting and fire inspections there has to be acknowledgement that we cannot balance the code on the backs of emergency responders. We need realistic balance that recognizes that sprinkler systems, though effective when properly installed, inspected and maintained, are not 100% perfect. The fire service needs time to perform their duties safely and effectively and that equates to a higher fire resistance rating of structural support as buildings get larger. This proposal does not stop large buildings from being built, it will only modify the threshold at which the higher levels of construction are required. The original reason statement is included for information and background.

Final Action: AS AM AMPC____ D

G99-09/10
506.3

Proposed Change as Submitted

Proponent: Sam Francis, representing American Forest & Paper Association

Revise as follows:

506.3 Automatic sprinkler system increase. Where a building is equipped throughout with an approved automatic sprinkler system in accordance with Section 903.3.1.1, in addition to the height and story increases in accordance with Section 504.2, the building area limitation in Table 503 is permitted to be increased by the amounts specified in either Item 1 or Item 2 as follows: ~~the building area limitation in Table 503 is permitted to be increased by an additional 200 percent (I_s = 2) for buildings with more than one story above grade plane and an additional 300 percent (I_s = 3) for buildings with no more than one story above grade plane. These increases are permitted in addition to the height and story increases in accordance with Section 504.2,~~

1. An additional 200 percent ($I_s = 2$) for buildings with more than one story above grade plane or an additional 300 percent ($I_s = 3$) for buildings with no more than one story above grade plane.
2. An additional 100 percent ($I_s = 1$) for buildings up to four stories above grade plane when the automatic sprinkler system is omitted from the unoccupied attic space and the roof is sheathed with fire retardant treated wood structural panels,

Exception: ~~The~~ Building area limitation increases shall not be permitted for the following conditions:
1. The automatic sprinkler system increase shall not apply to buildings with an occupancy in Group H-1.
2. The automatic sprinkler system increase shall not apply to the building area of an occupancy in Group H-2 or H-3. For buildings containing such occupancies, the allowable building area shall be determined in accordance with Section 508.4.2, with the sprinkler system increase applicable only to the portions of the building not classified as Group H-2 or H-3.
3. Fire-resistance rating substitution in accordance with Table 601, Note d.

Reason: AF&PA commissioned testing of three roof attic assembly configurations[1]:
1) FRT wood trusses and FRT wood sheathing
2) Untreated wood trusses and untreated wood sheathing
3) Untreated wood trusses and FRT wood sheathing.

These tests were conducted to the same ad-hoc test protocol[2] used to modify sprinkler head spacing and water pressure requirements in NFPA 13.

AF&PA tests demonstrated that the fire performance of a roof assembly constructed with fire retardant treated (FRT) wood trusses and FRT wood sheathing (Configuration 1) resulted in no fire growth which is better performing than a roof assembly protected with a NFPA 13 sprinkler system. This configuration is exempt from attic sprinkler systems in NFPA 13.

Configuration 2, a roof assembly constructed with untreated wood trusses and untreated wood sheathing, had sustained fire growth when using the ad-hoc test protocol.

Configuration 3, a roof assembly constructed with untreated wood trusses and FRT wood sheathing, had similar results to Configuration 1 affording better protection than the NFPA 13 attic sprinkler system. This code change proposal recognizes the improved fire performance demonstrated by this configuration. The area limitation in Table 503 for buildings using this configuration and otherwise sprinklered throughout in accordance with NFPA 13 are permitted to be increased 100%.

1. “Flammability of Full Scale Roof Attic Assemblies by Ignition with 6 lb and 35 lb Wood Crib and Measurement of Heat Release,” Omega Point Maboratories, Project 15475-117047, November 2004.

2. “Spray Sprinklers Installed in Sloped Combustible Concealed Spaces,” Underwriters Laboratories Inc., Project 01NK32756, EX5985, September 2001

Cost Impact: The code change proposal will not increase the cost of construction. Will reduce cost of construction by approximately $3/sq.ft. of roof area.

ICCFILENAME:FRANCIS-G1-506 3.doc

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee felt that while the code often has provisions different than, and superseding of, referenced standards, the departure from the NFPA standard contained in this proposal would be better reviewed by NFPA in the context of revising the sprinkler standard. While the proposal concentrated on the make-up of the roof sheathing, the committee noted the presence of other combustible materials in attics, especially structural framing supporting the roof, that would be unprotected.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Sam Francis, representing American Wood Council (FF&PA), requests Approval as Submitted.

Commenter's Reason: AF&PA commissioned testing of three roof attic assembly configurations[1]:
1) FRT wood trusses and FRT wood sheathing
2) Untreated wood trusses and untreated wood sheathing
3) Untreated wood trusses and FRT wood sheathing.

These tests were conducted to the **same ad-hoc test protocol**[2] used to modify sprinkler head spacing and water pressure requirements in NFPA 13. AF&PA tests demonstrated that the fire performance of a roof assembly constructed with fire retardant treated (FRT) wood trusses and FRT wood sheathing (Configuration 1) resulted in no fire growth which is better performing than a roof assembly protected with a NFPA 13 sprinkler system. **This configuration is currently exempt from attic sprinkler systems in NFPA 13**.

Configuration 2, a roof assembly constructed with untreated wood trusses and untreated wood sheathing, had sustained fire growth when using the ad-hoc test protocol.

Configuration 3, a roof assembly constructed with untreated wood trusses and FRT wood sheathing, had <u>similar results to Configuration 1</u> affording better protection than the NFPA 13 attic sprinkler system.

The report of the tests can be viewed at
http://www.awc.org/fire/testreport.html
username: guest
password: awc

This code change proposal recognizes the improved fire performance demonstrated by this configuration. The area limitation in Table 503 for buildings using this configuration and otherwise sprinklered throughout in accordance with NFPA 13 are permitted to be increased 100%. The question left for the membership to decide is this: do we wish to control the locations where we will require sprinklers to be place and where we will permit them to be omitted reserving the installation and design information to a standard. OR do we wish to revise this code and other codes which currently have similar execptions for sprinkers which allow omission of heads in certain specified spaces. As an example, the omission of heads in bathrooms and/or closets of come buildings is a condition decided by this membership.

AF&PA commissioned testing using the exact same ad hoc test protocol used by others to create the current exemption in the sprinkler standard: NFPA 13. Despite AF&PA's efforts, the committee ignored the alternate configurations which resulted in equally good fire performance when compared to either of the other configurations. This should be corrected.

1. "Flammability of Full Scale Roof Attic Assemblies by Ignition with 6 lb and 35 lb Wood Crib and Measurement of Heat Release," Omega Point Maboratories, Project 15475-117047, November 2004.
2. "Spray Sprinklers Installed in Sloped Combustible Concealed Spaces," Underwriters Laboratories Inc., Project 01NK32756, EX5985, September 2001

Final Action: AS AM AMPC____ D

G100-09/10
506.4.1, 506.5.2

Proposed Change as Submitted

Proponent: Dennis Richardson PE, dbr Group Inc., representing self

Revise as follows:

506.4 Single occupancy buildings with more than one story. The total allowable *building area* of a single occupancy building with more than one *story above grade plane* shall be determined in accordance with this section. The actual aggregate *building area* at all *stories* in the building shall not exceed the total allowable *building area*.

Exception: A single basement need not be included in the total allowable *building area*, provided such basement does not exceed the area permitted for a building with no more than one *story above grade plane*.

506.4.1 Area determination. The total allowable *building area* of a single occupancy building with more than one *story above grade plane* shall be determined by multiplying the allowable *building area* per *story* (*Aa*), as determined in Section 506.1, by the number of *stories above grade plane* as listed below:

1. For buildings with two *stories above grade plane*, multiply by 2;
2. For buildings with three or more *stories above grade plane*, multiply by 3; and
3. No *story* shall exceed the allowable *building area* per *story* (A_a), as determined in Section 506.1, for the occupancies on that *story*.

   Exceptions:

   1. Unlimited area buildings in accordance with Section 507.
   2. The maximum area of a building equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.2 shall be determined by multiplying the allowable area per *story (Aa),* as determined in Section 506.1, by the number of *stories above grade plane*.
   3. The first story of a single occupancy building with more than one *story above grade plane* shall not exceed the allowable *building area* permitted for a building of the same occupancy with one *story above grade plane* when all of the following criteria are met:
      - 3.1. The allowable area (A_a) of the first *story above grade plane* shall be determined individually based on the provisions in Section 506.1 for a building with no more than one *story above grade plane*.
      - 3.2. Each additional *story* shall not exceed the allowable *building area* per *story* (A_a), as determined in Section 506.1 for the occupancies on that *story*.
      - 3.3. The total allowable *building area* shall comply with Items 1 or 2 of Section 506.4.1 computed based on a building with more than one story above grade plane.

506.5 Mixed occupancy area determination. The total allowable *building area* for buildings containing mixed occupancies shall be determined in accordance with the applicable provisions of this section. A single basement need not be included in the total allowable *building area*, provided such basement does not exceed the area permitted for a building with no more than one *story above grade plane*.

506.5.1 No more than one story above grade plane. For buildings with no more than one *story above grade plane* and containing mixed occupancies, the total *building area* shall be determined in accordance with the applicable provisions of Section 508.1.

506.5.2 More than one story above grade plane. For buildings with more than one *story above grade plane* and containing mixed occupancies, each *story* shall individually comply with the applicable requirements of Section 508.1. For buildings with more than three *stories above grade plane*, the total *building area* shall be such that the aggregate sum of the ratios of the actual area of each *story* divided by the allowable area of such *stories* based on the applicable provisions of Section 508.1 shall not exceed 3.

Exception: The first story of a multi-story building shall not exceed the area permitted for a building with no more than one story above grade plane when all of the following criteria are met:

1. The allowable area of the first story above grade plane shall be determined individually in accordance with the applicable total building area provisions of Section 508.1 and comply with the building area provisions for a building with no more than one story above grade plane.
2. Each additional story shall individually comply with the applicable requirements of Section 508.1.
3. For buildings with two stories above grade plane, the total building area shall be such that the aggregate sum of the ratios of the actual area of each story divided by the allowable area of such story, computed based on a building with more than one story above grade plane, based on the applicable provisions of Section 508.1, shall not exceed 2.
4. For buildings with three or more stories above grade plane, the total building area shall be such that the aggregate sum of the ratios of the actual area of each story divided by the allowable area of such story, computed based on a building with more than one story above grade plane, based on the applicable provisions of Section 508.1, shall not exceed 3.

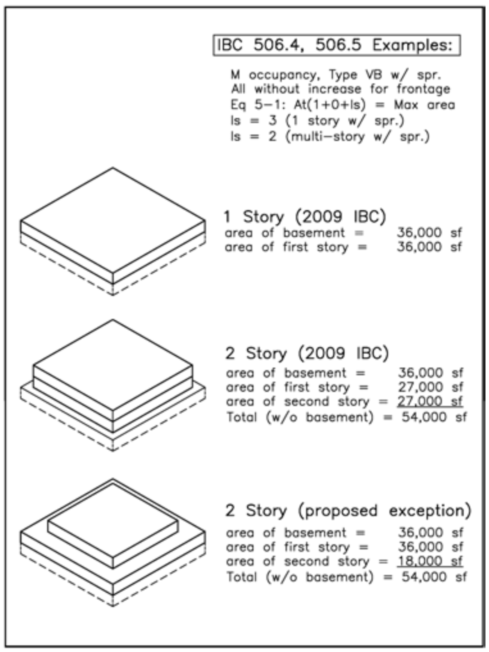
Reason: The proposed change would provide an exception allowing the first floor of a multi story building to be as large as a single story building which could be constructed on the same site as long as the total building area does not exceed the applicable code maximum allowable floor area.

Currently, based on Equation 5-1 and Section 506.3, a one story building with fire sprinklers throughout is permitted to be 4 times the Table 503 tabular area before considering any available area increase for frontage. However the first story of a multi-story building is limited to three times the tabular building area without consideration of any increase for frontage, even if the upper story levels are less than the maximum permitted area. The step function in the value of I_S between a one story building and all multistory buildings effectively limits the first story of multi-story buildings to 75% of the area allowed on that level for a one story building. This is true regardless of how small the second story is.

The current Section 506.4.1, item 3 indicates: No *story* shall exceed the allowable *building area* per *story* (Aa), as determined in Section 506.1 for occupancies on that *story*. This provision of the code encourages the construction of buildings that are box like in order to maximize building area with similar sized floors instead of allowing the flexibility for the designer to step back the upper floors giving the building the appearance of less mass and allowing more light to the street.

The exception to Section 506.4 and the last sentence in Section 506.5 each allow a single basement not to be included in the area calculation so long as the "basement area does not exceed the area permitted for a building with no more than one story above grade plane." Since a building with no more than one story above grade plane can be larger than the first floor of a similar multi-story building, this exception has the effect of allowing the basement to be larger in area than the area of first floor above it on a multi-story building.

The proposed code change is formatted as an exception so that it clear it does not change the existing code provisions unless utilized. When it is utilized it is intended to merely allow the first floor to be as large as it would otherwise be as a single story building without creating an increase in the total floor area of the entire building. As such the area of upper floors may have to be decreased from the maximum area that would otherwise be allowed so the total floor area is less than or equal to the total allowable building area. See attached example for a Group M occupancy, Type VB construction building. Similar examples would occur with other occupancies.



Cost Impact: The code change proposal will not increase the cost of construction. Because this exception does not have to be utilized by the designer and since it has the effect of allowing more construction to occur at grade where it is less expensive this proposed change would have the effect of decreasing construction cost if utilized by the designer.

ICCFILENAME: Richardson-G1-506.4.1 and 506.5.2

Public Hearing Results

Committee Action: Disapproved

Committee Reason: Although the committee thought the concept included in the proposal may be an appropriate option to add to the code, it found the language of the proposal unclear and misleading. The committee expressed concern that the resulting building would potentially have first stories approaching unlimited area scale without any provision to improve firefighter access surrounding the building. Significantly smaller upper stories could also be set back a significant distance from the walls of lower story, again providing a challenging firefighter access issue. There appeared to be a potential that under a mixed occupancy scenario that an even larger building than intended could be achieved.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

David S. Collins, The Preview Group, LLC, representing The American institute of Architects, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

506.4.1 Area determination. The total allowable *building area* of a single occupancy building with more than one *story above grade plane* shall be determined by multiplying the allowable *building area* per *story* (A_a), as determined in Section 506.1, by the number of *stories above grade plane* as listed below:

1. For buildings with two *stories above grade plane*, multiply by 2;
2. For buildings with three or more *stories above grade plane*, multiply by 3; and
3. No *story* shall exceed the allowable *building area* per *story* (A_a), as determined in Section 506.1, for the occupancies on that *story*.

Exceptions:

1. Unlimited area buildings in accordance with Section 507.
2. The maximum area of a building equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.2 shall be determined by multiplying the allowable area per *story (A_a),* as determined in Section 506.1, by the number of *stories above grade plane*.
3. ~~The first story of a single occupancy building with more than one *story above grade plane* shall not exceed the allowable *building area* permitted for a building of the same occupancy with one *story above grade plane* when all of the following criteria are met:~~

~~3.1.~~ 3. The allowable area (A_a) of the first *story above grade plane* shall be determined individually based on the provisions in Section 506.1 for a building with no more than one *story above grade plane*, when all of the following criteria are met.

- ~~3.2~~ 3.1. Each additional *story* shall not exceed the allowable *building area* per *story* (A_a), as determined in Section 506.1 for the occupancies on that *story*.
- ~~3.3~~ 3.2. The total allowable *building area* shall comply with Items 1 or 2 of Section 506.4.1 computed based on a building with more than one story above grade plane.

506.5.2 More than one story above grade plane. For buildings with more than one story above grade plane and containing mixed occupancies, each *story* shall individually comply with the applicable requirements of Section 508.1. For buildings with more than three stories above grade plane, the total building area shall be such that the aggregate sum of the ratios of the actual area of each story divided by the allowable area of such stories based on the applicable provisions of Section 508.1 shall not exceed 3.

Exception: ~~The first story of a multi-story building shall not exceed the area permitted for a building with no more than one story above grade plane when all of the following criteria are met:~~

~~1.~~ The allowable area of the first story above grade plane shall be permitted to be determined individually in accordance ~~with the applicable total building area provisions of Section 508.1 and comply~~ with the building area provisions for a building with no more than one story above grade plane per Section 508.1, provided the following are met:

~~2.~~ 1. Each additional story shall individually comply with the applicable requirements of Section 508.1.
~~3.~~ 2. For buildings with only two stories above grade plane, the total building area shall be such that the aggregate sum of the ratios of the actual area of each story divided by the allowable area of such story, computed based on a building with more than one story above grade plane, ~~based on the applicable provisions of~~ per Section 508.1, shall not exceed 2.
~~4.~~ 3. For buildings with three or more stories above grade plane, the total building area shall be such that the aggregate sum of the ratios of the actual area of each story divided by the allowable area of such story, computed based on a building with more than one story above grade plane, ~~based on the applicable provisions of~~ per Section 508.1, shall not exceed 3.

Commenter's Reason: The committee disapproved this code change proposal even though there was no testimony against the proposal from the floor. The proposed change allows the first story above grade plane of a building with multiple stories above grade plane to be the same size as a building with only one story above grade plane as long as the total building area (including all stories) does not exceed the applicable total maximum floor area.

This comment has editorially changed the original proposal to reduce redundant language while keeping the intent and meaning intact.

Currently a sprinklered, single story building with the maximum floor area for a given occupancy, type of construction and site configuration could not have a second story addition of any size. This is because a second floor addition would change the sprinkler increase (Is) from a factor of 3 (for a building with only one story above grade plane) to an Is factor of 2 (for a building with multiple stories). A code compliant second story could not be constructed no matter how small unless 25% of the first floor is removed. This defies common sense and should be fixed in the code.

For multiple occupancy buildings, G135-07/08 clarified and simplified the allowable area provisions for multi-story mixed occupancy buildings in Section 506.5.2. In doing so the 09 IBC acknowledged all three mixed occupancy design options (accessory occupancies, non-separated occupancies and separated occupancies).

The intent of this code change is to allow the first story above grade plane to be as large as a building with only one story above grade plane. The "sum of the ratios method of each story divided by the allowable maximum for that story as determined by any of the applicable methods" is used to ensure that the total building area does not exceed the maximum allowable area for the building.

Similar to single occupancy, multistory buildings, these mixed occupancy, multistory provisions only apply to buildings not permitted to be of unlimited area (unless of Type I and allowed to be unlimited by Table 503). As such, no reference to Section 507 was needed.

One final concern expressed by a committee member was that this could compromise firefighters due to building access and building step backs. This change does nothing to reduce the required yards and building access provisions and allows building step backs as is currently allowed by the code. Given total building area and access, most firefighters when asked would rather fight a fire close to the ground rather than having to shuttle air tanks up a stair for breathing apparatus.

In summary, this code change proposal resolves a disconnect in the code which defies common sense. The code change proposal does nothing to decrease firefighter access and, for the same maximum size building, results in more of the overall building area to be located closer to the ground.

Final Action: AS AM AMPC____ D

G101-09/10
507.1.1 (New)

Proposed Change as Submitted

Proponent: Sarah A. Rice, C.B.O., representing self

Add new text as follows:

507.1.1 Accessory occupancies. Occupancies not specifically listed in Section 507 shall be allowed to be located in unlimited area buildings provided the occupancy complies with Section 508.2 for an accessory occupancy.

Reason: The current text of Section 507 has been interpreted that unless an occupancy is specifically listed in that section it cannot be located within an unlimited area building. Unlimited area buildings are subject to the same guidelines as other buildings when it comes to 'accessory occupancies'. If the occupancy is one that is allowed and the area it occupies meets the size limitations of 508.2 they are allowed to be in an unlimited area building. The proposed language makes clear that occupancies which are not specifically listed in Section 507 are not prohibited from being in an unlimited area building as long as they meet the accessory occupancy provisions (including the 10% area limit in Section 508.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: RICE-G10-507.1.1.doc

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee understood the concept of the proposal, but felt it needed to be more specific as to the accessory occupancies of concern or how they be applicable in the various unlimited area building scenarios. The use of the term 'listed' is not as the term is defined. The committee speculated that because 10% of an unlimited area building could be quite a large area whether a limit to the tabular value of Table 503 might not be appropriate.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Gregory R. Keith, Professional heuristic Development, representing The Boeing Company, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

~~**507.1.1 Accessory occupancies.** Occupancies not specifically listed in Section 507 shall be allowed to be located in unlimited area buildings provided the occupancy complies with Section 508.2 for an accessory occupancy.~~

507.1 General. The area of buildings of the occupancies and configuration specified herein shall not be limited.

Exception: Other occupancies shall be permitted in unlimited area buildings in accordance with the provisions of Section 508.2.

Commenter's Reason: In its published reason for disapproval of G101-09/10, the ICC General Code Committee stated, "The committee understood the concept of the proposal, but felt it needed to be more specific as to the accessory occupancies of concern or how they be applicable in the various unlimited area building scenarios. The use of the term 'listed' is not as the term is defined. The committee speculated that because 10% of an unlimited area building could be quite a large area whether a limit to the tabular value of Table 503 might not be appropriate."

To simplify the concept of the inclusion of other occupancies in unlimited area buildings, the provision is relocated in context in the general charging language for unlimited area buildings as an exception to Section 507.1. Acknowledging the committee's concern about the term "listed," it has been removed.

As regards the committee's concern that limiting the accessory occupancy(s) to the tabular value(s) of Table 503 might be appropriate, Section 508.2.1 currently limits the area of the accessory occupancy to 10 percent of the floor area or the tabular limit without area increases.

Inasmuch as Section 507.8 allows for high hazard Group H occupancies in certain unlimited area buildings, it only stands to reason that ordinary hazard occupancies be permitted in unlimited area buildings under prescribed accessory mixed occupancy provisions. The clarification provided by this modification will greatly assist code users with this fairly obscure mixed occupancy condition. The Boeing Company has numerous two-story, unlimited area factories with additional occupancies such as cafeterias and day care facilities based on the requirements and limitations of Section 508.2. This is a common design practice nationwide.

Final Action: AS AM AMPC____ D

G103-09/10
507.3

Proposed Change as Submitted

Proponent: Tom Lariviere, Chairman, representing Joint Fire Service Review Committee

Revise as follows:

507.3 Sprinklered, one story. The area of a Group B, F, M or S building no more than one *story above grade plane*, or a Group A-4 building no more than one *story above grade plane* of other than Type V construction, shall not be limited when the building is provided with an *automatic sprinkler system* throughout in accordance with Section 903.3.1.1 and is surrounded and adjoined by *public ways* or *yards* not less than 60 feet (18 288 mm) in width.

Exception~~s~~:

~~1.~~ Buildings and structures of Type I and II construction for rack storage facilities that do not have access by the public shall not be limited in height, provided that such buildings conform to the requirements of Sections 507.3 and 903.3.1.1 and Chapter 23 of the *International Fire Code*.

~~2. The *automatic sprinkler system* shall not be required in areas occupied for indoor participant sports, such as tennis, skating, swimming and equestrian activities in occupancies in Group A-4, provided that:~~

~~2.1. *Exit* doors directly to the outside are provided for occupants of the participant sports areas; and~~

~~2.2. The building is equipped with a *fire alarm system* with *manual fire alarm boxes* installed in accordance with Section 907.~~

Reason: Code change F132-07/08 deleted the exception which allowed the elimination of a fire sprinkler system over participant sport areas in Group A-4 occupancies (See Section 903.2.1.4). However, when that code change was approved, a corresponding section in the IBC was overlooked. IBC 507.3 contains a similar exception to the item that was deleted in Chapter 9. Therefore, Exception 2 is proposed for deletion to be consistent with the action take last cycle in F132-07/08.

Section 507.3 allows for unlimited area buildings. Exception 2 would allow for an unlimited area Group A-4 occupancy and yet not require sprinklers over a major portion of the building.

The intention of the exception was for gymnasiums and similar areas where the probable occupant load was significantly less than what would be determined based on a square footage per occupant factor. However, these facilities have become multi-use and the occupant load is frequently higher than what was anticipated or expected when the exception was developed, and the fire load can vary based on the used to far exceed what would be expected for a sporting area.

For example, a community recreation center is constructed with no sprinklers over the gymnasium floor. The same area is also utilized for receptions and various community activities such as work fairs, rummage sale, art exhibits, emergency shelters for persons displaced by natural disasters, etc. Such uses could even include eating, sleeping, and fire loads far in excess of a few uniforms and leather volleyballs.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: LARIVIERE-G3-507.3

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee concluded that retaining this exception was not in conflict with the general limitations of Chapter 9 of the IBC and IFC because it was a specific provision that would take precedence over the general. The concerns expressed by supporters of the code change that these facilities get used for activities other than those listed were felt to be enforcement issues and should not be the basis of a code change. The listed activities are clearly those which have very limited fuel load on the sporting surface. The committee acknowledged that an amendment that would clarify that the exception applies to just the sporting area and not surrounding support functions such as spectator seating, locker or dressing facilities or concession areas would be appropriate.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Joe Pierce, Dallas Fire Department, representing Joint Fire Service Review Committee, requests Approval as Submitted.

Commenter's Reason: The code change was Disapproved at the Code Development Hearing because the Code Development Committee felt that the exception applied in this case.

In the last code change cycle, Item F132-07/08 deleted the exception which allowed the elimination of a fire sprinkler system over participant sport areas in Group A-4 occupancies (See Section 903.2.1.4). This code change is merely a clean-up item that was missed in the original proposal. Therefore this Public Comment is suggesting that Approval as Submitted is the appropriate solution.

Item F132-07/08 removed this exception from the general sprinkler requirements. The approved revision in Section 903.2.1.4 applies to all situations regardless of the size of the building. This follow-up code change only applies to IBC Section 507.3, and is specific for unlimited area buildings. Exception 2 currently allows unlimited area A-4 occupancies without providing fire sprinklers over a major portion of the buildings.

The assembled membership decided that this exception is not appropriate for smaller Group A-4 occupancies when they approved F132-07/08. It is consistent with that thinking to eliminate the allowance for unlimited area buildings.

Final Action: AS AM AMPC____ D

G104-09/10
507.8

Proposed Change as Submitted

Proponent: Gregory R. Keith, Professional heuristic Development, representing The Boeing Company

Revise as follows:

507.8 Group H occupancies. Group H-2, H-3 and H-4 occupancies shall be permitted in unlimited areas buildings containing Group F and S occupancies~~,~~ in accordance with Sections 507.3 and 507.4 and the provisions ~~limitations~~ of ~~this section~~ Sections 507.8.1 through 507.8.3.

507.8.1 Allowable area. The aggregate floor area of ~~the~~ Group H occupancies located ~~at the perimeter of the~~ in an unlimited area building shall not exceed 10 percent of the area of the building nor the area limitations for the Group H occupancies as specified in Table 503 as modified by Section 506.2.

507.8.1.1 Located on building perimeter. Except as provided for in Section 507.8.1.2, Group H occupancies shall be located on the perimeter of the building. ~~,based upon the percentage of the perimeter of each Group H floor area that fronts~~ In Group H-2 and H-3 occupancies, not less than 25 percent of the perimeter of such occupancies shall front on a public way or open ~~street or other unoccupied~~ space.

507.8.1.2 Located within the building. The aggregate floor area of Group H occupancies not located at the perimeter of the building shall not exceed 25 percent of the area limitations for the Group H occupancies as specified in Table 503.

507.8.1.2.1 Liquid use, dispensing and mixing rooms. Liquid use, dispensing and mixing rooms having a floor area of not more than 500 square feet (46.5m^2) need not be located on the outer perimeter of the building where they are in accordance with the International Fire Code and NFPA 30.

507.8.1.2.2 Liquid storage rooms. Liquid storage rooms having a floor area of not more than 1,000 square feet (93 m^2) need not be located on the outer perimeter where they are in accordance with the *International Fire Code* and NFPA 30.

507.8.1.2.3 Spray paint booths. Spray paint booths that comply with the *International Fire Code* need not be located on the outer perimeter.

507.8.2 Occupancy separations. Group H occupancies shall be separated from the remainder ~~rest~~ of the unlimited area building and from each other in accordance with Table 508.4.

507.8.3 Height limitations. For two-story unlimited area buildings, ~~the~~ Group H occupancies shall not be located more than one story above grade plane unless permitted based on ~~by~~ the allowable height in stories and feet as set forth in Table 503 for ~~based on~~ the type of construction of the unlimited area building.

Reason: This proposal is intended to clarify the provisions governing the placement of Group H occupancies in certain unlimited area buildings. Currently, all requirements are placed within a single run-on paragraph that does not separate thoughts or provisions. In its present format, it is easy to attempt to overlay requirements that are intended to address different design conditions. Additionally, Section 507.8 contains a very vague provision in that it states that Group H occupancies shall be located on the perimeter of the building based upon the "percentage of the perimeter" of each Group H floor area. No percentage figure is provided. Presumably, that is an indirect reference to Section 415.3. For purposes of continuity, Section 415.3 requirements have been incorporated into Section 507.8, including allowances for certain interior spaces. The format and clarity provided in this proposal will assist code users in the proper identification of requirements in this fairly rare, but very important provision.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: KEITH-G3-507.8.doc

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee found the format of the proposal very appealing in the clarity it would bring to these provisions, however it appeared that the reformat includes a technical change in the relationship of the hazardous material area located at the building perimeter and the measurement of that perimeter.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Gregory R. Keith, Professional heuristic Development, representing The Boeing Company, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

507.8 Group H occupancies. Group H-2, H-3 and H-4 occupancies shall be permitted in unlimited areas buildings containing Group F and S occupancies, in accordance with Sections 507.3 and 507.4 and the provisions of this section~~s 507.8.1 through 507.8.3~~.

507.8.1 Allowable area. The aggregate floor area of Group H occupancies in an unlimited area building shall not exceed 10 percent of the area of the building nor the area limitations for the Group H occupancies as specified in Table 503 as modified by Section 506.2, based upon the perimeter of each Group H floor area that fronts on a public way or open space.

~~507.8.1.2~~ 507.8.1.1 Located within the building. The aggregate floor area of Group H occupancies not located at the perimeter of the building shall not exceed 25 percent of the area limitations for the Group H occupancies as specified in Table 503.

~~507.8.1.2.1~~ 507.8.1.1.1 Liquid use, dispensing and mixing rooms. Liquid use, dispensing and mixing rooms having a floor area of not more than 500 square feet ($46.5 m^2$) need not be located on the outer perimeter of the building where they are in accordance with the International Fire Code and NFPA 30.

~~507.8.1.2.2~~ 507.8.1.1.2 Liquid storage rooms. Liquid storage rooms having a floor area of not more than 1,000 square feet ($93 m^2$) need not be located on the outer perimeter where they are in accordance with the *International Fire Code* and NFPA 30.

~~507.8.1.2.3~~ 507.8.1.1.3 Spray paint booths. Spray paint booths that comply with the *International Fire Code* need not be located on the outer perimeter.

~~507.8.1.1~~ 507.8.2 Located on building perimeter. Except as provided for in Section ~~507.8.1.2~~ 507.8.1.1, Group H occupancies shall be located on the perimeter of the building. In Group H-2 and H-3 occupancies, not less than 25 percent of the perimeter of such occupancies shall be an exterior wall ~~front on a public way or open space~~.

~~507.8.2~~ 507.8.3 Occupancy separations. Group H occupancies shall be separated from the remainder rest of the unlimited area building and from each other in accordance with Table 508.4.

~~507.8.3~~ 507.8.4 Height limitations. For two-story unlimited area buildings, Group H occupancies shall not be located more than one story above grade plane unless permitted based on the allowable height in stories and feet as set forth in Table 503 for the type of construction of the unlimited area building.

Commenter's Reason: In its published reason statement for the disapproval of Item G104-09/10, the ICC General Code Committee stated, 'The committee found the format of the proposal very appealing in the clarity it would bring to these provisions, however it appeared that the reformat includes a technical change in the relationship of the hazardous material area located at the building perimeter and the measurement of that perimeter." The committee was correct and the technical error has been corrected. The error was that the procedure for determining the allowable area in Section 507.8.1 did not specify that Group H allowable area increases are based on the perimeter of the Group H occupancy as opposed to the unlimited area building as a whole. With this correction, the improved format recognized by the committee will greatly assist code users in the proper determination of these important provisions.

Final Action: AS AM AMPC____ D

G105-09/10
507.10

Proposed Change as Submitted

Proponent: Joe Holland and Dave Bueche, representing Hoover Treated Wood Products

Revise as follows:

507.10 Group E buildings. The area of a Group E building no more than one *story above grade plane*, of Type II, ~~IIIA~~ III or IV construction, shall not be limited when all of the following criteria are met:

1. Each classroom shall have not less than two *means of egress*, with one of the *means of egress* being a direct *exit* to the outside of the building complying with Section 1020.
2. The building is equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1.
3. The building is surrounded and adjoined by *public ways* or *yards* not less than 60 feet (18 288 mm) in width.

Reason: The exterior wall fire resistance required in Table 601 is greater for Type III than what is required for Type II and is equal to what is required for Type IV. The interior fire resistance in Type III construction is equivalent to Type II and therefore should be allowed. In addition, in Table 503 for E occupancies, the code recognizes that Type IIB and IIIB are equivalent in overall height, number of stories, and allowable area.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: HOLLAND-BUECHE-G2-507.10

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The proponent did not provide sufficient technical support to justify reducing the allowed Type IIIA allowed unlimited area building to the unrated Type IIIB. This could result in a significant increase in combustible materials in the building construction that would not be protected by one hour assemblies.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Joseph Holland and Dave Bueche, representing Hoover Treated Wood Products, Inc., requests Approval as Submitted.

Commenter's Reason: The provisions for a one story unlimited area Group E building of Type II, IIIA or IV construction require that 1) each classroom have not less than two means of egress with one being a direct exit to the outside of the building: 2) The building is equipped through with a sprinkler system; and 3) the building is surrounded and enjoined by public ways or yards not less than 60 feet. The exterior fire resistance required in Table 601 is greater for Type III than what is required for Type II and is equivalent for what is required for Type IV. The interior fire resistance in Type III construction is equivalent to Type II and should therefore be allowed. In addition, in Table 503 for E occupancies, the code recognizes that Type IIB and IIIB are equivalent in overall height, number of stories, and allowable area. This unlimited area building is required to be protected by an approved automatic sprinkler system in accordance with Section 903.3.1.1. The code in footnote d of Table 601 recognizes that this type of sprinkler system can be substituted for 1-hour fire-resistance-rated construction provided such system is not otherwise required by other provisions of the code or used for an allowable area increase in accordance with Section 506.3 or an allowable height increase in accordance with Section 504.2. The 1-hour substitution for the fire resistance of exterior walls shall not be permitted. A Type IIB building with no exterior wall fire protection is allowed to be of unlimited area.

The committees concern (see below) that that TYPE IIIB construction would result in a significant increase in combustible materials in the building construction that would not be protected by one hour assemblies is unfounded. The current code allows TYPE IV construction of unlimited area which has similar or greater fixed fire loads and does not need to be protected by one hour assemblies (Section 602.4.6, Partitions shall be of solid wood construction formed by not less than two layers of 1-inch (25 mm) matched boards or laminated construction 4 inches (102 mm) thick, or of 1-hour fire-resistance-rated construction.

For consistency in the code, a Type IIIB building with 2-hour fire-resistance-rated exterior walls should be allowed to be of unlimited area.

Final Action: AS AM AMPC____ D

G106-09/10
507.11

Proposed Change as Submitted

Proponent: Joe Holland and Dave Bueche, representing Hoover Treated Wood Products

Revise as follows:

507.11 Motion picture theaters. In buildings of Type II or III construction, the area of a motion picture theater located on the first *story above grade plane* shall not be limited when the building is provided with an *automatic sprinkler system* throughout in accordance with Section 903.3.1.1 and is surrounded and adjoined by *public ways* or *yards* not less than 60 feet (18 288 mm) in width.

Reason: This change recognizes that Type III offers equivalent or superior fire resistance to Type II construction. The exterior wall fire resistance required in Table 601 is greater for Type III than what is required for Type II (2 hours versus 1 hour or none). The interior fire resistance in Type III construction is equivalent to Type II. In Table 503 for Group A-1 occupancies, the code recognizes that Type IIB and IIIB are equivalent in overall height, number of stories, and allowable area.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: HOLLAND-BUECHE-G3-507.11

Public Hearing Results

Committee Action: Disapproved

Committee Reason: The committee disapproved this change because there was not justification that allowing motion picture theaters of unlimited size in a combustible building construction type where they are now only allows in non-combustible construction types.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Joseph Holland and Dave Bueche, representing Hoover Treated Wood, Inc., requests Approval as Submitted.

Commenter's Reason: The provisions for a one story unlimited area motion picture building of Type II construction requires that 1) The building is equipped through with a sprinkler system; and 2) the building is surrounded and enjoined by public ways or yards not less than 60 feet. The exterior fire resistance required in Table 601 is greater for Type III than what is required for Type II. The interior fire resistance in Type III construction is equivalent to Type II and should therefore be allowed. In addition, in Table 503 for A-1 occupancies, the code recognizes that Type IIB and IIIB are equivalent in overall height, number of stories, and allowable area. This unlimited area building is required to be protected by an approved automatic sprinkler system in accordance with Section 903.3.1.1. The code in footnote d of Table 601 recognizes that this type of sprinkler system can be substituted for 1-hour fire-resistance-rated construction provided such system is not otherwise required by other provisions of the code or used for an allowable area increase in accordance with Section 506.3 or an allowable height increase in accordance with Section 504.2. The 1-hour substitution for the fire resistance of exterior walls shall not be permitted. A Type IIB building with no exterior wall fire protection is allowed to be of unlimited area. For consistency in the code, a Type IIIA or IIIB building with 2-hour fire-resistance-rated exterior walls should be allowed to be of unlimited area as well.

Final Action: AS AM AMPC____ D

G107-09/10
508, 509 (New)

Proposed Change as Submitted

Proponent: Maureen Traxler, City of Seattle, Seattle Dept of Planning & Development

Revise as follows:

SECTION 508
MIXED USE AND OCCUPANCY

508.1 General. Each portion of a building shall be individually classified in accordance with Section 302.1. Where a building contains more than one occupancy group, the building or portion thereof shall comply with the applicable provisions of Section 508.2, 508.3 or 508.4, or a combination of these sections.

Exceptions:

1. Occupancies separated in accordance with Section ~~509~~ 510.
2. Where required by Table 415.3.2, areas of Group H-1, H-2 and H-3 occupancies shall be located in a separate and detached building or structure.
3. Uses within live/work units, complying with Section 419, are not considered separate occupancies.

508.2 Accessory occupancies. Accessory occupancies are those occupancies that are ancillary to the main occupancy of the building or portion thereof. Accessory occupancies shall comply with the provisions of Sections 508.2.1 through 508.2.4 ~~508.2.5.3~~.

508.2.1 Area limitations. Aggregate accessory occupancies shall not occupy more than 10 percent of the *building area* of the *story* in which they are located and shall not exceed the tabular values in Table 503, without *building area* increases in accordance with Section 506 for such accessory occupancies.

508.2.2 Occupancy classification. Accessory occupancies shall be individually classified in accordance with Section 302.1. The requirements of this code shall apply to each portion of the building based on the occupancy classification of that space.

508.2.3 Allowable building area and height. The allowable *building area and height* of the building shall be based on the allowable *building area and height* for the main occupancy in accordance with Section 503.1. The height of each accessory occupancy shall not exceed the tabular values in Table 503, without increases in accordance with Section 504 for such accessory occupancies. The *building area* of the accessory occupancies shall be in accordance with Section 508.2.1.

508.2.4 Separation of occupancies. No separation is required between accessory occupancies and the main occupancy.

Exceptions:

1. Group H-2, H-3, H-4 and H-5 occupancies shall be separated from all other occupancies in accordance with Section 508.4.
2. Incidental ~~accessory occupancies~~ uses required to be separated or protected by Section ~~508.2.5~~ 509.
3. Group I-1, R-1, R-2 and R-3 *dwelling units* and *sleeping units* shall be separated from other *dwelling* or *sleeping units* and from accessory occupancies contiguous to them in accordance with the requirements of Section 420.

(Relocate Section 508.2.5 through 508.2.5.3 to new Section 509)

508.3 Nonseparated occupancies. Buildings or portions of buildings that comply with the provisions of this section shall be considered as nonseparated occupancies.

508.3.1 Occupancy classification. Nonseparated occupancies shall be individually classified in accordance with Section 302.1. The requirements of this code shall apply to each portion of the building based on the occupancy classification of that space except that the most restrictive applicable provisions of Section 403 and Chapter 9 shall apply to the building or portion thereof in which the nonseparated occupancies are located.

508.3.2 Allowable building area and height. The allowable *building area and height* of the building or portion thereof shall be based on the most restrictive allowances for the occupancy groups under consideration for the type of construction of the building in accordance with Section 503.1.

508.3.3 Separation. No separation is required between nonseparated occupancies.

Exceptions:

1. Group H-2, H-3, H-4 and H-5 occupancies shall be separated from all other occupancies in accordance with Section 508.4.
2. Group I-1, R-1, R-2 and R-3 *dwelling units* and *sleeping units* shall be separated from other *dwelling* or *sleeping units* and from other occupancies contiguous to them in accordance with the requirements of Section 420.

508.4 Separated occupancies. Buildings or portions of buildings that comply with the provisions of this section shall be considered as separated occupancies.

508.4.1 Occupancy classification. Separated occupancies shall be individually classified in accordance with Section 302.1. Each separated space shall comply with this code based on the occupancy classification of that portion of the building.

TABLE 508.4
REQUIRED SEPARATION OF OCCUPANCIES (HOURS)
[No change proposed to Table 508.4]

508.4.2 Allowable building area. In each *story*, the *building area* shall be such that the sum of the ratios of the actual *building area* of each separated occupancy divided by the allowable *building area* of each separated occupancy shall not exceed 1.

508.4.3 Allowable height. Each separated occupancy shall comply with the *building height* limitations based on the type of construction of the building in accordance with Section 503.1.

Exception: Special provisions permitted by Section ~~509~~ 510.

508.4.4 Separation. Individual occupancies shall be separated from adjacent occupancies in accordance with Table 508.4.

508.4.4.1 Construction. Required separations shall be fire barriers constructed in accordance with Section 707 or horizontal assemblies constructed in accordance with Section 712, or both, so as to completely separate adjacent occupancies.

SECTION 509
INCIDENTAL USES

~~508.2.5~~ 509.1 Separation of incidental uses ~~accessory occupancies~~. The incidental uses ~~accessory occupancies~~ listed in Table ~~508.2.5~~ 509.1 shall be separated from the remainder of the building or equipped with an automatic fire-extinguishing system, or both, in accordance with Table ~~508.2.5~~ 509.1.

Exception: Incidental uses ~~accessory occupancies~~ within and serving a *dwelling unit* are not required to comply with this section.

~~508.2.5.1~~ 509.2 Fire-resistance-rated separation. Where Table ~~508.2.5~~ 509.1 specifies a fire-resistance-rated separation, the incidental uses ~~accessory occupancies~~ shall be separated from the remainder of the *building* by a *fire barrier* constructed in accordance with Section 707 or a *horizontal assembly* constructed in accordance with Section 712, or both. Construction supporting 1-hour fire-resistance-rated *fire barriers* or *horizontal assemblies* used for incidental use ~~accessory occupancy~~ separations in buildings of Type IIB, IIIB and VB construction are not required to be fire-resistance rated unless required by other sections of this code.

TABLE ~~508.2.5~~ 509.1
INCIDENTAL ~~ACCESSORY OCCUPANCIES~~ USES

ROOM OR AREA	SEPARATION AND/OR PROTECTION
Furnace room where any piece of equipment is over 400,000 Btu per hour input	1 hour or provide automatic fire-extinguishing system
Rooms with boilers where the largest piece of equipment is over 15 psi and 10 horsepower	1 hour or provide automatic fire-extinguishing system
Refrigerant machinery room	1 hour or provide automatic sprinkler system
Hydrogen cutoff rooms, not classified as Group H	1 hour in Group B, F, M, S and U occupancies; 2 hours in Group A, E, I and R occupancies.
Incinerator rooms	2 hours and automatic sprinkler system
Paint shops, not classified as Group H, located in occupancies other than Group F	2 hours; or 1 hour and provide automatic fire-extinguishing system
Laboratories and vocational shops, not classified as Group H, located in a Group E or I-2 occupancy	1 hour or provide automatic fire-extinguishing system
Laundry rooms over 100 square feet	1 hour or provide automatic fire-extinguishing system
Group I-3 cells equipped with padded surfaces	1 hour
Group I-2 waste and linen collection rooms	1 hour
Waste and linen collection rooms over 100 square feet	1 hour or provide automatic fire-extinguishing system
Stationary storage battery systems having a liquid electrolyte capacity of more than 50 gallons, or a lithium-ion capacity of 1,000 pounds used for facility standby power, emergency power or uninterrupted power supplies	1 hour in Group B, F, M, S and U occupancies; 2 hours in Group A, E, I and R occupancies.
Rooms containing fire pumps in nonhigh-rise buildings	2 hours; or 1 hour and provide automatic sprinkler system throughout the building
Rooms containing fire pumps in high-rise buildings	2 hours

For SI: 1 square foot = 0.0929 m_2, 1 pound per square inch (psi) = 6.9 kPa, 1 British thermal unit (Btu) per hour = 0.293 watts, 1 horsepower = 746 watts, 1 gallon = 3.785 L.

~~508.2.5.2~~ 509.2.1 Nonfire-resistance-rate separation and protection. Where Table ~~508.2.5~~ 509.1 permits an automatic fire-extinguishing system without a *fire barrier*, the incidental uses ~~accessory occupancies~~ shall be separated from the remainder of the building by construction capable of resisting the passage of smoke. The walls shall extend from the top of the foundation or floor assembly below to the underside of the ceiling that is a component of a fire-resistance-rated floor assembly or roof assembly above or to the underside of the floor or roof sheathing, deck or slab above. Doors shall be self- or automatic closing upon detection of smoke in accordance with Section 715.4.8.3. Doors shall not have air transfer openings and shall not be undercut in excess of the clearance permitted in accordance with NFPA 80. Walls surrounding the incidental use shall not have air transfer openings unless provided with smoke dampers in accordance with Section 711.7.

~~508.2.5.3~~ 509.2.2 Protection. Except as specified in Table ~~508.2.5~~ 509.1 for certain incidental uses ~~accessory occupancies~~, where an automatic fire-extinguishing system or an *automatic sprinkler system* is provided in accordance with Table ~~508.2.5~~ 509.1, only the space occupied by the incidental use ~~accessory occupancy~~ need be equipped with such a system.

(Renumber subsequent sections.)

Reason: A change occurred in the 2009 IBC that we believe has unintended consequences. As written, "incidental accessory occupancies" are only required to be separated when they are part of an accessory occupancy. They are mentioned only in Section 508.2.5, and, since it is a subsection of Section 508.2, it only applies where 508.2 applies.

This proposal creates a separate section so that the incidental use provisions will apply in all buildings, including single use buildings. The rooms and areas listed in the incidental use table present special hazards that require special protection. They should be separated from other occupancies and uses regardless of whether the other occupancies in the building are treated as separated or nonseparated occupancies.

We are also proposing to change the term to "incidental uses" instead of "incidental accessory occupancies". Many of the items listed in the table are not occupancies in themselves—they are special uses that don't fall neatly into any occupancy category. The use of this term should be changed throughout the code if this code change proposal is approved.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: Traxler-G5-508.doc

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The committee found the code change appropriate because it clarifies that the activities and facilities listed in Table 508.2.5 present a special hazard regardless whether the building is a single occupancy or a mixed occupancy. The change would make sure that these standards are met regardless of the approach taken to address mixed occupancies. These things are uses or building support facilities and not occupancies unto themselves. The committee expressed concern that divorcing these provisions form the accessory use provisions would allow these features to exceed the 10% area limitation of accessory occupancy. While this part of the provision could be refined by public comment, the committee was comfortable that the term incidental was sufficiently clear that were such features/uses to become the primary or only use of a building, that it would judged to be not 'incidental'.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Gregory R. Keith, Professional heuristic Development, representing The Boeing Company, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

508.2.4 Separation of occupancies. No separation is required between accessory occupancies and the main occupancy.

Exceptions:

1. Group H-2, H-3, H-4 and H-5 occupancies shall be separated from all other occupancies in accordance with Section 508.4.
~~2.~~ ~~Incidental uses required to be separated or protected by Section 509.~~
2~~3~~. Group I-1, R-1, R-2 and R-3 *dwelling units* and *sleeping units* shall be separated from other *dwelling* or *sleeping units* and from accessory occupancies contiguous to them in accordance with the requirements of Section 420.

SECTION 509
INCIDENTAL USES

509.1 General ~~Separation of incidental uses.~~ Incidental uses located within single occupancy or mixed occupancy buildings shall comply with the provisions of this section. Incidental uses are ancillary functions associated with a given occupancy that generally pose a greater level of risk to that occupancy and are limited to those uses listed in Table 509.4. ~~The incidental uses listed in Table 509.1 shall be separated from the remainder of the building or equipped with an automatic fire- extinguishing system, or both, in accordance with Table 509.1.~~

Exception: Incidental uses within and serving a *dwelling unit* are not required to comply with this section.

509.2 Occupancy classification. Incidental uses shall not be individually classified in accordance with Section 302.1. Incidental uses shall be included in the building occupancies within which they are located.

509.3 Area limitations. Incidental uses shall not occupy more than 10 percent of the *building area* of the *story* in which they are located.

509.4 Separation and protection. The incidental uses listed in Table 509.4 shall be separated from the remainder of the building or equipped with an automatic fire-extinguishing system, or both, in accordance with the provisions of that table.

TABLE ~~509.1~~ 509.4
INCIDENTAL USES

(No change to table contents)

~~509.2~~ 509.4.1 ~~Fire-resistance-rated~~ Separation. Where Table ~~509.1~~ 509.4 specifies a fire-resistance-rated separation, the incidental uses shall be separated from the remainder of the *building* by a *fire barrier* constructed in accordance with Section 707 or a *horizontal assembly* constructed in accordance with Section 712, or both. Construction supporting 1-hour fire-resistance-rated *fire barriers* or *horizontal assemblies* used for incidental use separations in buildings of Type IIB, IIIB and VB construction are not required to be fire-resistance rated unless required by other sections of this code.

~~509.2.1~~ 509.4.2 ~~Nonfire-resistance-rate separation and~~ Protection. Where Table ~~509.1~~ 509.4 permits an automatic fire-extinguishing system without a *fire barrier*, the incidental use shall be separated from the remainder of the building by construction capable of resisting the passage of smoke. The walls shall extend from the top of the foundation or floor assembly below to the underside of the ceiling that is a component of a fire-resistance-rated floor assembly or roof assembly above or to the underside of the floor or roof sheathing, deck or slab above. Doors shall be self- or automatic closing upon detection of smoke in accordance with Section 715.4.8.3. Doors shall not have air transfer openings and shall not be undercut in excess of the clearance permitted in accordance with NFPA 80. Walls surrounding the incidental use shall not have air transfer openings unless provided with smoke dampers in accordance with Section 711.7.

~~509.2.2~~ 509.4.2.1 Protection limitation. Except as specified in Table ~~509.1~~ 509.4 for certain incidental uses, where an automatic fire-extinguishing system or an *automatic sprinkler system* is provided in accordance with Table ~~509.1~~, 509.4 only the space occupied by the incidental use need be equipped with such a system.

(Portions of proposal not shown remain unchanged.)

Commenter's Reason: The ICC General Code Committee approved Item G107-09/10 as submitted as they found the code change appropriate "because it clarifies the activities and facilities listed in Table 508.2.5 present a special hazard regardless whether the building is a single occupancy or a mixed occupancy." This proposed modification further clarifies the comments or concerns expressed during discussion of the item in Baltimore. As approved, the proposal contained no formal charging language. This public comment adds "General" provisions to Section 509.1 that include general applicability requirements.

Also mentioned in the committee reason statement was, "These things are uses or building support facilities and not occupancies unto themselves." This point has been clarified in new Section 509.2. Also mentioned was, "The committee expressed concern that divorcing these provisions form the accessory use provisions would allow these features to exceed the 10% area limitation of accessory occupancy. While this part of the provision could be refined by public comment, the committee was comfortable that the term incidental was sufficiently clear that where such features/uses become the primary or only use of a building, that it would be judged to be not "incidental." This public comment addresses the committee concern and the limitation is clearly stated in new Section 509.3.

A technical inconsistency has been eliminated by the deletion of Exception 2 to Section 508.2.4. Incidental uses are not accessory occupancies and therefore should not be referenced in that section.

Lastly, the provisions of Section 509 for incidental uses have been organized in a format similar to the various mixed occupancy design options contained in Section 508. This consistent format should assist users in determining applicable incidental use requirements. Approval of this public comment for approval as modified will address all committee concerns while placing the provisions in a logical format.

Final Action: AS AM AMPC____ D

G109-09/10
508.2, 508.2.1, 508.2.2, 508.2.3, 508.2.4

Proposed Change as Submitted

Proponent: Gregory R. Keith, Professional heuristic Development, representing The Boeing Company

Revise as follows:

508.2 Accessory occupancies. Buildings or portions of buildings that comply with the provisions of this section shall be considered as accessory occupancies. Accessory occupancies are those occupancies that are ancillary to the main occupancy of the building or portion thereof. Accessory occupancies shall comply with the provisions of Section 508.2.1 through ~~508.2.5.3~~ 508.2.4.3.

~~**508.2.1 Area limitations.** Aggregate accessory occupancies shall not occupy more than 10 percent of the area of the story in which they are located and shall not exceed the tabular values in Table 503, without area increases in accordance with Section 506 for such accessory occupancies.~~

~~508.2.2~~ 508.2.1 Occupancy classification. Accessory occupancies shall be individually classified in accordance with Section 302.1. The requirements of this code shall apply to each portion of the building based on the occupancy classification of that space.

~~508.2.3~~ 508.2.2 Allowable area and height. The allowable area and height of the building shall be based on the allowable area and height for the main occupancy in accordance with Section 503.1. Aggregate accessory occupancies shall not occupy more than 10 percent of the area of the story in which they are located and shall not exceed the tabular values in Table 503, without area increases in accordance with Section 506 for such accessory occupancies. The height of each accessory occupancy shall not exceed the tabular values in Table 503, without increases in accordance with Section 504 for such accessory occupancies. ~~The area of the accessory occupancies shall be in accordance with Section 508.2.1~~

~~508.2.4~~ 508.2.3 Separation of occupancies. No separation is required between accessory occupancies and the main occupancy or each other.

Exceptions:

1. Group H-2, H-3, H-4 and H-5 occupancies shall be separated from all other occupancies in accordance with Section 508.4.

2. Incidental accessory occupancies required to be separated or protected by Section ~~508.2.5~~.508.2.4.
3. Group I-1, R-1, R-2 and R-3 dwelling units and sleeping units shall be separated from other dwelling or sleeping units and from accessory occupancies contiguous to them in accordance with the requirements of Section 420.

~~508.2.5~~ 508.2.4 Separation of incidental accessory occupancies.

(The text of this and following sections are not changed; renumbering is shown for context of number changes in preceding sections.)

TABLE ~~508.2.5~~ 508.2.4
INCIDENTAL ACCESSORY OCCUPANCIES

~~508.2.5.1~~ 508.2.4.1 Fire-resistance-rated separation.

~~508.2.5.2~~ 508.2.4.2 Nonfire-resistance-rated separation and protection.

~~508.2.5.3~~ 508.2.4.3 Protection.

Reason: This proposal is intended to clarify accessory occupancy mixed occupancy provisions. Charging language has been added to Section 508.2 to duplicate that contained in Sections 508.3 and 508.4 for purposes of editorial and legal consistency. The area provisions in current Section 508.2.1 have been placed in context in proposed Section 508.2.2, “Allowable area and height.” Having accessory occupancy allowable area provisions in two different sections could result in oversight. Proposed Section 508.2.3 clarifies that no occupancy separation is required between adjacent accessory occupancies, the exceptions notwithstanding. Approval of this proposal will result in more consistent application of IBC accessory occupancy provisions.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: KEITH-G5-508.2.doc

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: While the intent of the proponent was to clarify the section, the committee felt that it did the opposite. Specifically the committee found the first sentence of new Section 508.2 could be read to imply that an accessory occupancy could be a total building, not a small area of a larger building. They found that the wording of Section 508.2.2 confused the determination of aggregate areas of accessory occupancies.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Gregory R. Keith, Professional heuristic Development, representing The Boeing Company, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

508.2 Accessory occupancies. ~~Buildings or portions of buildings that comply with the provisions of this section shall be considered as accessory occupancies.~~ Accessory occupancies are those occupancies that are ancillary to the main occupancy of the building or portion thereof. Accessory occupancies shall comply with the provisions of Section 508.2.1 through 508.2.4.3.

(Portion of proposal not shown remain unchanged.)

Commenter’s Reason: In the ICC General Code Committee’s published reason statement for disapproval of Item G109-09/10, it was stated that, “the committee found the first sentence of new Section 508.2 could be read to imply that an accessory occupancy could be a total building, not a small area of a larger building.” Not wanting to create or add to any confusion, Section 508.2 has been returned to original 2009 IBC language. The reason statement also noted that, “the wording of Section 508.2.2 confused the determination of aggregate areas of accessory occupancies.” This comment is somewhat confusing due to the fact that the accessory occupancy area limitations were moved verbatim from Section 508.2.1 to Section 508.2.2 simply to consolidate allowable area provisions, in context, in the appropriate location. The technical provision is unchanged. The location is consistent with mixed occupancy design option formatting contained throughout Section 508. Approval of this public comment will result in more consistent application of IBC accessory occupancy provisions.

Final Action: AS AM AMPC____ D

G111-09/10
508.2.3

Proposed Change as Submitted

Proponent: Todd Andersen, representing self

Revise as follows:

508.2.3 Allowable building area and height. The allowable building area and height of the building <u>containing accessory occupancies</u> shall be based on the allowable building area and height for the main occupancy in accordance with Section 503.1. ~~The height of any accessory occupancy shall not exceed the tabular values in Table 503, without height and area increases in accordance with Sections 504 and 506 for such accessory occupancies. The building area of the accessory occupancies shall be in accordance with Section 508.2.1.~~

Reason: The current text would limit the location of an accessory occupancy within a building such that it could not be located any higher in a building than the building area and height limits of Table 503 for the accessory would allow. From the Reason statement and testimony by the proponent this was never the intent. Code Change G14-04/05 relocated and rewrote the provisions for Mixed Occupancies in the 2006 IBC to move from Section 302 to new Section 508.

In the Reason statement the proponent wrote – "The purpose of this proposal is to organize and clarify the requirements for the various mixed occupancy and use design options recognized in the International Building Code…The various technical requirements for each design option have been articulated using consistent terminology and style. These requirements generally parallel current intent."

As stated in the Reason statement to Code Change G14-04/05, the intent of code change was to relocate the provisions in Section 302.2 of the 2003 IBC and put their requirements in a consistent format, not to make technical changes. Therefore to understand that the current language was never part of the requirements we need to look at the language in Section 302.2 of the 2003 IBC – it reads:

> **302.2 Accessory use areas.** A fire barrier shall be required to separate accessory use areas classified as Group H in accordance with Section 302.3.1, and incidental use areas in accordance with Section 302.1.1. Any other accessory use area shall not be required to be separated by a fire barrier provided the accessory use area occupies an area not more than 10 percent of the area of the story in which it is located and does not exceed the tabular values in Table 503 for the allowable height or area for such use.
> **302.2.1 Assembly areas.** Accessory assembly areas are not considered separate occupancies if the floor area is equal to or less than 750 square feet (69.7 m2). Assembly areas that are accessory to Group E are not considered separate occupancies. Accessory religious educational rooms and religious auditoriums with occupant loads of less than 100 are not considered separate occupancies.

Nowhere in Section 302.2 (2006 IBC) was there ever a limit on the location of an accessory use area within a building, and it was not the intent of the proponents of Code Change G14-04/05 to ever impose one in the 2006 IBC nor to carry over to the 2009 IBC.

Without this code change building design as we know it today would literally not be allowed.

Without this code change a conference room would never be allowed to be located on the top story in a office building (Group B) of Type IIA construction because the building height limit (in stories) for a Group A-3 occupancies is 3 stories, where the Group B building would be allowed to be 5 stories in building height (or 6 stories if sprinklered). The current language would limit the location of any conference room to not more than the 3rd story.

Another example would be storage rooms (Group S-1). Based on Table 503 the building height limit (in stories) for a Group S-1 occupancy is 4 stories, again where the Group B building would be allowed to be 5 stories in building height (or 6 stories if sprinklered). The current language would limit the location of any store rooms to not more than the 4th story.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: Andersen G-1(former RICE-G9)-508.2.3.doc

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee disapproved the change because they did not find it solved the issue raised by the proponent that of limiting accessory occupancy location in a building based on its tabular value in Table 503 rather than the tabular value of the primary occupancy of the building.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Sarah A. Rice, The Preview Group, representing self, requests Approval as Modified by this Public Comment.

508.2.3. Allowable building area and height.. The allowable building area and height of the building containing accessory occupancies shall be based on the allowable building area and height for the main occupancy in accordance with Section 503.1. The building area occupied by accessory occupancies shall be in accordance with Section 508.2.1.

Commenter's Reason: As the proponent indicated in the original reason statement the current text would literally limit the vertical location of an accessory occupancy within a building to only the limits of Table 503.

For example, a building housing mostly offices (classified as Group B) and constructed of Type IIA construction is allowed by Table 503, when sprinklered, to be 6 stories in height. Most office building have small dining rooms, conference rooms and storage rooms dispersed throughout the building and these spaces are typically of such a size that they qualify as "accessory uses." If literally applied, current Section 508.2.3 would not allow small dining rooms (Group A-2) and small conference rooms (Group A-3) to be located above the 4th story, and small storage rooms would not be allowed to be located above the 5th story. Because Section 508.2.3 says that "The height of any accessory occupancy shall not exceed the tabular values in Table 503…"

Research into the development of current Section 508.2.3 finds its roots in one of the legacy codes, the 1996 BOCA National Building Code (Section 302.1.2). Members of the original Development Committee for Chapter 3 of the Working Draft for the 1st edition of the International Building Code indicated that the provisions for the section that would become Section 302.2 Accessory use areas in the 2000 IBC were essentially taken Section 302.1.2 of the 1996 BOCA National Building Code, which read:

> *302.1.2 Accessory uses. Except for accessory areas of Use Group H in accordance with Section 302.1.2.1 and specific occupancy areas indicated in Section 302.1.1, a fire separation assembly shall not be required between the main use group and accessory areas when the aggregate area devoted to all accessory occupancies does not occupy more than 10 percent of any fire area; the aggregate area devoted to all accessory occupancies within a story does not exceed 10 percent of the area of the story and the aggregate area devoted to an accessory occupancy is not more than 10 percent of the allowable area permitted by Section 503.0 based on the accessory use group. The required type of construction and the automatic fire suppression requirements of Section 904.0 shall be based on the main use group of the fire area.*

No where in Section 302.1.2 is the relative vertical location of an accessory occupancy limited within a building? Only the amount of area occupied by accessory occupancies is regulated.

This comment also seeks to keep the last sentence of current 508.2.3 which reads "The building area occupied by accessory occupancies shall be in accordance with Section 508.2.1."

Final Action: AS AM AMPC____ D

G118-09/10
Table 508.4

Proposed Change as Submitted

Proponent: Tony Crimi, A.C., Consulting Solutions Inc., representing North American Insulation Manufacturers Association

Delete the entire Table 508.4 and substitute as follows:

Errata: The table, as published with the proposed code changes had errors in two cells. An errata note was included in the Report of Hearings which showed the table corrected. The intent of the proponent is to replicate Table 302.3.2 from the 2003 IBC without change. The two cells are shown below, with their proper values (E and H-5; F-2 and U).

TABLE 508.4
REQUIRED SEPARATION OF OCCUPANCIES (HOURS)

For SI: 1 square foot = 0.0929 m^2.
NP = Not permitted.

a. Except for Group H and I-2 occupancies, where the building is equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1, the fire-resistance ratings shall be reduced by 1 hour but to not less than 1 hour and to not less than the required floor construction according to the type of construction.
b. Occupancy separation need not be provided for storage areas within Groups B and M if the:
   1. Area is less than 10 percent of the floor area;
   2. Area is provided with an automatic sprinkler system and is less than 3,000 square feet; or
   3. Area is less than 1,000 square feet.
c. Areas used only for private or pleasure vehicles shall be allowed to reduce separation by 1 hour.
d. See Section 406.1.4. for private garages and carports.
e. Commercial kitchens need not be separated from the restaurant seating areas that they serve.

Reason: This proposal aims to restore the previous Table 302.3.2 from the 2003 IBC, but retain the modified text of section 508 on Mixed Use & Occupancy. In addition to restoring the separated uses (occupancies) concept previously prescribed in Section 302 of the 2003 IBC (and 2003 Supp), the proposal clarifies the distinction between separated uses and the non-separated use options. During the 2006 cycle the separated uses section of the IBC was changed based on public proposal G32-04/05 on the basis that it presented no significant technical changes. To the contrary, there are more than 100 changes in fire resistance ratings resulting from this proposal, most without justification or supporting rationale. The result of this Code change is to reduce the level of protection provided by the IBC over any of the previous Legacy Codes.

Approximately 40% of the jurisdictions who have adopted the IBC are now using the 2006 (or later) edition. In contrast, when this Code change was first accepted in the 2006 IBC, few jurisdictions had any history with the lack of fire resistance rated construction between occupancies which the 2006 and 2009 IBC now permits. As a result, there is a growing level of concern with the reductions in fire resistance ratings between separated occupancies in mixed occupancy buildings in the 2006 IBC. The adoption of this Code change in the 2006 and 2009 IBC arbitrarily reduced fire resistance ratings to levels significantly below most of the Legacy Codes, without providing any compensating safety measures. The full impact of this change has not yet been felt. This change needs to be corrected, and a selective process of review, consideration, and justification undertaken to determine which, if any, of these changes are desirable and justifiable.

The concept of separation of major occupancies exists in Building regulations throughout the world. Certainly, those occupancy separations requirements used in the separated occupancies option have stood the test of time. There continues to be a critical need to separate adjacent major occupancies of dissimilar use, with fire-resistance rated construction. This proposal would delete the current Table 508.4 in its entirety and substitute the previous Table 302.3.2 which was replaced in Code Change G32-04/05. The previous Table 302.3.2 had been is use for the three plus years it existed in the 2000 and 2003 editions of the IBC. Furthermore, the occupancy separation fire resistance ratings from this predecessor table were taken directly from the BOCA National Building Code, along with the entire concept of the non-separated and separated occupancies in mixed occupancy buildings. The occupancy separation Table had existed in the BOCA National Building Code for a very long time, and was incorporated into the first edition of the IBC. The concept of separation of major occupancies exists in Building regulations throughout the world. Certainly, those occupancy separations requirements used in the separated occupancies option have stood the test of time. There continues to be a

In the published "Report of the Public Hearing on the 2003 editions of the International Building Code", the committee's published reason for recommending adoption of G32-04/05 is reported as follows: "The proposal does not have any significant technical changes from the current requirements." In reality, this code change proposals has lead to over 100 changes to required fire resistance ratings for occupancy separation, in both sprinklered and unsprinklered occupancies, without providing individual justifications of any kind.

To illustrate some specific examples, this change has unilaterally reduced the fire separation between a mixed use office and a moderate hazard warehouse from the previously existing 3-hour minimum fire separation to zero, while providing no technical justification or compensating measures. Table 302.3.2 of the 2003 IBC, as well as the Exception to Section 302.2.3 (IBC 2003 Supplement), specified a minimum fire resistance for every occupancy separation and did not permit a fire resistance rating to be less than one hour, even when an automatic sprinkler system was provided. In contrast, the new Table 302.3.2 allows numerous instances where the fire resistance ratings are waived entirely. Further, while Exception 1 of the old section 302.3.2 did not apply to Group H and I-2 areas, the revised Table in the new section 508 shows a reduction of 1-h in fire resistance rating between all I occupancies and for F-2, S-2, U, B, F-1, M, and S-1 without any justification or compensation. While it has been argued that a number of these separated use combinations are unrealistic, an equal number are very realistic and represent an unjustified reduction from current code requirements for fire-resistant construction. To unilaterally propose that a mixed use office and moderate hazard warehouse be reduced from the current 3-hour minimum fire separation to a zero separation is unjustifiable.

Bibliography & References:

[3] 1997 Standard Building Code, SBCCI
[4] 1997 Uniform Building Code, ICBO

Cost Impact: The code change proposal will increase the cost of construction.

Analysis: Alternative locations for allowance in the footnotes to the table would be as exceptions to Sections 508.3.3 and 508.4.4.

ICCFILENAME: CRIMI-G3-TABLE 508.4.doc

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The committee approved the table as providing a better format for the information for occupancy separation requirements. It allows a simple reading of the table for the intersection each possible combination of occupancies. The values quickly force someone to consider the non-separated mix occupancy option. There was discomfort that the existing Table 508.4 combines in the same column and row occupancies that are distinctly different. It was acknowledged that the values contained in the table are still the subject of considerable debate but the format provides a clear route to consider different values. The committee intends that existing Table 508.4 be replaced by Table 302.3.2 from the 2003 Edition of the IBC, with no changes to the tabular values in the 2003 Table.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Gerald Anderson, City of Overland Park, representing self, requests Disapproval.

Commenter's Reason: It would be my opinion that the committee's reason statement gives no justification at all for this code change. You would think that this code change is nothing but a re-organization of existing data. But that is not the case. This code change represents a major reversal in thought process. I would also note that I don't see where the committee, supported any on the proponents reason for the change. I have to wonder why the committee did not latch on to some of the proponents reasons if they really believed in the code change. Below I have outlined the committee's reasoning statement and provided comment.

Committee Reasons:
I. The committee approved the table as providing a better format for the information on occupancy separation. It allows for a simple reading of the table for the intersection each possible combination of occupancies. In reading this reason one is led to believe that the change is more editorial in nature. That is not true this code change is a major role back.
2. The values quickly force someone to consider the non-separated mix occupancy option. Why is. this important? Is the committee suggesting that the non-separated use is the preferred method for dealing with mixed occupancies? Or are they suggesting the separation requirements are so stringent that one is automatically forced to use the non-separated use option.

3. There was discomfort that the existing table 508.4 combines the same column and row occupancies that are distinctly different. This is a comment concerning the format *or* readability of the table. It would be an appropriate comment if this code change simply re-arranged existing data but that is not the case.
4. It was acknowledged that the values contained in the table are still the subject of considerable debate but that format provides a clear route to consider different values. I am not sure what this reasoning statement is telling us other than the fact that the committee is acknowledging that the values in the table are still up for debate.

In the proponents reasoning statement, it is stated that the new proposed table is right out of the BOCA code and that the stated occupancy separations have stood the test of time. I am not going to dispute that statement. However, the problem with the proponents reasoning is that he is once again wishing to mix two very different concepts. Those concepts are separating are based on "occupancy" and separating occupancies and/or spaces into "fire areas". Fire Areas are closely associated with and can establish a threshold for the need for fire protection system. The need for occupancy separation is based on the inherent risk that one occupancy may pose to an adjacent occupancy. Fire Areas are based on potential fuel loading amongst one or a multitude of occupancies. Currently, the code adequately and correctly addresses occupancy separation in Table 504.8. Separating mixed occupancies into fire areas is addressed in Section 707.3.8. If one would go back and look at the proponents reasoning statement for G32·04/05 the explanation for the way the code currently exists is explained in great detail.

Furthermore, concerning the fact that the proponent is trying to address two very different concepts in One table" one only has to look the title of the BOCA Table 313.1.2 that the proponent wishes to bring into the code. That table is titled "Fire-resistance Separation Requirements for Fire Separation Assemblies of Fire Areas". Table 508.4 of the IBC is attempting to address occupancy separation.

There is no question that some dissimilar occupancies by themselves present a possible hazard to an adjacent occupancy. Table 508.4 currently recognizes this fact and does provide separation when needed. If the proponent really believes that all occupancies are such a hazard to one another that they need to be separated with these enhanced fire barriers then I think that begs the question as to why they support the concept of "non-separated mixed use".

I would also add that Table 508.4 is a heavily used table. It is not a table that we as code users can afford to be changing every other code cycle. The table as it currently exists adequately addresses occupancy separation. There is no need or justification to revert back to an old table in one of the legacy codes. Proper justification and reasoning was given and accepted when the existing table was brought forth. I urge your disapproval.

Public Comment 2:

Gene Boecker, Code Consultants, Inc., representing The National Association of Theatre Owners, requests Disapproval.

Commenter's Reason: The original code change that brought the current table into the code was an attempt to modernize the concept of separation of occupancies. Rather than consider each individual occupancy based simply on its being designated as a different occupancy from others, this change categorized occupancies according to relative levels of risk, a valid concept that is used in Chapter 8 of the IEBC. This concept better expresses the hazards shared among different occupancies, and rationally allows similar hazards and risks to be grouped together and therefore unseparated one from another. Based on this, the current language should be retained.

Public Comment 3:

Ron Clements, representing Chesterfield County Building Inspection Dept., requests Disapproval.

Commenter's Reason: The proponent of G118-09/10 would have you believe that the ICC General Code Committee for the 2004/2005 code cycle that voted to approve G32-04/05 and the membership at the final action hearings for the 2004/2005 code cycle that voted in support of the committee and against the public comment to deny G32-04/05 did not know what they were doing. And then again in the 2006/2007-code cycle this issue was brought up with G148-06/07, which attempted to do the same thing as the current G118-09/10 and return the old table and reverse the action of the membership during the 2004/2005 code cycle. Again the committee and the membership voted in support of the current mixed occupancies table and concept and denied change G148-06/07. I would suggest that since this has been voted on twice by two separate General Committees and twice by the membership that it is a flimsy argument to suggest that all those people did not understand what they were doing. I served on the ICC General Code Committee from 2003 to 2006. I served as Vice-Chair of the committee in for the last two cycles of those terms. In my opinion, every member of the committee understood G32-04/05 and G148-06/07 and what those code changes accomplished. Each committee member understood the technical ramifications of this issue. The published committee reason statement indicating that there were no technical changes was inaccurate and regrettable. Obviously, the format for the table and the fire-resistance rating requirements contained in the dedicated table were very different from the former consolidated table. I believe that the inference was intended to indicate that the new provisions were very similar to those contained in a former model code and therefore had historical precedence. In my opinion the membership also knew what they were doing based on comments I received from many of them. Therefore since this was the first time in three cycles that the committee voted to return to the old 2003 edition mixed occupancies table I felt it appropriate that the membership have the final vote to support their past actions.

The 2009 IBC Table 508.4 places similar risks together without a separation requirement and in those cases mixed occupancy is based solely on performing the ratio calculation. Only dissimilar risk requires a fire separation. All that table 508.4 is dealing with is allowable area limits; table 706.3.9 addresses separation of fire areas for fire protection thresholds. How much of a difference in allowable area is there between a group M and Group S1? In table 503 there is none with type 5B construction and only 5000sf with type 2B. The biggest difference is higher occupant loads but not higher fuel loads so it makes since to allow use of the ratio calculation only to mitigate the slight hazard disparity between the two similar uses thereby allowing slightly larger buildings than non-separated use would allow in those case. When you get to the next level where the fuel loading and occupant load risk differ, such as between Assembly and Storage use then in addition to the ration calculation you also get the fire rated separation. The current table 508.4 uses a more sensible stepped approach to handling mixed occupancies with the separated mixed-use method. This method also makes the method more usable. I can count on one hand the number of buildings I have seen in 16 years of code enforcement where separated mixed use was used to achieve allowable area requirements. With sprinkler and frontage increases and sprinkler thresholds that kick in most mixed-use buildings can comply as non-separated mixed use.

Public Comment 4:

David S. Collins, FAIA, The Preview Group, Inc., representing The American Institute of Architects, requests Disapproval.

Commenter's Reason: Under the provisions of the IBC, there are some groupings of occupancies that are very similar based on their risks as defined in Section 903 for fire, and Chapter 10 for egress. Often these occupancies are combined with business functions because of their need for such functional support. The question raised by G118-09/10 is whether or not such activities must be separated from each other. Historically the codes have treated these conditions differently, but both the 2006 and 2009 IBC have allowed these occupancies to be unseparated, but allowed them to be treated as if they were separated to determine the allowable area for a mixed use.

G118-09.10 changes the structure in Table 508.4 and takes the code back to the original separation requirements found in the 2003 IBC. Many of the "fixes" aren't fixes as all, and just add to the confusion of requiring separation where none is needed. A classic example is the mixed-use separated requirement for Business (B) and Low-Hazard Storage (S-2) occupancies. Table 503 establishes the numbers of stories and areas of a business and low-hazard storage as:

Table 1 Area Permitted Per Story
B and S-2 per Table 503

Type of Construction		IIB	IIIA	IIIB	VA	VB
Business	Stories	3	5	3	3	2
	Area	23,000	28,500	19,000	18,000	9,000
Storage (S-2)	Stories	4	4	4	4	1
	Area	26,000	39,000	26,000	21,000	13,500

When using G118-09/10 mixed-use options, you are limited by the smallest allowable area, or by a relative percentage of the allowed areas when separating them.

G118-09/10 ignores the safety factors associated with some groups that are so similar that the code treats them almost identically. They are often with each other in the same facility because of a business interrelationship. The following table shows the maximum allowable area for the mixed-use and the area of each occupancy if the B were strictly an accessory function.

Table 2 Area Permitted Per Story
B Accessory to S-2

Type of Construction		IIB	IIIA	IIIB	VA	VB
B/S-2 Combined	Stories	3	3	3	3	1
	Area	23,000	28,500	19,000	18,000	9,000
S-2 portion Area		20,700	25,650	17,100	16,200	8,100
B portion Area		2,300	2,850	1,900	1,800	900

If the B function were more than 10% of the building floor, G118-09/10 would require a 1 hour fire barrier between the business and storage occupancy in order to treat it as mixed-use separated. Under the 2009 IBC that same configuration would require no fire barrier. Assuming that 25% of the floor were business and 75% were low-hazard storage, the allowable floor area and the breakdown for the area for each occupancy would be as follows:

Table 3 Area Permitted Per Story
25% B and 75% S-2 (no Sprinklers)

Type of Construction		IIB	IIIA	IIIB	VA	VB
B + S-2 Combined	Stories	3	3	3	3	1
	Area	25,250	36,750	24,250	20,250	12,375
S-2 portion - Area		19,500	29,250	19,500	15,750	10,125
B portion - Area		5,750	7,125	4,750	4,500	2,250

In some cases the area of the low-hazard storage is smaller and in others it is larger than it would be if there were no mixed occupancy, but with G118-09/10, a 1 hour wall is required to protect it even though it is smaller in area than if it were a single occupancy.

Neither a B nor an S-2 occupancy require fire suppression, unless the S-2 is a commercial parking garage. The S-2 can be in a one story, unlimited area building without a fire suppression system, while the B could be in a one story and both a B and S-2 (unseparated) could be in two-story unlimited area buildings with fire suppression.

Both G118-09/10 (with a 1 hour fire barrier) and the current IBC (without the fire barrier) would allow the following if the building is sprinklered throughout assuming the same proportion of building area with 25% business and 75% low-hazard storage:

Table 4 Area Permitted Per Story
25% B and 75% S-2 (with Sprinklers)

Type of Construction		IIB	IIIA	IIIB	VA	VB
B/S-2	Stories	3	3	3	3	2
	Area	75,750	109,125	72,750	60,750	37,125

A similar phenomenon occurs in the group of at a B business combined with either M mercantile, or F-1 manufacturing, or S-1 moderate-hazard storage in a mixed-use. As designed, constructed and used, most of these cases the business activity is the minor portion of the facility. Table 503 permits these base areas:

Table 5 Area Permitted Per Story
B, M, F-1, S-1 Stories/Area per Table 503

Type of Construction		IIB	IIIA	IIIB	VA	VB
Business	**Stories**	3	5	3	3	2
	Area	23,000	28,500	19,000	18,000	9,000
Mercantile	**Stories**	4	4	4	3	1
	Area	12,500	18,500	12,500	14,000	9,000
Manufacturing (F-1)	**Stories**	2	3	2	2	1
	Area	15,500	19,000	12,000	14,000	8,500
Storage (S-1)	**Stories**	3	4	3	4	3
	Area	17,500	26,000	17,500	14,000	9,000

Because of the risk associated with these occupancies, Section 903.2 would require fire suppression for them at the following building area thresholds:

Section 903.2 Sprinkler thresholds for each occupancy is:

Business	None – based on area
Mercantile	12,000 or 24,000 combined
Manufacturing (F-1)	12,000 or 24,000 combined
Storage (S-1)	12,000 of 10,000 2 or more stories in height

Table 1004.1 The occupant load factor in each is:

Business	100 gross
Mercantile	300 gross (storage/stock/shipping)
Manufacturing (F-1)	100 gross
Storage (S-1)	500 gross (warehouses)

Table 1016.1 Travel distance limitation for each occupancy is:

Business	200 feet
Mercantile	200 feet
Manufacturing (F-1)	200 feet
Storage (S-1)	200 feet

To examine the question raised by G118-09/10, assume a mixed use of B with either M, F-1 or S-1 without separation, with the B being 25% of the building area (relatively large). The allowed total per floor area <u>without fire suppression</u> would be:

Table 6 Area Permitted Per Story
25% B with 75% M or F-1 or S-1 (no Sprinklers)

Type of Construction		IIB	IIIA	IIIB	VA	VB
B/M	**Stories**	2	2	2	2	1
	Area	11,999	11,999	11,999	11,999	9,000
B/F-1	**Stories**	2	2	2	2	1
	Area	11,999	11,999	11,999	11,999	8,500
B/S-1	**Stories**	1	1	1	1	1
	Area	11,999	11,999	11,999	11,999	9,000

Using the provisions from the 2009 IBC and assuming that an NFPA 13 fire suppression system were installed throughout the building, the total allowable area per floor for the uses (B @ 25%) in a multi-story application would be shown as B + M, F + F-1 and B + S-1. In the same table is the allowable area for only the M, F-1 and S-1 when totally sprinklered.

Table 7 Area Permitted Per Story
25% B with 75% M or F-1 or S-1 (with Sprinklers)

Type of Construction		IIB	IIIA	IIIB	VA	VB
B + M	**Stories**	3	3	3	3	3
	Area	45,375	63,000	42,375	45,000	27,000
M	**Stories**	3	3	3	3	2
	Area	37,500	55,500	37,500	42,000	27,000
B + F-1	**Stories**	3	3	3	3	3
	Area	52,125	64,125	41,250	45,000	25,875
F-1	**Stories**	3	3	3	3	2
	Area	46,500	57,000	36,000	42,000	25,500
B + S-1	**Stories**	3	3	3	3	3
	Area	56,625	79,875	53,625	45,000	27,000
S-1	**Stories**	3	3	3	3	3
	Area	52,500	78,000	52,500	42,000	27,000

Note: Because the code limits the overall building area, none of the values are shown for a building more than 3 stories in height. If a building with these occupancy groups were built higher, the area per floor would have to be fractionally reduced.

B group functions in these buildings would never trigger the requirement for the building to be sprinklered and does not play any role in the allowed height of the building except to limit it in some circumstances.

G118-10/11 requires a 1 hour fire barrier separation between the B portion of the building and the S-1 group, and a 2 hour fire barrier between the B functions and the M and F-1 areas. When you examine this question you should ask what has been accomplished. What additional safety exists? Except to significantly increase the cost of construction, no additional safety has been gained.

For example, in Type IIB structure, an M occupancy can be 37,500 sf per floor and have 10% of that floor area be an accessory business function (3,750 sf) with no separation and the building would not be classified as a B occupancy; it would be 100% M at 37,500 sf. However, if it is declared a B group mixed with an M group, the total building area could increase to 45,375 sf. and the building would be allowed to have 17,250 sf of B Group and 28,125 sf, M Group.

The assumed hazard (M Group) has been reduced by the less hazardous (B Group). The B function has such a low level of risk that including it in these buildings does not create a hazard for the M, F-1 and S-1 areas. It is the M, F-1 and S-1 areas that are the risk and that is why they have a fire suppression threshold at 12,000 sf.

G118-09/10 provides for additional construction cost without providing any additional safety in the building. I urge the membership to overturn the committee and deny this change.

Public Comment 5:

Bruce D. Dimmig, representing, Arizona Building Officials, request Disapproval.

Commenter's Reason: The occupancy separation table (508.3.3) should be left as it is in the 2009 codes, as it is more of a risk-based case than a prescriptive case as per the table in the 2003 code cycle. In the Proponent's reasoning statement provided with the proposal heard in Baltimore, they state that the 2006 code change resulted in over 100 fire-resistive ratings changes. However, information to show that this resulted in a decrease in fire safety or data showing that this increased the number of incidents (fires, etc.) was not provided. Moreover, very few projects are designed as separated occupancies.

Public Comment 6:

Sam Francis, representing American Wood Council (AF&PA), requests Disapproval.

Commenter's Reason: The proponent has stated that G118 is simply a restoration of previous Table 302.3.2 from the 2003 IBC. This is true. However, the proponent has failed to make the case for why such a drastic step is necessary. For example, separation from B to F-1 goes from <u>None Required</u> to <u>3 Hours</u>. Is that an appropriate increase with virtually no data to support it? And of course, several examples of separated uses become not permitted under this proposal. On the surface, this seems to be a continuation of the struggle by Legacy Code users to recreate tables to reflect their experiential situation. Such change should require the rigor of data. It is lacking here.

Public Comment 7:

Jonathan Humble, AIA, American Iron & Steel Institute, requests Disapproval.

Commenter's Reason: We ask that the membership disapprove this proposal. Our basis for recommending this action is based on both the proposers reasoning for modifying the table back to the 2003 format and tabular values, and the recommendation by the code development committee concerning primarily format issues and not necessarily technical substance.

Why the 2003 edition? Comparing the 2009 table to the 2003 edition of the table represents a silo approach, yet the reason statement takes us to BOCA. Since the proponent used as an example the BOCA National Building Code, let's go back to 1989 when Section 313 (Mixed use and occupancy) was introduced as we recognize it today. From that time to the publication of the 1999 BOCA National Building Code there were a number of changes concerning the fire-resistance tabular values. The same can be said with respect to a comparison between the 1999 BOCA National Building Code and the 2003 International Building Code. And again, changes took place from the 2003 International Building Code to the 2009 International Building Code. One must therefore ask why should we only focus on the 2003 edition of the table only? Unfortunately, there is no clear basis cited in the original proponent's reasons to technically justify this narrow focus.

Does the proposal take into effect other modifications? Further, we must question if other related modifications to the International Building Code were addressed. For example, in the 2009 International Building Code the table contains a number of entries under the category "non-sprinklered" where it specifies "not permitted". But the original proponent's reason statement lacks that comparison. Therefore, is the argument for the 2003 table really legitimate? If one compares, one finds that the values in the 2003 edition represent an hourly rating thus representing a lessening of the stringency. Does this represent a logical approach? We would submit not. Then there are the modifications to other provisions of the International Building Code since 2003, such as additional sprinkler requirements, requirements for the high rise provisions, fire resistance, etc. which also can impact the decisions made to this table. None of which is accounted for in the proponents original reason statement.

In view of the above, we recommend disapproval.

Public Comment 8:

Gregory R. Keith, Professional heuristic Development, representing The Boeing Company, requests Disapproval.

Commenter's Reason: The fundamental argument of the proponent of G118-09/10 for approval was that his proposal corrects an error made by the ICC General Code Development Committee during the 2006 code development cycle. The proponent's contention is that the 2003 IBC separated mixed occupancy fire-resistance rating requirements are time proven and necessary for occupant safety. In the published reason statement for G118-09/10 the proponent states, "Certainly, those occupancy separations requirements used in the separated occupancies option have stood the test of time. There continues to be a critical need to separate adjacent major occupancies of dissimilar use, with fire-resistance rated construction. This proposal would delete the current Table 508.4 in its entirety and substitute the previous Table 302.3.2 which was replaced in Code Change G32-04/05."

Additionally, it is implied that the ICC General Code Committee was remiss in its approval of G32-04/05. He states, "This change needs to be corrected, and a selective justification undertaken to determine which, if any, of these changes are desirable and justifiable." A misleading statement published in the committee report for the 04/05 code development cycle is offered as substantiation for that assertion. The proponent notes in his G118-09/10 reason statement, "In the published "Report of the Public Hearing on the 2003 editions of the International Building Code", the committee's published reason for recommending adoption of G32-04/05 is reported as follows: "The proposal does not have any significant technical changes from the current requirements." In reality, this code change proposals has lead to over 100 changes to required fire resistance ratings for occupancy separation, in both sprinklered and unsprinklered occupancies, without providing individual justifications of any kind." The G118-09/10 reason statement also declares, "Furthermore, the occupancy separation fire resistance ratings from this predecessor table were taken directly from the BOCA National Building Code, along with the entire concept of the non-separated and separated occupancies in mixed occupancy buildings. The occupancy separation Table had existed in the BOCA National Building Code for a very long time, and was incorporated into the first edition of the IBC."

It is true that 2003 separated mixed occupancy fire-resistive rating requirements were contained within the BOCA code and therefore could be deemed to "have stood the test of time." What is not mentioned is that most, if not all, of the former Table 302.3.2 requirements are intended to apply to fire barriers separating nonsprinklered fire areas. In fact, the title of BOCA code Table 313.1.2 that became ICC Table 302.3.2 was, "FIRERESISTANCE RATING REQUIREMENTS FOR FIRE SEPARATION ASSEMBLIES BETWEEN FIRE AREAS."

The proponent's reason statement notes, "There continues to be a critical need to separate adjacent major occupancies of dissimilar use, with fire-resistance rated construction." The fact of the matter is that the proponent's table is inconsistent with that technical philosophy. In reality, the proposed table impacts buildings of lesser heights and types of construction, and in many cases, creates illogical and excessive requirements. For example, in other than Group H occupancies, there are no occupancy separation requirements in unlimited area and height buildings of Type IA and IB construction. These buildings will always qualify for nonseparated mixed occupancy provisions. Similarly, Section 507 unlimited area buildings would often qualify for nonseparated or accessory mixed occupancy provisions, neither of which would require a fire-resistance rated occupancy separation in other than Group H occupancies. On the other hand, the proposed table requires a physical separation between certain occupancies that would typically qualify for nonseparated occupancy provisions. Various Group A occupancies, for example, are generally permitted the same allowable area based on the building type of construction at Table 503. Yet, the proposed table requires a 2-hour occupancy separation between different Group A occupancies. In this instance, there is negligible dissimilar risk, yet a significant requirement for passive fire protection. That 2-hour fire-resistance rating requirement is appropriate for separation between nonsprinklered fire areas. That requirement was incorporated into new Table 706.3.9 in 2003; however, was never removed from existing Table 302.3.2. The ICC General Code Committee did realize what had been accomplished through the creation of Table 706.3.9 in 2003. When they stripped the fire area separation provisions out of 2006 Table 508.3.3, the committee regarded the resulting table as not representing significant technical changes. It was largely a housekeeping exercise at that point in time. Another legacy code, the Uniform Building Code served as the historical precedent for new 2006 Table 508.3.3. It was the only legacy code that had an occupancy separation table based solely on dissimilar risk of adjacent occupancies. As was the case with the former BOCA table, the ICBO table has "stood the test of time."

In his reason statement, the proponent provides a specific example intended to demonstrate the need for a three-hour fire-resistance rated occupancy separation between Group B office and a Group S-1 warehouse. He expresses the opinion that, "To unilaterally propose that a mixed use office and moderate hazard warehouse be reduced from the current 3-hour minimum fire separation to a zero separation is unjustifiable." He fails to note that both Group B and Group S-1 are moderate or ordinary hazard occupancies exhibiting somewhat similar risks. The most glaring error in the proponent's argument is that he fails to mention a key requirement in the separated occupancy design option. That is, the mandatory performance of the sum of the ratios calculation. By requiring the ratio of actual occupancy areas divided by total allowable areas not to exceed 1.0, the calculation ensures that fuel loading remains balanced in the subject occupancies. This calculation accounts for minor dissimilarities in risk between occupancies of a similar nature such as Groups B, F-1, M and S-1 moderate hazard occupancies or Groups A-1, A-2, A-3, A-4, A-5 and E people intensive occupancies. Using the proponent's suggested occupancies as an example, Group B and Group S-1 occupancies of any size require no fire separation when constructed of Type IA or IB construction or unlimited area buildings as permitted in Sections 507.3 or 507.4. In other types of construction, a fire separation is not required where the relative areas qualify for accessory occupancy or nonseparated occupancy provisions. Contrary to the proponent's contention that, "There continues to be a critical need to separate adjacent major occupancies of dissimilar use, with fire-resistance rated construction," IBC mixed occupancy provisions (and cited former BOCA provisions) have always permitted the absence of a fire-resistance separation in a vast majority of buildings.

As previously mentioned, separated occupancy provisions illogically apply to smaller buildings with less inherent risk. The proponent makes a generalization without providing for any sense of scale. Type IIA construction provides the largest allowable areas for those construction types subject to separated occupancy provisions. The maximum allowable floor area of a sprinklered, Group S-1 occupancy is 97,500 square feet, including sprinkler and maximum frontage increases (Section 503.1). The basic maximum allowable floor area of a Group B occupancy is 140,625 square feet (Section 503.1). Separated occupancy provisions do <u>not</u> permit a story with a total combined floor area of 238,125 square feet (97,500 + 140,625). If such was the case, the fire-resistive separation requirement currently contained in Table 707.3.9 and previously contained in 2003 Table 302.3.2, would be entirely appropriate. However, the allowable area is regulated by Section 508.4.2.

The office occupancy could contain 14,062 square feet of Group S-1 use without fire separation based on Section 508.2, accessory occupancy provisions. Conversely, the warehouse occupancy could contain up to 9,750 square feet of office occupancy without separation. By increasing the Group S-1 area by 1 percent, to 10,725 square feet, the story no longer qualifies for accessory occupancy provisions. Assuming the design need for a total area greater than the most restrictive allowable area of 97,500 square feet, separated occupancy provisions would apply. In this instance, the total allowable area based on the required sum of the ratios calculation would be 135,851 square feet ([125,126 ÷ 140,625] + [10,725 ÷ 97,500]). Note that the maximum area is 4,774 square feet <u>less</u> than that normally permitted for a single occupancy Group B story. Although the Group B footprint has been decreased by almost 5,000 square feet and the Group S-1 occupancy is only 975 feet larger than that permitted by accessory occupancy provisions, the proponent believes that a <u>three-hour</u> fire-resistance rated occupancy separation should be required. The reverse proportion is just as dramatic. Assuming an 11 percent Group B floor area in a Group S-1 occupancy, the total allowable area would be 102,264 square feet ([86,775 ÷ 97,500] + [15,469 ÷ 140,625]). In this case, the floor area is only 4,764 square feet larger than the most restrictive Group S-1 allowable area while the area of the Group S-1 fuel load has been decreased by 10,725 square feet. Again, the proponent advocates a three-hour fire-resistance rated occupancy separation. Yet, no occupancy separation is required in unlimited area buildings containing the same occupancy groups.

During the 2006 code development cycle, the ICC General Code Committee fully understood the complexities of separated occupancies, and more importantly, the <u>system</u> of mixed occupancy design options in the IBC. Contrary to that suggested by the proponent, technical justifications for modifications to former Table 302.3.2 were not necessary because those values were largely applicable to unsprinklered fire area separation and out of context for the separation of dissimilar risk. Current Table 508.4 does not require correction. The current provisions were reviewed, considered and justified to be desirable and justifiable by the code committee over six code development cycles. Those conclusions were ratified by the membership at the conclusion of each of those cycles.

Although the proponent's primary opposition to current separated occupancy separation requirements was based on criticism of the committee's technical due diligence, the 2009 IBC General Code Committee report substantiating approval as submitted stated, "The committee approved the table as providing a better format for the information for occupancy separation requirements." Additionally, "There was discomfort that the existing Table 508.4 combines in the same column and row occupancies that are distinctly different." Lastly, it was stated that, "The committee intends that existing Table 508.4 be replaced by Table 302.3.2 from the 2003 Edition of the IBC, with no changes to the tabular values in the 2003 Table." Ironically, the proponent claims that current separated occupancy provisions were adopted without technical justification. Following many cycles of vetting current Table 508.4 requirements, there was no contextual technical justification for a return to former 2003 provisions. Nevertheless, this General Code Committee approved G118-09/10 as submitted, 7-5. The committee reason was somewhat contradictory. If it was desired to change the Table 508.4 format to include all possible occupancy combinations, the submittal should have modified the format while retaining the current separation requirements. The rationale for the format change is that it will accommodate future discussions of specific separation requirements. The current occupancy groupings were criticized by some. It should be noted that most tables in the IBC contain similar groupings. By way of example, the nonsprinklered fire area separation requirements formerly contained in 2000 IBC Table 302.3.2 were consolidated into Table 707.3.9 which has four lines of occupancy groupings. Table 508.4 currently has nine occupancy groupings. The groupings are based occupancy risk similarity. Individual groupings may be altered at any time during the code development process based on technical merit. There is no reason to create a table that isolates every occupancy group simply to "provide a clear route to <u>consider</u> different values," as stated in the committee reason statement.

The stated objective of G118-09/10 is to reformat the separated occupancy table, restore 2003 fire-resistive rating requirements between all mixed occupancy combinations and start over with the analysis for the justification of reduction of former requirements. Sustaining the approval of G118-09/10 would result in the taking of a giant technical step backwards and would serve to insult the countless hours that have been devoted to the ongoing development of a viable and effective system of mixed occupancy design options over the past decade. Current Table 508.4 values have been contained in the IBC for the last two editions. There is no loss history that would indicate that they are inadequate. The entire premise of the proponent's technical/philosophical contention is based on the fact that certain fire-resistance rating requirements were formerly contained in the two earliest editions of the IBC. Over years, the various IBC code committees have worked diligently to resolve technical discrepancies caused by the integration of the three former model (legacy) codes. One such discrepancy was the dual purpose table to which the proponent assigns so much importance and technical credibility. Based on considerable debate over numerous code development cycles, earlier ICC General Code Committees resolved those conflicts and developed a relative and pertinent system of mixed occupancy provisions. Achieving a wholesale return to out of context separated occupancy requirements is irresponsible code development. It will provide occupants with a false sense of security at considerable, unnecessary cost to building developers and owners. Please maintain the technical integrity of IBC mixed occupancy provisions and disapprove G118-09/10.

Public Comment 9:

Eirene Oliphant, MCP, City of Leawood, representing Metropolitan Kansas City Chapter of the ICC requests Disapproval.

Commenter's Reason: At first glance, it appears that this code change is nothing but a re-organization of existing data, but that is not the case. While the proposed table does indeed provide for simpler reading, it has introduced considerable changes from the current table. Refer to the table below for a comparison of the current code to what is provided for in this code change:

The proponent states in his reasoning that G32-04/05, "has unilaterally reduced the fire separation between a mixed use office and a moderate hazard warehouse from the previously existing 3-hour fire separation to zero, while providing no technical justification or compensating measures." The same could be said about this proposed code change which now allows for as little as a one-hour separation between "H" occupancy groups which are "not permitted" under the current table.

The proponent also states in their reasoning that "there is a growing level of concern with the reductions in the fire resistance ratings between separated occupancies in mixed occupancy in the 2006 IBC. The adoption of this code change in the 2006 and 2009 IBC arbitrarily reduced fire resistance ratings to levels significantly below most of the Legacy Codes, without providing any compensating safety measures." The same can be said of the proposed code change.

There is no question that some occupancy groups by themselves present a possible hazard to an adjacent occupancy. This is usually because of the fire load or other hazard associated with one of the occupancies. The current Table 508.4 recognizes this fact and does provide separation when needed. If the proponent really believes that all occupancies need to be separated from one another, then one is left wondering why the code allows for "non-separated mixed use."

It is unclear which of the proponent's reasons for the change the committee supported. As a result, one is left wondering why the committee took the action it did. Is the committee suggesting that the non-separated use is the preferred method for dealing with mixed occupancies; or is it suggesting the separation requirements are so stringent that one is automatically forced to use the non-separated use option? The committee's response does not appear to provide justification for changing the separation requirements.

This table is vital to the enforcement of the building code for both plan review and inspection purposes. It is not a section of the code that as code officials we can afford to change with every code cycle. There needs to be consistency in the application of occupancy separations. The current table provides adequate separation and does not need to be modified by reverting back to an old table.

Public Comment 10:

Stephen Thomas, Colorado Code Consulting, LLC, representing Colorado Chapter of ICC, requests Disapproval.

Commenter's Reason: Approval of this change is a reversal of hours of research and work by the committee and proponents of previous changes to this table. There was not technical justification given to go back to what was in the 2003 IBC. The proponent states that the change restores the concept of separated occupancies. Separated uses are still permitted within the IBC. It was never removed. The revisions that were made in the 2006 code were investigated and discussed for at least two code cycles. It was not an arbitrary decision by the previous committee.

The proposal also perpetuates mistakes in the table that have subsequently be fixed over the last few code cycles between the table and the footnotes. Footnote c permits a one-hour reduction in the separation between a parking garage used to store private and pleasure vehicles. There are some occupancies that only require a one-hour separation to start with. Does that mean that there is no separation required? Footnote b is not needed. Both B and M occupancies permit storage within the use (Ref. 304.1 & 309.1) Storage areas are included within the particular occupancy and therefore not a separate occupancy. The mixed occupancies provisions do not apply in this case.

The committee approved the proposal because they said it would be easier to read and provide a better format. They did not discuss any of the technical revisions and confirm that there was any technical justification provided to go back to the 2003 requirements. In my experience, the table in

	A-1 (2009)	A-1 (proposed)	A-2 (2009)	A-2	A-3 (2009)	A-3	A-4 (2009)	A-4	A-5 (2009)	A-5	B (2009)	B	E (2009)	E	F-1 (2009)	F-1	F-2 (2009)	F-2	H-1 (2009)	H-1	H-2 (2009)	H-2	H-3 (2009)	H-3	H-4 (2009)	H-4	H-5 (2009)	H-5	I-1 (2009)	I-1	I-2 (2009)	I-2	I-3 (2009)	I-3	I-4 (2009)	I-4	M (2009)	M	R-1 (2009)	R-1	R-2 (2009)	R-2	R-3, R-4 (2009)	R-3, R-4	S-1 (2009)	S-1	S-2 (2009)	S-2	U (2009)	U

the 2003 code was more difficult to read than the 2006 revision. The committee also stated that the "The values quickly force someone to consider the non-separated mix occupancy option. Is that really the intent of the code, to force someone to consider one option or the other? Isn't it really to allow the design professional to use the code in a way that works with the building they are designing?

Final Action: AS AM AMPC____ D

G120-09/10
Table 508.4

Proposed Change as Submitted

Proponent: Stephen Thomas, Colorado Code Consulting, LLC, representing The Colorado Chapter ICC

Revise table notes as follows:

TABLE 508.4
REQUIRED SEPARATION OF OCCUPANCIES (HOURS)

(Portions of table not shown are unchanged.)

For SI: 1 square foot = 0.0929 m^2.
S = Buildings equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1.
NS = Buildings not equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1.
N = No separation requirement.
NP = Not permitted.

a. For Group H-5 occupancies, see Section 903.2.4.2.
b. The required separation from areas used only for private or pleasure vehicles shall be reduced by 1 hour but to not less than one hour.
c. See Section 406.1.4.
d. Commercial kitchens need not be separated from the ~~restaurant seating~~ dining areas that they serve.
e. Separation is not required between occupancies of the same classification.
f. For H-5 occupancies, see Section 415.8.2.2.

Reason: Even though footnote e is included with the E occupancies in Table 508.4, a code official has interpreted that this footnote does not apply to the cafeteria in a school. In my opinion there is no difference in the two uses. However, it can be argued that a cafeteria in a school is not a "restaurant" which is specifically stated in the footnote. This change clarifies the intent that the footnote applies to any type of dining area that is adjacent to a commercial kitchen.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: THOMAS-G2-T508.4

Public Hearing Results

Committee Action: **Approved as Modified**

Modify the proposal as follows:

TABLE 508.4
REQUIRED SEPARATION OF OCCUPANCIES (HOURS)

(Portions of table not shown are unchanged)

a. For Group H-5 occupancies, see Section 903.2.4.2.
b. The required separation from areas used only for private or pleasure vehicles shall be reduced by 1 hour.
c. See Section 406.1.4.
d. Commercial kitchens need not be separated from dining or seating areas that they serve.
e. Separation is not required between occupancies of the same classification.
f. For H-5 occupancies, see Section 415.8.2.2.

Committee Reason: The revision provides clarification that a separation is not needed between a 'commercial kitchen' and the associated dining and seating areas regardless if the activity is a restaurant of other use. Some of the committee felt the footnote wasn't needed at all because such kitchens are part of the occupancy and separation is not required. As there is not universal agreement on that interpretation, the change provides consistency regardless of the occupancy classifications assigned. The change also allows the exception clearly apply to such applications as school lunchrooms, places of religious worship and fire stations.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Tony Crimi, A.C. Consulting Solutions Inc, representing International Firestop Council (IFC), requests Disapproval.

Commenter's Reason: Available statistics on fires in Commercial Cooking establishments does not support a relaxation of the separation requirements between the commercial kitchens and dining or seating areas, particularly in Educational facilities.

According to the most recent statistics from U.S. Fire Administration's (USFA) National Fire Incident Reporting System (NFIRS) and the National Fire Protection Association's (NFPA) annual fire department experience survey, there were an estimated 7,670 fires reported to public fire departments nationwide each year in restaurants between 1999 and 2002, per NFPA statistics. These fires resulted in direct property damage of $153 million annually.[1]

Cooking equipment was the leading cause of structure fires in college classroom buildings and adult education centers. Almost half (45%) of the structure fires in college classroom buildings and adult education centers were cooking equipment fires, including 42% which were reported as confined to cooking equipment.[2]

An estimated 4,870 structure fires involving pre-school through grade 12 buildings were reported per year in 2003-2006.

During the four-year period of 2003-2006, an estimated average of 4,870 structure fires in these properties were reported per year. These fires caused an annual average of 65 civilian fire injuries and $74.2 million in direct property damage. There were no civilian deaths reported in these properties during this time period. Eighteen percent of fires in these properties were caused by cooking equipment, which includes 16% of fires reported as confined cooking equipment fires, and 21% of civilian injuries.[2]

Cooking equipment was the leading cause of structure fires in day-care centers. The leading causes of fires in these properties with data summarized from several NFIRS fields. In some cases, the equipment involved in ignition is most relevant; heat source, the field "cause," and factor contributing to ignition also provide relevant information. Almost two of every three (65%) structure fires in day-care centers were cooking equipment fires, including 59% which were reported as confined to cooking equipment. Another 8% of these fires were heating equipment fires, including 5% which were reported as confined heating equipment. Another 5% of fires in these properties were caused by electrical distribution and lighting equipment.[2]

R	—	—	—	—	—	—	N	N	1[c]	2[c]	1	2	NP	NP	3	NP	2	NP
F-2, S-2[b], U	—	—	—	—	—	—	—	—	N	N	1	2	NP	NP	3	4	2	3[a]
B, F-1, M, S-1	—	—	—	—	—	—	—	—	—	—	N	N	NP	NP	2	3	1	2[a]
H-1	—	—	—	—	—	—	—	—	—	—	—	—	N	NP	NP	NP	NP	NP
H-2	—	—	—	—	—	—	—	—	—	—	—	—	—	—	N	NP	1	NP
H-3, H-4, H-5	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	1 [d,e,~~f~~]	NP

For SI: 1 square foot = 0.0929 m^2.
S = Buildings equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1.
NS = Buildings not equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1.
N = No separation requirement.
NP = Not permitted.

a. For Group H-5 occupancies, see Section 903.2.4.2.
b. The required separation from areas used only for private or pleasure vehicles shall be reduced by 1 hour but to not less than 1 hour.

c. See Section 406.1.4.
~~d. Commercial kitchens need not be separated from the restaurant seating areas that they serve.~~
~~e~~ d. Separation is not required between occupancies of the same classification.
~~f~~ e. For Group H-5 occupancies, see Section 415.8.2.2.

303.1 (IFC [B] 202) Assembly Group A. Assembly Group A occupancy includes, among others, the use of a building or structure, or a portion thereof, for the gathering of persons for purposes such as civic, social or religious functions; recreation, food or drink consumption or awaiting transportation.

A-2 Assembly uses intended for food and/or drink consumption including, but not limited to:

Banquet halls
Nightclubs
Restaurants (including associated commercial kitchens)
Taverns and bars

(Portions not shown are unchanged.)

Reason: This proposal deletes a somewhat confusing and unnecessary commercial kitchen exception from Table 508.4 in favor of clarifying that the restaurant and associated kitchen are the same Group A-2 occupancy in Section 303.1. The current footnote reference d is shown as applicable to Group A occupancies. Occupancy separations are not required within Group A occupancies, therefore the footnote is extraneous and moot. Approval of this proposal will place the commercial kitchen provision in the proper context of occupancy classification as opposed to mixed occupancy.

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: Because the code requires buildings containing either Group I or R occupancies to be fully sprinkler protected, the Code Correlation Committee has replaced all numeric values in cells indicating a NS (non sprinklered) Group I or R occupancy building with NP for not permitted.

ICCFILENAME: KEITH-G6A-508.4

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: Deleting the footnote and adding provisions to only Group A-2 would leave in questions the application to kitchens serving schools, places of religious worship and fire houses. A definition of commercial kitchen would need to be provided; and would be helpful in clarifying this activity in this and other situations such as catering kitchens.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Gregory R. Keith, Professional heuristic Development, representing The Boeing Company, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

303.1 (IFC [B] 202) Assembly Group A. Assembly Group A occupancy includes, among others, the use of a building or structure, or a portion thereof, for the gathering of persons for purposes such as civic, social or religious functions; recreation, food or drink consumption or awaiting transportation.

A-2 Assembly uses intended for food and/or drink consumption including, but not limited to:

Banquet halls
Nightclubs
Restaurants, cafeterias and similar dining facilities (including associated commercial kitchens)
Taverns and bars

(Portions of text not shown remain unchanged)

306.2 Factory Industrial F-1 Moderate-hazard Occupancy. Factory industrial uses which are not classified as Factory Industrial F-2 Low Hazard shall be classified as F-1 Moderate Hazard and shall include, but not be limited to, the following:

Food processing and commercial kitchens not associated with restaurants, cafeterias and similar dining facilities.

(Portions of text not shown remain unchanged)

Commenter's Reason: At the code development hearings in Baltimore, three separate proposals addressed Footnote d to Table 508.4. Each addressed the limiting and potentially confusing language of the footnote. The approach of G122-09/10 was to eliminate the footnote in favor of simply clarifying the commercial kitchens associated with restaurants were a portion of the same Group A-2 occupancy. The fact that there is a footnote in the table that potentially requires occupancy separations between different occupancies, indicates that commercial kitchens are a separate occupancy unto themselves. Traditionally, commercial kitchens associated with restaurants have been included as a portion of those restaurants. In fact, the presence of such kitchens was included in establishing the relative risk of Group A-2 occupancies.

Discussion of G122 in Baltimore revealed a number of related concerns. Some felt that reference to restaurants alone was too limiting and did not recognize cafeterias and similar dining facilities. Also, there was the concern about the classification of commercial kitchens not associated with dining facilities such as catering kitchens.

This public comment for approval as modified attempts to address those concerns. First, the description at Section 303.1 has been expanded to include all dining facility and associated kitchen contingencies, whether formal or informal. Also, it clarifies that stand-alone food preparation facilities such as catering kitchens shall be classified as Group F-1 Moderate Hazard occupancies. Approval of this public comment will demystify occupancy separation provisions associated with commercial kitchens. The current default assumes that an occupancy separation may be required if it were not for Footnote d to Table 508.4. This of course, presumes that dining facilities and commercial kitchens are different occupancies. The issue is best resolved by the proper initial classification of the occupancies. Historically, commercial kitchens associated with dining facilities have been included within the Group A-2 occupancy classification of the restaurant (or other dining facility). This public comment speaks to technical concerns expressed in Baltimore and will assist in the consistent application of code requirements applicable to commercial kitchens.

Final Action: AS AM AMPC____ D

G124-09/10
Table 508.4

Proposed Change as Submitted

Proponent: Jason Thompson, National Concrete Masonry Association, representing the Masonry Alliance for Codes and Standards

Revise as follows:

TABLE 508.4
REQUIRED SEPARATION OF OCCUPANCIES (HOURS)

	A[d], E		I-1, I-3, I-4		I-2,		R		F-2, S-2[b], U		B, F-1, M, S-1		H-1		H-2		H-3,H-4, H-5	
OCCUPANCY	**S**	**NS**	**S**	**NS**	**S**	**NS**	**S**	**NS**	**S**	**NS**	**S**	**NS**	**S**	**NS**	**S**	**NS**	**S**	**NS**
A[d], E	N	N	1	2	2	NP	~~1~~ 2	~~2~~NP	N	1	1	2	NP	NP	3	4	2	3[a]
I-1, I-3, I-4	—	—	N	N	2	NP	~~1~~ 2	NP	1	~~2~~NP	1	2	NP	NP	3	NP	2	NP
I-2	—	—	—	—	N	N	2	NP	2	NP	2	NP	NP	NP	3	NP	2	NP
R	—	—	—	—	—	—	N	N	~~1~~[c] 2	~~2~~[c]NP	~~1~~ 2	2	NP	NP	3	NP	2	NP
F-2, S-2[b], U	—	—	—	—	—	—	—	—	N	N	1	2	NP	NP	3	4	2	3[a]
B, F-1, M, S-1	—	—	—	—	—	—	—	—	—	—	N	N	NP	NP	2	3	1	2[a]
H-1	—	—	—	—	—	—	—	—	—	—	—	—	N	NP	NP	NP	NP	NP
H-2	—	—	—	—	—	—	—	—	—	—	—	—	—	—	N	NP	1	NP
H-3, H-4, H-5	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	1[e,f]	NP

For SI: 1 square foot = 0.0929 m^2.

S = Buildings equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1.
NS = Buildings not equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1.
N = No separation requirement.
NP = Not permitted.

a. For Group H-5 occupancies, see Section 903.2.5.2.
b. The required separation from areas used only for private or pleasure vehicles shall be reduced by 1 hour but to not less than 1 hour.
c. See Section 406.1.4.
d. Commercial kitchens need not be separated from the restaurant seating areas that they serve.

e. Separation is not required between occupancies of the same classification.
f. For H-5 occupancies, see Section 415.8.2.2.

Reason: Group R occupancies involve a living environment that has persons sleeping and who may not be aware of their surroundings should an emergency due to fire begin to develop. Because of this there is need to provide a higher degree of fire resistive separation than might normally be provided between occupancies where the persons in the buildings are alert to their surroundings such as Group A, B, E, F, M or S . This proposal increases the fire resistance between Group R occupancies and all other occupancies to 2-hours to reduce the risk of fire spreading while the occupants are sleeping.

The code change also corrects several cells in the table where the table implies you can have fire separation between an unsprinklered Group I-1, I-3, I-4 and R occupancies and other occupancy groups. All Group I-1, I-3, I-4 and R occupancies are required to be fully sprinklered.

Cost Impact: The code change proposal will increase the cost of construction.

Analysis: A question is how this proposed change would coordinate with the separation requirements in Section 406.1.4, which is referenced in note c.

ICCFILENAME: Thompson-G1-T508.4

Public Hearing Results

Committee Action: Disapproved

Committee Reason: The committee preferred the changes approved under G118-09/10 and this change would be unnecessary.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jason Thompson, National Concrete Masonry Alliance (NCMA), representing, Masonry Alliance for Codes and Standards (MACS), requests Approval as Submitted.

Commenter's Reason: We are submitting this Public Comment requests Approval of our Code Change G124-09/10 as a fallback position should there be Public Comments submitted to Code Change G118-09/10 requesting disapproval of that Code Change which was recommended for approval by the IBC General Code Development Committee. As noted in the Committee Reason statement, the Committee preferred the changes they approved in G118-09/10 so they considered this Code Change unnecessary. We agree with that approach and, in fact, at the ICC Code Development Committee Hearings held in Baltimore last year, we supported the approval of G118-09/10 and indicated that if it were approved, we would withdraw our Code Change G124-09/10.

We still believe that Code Change G118-09/10 is the best solution to the issue of requiring appropriate fire-resistance ratings for the separation of mixed occupancies under the separated occupancies option in Section 508.4 of the IBC. It takes a comprehensive approach to the issue as compared to this code change which focuses on the modification of several cells in Table 508.4 Required Separation of Occupancies. Our goal is to assure that Code Change G118-09/10 is approved at the ICC Final Action Hearings in which case we would withdraw this Public Comment to our Code Change G124-09/10. However, if Code Change G118-09/10 is voted for disapproval at the ICC Final Action Hearings, then we believe this Code Change should be approved as submitted based on our original Reason Statement.

Final Action: AS AM AMPC____ D

G125-09/10
Table 508.4

Proposed Change as Submitted

Proponent: Maureen Traxler, City of Seattle, Seattle Dept of Planning & Development

Revise as follows:

Table 508.4
REQUIRED SEPARATION OF OCCUPANCIES (HOURS)

Occupancy	**A[d], E**		**I-1, I-3, I-4**		**I-2**		**R**		**F-2, S-2[b], U**		**B, F-1, M, S-1**		**H-1**		**H-2**		**H-3, H-4, H-5**	
	S	NS	S	NS	S	NS	S	NS	S	NS	S	NS	S	NS	S	NS	S	NS
A[d], E	N	N	1	2	2	NP	1	2	N	1	1	2	NP	NP	3	4	2	3[a]
I-1, I-3, I-4	-	-	N	N	2	NP	1	NP	1	2	1	2	NP	NP	3	NP	2	NP
I-2	-	-	-	-	N	N	2	NP	2	NP	2	NP	NP	NP	3	NP	2	NP
R	-	-	-	-	-	-	N	N	1[c]	2[c]	1	2	NP	NP	3	NP	2	NP
F-2, S-2[b], U	-	-	-	-	-	-	-	-	N	N	~~1~~N	~~2~~N	NP	NP	3	4	2	3[a]
B, F-1, M, S-1	-	-	-	-	-	-	-	-	-	-	N	N	NP	NP	2	3	1	2[a]
H-1	-	-	-	-	-	-	-	-	-	-	-	-	N	NP	NP	NP	NP	NP
H-2	-	-	-	-	-	-	-	-	-	-	-	-	-	-	N	NP	1	NP
H-3, H-4, H-5	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	1[e,f]	NP

For SI: 1 square foot = 0.0929 m^2.

S = Buildings equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1.
NS = Buildings not equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1.
N = No separation requirement.
NP = Not permitted.

(Notes a through f to the table remain unchanged.)

Reason: Table 508.4 allows an unrated separation between Groups B/M/U occupancies and Group F-1/S-1 (moderate-hazard) occupancies yet requires a 2-hr separation between Groups B/M/U occupancies and Group F-2/S-2 (low-hazard) occupancies. It is not appropriate to require a higher level of separation from an occupancy of lower hazard. This proposal amends the separation requirements so the low-hazard occupancies Group F-2 and S-2 no longer require a level of separation higher than that of the moderate-hazard occupancies Groups F-1 and S-1.

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: Because the code requires buildings containing either Group I or R occupancies to be fully sprinkler protected, the Code Correlation Committee has replaced all numeric values in cells indicating a NS (non sprinklered) Group I or R occupancy building with NP for not permitted.

ICCFILENAME: TRAXLER-G4-T508.4.doc

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee preferred the changes approved under G118-09/10 and this change would be unnecessary.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Maureen Traxler, City of Seattle Dept. of Planning & Development, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

Table 508.4
REQUIRED SEPARATION OF OCCUPANCIES (HOURS)

Occupancy	A[d], E		I-1, I-3, I-4		I-2		R		F-2, S-2[b], U		B, F-1, M, S-1		H-1		H-2		H-3, H-4, H-5	
	S	NS	S	NS	S	NS	S	NS	S	NS	S	NS	S	NS	S	NS	S	NS
A[d], E	N	N	1	2	2	NP	1	2	N	1	1	2	NP	NP	3	4	2	3[a]
I-1, I-3, I-4	-	-	N	N	2	NP	1	NP	1	2	1	2	NP	NP	3	NP	2	NP
I-2	-	-	-	-	N	N	2	NP	2	NP	2	NP	NP	NP	3	NP	2	NP
R	-	-	-	-	-	-	N	N	1[c]	2[c]	1	2	NP	NP	3	NP	2	NP
F-2, S-2[b], U	-	-	-	-	-	-	-	-	N	N	1	2	NP	NP	3	4	2	3[a]
B, F-1, M, S-1	-	-	-	-	-	-	-	-	-	-	~~N~~ 1	~~N~~ 2	NP	NP	2	3	1	2[a]
H-1	-	-	-	-	-	-	-	-	-	-	-	-	N	NP	NP	NP	NP	NP
H-2	-	-	-	-	-	-	-	-	-	-	-	-	-	-	N	NP	1	NP
H-3, H-4, H-5	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	1[e,f]	NP

For SI: 1 square foot = 0.0929 m^2.
S = Buildings equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1.
NS = Buildings not equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1.
N = No separation requirement.
NP = Not permitted.

(Notes a through f to the table remain unchanged.)

Commenter's Reason: Table 508.4 allows an unrated separation between B/M occupancies and F-1/S-1 (moderate-hazard) occupancies yet requires a 2-hr separation between B/M occupancies and F-2/S-2 (low-hazard) occupancies. It is not appropriate to require a higher level of separation from an occupancy of lower hazard. To address some of the issues raised during testimony on this proposal, rather than reducing the separation requirement of the low-hazard occupancies to match the separation requirement of the moderate-hazard occupancies (as was done in the original proposal), this modification increases the separation requirement of the moderate-hazard occupancies to match the separation requirements of the low-hazard separation requirements.

Final Action: AS AM AMPC____ D

S = Buildings equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1.
NS = Buildings not equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1.
N = No separation requirement.
NP = Not permitted.

a. For Group H-5 occupancies, see Section 903.2.5.2.
b. The required separation from areas used only for private or pleasure vehicles shall be reduced by 1 hour but to not less than 1 hour.
c. See Section 406.1.4.
d. Commercial kitchens need not be separated from the restaurant seating areas that they serve.
e. Separation is not required between occupancies of the same classification.
f. For H-5 occupancies, see Section 415.8.2.2.
<u>g.</u> <u>Occupancy separation need not be provided for storage areas associated with a Group B occupancy if the:</u>
   1. <u>Area is less than 10 percent of the floor areas;</u>
   2. <u>Area is provided with an automatic sprinkler system and is less than 3,000 square feet; or</u>
   3. <u>Area is less than 1,000 square feet.</u>

Reason: The purpose of this Code change is to break out the Group B Occupancies from Groups F-1, M, and S-1 since the current grouping in Table 508.4 does not represent similar hazards, and results in no fire separations being required between these.

This proposal aims to restore a portion of the level of protection afforded in the 2003 IBC and many of the Legacy Codes. While the current Table 508.4 was first revised for the 2006 IBC, few jurisdictions had any history with the lack of fire resistance rated separations between occupancies which the 2006 IBC would now permit.

As the table is currently formatted for required separation of occupancies under the separated occupancies option of Section 508.4, there is no occupancy separation required between any of the occupancies in the B, F-1, M, and S-1 Grouping, as indicated by the letter "N" contained in the table for those occupancy groups. However, a Group B occupancy generally has a significantly lower fire load than the Group F-1, M, and S-1 occupancies, and the occupancy hazard is different as well.

If Table 508.4 truly implements the separated occupancies option which mandates occupancy separations as compared to the nonseparated occupancies option in Section 508.3 which does not, it follows that there should be occupancy separations required between occupancies with different hazard characteristics. Group B occupancies generally have combustible fire loads less than 10 pounds per sq ft, as compared to the Group F-1, M, and S-1 occupancies which could have fire loads as much as 20 to 30 pounds per sq ft or more. Therefore, we have proposed a minimum 2-hour occupancy separation between the Group B occupancies and the Group F-1, M, and S-1 occupancies in nonsprinklered buildings and a minimum 1-hour fire-resistance rating in sprinklered buildings. This is consistent with the other occupancy classifications requiring occupancy separations between them and the Group F-1, M, and S-1 occupancies.

It should also be noted that this is consistent with the required occupancy separation for Group B/M mixed occupancies in former Table 302.3.2 of the 2003 IBC which Table 508.4 replaced in the 2006 IBC. And it is actually less restrictive than former Table 302.3.2 for the Group B/F-1 and Group B/S-1 mixed occupancies separations.

The concept of separation of major occupancies exists in Building regulations throughout the world. Certainly, those occupancy separations requirements used in the separated occupancies option have stood the test of time. There continues to be a critical need to separate adjacent major occupancies of dissimilar use, with fire-resistance rated construction. The previous Table 302.3.2 had been is use for the three plus years it existed in the 2000 and 2003 editions of the IBC. Furthermore, the occupancy separation fire resistance ratings from this predecessor table were taken directly from the BOCA National Building Code, along with the entire concept of the non-separated and separated occupancies in mixed occupancy buildings.

As currently published, the 2009 Code provisions in Section 508 blur the distinction between separated uses and the non-separated use options previously prescribed in Section 302.3.1. The full impact of this change has not yet been felt.

The proposal also adds a footnote g which is essentially the footnote that was provided for storage associated both Group B and M occupancies in Table 508.3.3 of the 2006 IBC. Based on the limited separations between the B, M and S occupancies, the footnote was determined unneeded and removed for the 2009 edition. With the reestablishment of separations between Group B and the S occupancies, this previous footnote should be re-established.

Bibliography & References:
[1] 2003 IBC, International Codes Council, Table 302.3.2
[2] 1996 BOCA National Building Code, BOCA
[3] 1997 Standard Building Code, SBCCI
[4] 1997 Uniform Building Code, ICBO

Cost Impact: The code change proposal will increase the cost of construction.

Analysis: Alternative locations for this allowance rather than as a footnote to a table would be as exceptions to Sections 508.3.3 and 508.4.4. Because the code requires buildings containing either Group I or R occupancies to be fully sprinkler protected, the Code Correlation Committee has replaced all numeric values in cells indicating a NS (non sprinklered) Group I or R occupancy building with NP for not permitted.

M													N	N	NP	NP	2	3	1	2[a]
H-1															N	NP	NP	NP	NP	NP
H-2																	N	NP	1	NP
H-3, H-4, H-5																			1[e,f]	NP

For SI: 1 square foot = 0.0929 m^2.

S = Buildings equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1.
NS = Buildings not equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1.
N = No separation requirement.

NP = Not permitted.

a. For Group H-5 occupancies, see Section 903.2.5.2.
b. The required separation from areas used only for private or pleasure vehicles shall be reduced by 1 hour but to not less than 1 hour.
c. See Section 406.1.4.
d. Commercial kitchens need not be separated from the restaurant seating areas that they serve.
e. Separation is not required between occupancies of the same classification.
f. For H-5 occupancies, see Section 415.8.2.2.
g. Occupancy separation need not be provided for storage areas associated with a Group M occupancy if the:
    4. Area is less than 10 percent of the floor areas;
    5. Area is provided with an automatic sprinkler system and is less than 3,000 square feet; or
    6. Area is less than 1,000 square feet.

Reason: In this code change we propose to separate out the Group M occupancies from the grouping of occupancies which includes Groups B, F-1, M, and S-1 as is currently the case in Table 508.4 which is used for implementing the separated occupancies option of Section 508.4. It should be noted that the separated occupancies option requires different occupancies in the same building to be separated from each other based on the fire-resistance ratings specified in Table 508.4, as compared to the nonseparated occupancies option in Section 508.3 which does not require any fire-resistance-rated separation between occupancies. However, no occupancy separations are required between any of the occupancies in the grouping containing Group B, F-1, M, and S-1 occupancies since the letter "N" is entered in the table for those occupancy groups. This means that there is no separation requirement whatsoever.

By removing the Group M occupancies from that grouping and creating a separate entry for them, we have achieved a required separation of occupancies for the Group M occupancy from any of the Group B, F-1, or S-1 occupancies. We believe Group M occupancies should be separated from these other occupancies because of the relative hazard of a Group M occupancy as compared to the other occupancies both in terms of fire load and occupant life safety. Group M occupancies can contain fire loads as much as 20 pounds per sq ft or more depending upon the type of retail operations and, of course, they can contain high densities and numbers of people, especially during holiday seasons and special sales events, as compared to the other occupancies. Group B occupancies generally contain fire loads less than 10 pounds per sq ft so they should be separated in order to protect that occupancy from the higher fire exposure of the Group M occupancies. The Group F-1 and S-1 occupancies should be separated from the Group M occupancies mainly because of the occupant life safety hazard exposures from those occupancies to the occupants of the Group M occupancy. In this code change we are proposing a 2-hour occupancy separation for fire barrier walls and horizontal assemblies in nonsprinklered buildings and 1-hour for sprinklered buildings. This is consistent with the occupancy separations contained in the current table between the Group B, F-1, M, and S-1 occupancies and all other occupancies except Group H-2. We believe that those occupancy combinations represent similar relative hazards in terms of fire and life safety.

The proposal also adds a footnote g which is essentially the footnote that was provided for storage associated both Group B and M occupancies in Table 508.3.3 of the 2006 IBC. Based on the limited separations between the B, M and S occupancies, the footnote was determined unneeded and removed for the 2009 edition. With the reestablishment of separations between Group M and the S occupancies, this previous footnote should be re-established.

Cost Impact: The code change proposal will increase the cost of construction.

Analysis: Alternative locations for this allowance rather than as a footnote to a table would be as exceptions to Sections 508.3.3 and 508.4.4. Because the code requires buildings containing either Group I or R occupancies to be fully sprinkler protected, the Code Correlation Committee has replaced all numeric values in cells indicating a NS (non sprinklered) Group I or R occupancy building with NP for not permitted.

H-3, H-4, H-5	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	1[e,f]	NP

For SI: 1 square foot = 0.0929 m^2.

S = Buildings equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1.
NS = Buildings not equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1.
N = No separation requirement.
NP = Not permitted.

a. For Group H-5 occupancies, see Section 903.2.5.2.
b. The required separation from areas used only for private or pleasure vehicles shall be reduced by 1 hour but to not less than 1 hour.
c. See Section 406.1.4.
d. Commercial kitchens need not be separated from the restaurant seating areas that they serve.
e. Separation is not required between occupancies of the same classification.
f. For H-5 occupancies, see Section 415.8.2.2.

Reason: This proposed code change accomplishes several things. First, it relocates the Group I-3 occupancies to the same cells as the Group I-2 occupancies. Second, it requires that the Group I-1 and Group I-4 occupancies be separated from each other with a minimum 1-hour fire-resistance rating. Third, it also clarifies the table regarding the Group I occupancies for the NS columns where some of the individual cell entries have been changed to "NP." This recognizes the fact that the entire building containing a Group I occupancy is required to be protected with an automatic sprinkler system throughout even where there are other mixed occupancies that may be separated with fire barriers or horizontal assemblies that would otherwise not be required to be sprinklered.

Group I-3 occupancies should be treated the same as the Group I-2 occupancy when the separated occupancies option of Section 508.4 is used since they have similar relative hazards. This is also consistent with the 2009 NFPA 101 Life Safety Code which requires a minimum 2-hour fire-resistance rating for all occupancy separations involving detention and correctional facilities and other occupancies in the same building as specified in Tables 6.1.14.4.1(a) and (b) Required Separation of Occupancies (hours), Part 1 and Part 2. The separated occupancies option section in Section 508.4 of the 2009 IBC, refers to Table 508.4 Required Separation of Occupancies (hours) for determining the fire-resistance rating of the occupancy separation depending upon the occupancies being separated. However, the way the table is currently structured, a Group I-3 occupancy would not be required to be separated from a Group I-1 or I-4 occupancy because they are grouped together.

As indicated previously, this amendment will also require that a Group I-1 occupancy be separated from a Group I-4 occupancy with a minimum 1-hour fire-resistance-rated separation. This would be consistent with the Table 508.4 requirement that these occupancies be separated from Group R occupancies with a minimum 1-hour fire-resistance rating.

Also Footnote e has been added to the 1-hour rating for the I-1/I-4 occupancies to indicate that where the occupancy classification is the same, then there is no separation required. In other words, this would not require, as is currently the case, an occupancy separation for a Group I-1 occupancy and an adjacent Group I-1 occupancy in the same building, or similarly for a Group I-4 occupancy adjacent to another Group I-4 occupancy in the same building. And, a footnote has been added for the Group I-2 and I-3 occupancies for the same reason.

Finally, for the Group I-1 occupancies, this amendment is consistent with Exception 3 to Section 508.2.4 Separation of Occupancies for accessory occupancies, Exception 2 to Section 508.3.3 Separation for nonseparated occupancies, and Section 420.2 Separation Walls for Group I-1 sleeping/dwelling units.

The code change also corrects several cells in the table where the table implies you can have fire separation between an unsprinklered Group 1-1, I-3, I-4 occupancies and other occupancy groups. All Group I and R occupancies are required to be fully sprinklered.

In conclusion, this amendment will clarify where the required occupancy separations are to be provided under the separated occupancies option of the 2009 IBC for all Group I occupancies while making the code internally consistent.

Cost Impact: The code change proposal will increase the cost of construction.

Analysis: Because the code requires buildings containing either Group I or R occupancies to be fully sprinkler protected, the Code Correlation Committee has replaced all numeric values in cells indicating a NS (non sprinklered) Group I or R occupancy building with NP for not permitted.

ICCFILENAME: Thompson-G3-T508.4

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee preferred the changes approved under G118-09/10 and this change would be unnecessary.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jason Thompson, National Concrete Masonry Alliance (NCMA), representing Masonry Alliance for Codes and Standards (MACS), requests Approval as Submitted.

Commenter's Reason: We are submitting this Public Comment requests Approval of our Code Change G129-09/10 as a fallback position should there be Public Comments submitted to Code Change G118-09/10 requesting disapproval of that Code Change which was recommended for approval by the IBC General Code Development Committee. As noted in the Committee Reason statement, the Committee preferred the changes they approved in G118-09/10 so they considered this Code Change unnecessary. We agree with that approach and, in fact, at the ICC Code Development Committee Hearings held in Baltimore last year, we supported the approval of G118-09/10 and indicated that if it were approved, we would withdraw our Code Change G129-09/10.

We still believe that Code Change G118-09/10 is the best solution to the issue of requiring appropriate fire-resistance ratings for the separation of mixed occupancies under the separated occupancies option in Section 508.4 of the IBC. It takes a comprehensive approach to the issue as compared to this code change which focuses on the modification of several cells in Table 508.4 Required Separation of Occupancies. Our goal is to assure that Code Change G118-09/10 is approved at the ICC Final Action Hearings in which case we would withdraw this Public Comment to our Code Change G129-09/10. However, if Code Change G118-09/10 is voted for disapproval at the ICC Final Action Hearings, then we believe this Code Change should be approved as submitted based on our original Reason Statement.

Final Action: AS AM AMPC____ D

G130-09/10
Table 508.4

Proposed Change as Submitted

Proponent: Stephen V. Skalko, P.E., Portland Cement Association

Revise as follows:

H-1															N	NP	NP	NP	NP	NP
H-2																	N	NP	1	NP
H-3, H-4, H-5																			1[e,f]	NP

For SI: 1 square foot = 0.0929 m^2.

S = Buildings equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1.
NS = Buildings not equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1.
N = No separation requirement.
NP = Not permitted.

a. For Group H-5 occupancies, see Section 903.2.5.2.
b. The required separation from areas used only for private or pleasure vehicles shall be reduced by 1 hour but to not less than 1 hour.
c. See Section 406.1.4.
d. Commercial kitchens need not be separated from the restaurant seating areas that they serve.
e. Separation is not required between occupancies of the same classification.
f. For H-5 occupancies, see Section 415.8.2.2.

Reason: In this code change Group F-1 and S-1 occupancies are proposed to be separated out from the grouping of occupancies which includes Groups B, F-1, M, and S-1 as is currently the case in Table 508.4 which is used for implementing the separated occupancies option of Section 508.4. It should be noted that the separated occupancies option requires different occupancies in the same building to be separated from each other based on the fire-resistance ratings specified in Table 508.4 as compared to the nonseparated occupancies option in Section 508.3 which does not require any fire-resistance-rated separation between different occupancies. However, no occupancy separations are required between any of the occupancies in the grouping containing Group B, F-1, M, and S-1 occupancies since the letter "N" is entered in the table for those occupancy groups. This means that there is no separation requirement whatsoever even though the Group F-1 and S-1 occupancies may contain significantly greater fire loads than the Group B and M occupancies.

If Table 508.4 truly implements the separated occupancies option which mandates occupancy separations between mixed occupancies in the same building as compared to the nonseparated occupancies option in Section 508.3 which does not, it follows that there should be occupancy separations required between occupancies with different hazard characteristics. By removing the Group F-1 and S-1 occupancies from the grouping of the Group B, F-1, M, and S-1 occupancies and creating a separate entry for them in the table, a required separation of occupancies for the Group F-1 and S-1 occupancies from any of the Group B and M occupancies is achieved. This is based on the premise that the Group F-1 and S-1 occupancies should be separated from these occupancies because of the relative hazard of the Group F-1 and S-1 occupancy as compared to the Group B and M occupancies both in terms of the fire load and occupant life safety. Group F-1 and S-1 occupancies can contain fire loads as much as 20 to 30 pounds per sq ft or more. This can represent a significant fire exposure to the adjacent Group B and/or M occupancies in the same building which may also have significant numbers of occupants representing a potential life safety hazard.

Therefore, this proposal requires a minimum 3-hour occupancy separation for fire barrier walls and horizontal assemblies in nonsprinklered buildings and 2-hours for sprinklered buildings. This is consistent with the occupancy separations contained in the current table between the Group B, F-1, M, and S-1 occupancies and the Group H-2 occupancies. This occupancy usually has an occupancy combination that represents a similar relative hazard in terms of fire and life safety. This is also consistent with Table 707.3.9 for the separation of fire areas and Table 706.4 Fire Wall Fire-Resistance Ratings. It should also be noted that these proposed occupancy separations are consistent with the required occupancy separations for Group F-1 and S-1 mixed occupancies in former Table 302.3.2 of the 2003 IBC which Table 508.4 replaced in the 2006 IBC.

The code change also corrects several cells in the table where the table implies you can have fire separation between an unsprinklered Group I-1, I-3, I-4 and R occupancies and other occupancy groups. All Group I-1, I-3, I-4 and R occupancies are required to be fully sprinklered.

Cost Impact: The code change proposal will increase the cost of construction.

Analysis: Because the code requires buildings containing either Group I or R occupancies to be fully sprinkler protected, the Code Correlation Committee has replaced all numeric values in cells indicating a NS (non sprinklered) Group I or R occupancy building with NP for not permitted.

ICCFILENAME: Skalko-G1-T508.4

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee preferred the changes approved under G118-09/10 and this change would be unnecessary.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Stephen V. Skalko, PE, Porland Cement Association, requests Approval as Submitted.

Commenter's Reason: G130 was submitted to correct a deficiency in TABLE 508.4 REQUIRED SEPARATION OF OCCUPANCIES. In the existing table F-1 and S-1 occupancies are not required to have a fire rated separation between them and B and M occupancies. But F-2 and S-2 occupancies, which present a lesser fire risk to B and M occupancies, are required to have a fire rated separation from the B and M occupancies. This change will place F-1 and S-1 occupancies into a separate column and require a fire rated separation between these occupancies and all others.

The committee reason for disapproval of G130 was the action on code change G118 of recommending approval as submitted. We agree with the committee action on G118 and support the membership voting to sustain that recommendation. If the committee recommendation on G118 is sustained then G130 is not necessary. However, should the membership decide that the committee recommendation on G118 be overturned and then disapproved, G130 should be approved as submitted to correct the deficiency noted above.

Final Action: AS AM AMPC____ D

G131-09/10
509.2

Proposed Change as Submitted

Proponent: Lou Malattia representing Washington Association of Building Officials

Revise as follows:

509.2 Horizontal building separation allowance. A building shall be considered as separate and distinct buildings for the purpose of determining area limitations, continuity of *fire walls,* limitation of number of stories and type of construction where all of the following conditions are met:

1. The buildings are separated with a horizontal assembly having a minimum 3-hour fire-resistance rating.
2. The building below the horizontal assembly is no more than one story above grade plane.
3. The building below the horizontal assembly is of Type IA construction.
4. Shaft, stairway, ramp and escalator enclosures through the horizontal assembly shall have not less than a 2-hour fire-resistance rating with opening protectives in accordance with Section 715.4.

   Exception: Where the enclosure walls below the horizontal assembly have not less than a 3-hour fire resistance rating with opening protectives in accordance with Section 715.4, the enclosure walls extending above the horizontal assembly shall be permitted to have a 1-hour fire-resistance rating, provided:

   1. The building above the horizontal assembly is not required to be of Type I construction;
   2. The enclosure connects less than four stories <u>above the horizontal assembly</u>; and

3. The enclosure opening protectives above the horizontal assembly have a minimum 1-hour fire protection rating.

5. The building or buildings above the horizontal assembly shall be permitted to have multiple Group A occupancy uses, each with an occupant load of less than 300, or Group B, M, R or S occupancies.
6. The building below the horizontal assembly shall be protected throughout by an approved automatic sprinkler system in accordance with Section 903.3.1.1, and shall be permitted to be any of the following occupancies:
   6.1. Group S-2 parking garage used for the parking and storage of private motor vehicles;
   6.2. Multiple Group A, each with an occupant load of less than 300;
   6.3. Group B;
   6.4. Group M;
   6.5. Group R; and
   6.6. Uses incidental to the operation of the building (including entry lobbies, mechanical rooms, storage areas and similar uses).
7. The maximum building height in feet shall not exceed the limits set forth in Section 503 for the building having the smaller allowable height as measured from the grade plane.

Reason: To provide clarification of this exception. There has been some conflicting code opinions and this exception. Section 509.2, Condition #4, the exception Item 4.2, which reads, "The enclosure connects less than four stories;", has been interpreted by some jurisdictions to mean that the Group S-2 level below the 3-hour separation is considered to be a level for the purposes of this exception, and therefore only permitting two stories above the horizontal separation.

The intent of the code is to permit Group A occupancies less than 300, Groups B or M occupancies to be considered separate buildings for the purpose of determining area limitations, continuity of fire wall, limitation of number of stories and type of construction. A typical building type using this provision is a three story wood framing apartment building above an enclosed concrete parking level.

The exception to condition #4 permits the two hour shaft to be reduced to one hour provided that the enclosure walls below the horizontal assembly is increased to a three hour fire-resistance rating. This additional protection permits three levels above the horizontal assembly to be protected with one hour shafts instead of the two- hour assembly.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: MALATTIA-G3-509.2

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee was uncomfortable that the apparent effect of the change would be to allow a 5 story shaft which would only be rated as a one hour enclosure for four stories.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Maureen Traxler, City of Seattle, representing Washington Association of Building Officials Technical Code Development Committee, requests Approval as Submitted.

Commenter's Reason: This proposal clarifies that the exception applies to shafts that connect 3 or fewer stories above the 3-hour assembly, and the story below the assembly. The current text can be interpreted to limit the total stairway enclosure to 3 stories as shown in Figure 1. However, the intent of the legacy code from which this provision is taken was to allow 3 stories above the three-hour separation as shown in Figure 2. The reduction in the rating of the enclosure above the 3-hour separation is mitigated by the requirement for 3-hour walls and 90-minute opening protectives below the 3-hour assembly. The proposed modification clarifies that the one-hour portion of the stairway can connect no more than 3 stories.

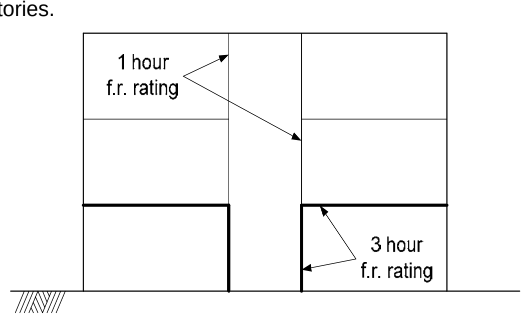

FIG. 1

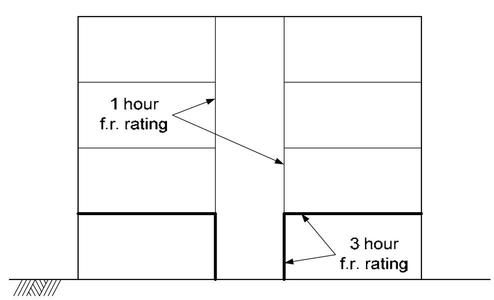

FIG. 2

Final Action: AS AM AMPC____ D

G136-09/10
Table 601

Proposed Change as Submitted

Proponent: Mike Ennis, Single Ply Roofing Industry (SPRI), representing the Single Ply Roofing Industry (SPRI)

Revise as follows:

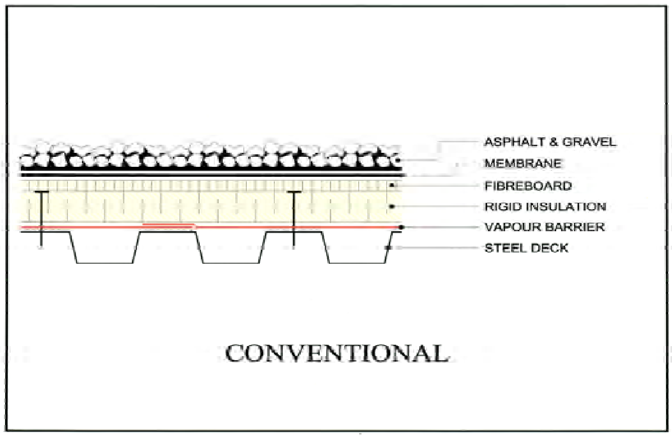
TABLE 601
FIRE-RESISTANCE RATING REQUIREMENTS FOR BUILDING ELEMENTS (hours)

BUILDING ELEMENT	TYPE I		TYPE II		TYPE III		TYPE IV	TYPE V	
	A	B	A[d]	B	A[d]	B	HT	A[d]	B
Primary structural frame[g] (see Section 202)	3[a]	2[a]	1	0	1	0	HT	1	0
Bearing walls									
Exterior[f, g]	3	2	1	0		2	2	1	0
Interior	3[a]	2[a]	1	0	1	0	1/HT	1	0
Nonbearing walls and partitions Exterior	See Table 602								
Nonbearing walls and partitions Interior[e]	0	0	0	0	0	0	See Section 602.4.6	0	0
Floor construction and secondary members (see Section 202)	2	2	1	0	1	0	HT	1	0
Roof construction and secondary members<u>[h]</u> (see Section 202)	1½[b]	1[b, c]	1[b, c]	0 c	1[b, c]	0	HT	1[b, c]	0

For SI: 1 foot = 304.8 mm.

a. Roof supports: Fire-resistance ratings of primary structural frame and bearing walls are permitted to be reduced by 1 hour where supporting a roof only.
b. Except in Groups F-1, H, M and S-1 occupancies, fire protection of structural members shall not be required, including protection of roof framing and decking where every part of the roof construction is 20 feet or more above any floor immediately below. Fire-retardant-treated wood members shall be allowed to be used for such unprotected members.
c. In all occupancies, heavy timber shall be allowed where a 1-hour or less fire-resistance rating is required.
d. An approved automatic sprinkler system in accordance with Section 903.3.1.1 shall be allowed to be substituted for 1-hour fire-resistance-rated construction, provided such system is not otherwise required by other provisions of the code or used for an allowable area increase in accordance with Section 506.3 or an allowable height increase in accordance with Section 504.2. The 1-hour substitution for the fire resistance of exterior walls shall not be permitted.
e. Not less than the fire-resistance rating required by other sections of this code.
f. Not less than the fire-resistance rating based on fire separation distance (see Table 602).
g. Not less than the fire-resistance rating as referenced in Section 704.10
<u>h. The requirements of this table for roof construction are not applicable to above deck components. For construction Types I and II, the materials used in above deck components shall meet the requirements of Section 603.1.</u>

Reason: Table 601 contains footnote b which states, "Except in Group F-1, H, M and S-1 occupancies, fire protection of structural members shall not be required, including protection of roof framing and decking where every part of the roof construction is 20 feet or more above any floor immediately below. Fire-retardant-treated wood members shall be allowed to be used for such unprotected members." This footnote is referenced for all Types (I through V) of roof construction where a rated assembly is required. In many cases this footnote is being interpreted as meaning that fire-retardant-treated wood is required whenever wood is used in a roof assembly that requires an hourly rating.
A typical roofing assembly contains the components shown below:



The roof deck is typically steel, concrete or wood. On top of the roof deck is a layer of insulation, in many cases a coverboard and them a waterproofing system. The waterproofing system may be a asphalt/gravel system as shown above, a single ply roof membrane, or for steeper slope applications shingles or tile. The current footnote b references structural members, components installed above the roof deck are not structural, they are supported by the structure.

Insulation suppliers to the roofing industry manufacture a nailable insulation product (see included Atlas Nailbase Datasheet). This product consists of foam plastic insulation with a layer of wood (OSB, Plywood, or fire-retardant-treated wood) laminated to it, thus combining two of the components shown above (insulation and fiberboard) into one product This product is installed on top of the roof deck and is used as the nailable substrate for various roofing materials such as shingles, shakes and tile.

In many instances designers feel that footnote b of Table 601 requires that fire-retardant-treated wood be used as the nailable component of this product when a rated assembly is required. While this product can be made with fire-retardant-treated wood as the nailable component this unnecessarily increases the cost of construction.

The proposed footnote h would provide clarifying language while maintaining important fire safety requirements. For example, this footnote is no way removes the hourly rating requirements of the roof assembly. Hourly ratings can be achieved with OSB as the nailable substrate on this product. It also retains the requirement that the product meet the requirements of Section 603 COMBUSTIBLE MATERIALS IN TYPE I AND II CONSTRUCTION.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: ENNIS-G1-Table 601

Public Hearing Results

Committee Action: Disapproved

Committee Reason: At the proponent's request, the committee disapproved the code change acknowledging that it needed further study and refinement. Of particular concern that it would allow a lessening of structural stability of roof assemblies.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Mike Ennis, representing Single Ply Roofing Industry (SPRI), requests Approval as Modified by this Public Comment.

Modify proposal as follows:

h. ~~The requirements of this table for roof construction are not applicable to above deck components~~. <u>Fire-retardant treated wood is not required for non-structural components installed above the roof deck.</u> For construction Types I and II, the materials used in above <u>roof</u> deck components shall meet the requirements of Section 603.1.

(Portions of proposal not shown remain unchanged)

Commenter's Reason: The proposed modification is provided to clarify the intent of the proposed Note h and to remove a potential conflict with Note a. As currently worded Note h could be used to ignore the fact that Note a should not be applied when any load is imposed on a roof by above deck installations.

The intent of Note h is to provide clarification to wording contained in Note b of Table 601. In part the intent of Note b is that fire-retardant treated wood is allowed for use in unprotected wood framing and decking if the roof construction is at least 20' above the floor. Some designers are interpreting Note b to mean that only fire-retardant treat wood can be used in roof assemblies. This has resulted in increased material costs and lead times for a product commonly used in steep slope (>2:12) roofing applications. This product is composed of foam plastic insulation with OSB laminated to it. It is installed on top of the roof deck and is non-structural. This product provides both insulation and a nailable substrate for the attachment of roof shingles/tiles, etc. Requiring the use of fire-retardant treated wood instead of OSB increases the cost and lead-time for this product.

The proposed modification states in much clearer words the intent of Note h

Public Comment 2:

Rich Roe, representing Atlas Roofing Corporation, requests Approval as Modified by this Public Comment.

Modify proposal as follows:

b. Except in Group F-1, H, M and S-1 occupancies, fire protection of structural members shall not be required, including protection of roof framing and deck where every part of the roof construction is 20 feet or more above any floor immediately below. Fire-retardant-treated wood members shall be allowed for such unprotected members. Fire-retardant treated wood is not required for non-structural components installed above the roof deck. For construction Types I and II, the materials used in above roof deck components shall meet the requirements of Section 603.1.

~~h. The requirements of this table for roof construction are not applicable to above deck components. For construction Types I and II, the materials used in above roof deck components shall meet the requirements of Section 603.1.~~

(Portions of proposal not shown remain unchanged)

Commenter's Reason: The proposed modification is provided to clarify the intent of the proposed Note b. The original proposal included the addition of Note h to provide this clarification. However as written Note h could be used to ignore the fact that Note a should not be applied when any load is imposed on a roof by above deck installations.

In part the intent of Note b is that fire-retardant treated wood is allowed for use in unprotected wood framing and decking if the roof construction is at least 20' above the floor. Some designers are interpreting Note b to mean that only fire-retardant treat wood can be used in roof assemblies. This has resulted in increased material costs and lead times for a product commonly used in steep slope (>2:12) roofing applications. This product is composed of foam plastic insulation with OSB laminated to it. It is installed on top of the roof deck and is non-structural. This product provides both insulation and a nailable substrate for the attachment of roof shingles/tiles, etc. Requiring the use of fire-retardant treated wood instead of OSB increases the cost and lead-time for this product.

The proposed modification provides wording directly in Note b to provide additional clarification instead of adding Note h.

Final Action: AS AM AMPC____ D

G138-09/10
Table 602

Proposed Change as Submitted

Proponent: Joe Holland or Dave Bueche, representing Hoover Treated Wood Products

Revise as follows:

TABLE 602
FIRE-RESISTANCE RATING REQUIREMENTS FOR ECTERIOR WALLS BASED ON FIRE SEPARATION DISTANCE[a, e]

FIRE SEPARATION DISTANCE = X (feet)	TYPE OF CONSTRUCTION	OCCUPANCY GROUP H[f]	OCCUPANCY GROUP F-1, M S-1[g]	OCCUPANCY GROUP A, B, E, F-2, I, R, S-2[g], U[b]
X < 5[c]	All	3	2	1
5 ≤ X <10	IA Others	3 2	2 1	1 1
10 ≤ X 30	IA, IB IIB, IIIB, VB Others	2 1 1	1 0 1	1[c] 0 1[c]
X ≤ 30	All	0	0	0

For SI: 1 foot = 304.8 mm.

a. Load-bearing exterior walls shall also comply with the fire-resistance rating requirements of Table 601.
b. For special requirements for Group U occupancies, see Section 406.1.2.
c. See Section 706.1.1 for party walls.
d. Open parking garages complying with Section 406 shall not be required to have a fire-resistance rating.
e. The fire-resistance rating of an exterior wall is determined based upon the fire separation distance of the exterior wall and the story in which the wall is located.
f. For special requirements for Group H occupancies, see Section 415.3.
g. For special requirements for Group S aircraft hangars, see Section 412.4.1.

Reason: The exterior wall fire resistance required in Table 601 is greater for Type IIIB than what is required for either Type IIB or VB. The interior fire resistance in Type IIIB construction is equivalent to Type IIB and Type VB and therefore should be allowed in the same category.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: HOLLAND-BUECHE-G6-T602.doc

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: No technical substantiation was provided to justify reducing the protection of Type IIIB construction.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Joseph Holland and Dave Bueche, representing Hoover Treated Wood Products, Inc., requests Approval as Submitted.

Commenter's Reason: The exterior bearing wall fire resistance required in Table 601 is greater for Type IIIB than what is required for either Type IIB or VB. The interior fire resistance in Type IIB construction is equivalent to Type IIB and Type VB and therefore should be allowed in the same category.

Final Action: AS AM AMPC____ D

G140-09/10
602.3, 602.4

Proposed Change as Submitted

Proponent: Jason Thompson, National Concrete Masonry Association (NCMA), representing Masonry Alliance for Codes and Standards (MACS)

Revise as follows:

602.3 Type III. Type III construction is that type of construction in which the exterior walls are of noncombustible materials and the interior building elements are of any material permitted by this code. Fire-retardant-treated wood framing complying with Section 2303.2 shall be permitted within exterior wall assemblies ~~of~~ having not greater than a 2-hour fire-resistance rating ~~or less~~ where the exposed outer and inner faces of such walls are of noncombustible materials.

602.4 Type IV. Type IV construction (Heavy Timber, HT) is that type of construction in which the exterior walls are of noncombustible materials and the interior building elements are of solid or laminated wood without concealed spaces. The details of Type IV construction shall comply with the provisions of this section. Fire-retardant-treated wood framing complying with Section 2303.2 shall be permitted within exterior wall assemblies ~~with~~ having not greater than a 2-hour fire-resistance rating ~~or less~~ where the exposed outer and inner faces of such walls are of noncombustible materials.

Reason: This code change adds to the provision for exterior walls using fire-retardant-treated wood framing in buildings of Types III and IV construction by requiring that the framing be covered on the outer and inner faces with noncombustible materials. This additional provision when fire-retardant-treated wood is used in exterior walls otherwise required to be constructed of noncombustible materials is taken from the 1997 ICBO Uniform Building Code (UBC) Section 503.4.3 Fire-Retardant-Treated Wood Framing. That section was the source for the justification in the IBC to allow fire-retardant-treated wood in these exterior wall assemblies where the fire-resistance rating did not exceed 2-hours.

A significant number of Type III construction buildings have taken advantage of this provision to allow the exterior wall to be framed of wood rather than constructed entirely of noncombustible materials, while also taking advantage of Section 1406.2.2. Section 1406.2.2 allows combustible exterior wall coverings to be installed on the exterior faces of these walls. That application does not meet the code intent for limiting the combustible materials in the exterior walls of Type III construction which is a basic fire safety component of that type of construction. Since the legacy code provision was used to justify the use of fire-retardant-treated wood, then the other requirements applicable thereto in that legacy code should also be incorporated into the IBC to achieve the intended level of fire safety.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: Thompson-G5-602.3

Public Hearing Results

Committee Action: Disapproved

Committee Reason: The proposal defeats the allowance for fire-retardant-treated wood in these assemblies especially the application of FRTW sheathing. Language addressing inner and outer faces was unclear to the committee as how it should be interpreted.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jason Thompson, National Concrete Masonry Alliance (NCMA), representing Masonry Alliance for Codes and Standards (MACS), requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

602.3 Type III. Type III construction is that type of construction in which the exterior walls are of noncombustible materials and the interior building elements are of any material permitted by this code. Fire-retardant-treated wood framing complying with Section 2303.2 shall be permitted within exterior wall assemblies having not greater than a 2-hour fire-resistance rating where the exposed outer face of the exterior wall covering ~~and inner faces~~ of such walls is constructed ~~are~~ of noncombustible materials and a noncombustible membrane is applied over the interior face of the fire-retardant-treated wood framing to separate the framing from the interior of the building.

602.4 Type IV. Type IV construction (Heavy Timber, HT) is that type of construction in which the exterior walls are of noncombustible materials and the interior building elements are of solid laminated wood without concealed spaces. The details of Type IV construction shall comply with the provisions of this section. Fire-retardant-treated wood framing complying with Section 2303.2 shall be permitted within exterior wall assemblies having not greater than a 2-hour fire-resistance rating where the exposed outer face of the exterior wall covering ~~and inner faces~~ of such walls is constructed ~~are~~ of noncombustible materials and a noncombustible membrane is applied over the interior face of the fire-retardant-treated wood framing to separate the framing from the interior of the building.

Commenter's Reason: We are submitting this Public Comment to request approval as modified of our Code Change Proposal G140-09/10 with appropriate revisions that respond to the IBC General Code Development Committee's Reason Statement for disapproval. The Committee felt that the language addressing inner- and outer-faces was unclear as to how it would be interpreted. Although this language was taken directly from the legacy building code from which the original provisions were taken and incorporated into the IBC, we have revised it to make it clear as to what is meant. The intent of this Code Change is to require some type of a noncombustible exterior covering on the outside of the exterior walls of Type III and IV buildings that are otherwise required to noncombustible, but are allowed to contain fire-retardant-treated wood framing within the wall construction. A noncombustible covering would also be required to be applied to the inner face of the fire-retardant-treated wood framing so that it is separated from the interior of the building. Thus, both the inner-face and the outer-face of the exterior wall construction covering the fire-retardant-treated wood framing would be required to be noncombustible by this Code Change Proposal as revised by this Public Comment.

As stated in our original Reason Statement for this Code Change, that is what the legacy building code, the 1997 ICBO Uniform Building Code (UBC), required in order to allow fire-retardant-treated wood framing within these exterior walls that are otherwise required to be constructed entirely of noncombustible materials.

Contrary to the Committee's Reason Statement that this code change defeats the allowance for fire-retardant-treated wood, especially in the application of FRTW sheathing, the code allowance for the use of fire-retardant-treated wood in the exterior walls of Types III and IV construction buildings only applies to the framing and not to the sheathing. In our opinion, fire-retardant-treated wood sheathing could still be applied over the noncombustible exterior wall covering applied over the fire-retardant-treated wood framing based on allowances in Section 1405.5 Wood Veneers and Section 1406.2.2 Type I, II, III and IV construction for combustible materials on the exterior side of exterior walls.

Section 1405.5 allows fire-retardant-treated wood veneer to be used on buildings of Type III and IV construction provided it is attached to, or furred from, a noncombustible backing that is fire-resistance rated as required by other provisions of this code based on Item 2 of that section. So this section would require a noncombustible backing which would be similar to the noncombustible exterior wall covering we are proposing in our Code Change Proposal allowing fire-retardant-treated wood framing in these exterior walls.

Section 1406.2.2 will allow combustible exterior wall coverings of fire-retardant-treated wood on buildings of Types III and IV construction as well, permitted to a height of 60 feet, just as that allowed by Section 1405.5. In our opinion, this assumes that the fire-retardant-treated wood will be applied over a noncombustible substrate represented by the noncombustible wall construction typically required by these types of construction.

In conclusion, we believe that the allowable use of fire-retardant-treated wood framing in exterior walls of Types III and IV construction, which are otherwise required to be constructed entirely of noncombustible materials, should be continued to be allowed within the scope of the original allowance from which this was derived, i.e. the 1997 ICBO UBC as indicated in our Reason Statement for our original Code Change Proposal. Therefore, we respectfully request that the Class A voting members overturn the Committee recommendation for disapproval of our Code Change and approve this Public Comment which will result in Code Change G140-09/10 being approved as modified.

Final Action: AS AM AMPC____ D

G143-09/10
603.1

Proposed Change as Submitted

Proponent: Joe Holland and Dave Bueche, representing Hoover Treated Wood Products

Revise as follows:

603.1 Allowable materials. Combustible materials shall be permitted in buildings of Type I or II construction in the following applications and in accordance with Sections 603.1.1 through 603.1.3:

1. Fire-retardant-treated wood shall be permitted in:
   - 1.1. Nonbearing partitions where the required fire-resistance rating is 2 hours or less.
   - 1.2. Nonbearing exterior walls where no fire rating is required.
   - 1.3. Roof construction, including girders, trusses, framing and decking.
   - <u>1.4. Blocking such as for handrails, millwork, cabinets and window and door frames.</u>

   Exception: In buildings of Type IA construction exceeding two stories above grade plane, fire-retardant-treated wood is not permitted in roof construction when the vertical distance from the upper floor to the roof is less than 20 feet (6096 mm).

2. through 13. *(No change to current text)*
~~14. Blocking such as for handrails, millwork, cabinets and window and door frames.~~
15. through 25. *(No change to current text)*

Reason: The primary members of partitions in Type I and Type II construction must be noncombustible or fire-retardant-treated wood. To allow untreated wood in the partitions for blocking is inconsistent with Type I and Type II construction. In some cases it can be flush mounted exposed with the wallboard behind cabinets or millwork. It certainly is not prudent. Two of the three legacy codes did not allow.

Cost Impact: The code change proposal will increase the cost of construction.

Staff Note: In the first 2 editions of the 2009 IBC, Item 1 of Section 603.1 was shown as Item 25.

ICCFILENAME: HOLLAND-BUECHE-G4-603.1

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The proponent did not provide technical justification to restrict use of standard wood for simply blocking purposes. It was questioned whether there were fire retardant products available for all typical blocking situations. There was no information presented of a loss history because blocking materials were wood other than FRTW.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Joseph Holland and Dave Bueche representing Hoover Treated Wood Products Inc, requests Approval as Submitted.

Commenter's Reason: The committee disapproved the proposal because no technical justification was submitted or fire data. This is Type I and Type II construction. The use of untreated wood is typically limited to areas where is can be seen. There appears to be a conflict. Section 1 addresses the use of a combustible material, fire-retardant-treated wood, in partitions, exterior walls, and roofs. Section 14 allows untreated wood. This a conflict. To be consistent, all the wood should be treated. Most species of untreated wood used for backing and blocking has a Class C rating. FRTW is Class A. That can be a difference in the flame spread as great as 190 compared to less than 25. The FRTW products in the marketplace are actually in the 10 to 15 range. In addition, smoke generated by FRTW is substantially less that untreated wood. Depending on the species the smoke developed rating for untreated wood is in the 250 to 350 range. FRTW is 50 or less.

Final Action: AS AM AMPC____ D

G145-09/10, PART II
IRC R806.2

NOTE: PART I DID NOT RECEIVE A PUBLIC COMMENT AND IS ON THE CONSENT AGENDA. PART I IS REPRODUCED FOR INFORMATIONAL PURPOSES ONLY FOLLOWING ALL OF PART II.

Proposed Change as Submitted

Proponent: Lee Kranz representing Washington Association of Building Officials (WABO), Technical Code Development Committee

PART II – IRC BUILDING/ENERGY

Revise as follows:

R806.2 Minimum area. The total net free ventilating area shall not be less than 1/150 of the area of the space ventilated. ~~except that reduction of the total area~~

Exceptions:

1. The net free-cross ventilation area shall be permitted to be reduced to 1/300 ~~is permitted~~ provided that at least 50 percent and not more than 80 percent of the required ventilating area is provided by ventilators located in the upper portion of the space to be ventilated at least 3 feet (914 mm) above the eave or cornice vents with the balance of the required ventilation provided by eave or cornice vents.
2. ~~As an alternative,~~ The net free cross-ventilation area ~~may~~ shall be permitted to be reduced to 1/300 when a Class I or II vapor barrier is installed on the warm-in-winter side of the ceiling.

Reason: IBC 1203.2. Current attic ventilation provisions do not address ventilation of low slopped or flat roof attics. It is appropriate to require more ventilation area (i.e. 1/150th) when 3' of vertical separation between the upper and lower vent areas is not possible. A reduction of required vent area (i.e. 1/300th) is appropriate when vertical separation of the vents is provided as natural convection provides additional air movement within the attic space. It is also appropriate to reduce the vent area when a vapor barrier is installed on the ceiling to reduce moisture transmission from the occupied space into the attic. This change also creates consistency with Section 806.2 of the 2009 IRC.

IRC R806.2. The current language found in IRC Section 806.2 includes two exceptions within the charging text. The proposal reformats the section to be consistent with the typical grammatical format found elsewhere in the codes. The change creates consistency with Section 1203.2 of the IBC.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: KRANZ-G2-1203.2

Public Hearing Results

PART II – IRC- B/E

Committee Action: **Disapproved**

Committee Reason: The committee feels that the language of proposal RB158-09/10 more adequately addresses this issue.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Lee J. Kranz, City of Bellevue, representing Washington Association of Building Officials Technical Development Committee, requests Approval as Submitted.

Commenter's Reason: G-145 Part I was submitted to correct a problem related to ambiguity on how to ventilate low slope roof attics with less than 3' of vertical separation between the upper and lower vents. In the 2009 IBC, the requirement in Section 1203.2 to provide not less than 3' of vertical separation between the upper and lower vents is impossible to achieve in low slope roof attics. The IBC-General committee agreed and voted for approval of G-145 Part I as submitted.

G-145 Part II was submitted to correlate IRC Section R806.2 with IBC Section 1203.2; there are no substantive changes proposed for R806.2, only format. The IRC-B/E committee disapproved Part II because they thought RB-158 more adequately addressed the issue but subsequently disapproved RB-158 as well. As such we are recommending approval as submitted for G-145 Part II for correlation between the 2012 editions of the IBC and IRC.

Final Action: AS AM AMPC____ D

NOTE: PART I REPRODUCED FOR INFORAMATION PURPOSES ONLY – SEE ABOVE

G145-09/10, PART I
1203.2

Proposed Change as Submitted

Proponent: Lee Kranz representing Washington Association of Building Officials (WABO), Technical Code Development Committee

PART I – IBC GENERAL

Revise as follows:

1203.2 Attic Spaces. Enclosed attics and enclosed rafter spaces formed where ceilings are applied directly to the underside of roof framing members shall have cross ventilation for each separate space by ventilating openings protected against the entrance of rain and snow. Blocking and bridging shall be arranged so as not to interfere with the movement of air. A minimum of 1 inch of airspace shall be provided between the insulation and the roof sheathing.
The net free ventilating area shall not be less than ~~1/300th~~ 1/150th of the area of the space ventilated.

Exceptions:

1. The net free cross-ventilation area shall be permitted to be reduced to 1/300 provided that ~~with~~ at least 50 percent and not more than 80 percent of the required ventilating area is provided by ventilators located in the upper portion of the space to be ventilated at least 3 feet (914 mm) above the eave or cornice vents with the balance of the required ventilation provided by eave or cornice vents.
2. The net free cross-ventilation area shall be permitted to be reduced to 1/300 when Class I or II vapor barrier is installed on the warm-in-winter side of the ceiling.

Public Hearing Results

PART I- IBC GENERAL

Committee Action: **Approved as Submitted**

Committee Reason: The change resolves issues imposed by the current text. It puts the incentive in correct format to direct the code user to provide better ventilation. It also allows flat roof situations to be addressed where a 3 foot vertical distance between upper and lower vents cannot be achieved. It also eliminates the ability to interpret the section to allow all ventilation openings on the ridge of a roof.

Assembly Action: **None**

G146-09/10 – Part I
1203.2

Proposed Change as Submitted

Proponent: Ali M. Fattah, City of San Diego, representing San Diego Area Chapter ICC Code Committee

Revise as follows:

1203.2 Attic spaces. Where determined necessary by the building official due to atmospheric or climatic conditions, ~~Enclosed~~ enclosed attics and enclosed rafter spaces formed where ceilings are applied directly to the underside of roof framing members shall have cross ventilation for each separate space by ventilating openings protected against the entrance of rain and snow. Blocking and bridging shall be arranged so as not to interfere with the movement of air. A minimum of 1 inch (25 mm) of airspace shall be provided between the insulation and the roof sheathing. The net free ventilating area shall not be less than 1/300 of the area of the space ventilated, with 50 percent of the required ventilating area provided by ventilators located in the upper portion of the space to be ventilated at least 3 feet (914 mm) above eave or cornice vents with the balance of the required ventilation provided by eave or cornice vents.

Reason: The proposed code change deletes a current requirement. There are many conditions that can preclude providing attic ventilation where climactic conditions do not warrant attic ventilation, for example the installation of solar photovoltaics. Additionally, it is very impractical or not possible to ventilate occupied roof decks, low slope (flat) roofs or vaulted ceilings using rafters with drywall attached to directly to the underside of the solid combination rafter-ceiling joist. In many cases it is not possible to provide the 3 ft elevation difference between the high and low vents on low slope roofs and where low slope roofs include parapets and therefore no eave vents. The proposed change will not preclude applicants from providing attic ventilation to satisfy manufacturer's installation instructions for roof covering and therefore preserving the roof warranty. The language existed in the Uniform Building Code (Section 1505.3). That legacy building code was enforced in climates ranging from cold winter regions to hot desert regions in the southwest and had been in effect for more than 20 years. We are not aware of any moisture damage issues in attic spaces within jurisdictions that did not require attic ventilation, for example the City of San Diego and many surrounding jurisdictions.

This section can conflict with required one hour protection for projections such at eaves, as well as eave protection required by the International Wildland Urban interface Code.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: FATTAH-G2.doc

Public Hearing Results

IBC GENERAL

Committee Action: **Disapproved**

Committee Reason: The change would introduce highly discretionary language into the code without providing the building official ample guidance for its use. A more detailed exception addressing the variety of climatic conditions that might warrant the waiver of attic ventilation would be appropriate. The discussion regarding installation of photovoltaic equipment on roof tops seemed irrelevant to the proposal to allow a waiver of attic ventilation.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Ali M. Fattah, PE, City of San Diego, Development Services Department, representing San Diego Area Chapter of ICC, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

1203.2 Attic spaces. ~~Where determined necessary by the building official due to atmospheric or climatic conditions,~~ ~~enclosed~~ Enclosed attics and enclosed rafter spaces formed where ceilings are applied directly to the underside of roof framing members shall have cross ventilation for each separate space by ventilating openings protected against the entrance of rain and snow. Blocking and bridging shall be arranged so as not to interfere with the movement of air. A minimum of 1 inch (25 mm) of airspace shall be provided between the insulation and the roof sheathing. The net free ventilating area shall not be less than 1/300 of the area of the space ventilated, with 50 percent of the required ventilating area provided by ventilators located in the upper portion of the space to be ventilated at least 3 feet (914 mm) above eave or cornice vents with the balance of the required ventilation provided by eave or cornice vents.

Exception: Attic ventilation shall not be required when determined not necessary by the code official due to atmospheric or climatic conditions.

Commenter's Reason: This public comment is submitted in response to feedback from the committee and public testimony in Baltimore. Reference to solar photovoltaic's was only used as an example to demonstrate cases where our jurisdiction has had to modify the code to allow the installation of solar PV since and alternative to required ventilation could not be provided. Code officials applying the section under a legacy code that enforced in major portions of the country did not need specific guidance to determine whether attic ventilation is required due to local conditions. By revising the proposed code change from that initially proposed to an exception a building official does not have to grant the exception if data or justification is not available. We stand on the remainder of our initial statement of reasons and urge the voting membership to support this public comment.

Final Action: AS AM AMPC____ D

G146-09/10 – Part II
IRC R806.1

Proposed Change as Submitted

Proponent: Ali M. Fattah, City of San Diego, representing San Diego Area Chapter ICC Code Committee

Revise as follows:

R806.1 Ventilation required. Where determined necessary by the building official due to atmospheric or climatic conditions, ~~Enclosed~~ enclosed attics and enclosed rafter spaces formed where ceilings are applied directly to the underside of roof rafters shall have cross ventilation for each separate space by ventilating openings protected against the entrance of rain or snow. Ventilation openings shall have a least dimension of $^1/_{16}$ inch (1.6 mm) minimum and ¼ inch (6.4 mm) maximum. Ventilation openings having a least dimension larger than ¼ inch (6.4 mm) shall be provided with corrosion-resistant wire cloth screening, hardware cloth, or similar material with openings having a least dimension of $^1/_{16}$ inch (1.6 mm) minimum and ¼ inch (6.4 mm) maximum. Openings in roof framing members shall conform to the requirements of Section R802.7.

Reason: The proposed code change deletes a current requirement. There are many conditions that can preclude providing attic ventilation where climactic conditions do not warrant attic ventilation, for example the installation of solar photovoltaics. Additionally, it is very impractical or not possible to ventilate occupied roof decks, low slope (flat) roofs or vaulted ceilings using rafters with drywall attached to directly to the underside of the solid combination rafter-ceiling joist. In many cases it is not possible to provide the 3 ft elevation difference between the high and low vents on low slope roofs and where low slope roofs include parapets and therefore no eave vents. The proposed change will not preclude applicants from providing attic ventilation to satisfy manufacturer's installation instructions for roof covering and therefore preserving the roof warranty. The language existed in the Uniform Building Code (Section 1505.3). That legacy building code was enforced in climates ranging from cold winter regions to hot desert regions in the southwest and had been in effect for more than 20 years. We are not aware of any moisture damage issues in attic spaces within jurisdictions that did not require attic ventilation, for example the City of San Diego and many surrounding jurisdictions.

This section can conflict with required one hour protection for projections such at eaves, as well as eave protection required by the International Wildland Urban interface Code.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: FATTAH-G2.doc

Public Hearing Results

IRC Building and Energy

Committee Action: **Disapproved**

Committee Reason: This proposal would add language that would require the Building Official to decide the code requirements. This is a local issue and should be handled through local amendment to the code.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Ali M. Fattah, PE, City of San Diego, Development Services Department, representing San Diego Area Chapter of ICC, requests Approval as Modified by this Public Comment.

R806.1 Ventilation required. ~~Where determined necessary by the building official due to atmospheric or climatic conditions, enclosed~~ Enclosed attics and enclosed rafter spaces formed where ceilings are applied directly to the underside of roof rafters shall have cross ventilation for each separate space by ventilating openings protected against the entrance of rain or snow. Ventilation openings shall have a least dimension of 1/16 inch (1.6 mm) minimum and ¼ inch (6.4 mm) maximum. Ventilation openings having a least dimension larger than ¼ inch (6.4 mm) shall be provided with corrosion-resistant wire cloth screening, hardware cloth, or similar material with openings having a least dimension of 1/16 inch (1.6 mm) minimum and ¼ inch (6.4 mm) maximum. Openings in roof framing members shall conform to the requirements of Section R802.7.

Exception: Attic ventilation shall not be required when determined not necessary by the code official due to atmospheric or climatic conditions.

Commenter's Reason: See commenter's reason for Part I.

Final Action: AS AM AMPC____ D

G150-09/10
1210.1.1 (New)

Proposed Change as Submitted

Proponent: Timothy Kyle Hantz, PE, General Services Administration, representing self

Add new text as follows:

1210.1.1 Diaper changing station. In assembly occupancies where a toilet room has two or more water closets, a diaper changing station shall be provided in the toilet room. Diaper changing stations shall comply with the work surface requirements of ICC A117.1.

Reason: IBC 101. 3 states that the intent of the code is to provide minimum standards for public health, safety and general welfare. I have noticed diaper changing stations in restaurants, trains, airports, convention centers, etc. It is hard to believe that in 2009, we still have to change our children's diapers on a toilet room floor. This is very unsanitary for the baby and the changer. This proposal would also help people who have trouble bending over, or getting on their hands and knees to change diapers.

Cost Impact: The code change proposal will increase the cost of construction.

Analysis: The Code Correlation Committee approved an editorial combining of Sections 1210 and 2903 of the 2009 IBC into a single section 1210 on Toilet and Bathroom requirements. This proposal, if approved would be located as Section 1210.1.1 of the new combined section.

ICCFILENAME: Hantz-G1-1211.1.doc

Public Hearing Results

Committee Action: Disapproved

Committee Reason: The concept of the proposal was welcomed by some of the committee but they were concerned that the threshold numbers would not result in equal access to such stations for both fathers and mothers. The application to just assembly occupancies was too limited. Application to mercantile facilities, especially covered/open malls seemed essential. Other committee members were not convinced that as important as it is to provide these diaper changing stations, that it is an appropriate item for either building or plumbing codes.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Timothy Kyle Hantz, PE, General Services Administration, representing self, requests Approval as Modified by this Public Comment.

Replace proposal as follows:

1210.6. Diaper Changing Stations. A diaper changing station shall be provided in each restroom that contains two or more water closets, or that contains a combination of two or more water closets and urinals, and that serve the following occupancies:

Assembly occupancies; except taverns and bars
Mercantile occupancies.

Exception: Diaper changing stations are not required in restrooms limited to employee use only.

Commenter's Reason: Based on the Committee's reason for disapproval, I have expanded my proposal to include Mercantile occupancies, and also included language for "potty parity" (both restrooms having a diaper changer if only one is required by water closet count.). I also changed the code section from 1210.1.1 to 1210.6. (as a stand alone code reference).

Final Action: AS AM AMPC____ D

G153-09/10, PART I
3001.2.1

Proposed Change as Submitted

Proponent: Philip M. Chandler representing New York State, Department of State, Office of Fire Prevention & Control.

PART I – IBC

Add new text as follows:

3001.2 Referenced standards. Except as otherwise provided for in this code, the design, construction, installation, *alteration*, repair and maintenance of elevators and conveying systems and their components shall conform to ASME A17.1/CSA B44, ASME A90.1, ASME B20.1, ALI ALCTV, and ASCE 24 for construction in flood hazard areas established in Section 1612.3.

<u>**3001.2.1 Certificate of inspection.** The most current certificate of inspection shall be on display at all times within the elevator or attached to the escalator or dumbwaiter, be available for public inspection in the office of the building *operator* or be posted in a publicly conspicuous location *approved* by the *building official*. The inspection and witnessing of tests required by ASME A17.1 shall be performed by an impartial, third-party inspector that meets the minimum qualifications as set forth in the referenced standard. The inspection and tests shall be performed at not less than the periodic intervals listed in ASME A17.1, Appendix N, except where otherwise specified by the authority having jurisdiction.</u>

Reason: These three companion proposals will provide consistent provisions in the IBC, IFC and IPMC regarding elevator inspection and posting the appropriate certificate.

IBC Section 3001.2: As 3001.2 pertains to maintenance as well as to design, construction and installation, it is appropriate to use the same language found in IPMC here. Additionally, it is helpful to reiterate the qualifications needed by elevator inspectors and the importance of their impartiality.

Cost Impact: The code change proposal will not increase the cost of construction

ICCFILENAME: CHANDLER-G1-3001.2.1.doc

<u>Public Hearing Results</u>

PART I- IBC GENERAL

Committee Action: **Disapproved**

Committee Reason: The committee disapproved the proposal because they felt that the requirement is adequately covered by the standard and the requirement doesn't need to be repeated in the code. In addition, the proposed language is poorly crafted, and would seem to prohibit inspection by qualified inspectors employed by the jurisdiction. The proponent did not clarify why this language was necessary in the code.

Assembly Action: **None**

<u>Individual Consideration Agenda</u>

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Part I – IBC General

Philip M. Chandler, representing New York State Department of State, Office of Fire Prevention & Control, requests Approval as Submitted.

Commenter's Reason: It is urged that proposed changes to IBC 3001.2.1, IFC 607.4 and IPMC 606.1, having been heard together as G153-09/10, be adopted for the following reasons:

First and foremost, it makes good sense to provide consistent language on elevator inspection in the above referenced codes. It is proposed that the language of the IPMC be ostensibly used as the model with some modification. Inasmuch as elevators have a significant impact on a building's overall fire safety, this language is needed in the IFC as well as the IBC and IPMC. There are those conducting life safety inspections of existing buildings, often fire code officials or firefighters, that might conclude that the IBC applies only to new construction and not to elevator maintenance. Similarly, there are those jurisdictions that may not choose to adopt the IPMC altogether. Accordingly, by inserting this same important inspection requirement into the IFC, we ensure the greatest likelihood that elevators will get the inspection and testing they need.

It is also argued that the inspection and testing of elevators be done by impartial, third parties. While inspecting one's own work may violate the canon of ethics subscribed to by those having QEI certification, the actual language of the referenced standards does not unambiguously spell it out. Impartiality is too important a requirement for assuring the safety of the public as well as firefighters and emergency responders to leave to inference alone.

The Committee worried that the language "impartial, third party," might serve to disenfranchise municipal elevator inspectors. This concern is unfounded. Government inspectors are by definition impartial third parties. What this proposal comes to exclude is the inspection and testing of elevators by agents of the building's owner (1^{st} party), or of the installing or maintaining contractor (2^{nd} party). QEI elevator inspection firms, or QEI certified governmental inspectors are exactly the parties that we want inspecting our elevators!

Final Action: AS AM AMPC____ D

G153-09/10, PART II
IFC 607.4

Proposed Change as Submitted

PART II – IFC

Add new text as follows:

607.4 Maintenance. Elevators, dumbwaiters and escalators shall be maintained in compliance with ASME A17.1. The most current certificate of inspection shall be on display at all times within the elevator or attached to the escalator or dumbwaiter, be available for public inspection in the office of the building *operator* or be posted in a publicly conspicuous location *approved* by the *code official*. The inspection and witnessing of tests required by ASME A17.1 shall be performed by an impartial, third-party inspector that meets the minimum qualifications as set forth in the referenced standard. The inspection and tests shall be performed at not less than the periodic intervals listed in ASME A17.1, Appendix N, except where otherwise specified by the authority having jurisdiction.

Reason: These three companion proposals will provide consistent provisions in the IBC, IFC and IPMC regarding elevator inspection and posting the appropriate certificate.

IFC Section 607.4: Elevators, dumbwaiters and escalators have a significant impact on a building's overall fire safety. Accordingly, this new text will coordinate IFC requirements with those of the IBC and IPMC and at the same time, reiterate the qualifications needed by elevator inspectors and the importance of their impartiality.

Cost Impact: The code change proposal will not increase the cost of construction

ICCFILENAME: CHANDLER-G1-3001.2.1.doc

Public Hearing Results

PART II- IFC

Committee Action: **Disapproved**

Committee Reason: Disapproved for consistency with the action taken on Part I.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Philip M. Chandler, representing New York State Department of State, Office of Fire Prevention & Control, requests Approval as Submitted.

Commenter's Reason: See commenter's reason for Part I.

Final Action: AS AM AMPC____ D

G153-09/10, PART III
IPMC 606.1

Proposed Change as Submitted

PART III – IPMC

Revise as follows:

606.1 General. Elevators, dumbwaiters and escalators shall be maintained in compliance with ASME A17.1. The most current certificate of inspection shall be on display at all times within the elevator or attached to the escalator or dumbwaiter, be available for public inspection in the office of the building *operator* or be posted in a publicly conspicuous location *approved* by the *code official*. <u>The inspection and witnessing of tests required by ASME A17.1 shall be performed by an impartial, third-party inspector that meets the minimum qualifications as set forth in the referenced standard.</u> The inspection and tests shall be performed at not less than the periodic intervals listed in ASME A17.1, Appendix N, except where otherwise specified by the authority having jurisdiction.

Reason: These three companion proposals will provide consistent provisions in the IBC, IFC and IPMC regarding elevator inspection and posting the appropriate certificate.

IPMC Section 606.1: This eliminates much confusion surrounding the minimum qualifications of elevator inspectors explicit in the referenced standard and the need for impartiality implicit in the requirements for QEI-1certification. The need for impartiality is fundamental to the QEI process.

Cost Impact: The code change proposal will not increase the cost of construction

ICCFILENAME: CHANDLER-G1-3001.2.1.doc

Public Hearing Results

PART III- IPMC

Committee Action: **Disapproved**

Committee Reason: Disapproved for consistency with the action taken on Parts I and II.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Philip M. Chandler, representing New York State Department of State, Office of Fire Prevention & Control, requests Approval as Submitted.

Commenter's Reason: See commenter's reason for Part I.

Final Action: AS AM AMPC____ D

G154-09/10
3002.3

Proposed Change as Submitted

Proponent: Brian Black, BDBlack Codes, Inc., representing National Elevator Industry, Inc. (NEII)

Revise as follows:

3002.3 Emergency signs. An approved pictorial sign of a standardized design shall be posted adjacent to each elevator call station on all floors instructing occupants to use the exit stairways and not to use the elevators in case of fire. The sign shall ~~read: IN FIRE EMERGENCY, DO NOT USE ELEVATOR. USE EXIT STAIRS~~ comply with ASME A17.1/CSA B44.

Exceptions:

1. The emergency sign shall not be required for elevators that are part of an *accessible means of egress* complying with Section 1007.4.

2. The emergency sign shall not be required for elevators that are used for occupant self-evacuation in accordance with Section 3008.

Reason: The message for these elevator signs is already addressed in the referenced standard:
ASME A17,1/CSA B44, Section 2.27.9 Elevator Corridor Call Station Pictograph. When the building code requires a sign be posted adjacent to hall call fixtures instructing occupants not to use the elevator in case of fire, the sign shown in Fig. 2.27.9 shall be provided. The sign shall include only the wording and graphics shown in Fig. 2.27.9. When the building code specifies a different design, 2.27.9 shall not apply.

(The Figure 2.27.9 uses the text "IN CASE OF FIRE ELEVATORS ARE OUT OF SERVICE. USE EXIT".)

ASME A17,1/CSA B44 already provides the "standardized design" required by IBC Section 3002.3 but provides non-standardized text to accompany the pictograph. This is essentially a harmonization between the IBC requirement and the code referenced in 3001.2.

Cost Impact: This code change proposal will not increase the cost of construction.

ICCFILENAME: BLACK-G2-3002.3.doc

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: This language needs to be provided in the code and not force building officials or designers to consult the standard for 10 simple words.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Brian Black, BDBlack Codes, Inc., representing National Elevator Industry Inc., requests Approval as Modified by this Public Comment.

3002.3 Emergency signs. An approved pictorial sign of a standardized design shall be posted adjacent to each elevator call station on all floors instructing occupants to use the exit stairways and not to use the elevators in case of fire. The sign shall read: ~~comply with ASME A17.1/CSA B44~~ IN CASE OF FIRE ELEVATORS ARE OUT OF SERVICE. USE EXIT STAIRS.

Exceptions:

1. The emergency sign shall not be required for elevators that are part of an *accessible means of egress* complying with Section 1007.4.
2. The emergency sign shall not be required for elevators that are used for occupant self-evacuation in accordance with Section 3008.

Commenter's Reason: The intent of this code change was to coordinate the requirements of the IBC with those in the ASME A17.1/CSA B44 Safety Code for Elevators and Escalators. The committee disapproved the direct reference to the ASME code as it felt a code official should not have to go to a separate document "for 10 simple words". It also preferred the word "stairs" be retained in the sign.

The proposed new text is identical to the text on the sign required by ASME A17.1/CSA B44 with the addition of the word "STAIRS". If this is approved, NEII will submit a Technical Revision to the ASME A17 Standards Committee to harmonize that code's text with the IBC.

Final Action: AS AM AMPC____ D

G155-09/10
3003.3 (New), 3007.3

Proposed Change as Submitted

Proponent: Dave Frable, representing U.S. General Services Administration

Revise as follows:

3003. 3 Hoistway lighting. When firefighters' emergency operation is active, the entire height of the hoistway shall be illuminated at not less than 1 foot-candle (11 lux) as measured from the top of the car of each elevator.

~~**3007.3 Hoistway lighting.** When firefighters' emergency operation is active, the entire height of the hoistway shall be illuminated at not less than 1 foot-candle (11 lux) as measured from the top of the car of each fire service access elevator.~~

(Renumber subsequent sections)

Reason: The intent of this code change is to provide illumination within elevator hoistways when firefighter's emergency operation has been enabled. It relocates the provisions currently only applicable to fire service access elevators applicable to high-rise buildings, to be a requirement for all elevator hoistways regardless of height or whether the elevator is designated for a specific use or not.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: FRABLE-G3-3003.3

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The lighting is only needed for the use of firefighters. It has no relationship to the use of any elevator for accessible means of egress or for occupant self evacuation.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Dave Frable, representing U.S. General Services Administration, requests Approval as Submitted

Commenter's Reason: The intent of this code change is to provide illumination within all elevator hoistways of a building when firefighter's emergency operation has been enabled. This requirement would apply to all elevator hoistways within a building in lieu of just the elevator hoistways that are used for fire service access elevators. This new requirement will provide firefighters the ability to view the elevator hoistway for smoke without the need to shine a flashlight up the hoistway prior to using any elevator to transport equipment and/or personnel as well as evacuating mobility impaired individuals from a building regardless of height or whether the elevator is designated for a specifically as a fire service access elevator. Regarding the Committee's reason for disapproval; we feel the reasons stated have no bearing on the overall intent of this code change.

Final Action: AS AM AMPC____ D

G158-09/10

3007.2 (New), 3007.3 (New)

Proposed Change as Submitted

Proponent: Dave Frable, representing U.S. General Services Administration

Add new text as follows:

3007.2 Automatic sprinkler system. The building shall be equipped throughout by an automatic sprinkler system in accordance with Section 903.3.1.1, except as otherwise permitted by Section 903.3.1.1.1 and as prohibited by Section 3007.2.1.

3007.2.1 Prohibited locations. Automatic sprinklers shall not be installed in elevator machine rooms, elevator machine spaces, and elevator hoistways of fire service access elevators.

3007.2.2 Sprinkler system monitoring. The sprinkler system shall have a sprinkler control valve supervisory switch and waterflow-initiating device provided for each floor that is monitored by the building's fire alarm system.

3007.3 Shunt trip. Means for elevator shutdown in accordance with Section 3006.5 shall not be installed on elevator systems used for fire service access elevators.

(Renumber subsequent sections.)

Reason: 3007.2: The intent of this code change is to provide further clarification in meeting the original intent of Section 3007 regarding prohibiting the installation of automatic sprinklers in the associated elevator machine rooms and elevator machine spaces for fire service access elevators. . The subject proposed language is similar to the language in Section 3008.6 for occupant evacuation elevators.

3007.3: The intent of this code change is to provide further clarification in meeting the original intent of Section 3007 regarding prohibiting the installation of shunt trip for fire service access elevators. The subject proposed language is similar to the language in Section 3008.8 for occupant evacuation elevators.

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: Would this requirement take precedence over Sections 403.2 and 903.2.11.3 which allow certain portions of a high-rise building not to be provided with sprinkler protection?

ICCFILENAME: FRABLE-G9-3007.2

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: This clarifies that the same exemptions for sprinklers installed in the elevator machine room and shaft and the installation for shunt trips permitted for Occupant Evacuation Elevators in Section 3008.6 should also be permitted in Fire Service Access Elevators.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Gerald Anderson, City of Overland Park, representing self, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

~~**3007.2 Automatic sprinkler system.** The building shall be equipped throughout by an automatic sprinkler system in accordance with Section 903.3.1.1, except as otherwise permitted by Section 903.3.1.1.1 and as prohibited by Section 3007.2.1.~~

~~**3007.2.1 Prohibited locations.** Automatic sprinklers shall not be installed in elevator machine rooms, elevator machine spaces, and elevator hoistways of fire service access elevators.~~

~~**3007.2.2 Sprinkler system monitoring.** The sprinkler system shall have a sprinkler control valve supervisory switch and waterflow-initiating device provided for each floor that is monitored by the building's fire alarm system.~~

~~**3007.3**~~ **3007.2 Shunt trip.** Means for elevator shutdown in accordance with Section 3006.5 shall not be installed on elevator systems used for fire service access elevators.

Commenter's Reason: The proposed Section 3007.2 Automatic sprinkler systems is not necessary. Automatic sprinkler systems are already required by Chapter 9, another charging statement is not necessary.

Floor control valves are already required in high-rise buildings by section 903.4.3. A water flow initiating device for each floor is required in high-rise by section 907.6.3.2. Section 903.3.1.1.1 already exempts fire service access elevators from the general requirement for fire sprinklers and Section 8.14.5.5 of NFPA 13 exempts sprinklers for the tops of non-combustible elevator shafts.

Therefore the proposed language is not necessary.

I left the requirement for shunt trips in this proposal because I think that it is important to get this requirement into the code. However, this requirement should be an exception to 3006.5 not a stand alone requirement under fire service access elevators. A code change can be submitted for this at a later date.

Final Action: AS AM AMPC____ D

G159-09/10
3007.2 (New)

Proposed Change as Submitted

Proponent: Dave Frable, representing U.S. General Services Administration

Add new section as follows:

3007.2 Phase I Emergency Recall Operation. An independent, three-position, key-operated "Fire Recall" switch shall be provided at the designated level for each fire service access elevator or for each group of fire service access elevators in accordance with the requirements in ASME A17.1/CSA B44. In addition, actuation of any building fire alarm initiating device shall initiate Phase I emergency recall operation on all fire service access elevators in accordance with the requirements in ASME A17.1/CSA B44. All other elevators shall remain in normal service unless Phase I emergency recall operation is manually initiated by a separate, required three-position key-operated "Fire Recall" switch or automatically initiated by the associated elevator lobby and elevator machine room smoke detectors.

(Renumber subsequent sections)

Reason: The intent of this code change is to provide further clarification in meeting the original intent regarding the design and operation of fire service access elevators. This code change will also ensure the subject elevators can be recalled quickly at the designated level by the responding firefighters.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: FRABLE-G7-3007.2

Public Hearing Results

Committee Action: **Approved as Modified**

Modify the proposal as follows:

3007.2 Phase I Emergency recall operation. An independent, three-position, key-operated "Fire Recall" switch shall be provided at the designated level for each fire service access elevator or for each group of fire service access elevators in accordance with the requirements in ASME A17.1/CSA B44. In addition, actuation of any building fire alarm initiating device shall initiate Phase I emergency recall operation on all fire service access elevators in accordance with the requirements in ASME A17.1/CSA B44. All other elevators shall remain in normal service unless Phase I emergency recall operation is manually initiated by a separate, required three-position key-operated "Fire Recall" switch or automatically initiated by the associated elevator lobby ~~and~~ , hoistway or elevator machine room smoke detectors.

Committee Reason: The modification to the proposal is to coordinate with what is required in ASME A17.1 and will require activation of the fire recall from all three locations listed. The proposal provides the fire service a standardized way to initiate the fire recall process.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Dave Frable, representing U.S. General Services Administration, request Approval as Modified by this Public Comment.

Further modify the proposal as follows:

3007.2 Phase I Emergency recall operation. ~~An independent, three-position, key-operated "Fire Recall" switch shall be provided at the designated level for each fire service access elevator or for each group of fire service access elevators in accordance with the requirements in ASME A17.1/CSA B44. In addition, a~~Actuation of any building fire alarm initiating device shall initiate Phase I emergency recall operation on all fire service access elevators in accordance with the requirements in ASME A17.1/CSA B44. All other elevators shall remain in normal service unless Phase I emergency recall operation is manually initiated by a separate, required three-position key-operated "Fire Recall" switch or automatically initiated by the associated elevator lobby, hoistway or elevator machine room smoke detectors. In addition, if the building also employs occupant evacuation

<u>elevators in accordance with Section 3008, an independent, three-position, key-operated “Fire Recall” switch conforming to the applicable requirements in ASME A17.1/CSA B44 shall be provided at the designated level for each fire service access elevator.</u>

Commenter’s Reason: The intent of the modification is for clarification purposes and to correct any misinterpretation of the subject paragraph. As currently written, we are unsure how the subject text will be interpreted and enforced by the Building Official. The subject revised text will not adversely impact the overall intent of the proposal to provide the fire service a standardized way to initiate the fire recall process for the fire service access elevators.

Public Comment 2:

Brian Black, BDBlack Code, Inc., representing National Elevator Industry Inc., request Disapproval.

Commenter's Reason: The ability to place elevators into service while others in a group of elevators are being used to fight a fire is both unnecessary and dangerous. It would allow the public to reenter the upper stories of a building, move from floor to floor within the building, and possibly reach a fire floor during an active fire. In an emergency situation, a firefighter could mistakenly recall a single elevator and not even be aware that the remaining elevators have not been recalled and are thus available to the public.

This type of requirement is appropriate where Occupant Evacuation Elevators (OEE) are in place because it allows fire fighters to release elevators from Phase II operation so that they can return to the affected floors and be used for evacuation purposes. The critical distinction is that the elevators in OEE mode cannot be used by the public to reenter the upper stories of the building or migrate from floor to floor within the building. There is no need for this type of operation where OEE is not installed in the building.

Finally, operation and function of the fire recall elevator keys are controlled by ASME A17.1/CSA B44. Any modifications to the code’s requirements to account for Fire Service Access or Occupant Evacuation Elevators should remain in that reference standard.

Final Action: AS AM AMPC____ D

G160-09/10
3007.2.1

Proposed Change as Submitted

Proponent: Rick Thornberry, PE, The Code Consortium, Inc., representing: California Fire Safety Advisory Council (CFSAC)

Revise as follows:

3007.2 Hoistway enclosures protection. The fire service access elevator <u>hoistway</u> shall be located in a shaft enclosure complying with Section 708.

<u>**3007.2.1 Structural integrity of hoistway enclosures.** The fire service access elevator hoistway shaft enclosure shall comply with Section 403.2.3.</u>

Reason: This proposed code change is a follow up to the Cal Chiefs Code Change G194-07/08 which was disapproved in Minneapolis.
That code change was disapproved mainly because it was based on a reference to the hose stream test in ASTM E119 for determining the structural integrity of the shaft enclosure. However, Code Change G65-07/08 by the Gypsum Association, which also addressed the issue of structural integrity of exit stairway and elevator hoistway shaft enclosures, was approved as modified in Minneapolis by Public Comment #2. That code change provided for another means for assessing the structural integrity of shaft enclosures, specifically for buildings known as super high-rise buildings (those greater than 420 ft in height). And it was supported by a NIST representative in response to one of the recommendations made in the NIST World Trade Center Report. Since it was approved for those conditions, it also seems appropriate that such structural integrity criteria should also be provided for the protection of fire service access elevator hoistways. These hoistways perform a very critical function protecting the responding fire fighters while the elevator assists them in gaining access to the fire floor in buildings generally more than 120 ft in height.

Cost Impact: The code change proposal will increase the cost of construction.

Analysis: Does the reference to Section 403.2.3 in the proposal result in requiring ‘hardening’ of the hoistway shaft at the 120 foot threshold for fire service access elevators or the 420 foot threshold provided in Section 403.2.3?

ICCFILENAME: THORNBERRY-G3-3007.2

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: With the reference to Section 403.2.3, it is not clear if the requirement for hardened shaft would be applicable for all Fire Service Access elevators (starting at 120 feet), or just those in Seismic Category III and IV or only at buildings taller than 420 feet. The intent of the proponent is for all Fire Service Access elevators to be hardened at 120 feet regardless of seismic category. The correct placement for this requirement is in Section 402.3.2. Justification for the additional costs must be provided.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Rick Thornberry, PE, The Code Consortium, Inc., representing California Fire Safety Advisory Council (CFSAC), requests Approval as Modified by the Public Comment.

Modify this proposal as follows:

3007.2.1 Structural integrity of hoistway enclosures. The fire service access elevator hoistway shaft enclosure shall comply with Sections 403.2.3.1 through 403.2.3.4.

(Portions of proposal not shown remain unchanged)

Commenter's Reason: This Public Comment responds to the main reason the IBC Means of Egress Code Development Committee recommended disapproval. The Committee was basically in support of the concept of the code change but was concerned about the confusion that would occur based on how Section 403.2.3 was referenced and how it was intended to apply regarding the height and type of high-rise building that would trigger the requirement for the structural integrity of fire service access elevator hoistway enclosures. So the proposed revision in this Public Comment makes specific reference to Sections 403.2.3.1 through 403.2.3.4 which describe how the structural integrity of the hoistway enclosure is to be constructed. Thus, the requirement applies to any fire service access elevator hoistway provided in a building as required by Section 403.6.1 which is triggered at 120 ft in height above the lowest level of fire department vehicle access.

Final Action: AS AM AMPC____ D

G165-09/10
3007.7.1, 3008.15.1

Proposed Change as Submitted

Proponent: Brian Black BDBlack Codes, Inc., representing National Elevator Industry, Inc. (NEII), Sean DeCrane, representing, International Association of Fire Fighters (IAFF), Jack Murphy, representing Fire Safety Directors Association of Greater New York (FSDAGNY)

Revise as follows:

3007.7.1 Protection of wiring or cables. Wires or cables that provide normal or standby power, control signals, communication with the car, lighting, heating, air conditioning, ventilation and fire-detecting systems to fire service access elevators shall be protected by construction having a minimum ~~1-~~2-hour fire-resistance rating or shall be circuit integrity cable having a minimum ~~1-~~2-hour fire resistance rating.

3008.15.1 Protection of wiring or cables. Wires or cables that provide normal or standby power, control signals, communication with the car, lighting, heating, air conditioning, ventilation and fire-detecting systems to fire service access elevators shall be protected by construction having a minimum ~~1-~~2-hour fire-resistance rating or shall be circuit integrity cable having a minimum ~~1-~~2-hour fire resistance rating.

Reason: RE: 3007.7.1: The safety of firefighters during their firefighting operations is dependent upon the life safety support systems listed in Section 3007 being maintained during the critical first 2 hours of their efforts. Locating, surrounding, confining and extinguishing the fire, as well as removing those whose lives are in jeopardy, will take time. If the fire is not under control by 2 hours into the effort, then it is probably time to evacuate. Providing the 2 hour protection will provide the necessary safety factor for firefighters to undertake the firefighting and rescue operations without increased concern for system failure. The 2-hour rating is consistent with the hoistway fire rating and fire pump feeder enclosure rating. This request has the full support of the firefighting community and is not unreasonable when it is considered that this will allow for more time to ensure the full evacuation of the building.

RE: 3008.15.1: The safety of building occupants evacuating a building is dependent upon the life safety support systems listed in Section 3008 being maintained during the critical hours of evacuation. The 2-hour rating is consistent with the hoistway fire rating and fire pump feeder enclosure rating. This request has the full support of the firefighting community and is not unreasonable when it is considered that this will allow for more time to ensure the full evacuation of a building.

Cost Impact: This code change proposal will increase the cost of construction.

ICCFILENAME: BLACK-G8-10-3008.15.1.doc

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The proposal was disapproved because no technical justification was provided for the increase for the fire-resistance rating for cable protection. Most of the wiring for elevators can be run inside the protected shaft.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Brian Black, BDBlack Code, Inc., representing National Elevator Industry Inc., requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

3007.7.1 Protection of wiring or cables. Wires or cables <u>that are located outside of the elevator hoistway and machine room and</u> that provide normal or standby power, control signals, communication with the car, lighting, heating, air conditioning, ventilation and fire-detecting systems to fire service access elevators shall be protected by construction having a minimum 2-hour fire-resistance rating or shall be circuit integrity cable having a minimum 2-hour fire resistance rating.

3008.15.1 Protection of wiring or cables. Wires or cables <u>that are located outside of the elevator hoistway and machine room and</u> that provide normal or standby power, control signals, communication with the car, lighting, heating, air conditioning, ventilation and fire-detecting systems to occupant evacuation elevators shall be protected by construction having a minimum 2-hour fire-resistance rating or shall be circuit integrity cable having a minimum 2-hour fire resistance rating.

Commenter's reason: The committee stated "no technical justification was provided" for this proposal in that "most of the wiring for elevators can be run inside the elevator shaft". This proposed modification addresses the portion of the wiring that is outside of the 2-hour protected hoistway (power feeders for elevators, HVAC feeders, etc.). It essentially fixes the weak link created by horizontal runs from the transformer to the machine room. The cost will be negligible when compared to the original proposal.

Final Action: AS AM AMPC____ D

G169-09/10
3008.1.1 (New)

Proposed Change as Submitted

Proponent: Bill Ziegert, Smoke Guard, Inc, representing self.

Add new text as follows:

<u>**3008.1.1 Occupant evacuation elevators permitted.** Occupant evacuation elevators shall be permitted only when the elevator code (ASME A17.1/CSA B44 or other) adopted by the jurisdiction contains specific requirements for the design, operation and maintenance of emergency evacuation operation (EEO).</u>

Reason: Occupant Evacuation Elevators require many special operational / design requirements not found in the Building Code, and currently not included in any edition issued or under development of the ASME A17.1/CSA B44 Elevator Code. The proper operation and sequencing of the elevators to efficiently move occupants from the affected floors is the most important part of the occupant evacuation system and incorporation of this functionality currently allowed under the building code should not be allowed until the Elevator systems are designed with this additional functionality adequately addressed.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: ZIEGERT-G2-3008.1.1

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The AMSE standard does not currently include specifics for Occupant Evacuation Elevators. Requiring the standard to have specific requirements before this option could be used would effectively prohibit Occupant Evacuation Elevators at this time. ASME should move forward to include specific information. The IBC needs to move forward to provide direction for this new technology. Involvement of the fire department and code official during construction and development of the fire and safety evacuation plans will address specific control issues on a case by case basis until the ASME standard is complete.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Bill Ziegert, Smoke Guard, Inc., representing self, requests Approval as Submitted.

Commenter's Reason: Occupant Evacuation Elevators require many special operational / design requirements not found in the *International Building Code*, and currently not included in any issued edition of the ASME A17.1/CSA B44 Elevator Code. While a volunteer task group chartered by ASME A17.1 including NIST, elevator experts, fire service representatives, human factors experts, and building code representatives from NFPA and ICC, have been working diligently on developing the proper requirements to be included in the elevator code, the new language will not appear before the 2013 version of A17.1.

It is impossible to safely conduct Occupant Evacuation using elevators until significant and substantial design enhancements are included in the elevator system design. The guidance for these is absent in the IBC, since all parties recognize that they should be appropriately included in the elevator code.

This change would not prohibit the consideration of Occupation Evacuation Elevator systems, just delay the implementation until both the adopted building code and elevator code concurrently contain the minimum design requirements for these systems.

The committee rational that "Involvement of the fire department and code official during construction and development of the fire and safety evacuation plans will address specific control issues on a case by case basis until the ASME standard is complete" fails to recognize the exceptional complexity of how these systems must integrate with not only the elevator system, but also fire service protocols during high rise fires. No building or fire official should undertake these decisions, particularly since a high level of understanding of the current requirements of A17.1 is required.

Final Action: AS AM AMPC____ D

G171-09/10

3008.4 (New)

Proposed Change as Submitted

Proponent: Dave Frable, representing U.S. General Services Administration

Add new text as follows:

<u>**3008.4 Phase I Emergency Recall Operation**. An independent, three-position, key-operated "Fire Recall" switch shall be provided at the designated level for each occupant evacuation elevator in accordance with the requirements in ASME A17.1/CSA B44.</u>

(Renumber subsequent sections)

Reason: The intent of this code change is to provide further clarification in meeting the original intent regarding the design and operation of fire service access elevators. This code change will also ensure the subject (as specific) elevators can be recalled quickly at the designated level by the responding firefighters.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: FRABLE-G8-3008.4

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: This proposed text allows flexibility for individual recall in addition to bank recall. This will help fire department efficiency when using the Occupant Evacuation Elevators during evacuation events.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Dave Frable, representing U.S. General Services Administration, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

3008.4 Phase I Emergency recall operation. An independent, three-position, key-operated “Fire Recall” switch complying to the applicable requirements in ASME A17.1/CSA B44 shall be provided at the designated level for each occupant evacuation elevator ~~in accordance with the requirements in ASME A17.1/CSA B44~~.

Commenter’s Reason: The intent of the modification is for clarification purposes and to correct any misinterpretation of the subject paragraph. As currently written, we are unsure how the subject text will be interpreted and enforced by the Code Official. The subject revised text will not adversely impact the overall intent of the proposal.

Public Comment 2:

Brian Black, BDBlack Codes, Inc., representing National Elevator Industry Inc., requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

3008.4 Phase I Emergency recall operation. An independent, three-position, key-operated “Fire Recall” switch complying with ASME A17.1/CSA B44 shall be provided at the designated level for each occupant evacuation elevator ~~in accordance with the requirements in ASME A17.1/CSA B44~~.

Commenter’s Reason: This revision makes it clear that it is the three-position, key-operated “Fire Recall” switch and not the Occupant Evacuation Elevator (OEE) system that must comply with ASME A17.1/CSA B44. This is critical as the Safety Code for Elevators and Escalators has yet to have OEE requirements in it. A

Final Action: AS AM AMPC____ D

G173-09/10

3008.9, 3008.9.1 (New)

Proposed Change as Submitted

Proponent: Rick Thornberry, PE, The Code Consortium, Inc., representing: California Fire Safety Advisory Council (CFSAC)

Revise as follows:

3008.9 Hoistway enclosure protection. ~~The~~ Occupant evacuation elevator~~s~~ hoistways shall be located in ~~a hoistway~~ shaft enclosure~~(s)~~ complying with Section 708.

3008.9.1 Structural integrity of hoistway enclosures. Occupant evacuation elevator hoistway shaft enclosures shall comply with Section 403.2.3.

Reason: This code change is a follow up to Code Change G65-07/08 by the Gypsum Association which also addressed the issue of structural integrity of exit stairway and elevator hoistway shaft enclosures in super high-rise buildings (those greater than 420 ft in height). It was approved as revised by Public Comment #2 at the ICC Final Action Hearings held in Minneapolis, MN.

In our opinion, it follows that the structural integrity requirements for super high-rise building exit stairway and elevator hoistway shaft enclosures should also apply to elevator hoistway shaft enclosures provided for occupant evacuation elevators which are just as critical for life safety protection. Such new technology for evacuation of occupants should be provided with the highest level of fire protection that is reasonably possible in order to assure that the elevators will be available during a fire emergency to serve their intended purpose of evacuating the occupants. Certainly, the structural integrity of the elevator hoistway shaft enclosures should be required to have some reasonable degree of physical protection to assure that the hoistway shaft enclosures will remain in place when needed during a fire or other emergency.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: THORNBERRY-G5-3008.9

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: This is the wrong place in the code for this requirement. This requirement for structural integrity needs to be incorporated into the high-rise provisions in Section 403.2.3. With this referenced, if the designer chose to provide Occupant Evacuation Elevators in building less than 420 feet it is not clear if the shaft would still have to meet the structural integrity requirements in Category I and II Seismic areas.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Rick Thornberry, PE, The Code Consortium, Inc., representing California Fire Safety Advisory Council (CFSAC) requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

3008.9.1 Structural integrity of hoistway enclosures. Occupant evacuation elevator hoistway shaft enclosures shall comply with Sections ~~403.2.3~~ 403.2.3.1 through 403.2.3.4.

(Portions or proposal not shown remain unchanged)

Commenter's Reason: This Public Comment responds to the main reason the IBC Means of Egress Code Development Committee recommended disapproval. The Committee was basically in support of the concept of the code change but was concerned about the confusion that would occur based on how Section 403.2.3 was referenced and how it was intended to apply regarding the height and type of high-rise building that would trigger the requirement for the structural integrity of occupant evacuation elevator hoistway enclosures. So the proposed revision in this Public Comment makes specific reference to Sections 403.2.3.1 through 403.2.3.4 which describe how the structural integrity of the hoistway enclosure is to be constructed. Thus, the requirement applies to any occupant evacuation elevator hoistway provided in a building regardless of height.

Final Action: AS AM AMPC____ D

G189-09/10
3401.3

Proposed Change as Submitted

Proponent: David Bonowitz, David Bonowitz, S.E., National Council of Structural Engineers Associations, Code Advisory Committee, Existing Buildings Subcommittee (NCSEA EBS)

Revise as follows:

3401.3 Compliance. Alterations, repairs, additions and changes of occupancy to existing structures shall comply with the provisions for alterations, repairs, additions and changes of occupancy, respectively, in the *International Fire Code, International Fuel Gas Code, International Mechanical Code, International Plumbing Code, International Property Maintenance Code, International Private Sewage Disposal Code, International Residential Code* and NFPA 70. Where provisions of the other codes conflict with provisions of this Chapter, the provisions of this Chapter shall take precedence.

Reason: The proposal clarifies and confirms the intent of Section 3401.3.

Cost Impact: No cost increase.

ICCFILENAME: Bonowitz-G5-3401.3.doc

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The revisions would seem to conflict with the general references to other codes as contained in Chapter 1 and the reasons for the differences are unclear.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

David Bonowitz, S.E., representing National Council of Structural Engineers Associations, Code Advisory Committee, Existing Buildings Subcommittee (NCSEA EBS), requests Approval as Submitted.

Commenter's Reason: NCSEA EBS recommends approval as submitted for the following reasons:

The proposal makes two revisions. The first introduces the word "respectively" into section 3401.3. This clarifies that Alterations under Chapter 34, for example, need only comply with the provisions for Alterations in the referenced codes, and need *not* comply with the provisions in referenced codes for repairs, change of occupancy, etc. This should be obvious, but clarification by adding the word "respectively" is certainly consistent with the intent and does no harm.

The second proposed revision again clarifies the intent that *where conflicts occur*, specific provisions in Chapter 34 should take precedence over more general provisions in the referenced codes. The IBC General committee disapproved this change, referring to Chapter 1, presumably to section 101.4 Referenced codes.

However, this reasoning does not acknowledge the special circumstances inherent in Chapter 34 and other provisions for existing buildings. For new construction, it is quite likely that there is no overlap between the IBC and the referenced codes, so section 101.4 is relatively straightforward. For existing buildings, however, there is always a substantial overlap between the intended scope of alteration, repair, etc. covered by Chapter 34 and the condition of associated systems covered by the referenced codes. Thus there is an inherent conflict between Chapter 34 – which triggers compliance only in certain situations, only in prescribed areas, and often with scope reductions – and the general application of any referenced code.

The conflict, real or potential, is easily solved by adding the sentence as proposed, to clarify that where Chapter 34 limits the scope of triggered work, the referenced codes should not override it. (Without this proposed sentence, a full review and coordination of all the referenced codes will be required with each code cycle.)

Four examples of potential conflicts, all solved by adding the proposed additional sentence:

For historic buildings, 3409 clearly (and substantially) limits the extent of triggered work. Section 3401.3, however, does not on its face acknowledge that scope limitation.

For buildings potentially covered by the IRC, section 3401.3 would invoke existing building provisions of that reference code. But the IRC structural upgrade provisions and triggers are substantially different from and less complete than those in Chapter 34 or in the IEBC.

A new section in the 2009 IBC allows the use of the IEBC as deemed to comply with Chapter 34. The IEBC has even more specific and appropriate variations from the referenced codes than Chapter 34 does. It is certainly not the intent to both allow the use of the IEBC and require compliance with all the referenced codes in ways that might be inconsistent.

There are likely other cases where Chapter 34 intends a limited scope of work, but the referenced codes, by addressing a broad range of possibilities, could be invoked improperly under a misreading of 3401.3.

Any such potential conflicts are clearly unintended. To avoid them, the additional sentence should be added as proposed by G189.

Final Action: AS AM AMPC____ D

G192-09/10

3401.5 (New), 3405.1.1 (IEBC [B] 301.3 (New), 304.1.1)

Proposed Change as Submitted

Proponent: David Bonowitz, David Bonowitz, S.E., National Council of Structural Engineers Associations, Code Advisory Committee, Existing Buildings Subcommittee (NCSEA EBS)

1. Add new text as follows:

3401.5 (IEBC [B] 301.3) Dangerous conditions. The building official shall have the authority to require the elimination of conditions deemed dangerous.

(Renumber subsequent sections in IBC.)

2. Delete without substitution:

~~**3405.1.1 (IEBC 304.1.1) Dangerous conditions.** Regardless of the extent of structural or nonstructural damage, the building code official shall have the authority to require the elimination of conditions deemed dangerous.~~

Reason: This proposal relocates a provision from Section 3405.1.1 to Section 3401. This provision, dealing with the elimination of dangerous conditions, should be at the top of the chapter, as proposed, because it has broad applicability throughout Chapter 34, not just in the Repairs subsection.

Cost Impact: No cost increase.

ICCFILENAME: BONOWITZ-G10-3401.6.doc

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The code change appropriately relocates the section on dangerous conditions to the beginning of Chapter 34 to reflect its broad applicability.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Michael L. Perrino, Code Consultants, Inc., representing self, requests Disapproval.

Commenter's Reason: This change is overly broad. Section 3401.2 already covers maintenance of buildings. Dangerous conditions created by existing materials are already covered in Section 3401.4.1. Within the context of its original location in Section 3405, the relocated language limits the application of the concept of 'dangerous' to those conditions defined in Section 3402.1 relating to structural and/or nonstructural damage.

This change gives the official no guidance as to what constitutes a dangerous condition outside the context of the sections cited above. This change will create conditions for wildly inconsistent code enforcement, defeating one of the main goals for the development and adoption of building codes.

Final Action: AS AM AMPC____ D

G199-09/10

3410.1, 3410.2 through 3410.8 (New)

Proposed Change as Submitted

Proponent: Patrick Vandergriff, Vandergriff Code Consulting Services, representing Modular Building Institute

1. Delete text as follows:

~~**3410.1 Conformance.** Structures moved into or within the jurisdiction shall comply with the provisions of this code for new structures.~~

2. Add new section as follows:

3410.1 General. The relocation of any building to another location where the effects of wind, snow, flood or seismic provisions is greater than the percentage of increased loads allowed by this section relocated buildings shall comply with the requirements of Sections 3410.2 and Section 3410.8.

3410.2 Location on the lot. The building shall be located on the lot in accordance with the requirements of this code, or the *International Residential Code,* as applicable.

3410.3 Foundation. The foundation system of relocated buildings shall comply with Chapter 18, or the *International Residential Code* as applicable.

Exception: Foundations for modular structures are permitted to be of any materials allowed by the code and installed in accordance with either:

1. The manufacturers design requirements; or
2. An approved engineered design.

3410.3.1 Connection to the foundation. The connection of the relocated building to the foundation shall comply with Chapter 18, or the *International Residential Code,* as applicable.

3410.4 Wind loads. Buildings shall comply with Section 1609, or *International Residential Code* wind provisions, as applicable.

Exceptions:

1. Detached one- and two-family dwellings and Group U occupancies where wind loads at the new location are not higher than those at the previous location.
2. Structural elements whose stress is not increased by more than 5 percent.

3410.5 Seismic loads. Buildings shall comply with Section 1613, or *International Residential Code* seismic provisions, as applicable, to the new location.

Exceptions:

1. Structures in Seismic Design Categories A and B and detached one- and two-family dwellings in Seismic Design Categories A, B, and C where the seismic loads at the new location are not higher than those at the previous location.
2. Structural elements whose stress is not increased by more than 5 percent.

3410.6 Snow loads. Structures shall comply with Section 1608, or *International Residential Code* snow loads, as applicable, where snow loads at the new location are higher than those at the previous location.

Exception: Structural elements whose stress is not increased by more than 5 percent.

3410.7 Flood hazard areas. If relocated or moved into a *flood hazard area*, structures shall comply with Section 1612.

3410.8 Required inspection and repairs. The building official shall be authorized to inspect, or to require approved professionals to inspect at the expense of the owner, the various structural parts of a relocated building to verify that structural components and connections have not sustained structural damage. Any repairs required by the building official as a result of such inspection shall be made prior to the final approval.

Reason: This corresponds to several code change proposals establishing more clear definition and use issue with modular construction. This language provides the same language of the International Existing Building Code, Chapter 12 provisions dealing with the relocation of structures.

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: This text is a copy of IEBC Chapter 12. If this proposal is approved, the Code Correlation Committee will decide if IEBC or IBC will control these provisions.

ICCFILENAME: VANDERGRIFF-G7-3410.1 NEW.doc

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: At the proponent's request, the committee disapproved the proposal. The proposal is in need of refinement to provide references other than the IRC; to consider if needed provisions were not included and reconsider it all of the repetitive code language and referencing to other sections are truly needed.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Patrick Vandergriff, Vandergriff Code Consulting Services, representing Modular Building Institute, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

3410.2 Location on the lot. The building shall be located on the lot in accordance with the requirements of this code, ~~or the *International Residential Code,* as applicable~~.

3410.3 Foundation. The foundation system of relocated buildings shall comply with Chapter 18~~, or the *International Residential Code* as applicable~~.

Exception: Foundations for modular structures are permitted to be of any materials allowed by the code and installed in accordance with either:

1. The manufacturers design requirements; or
2. An approved engineered design.

3410.3.1 Connection to the foundation. The connection of the relocated building to the foundation shall comply with Chapter 18~~, or the *International Residential Code,* as applicable~~.

3410.4 Wind loads. Buildings shall comply with Section 1609, ~~or *International Residential Code* wind provisions, as applicable~~.

Exceptions:

1. Detached one- and two-family dwellings and Group U occupancies where wind loads at the new location are not higher than those at the previous location.
2. Structural elements whose stress is not increased by more than 5 percent.

3410.5 Seismic loads. Buildings shall comply with Section 1613~~, or *International Residential Code* seismic provisions, as applicable,~~ to the new location.

Exceptions:

1. Structures in Seismic Design Categories A and B and detached one- and two-family dwellings in Seismic Design Categories A, B, and C where the seismic loads at the new location are not higher than those at the previous location.
2. Structural elements whose stress is not increased by more than 5 percent.

3410.6 Snow loads. Structures shall comply with Section 1608~~, or *International Residential Code* snow loads, as applicable,~~ where snow loads at the new location are higher than those at the previous location.

Exception: Structural elements whose stress is not increased by more than 5 percent.

(Portions of proposal not shown remain unchanged.)

Commenter's Reason: At the code committee hearings I discussed the need for this change to the code and then requested that it be disapproved to allow me time to make changes to the language to eliminate the references to the International Residential Code, IRC, as it was too late to submit a modification in writing in the manner prescribed. This language corresponds to the language in the International Existing Building Coded, IEBC, chapter 12 provisions on relocation of structures.

Final Action: AS AM AMPC____ D

G200-09/10

3411.8.8 (IEBC [B] 310.8.8)

Proposed Change as Submitted

Proponent: Karen L. Braitmayer, FAIA, Studio Pacifica, Ltd, representing self

Revise as follows:

3411.8.8 (IEBC [B] 310.8.8) Type A dwelling or sleeping units. Where more than 20 Group R-2 *dwelling* or sleeping units are being <u>altered or</u> added, the requirements for Section 1107 for Type A units apply only to the quantity of spaces being <u>altered or</u> added.

Reason: This proposal retains language that has been in the IBC since 2003. Loss of this language in the 2009 reduces the percentage of Type A housing stock required by IBC.

Cost Impact: This code change will increase the cost of construction.

Analysis: The correlative text in the International Existing Building Code is in Sections 605.1.9 and 706.4.

ICCFILENAME:Braitmayer-G1-3411.8.8

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: It is not clear what level of alteration is required within a dwelling unit before the unit would be expected to comply with Type A dwelling unit requirements.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Dominic Marinelli, representing United Spinal Association, requests Approval as Submitted.

Commenter's Reason: United Spinal supports the availability of the more wheelchair friendly apartments (Type A) for it's members. What is being requested is minimal. These Type A units are only requested in facilities where more than 20 units are being altered at one. If they Type A units are already in the complex, there would be no requirements for additional Type A units (per Section 3411.3).

It is also important to note that right now IBC Section 3411.8.8 is copied as IEBC Section 310.8.8 (which addresses only when units are added). IEBC Section 605.1.9 includes a requirement for Type A units when units are being altered. IEBC Section 706.4 is a requirement for when Type A units when units are being added. It is confusing to users of the IEBC why these requirements are not coordinated between Chapters 3, 6 and 7.

Final Action: AS AM AMPC____ D

G208-09/10
Table 602

Proposed Change as Submitted

Proponent: John Berry, AIA – CR architecture + design (formerly Cole & Russell Architects) - representing self

Revise as follows:

TABLE 602
FIRE-RESISTANCE RATING REQUIREMENTS FOR EXTERIOR WALLS BASED UPON FIRE SEPARATION DISTANCE [a,e,h]

FIRE SEPARATION DISTANCE = X (feet)	TYPE OF CONSTRUCTION	OCCUPANCY GROUP H[f]	OCCUPANCY GROUP F-1, M, S-1[g]	OCCUPANCY GROUP A, B, E, F-2, I, R, S-2[g], U[b]
X <5[c]	All	3	2	1
5 < X < 10	IA	3	2	1
	Others	2	1	1
10 < X < 30	IA, IB	2	1	1[d]
	IIB, VB	1	0	0
	Others	1	1	1[d]
X ≥ 30	All	0	0	0

(No Change to footnotes "a" through "g")

h. Where Table 705.8 permits exterior walls to contain unprotected openings with no limit of the allowable area, the required fire resistance rating for the exterior walls is 0 hours.

Reason: Currently Table 705.8 allows unlimited openings in a building suppressed per NFPA 13 and a fire separation distance as small as 20 feet. However Table 602 would still require the exterior wall to be rated 1 hour. This is a contradiction and makes no sense; why would I rate an exterior wall per Table 602 when that wall could be entirely open per Table 705.8. It is important to note that this would not apply to H-1, H-2 & H-3 Uses, as they are specifically exempted from this provision by footnote “i” to Table 705.8. This would only effect buildings w/ a fire separation distance equal to or greater than 20 feet. There would be no change to buildings with a fire separation distance less than 20 feet.

Cost Impact: The code change proposal will not increase the cost of construction.

Note: This code change was contained in the errata posted on the ICC website. Please go to http://www.iccsafe.org/cs/codes/Pages/09-10ProposedChanges.aspx.

ICCFILENAME: BERRY-G1-Table 602

Public Hearing Results

Committee Action: Disapproved

Committee Reason: The proposed footnote is so complex with so many references out of the section that this revisions would not make this provision simpler, but definitely more confusing. What happens to the framing needs to be addressed.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Maureen Traxler, City of Seattle Dept. of Planning & Development, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

h. Where Table 705.8 permits nonbearing exterior walls ~~to contain~~ with unlimited area of unprotected openings ~~with no limit of the allowable area~~, the required fire-resistance rating for ~~the~~ those exterior walls is 0 hours.

(Portions of proposal not shown remain unchanged)

Commenter’s Reason: Tables 705.8 and 602 are in conflict. Table 705.8 allows unlimited unprotected openings in exterior walls of a sprinklered building with a fire separation distance of 20 feet or greater. However, Table 602 may require those same exterior walls to be rated 1 hour. An exterior wall that is allowed to be entirely open per Table 705.8 should not be required to be rated by Table 602. With this modification, the footnote specifies that the exterior walls must be nonbearing in order to have the fire-resistance rating reduced to 0 hours, ensuring that load-bearing exterior walls do not get this reduction for fire-resistance rating (which is consistent with Table 602 footnote “a” that states “Load-bearing exterior walls shall also comply with the fire-resistance rating requirements of Table 601.”) It is important to note that this new footnote would have no effect on H-1, H-2 & H-3 occupancies, as they are specifically exempted from unlimited openings by Table 705.8 footnote “i”. This new footnote would only affect buildings with a fire separation distance greater than 20 feet and less than 30 feet. There would be no change to buildings with a fire separation distance less than 20 feet.

Final Action: AS AM AMPC____ D

FS2-09/10
701.2 (New)

Proposed Change as Submitted

Proponent: Stephen Thomas, Colorado Code Consulting, LLC, representing the Colorado Chapter

Add new text as follows:

701.2 Multiple use fire assemblies. Fire assemblies that serve multiple purposes in a building shall comply with all of the requirements that are applicable for each of the individual fire assemblies.

Reason: A single fire assembly can serve multiple purposes in a structure. For example, a fire barrier along a fire-resistant rated corridor would also serve as a fire partition. The current code does not provide any direction on what requirements apply to that assembly. The intent of this proposal is to clarify that the requirements for each of the different assemblies must be met. In the example above, an opening protective would need to comply with the not only the fire-resistance rating for a fire barrier, but also the smoke and draft control requirements for an opening in a fire partition.

Cost Impact: The code change proposal will not increase the cost of construction.

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: This proposal clarifies the current intent of the code by requiring compliance with all applicable code requirements for fire assemblies that serve multiple purposes.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Stephen Thomas representing Colorado Chapter ICC, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

701.2 Multiple use fire and/or smoke assemblies. Fire and/or smoke assemblies that serve multiple purposes in a building shall comply with all of the requirements that are applicable for each of the individual fire assemblies.

Commenter's Reason: During the testimony in Baltimore, the committee identified a shortfall in the proposed language. It did not address smoke assemblies. Therefore, language has been added to confirm that this section would apply to fire and/or smoke assemblies. For example, a smoke barrier in a hospital that also serves as a fire barrier would need to comply with the requirements of both types of assemblies. This public comment does not change the overall intent or purpose of the proposed change.

Final Action: AS AM AMPC____ D

FS3–09/10
702.1

Proposed Change as Submitted

Proponent: Tony Crimi, A.C. Consulting Solutions Inc., representing International Firestop Council

Revise as follows:

JOINT. The ~~linear opening~~ void created at the interface in or between adjacent fire-resistance-rated ~~assemblies~~ building elements that is created due to building tolerances, or is designed to allow independent movement of the building in any plane caused by thermal, seismic, wind or any other loading.

Reason: The purpose of this proposal is to clarify that a "Joint", as defined in the IBC, may or may not be linear, and that the Joint is not the "opening" between fire resistance rated assemblies, but rather the materials or methods used to treat these openings

Justification: "Joints" are interfaces created in or between building elements such as walls, floors, columns or other building items. A joint typically involves a continuous void at the interface of two or more distinct components. When joints are designed into a structure, they are intended to allow independent movement of the building in any plane caused by thermal, seismic, wind or any other loading. However, joints are sometimes created as a result of building construction tolerances.

In fact, a Joint is never an "opening" as the current definition suggests, but instead they are the closures that go into the opening to provide continuity. The existing language in the definition already clarifies that the definition applies to both locations that are "… designed to allow independent movement" and also those created due to construction tolerances, and need to be treated. Consequently, the additional language addresses' that portion of the scope of the definition.

.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: CRIMI-FS6-702.1

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: Using the term "building elements" limits the scope of the definition, based on the definition of building elements. Further, the term "linear opening" is specific and descriptive and should remain in the definition. Also, the term "linear" is consistent with terminology used in the referenced standards dealing with joints. Lastly, the term "void" is too broad.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Tony Crimi, A.C. Consulting Solutions Inc., representing International Firestop Council, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

JOINT. The opening ~~void created at the interface~~ in or between adjacent fire-resistance-rated assemblies ~~building elements~~ that is created due to building tolerances, or is designed to allow independent movement of the building in any plane caused by thermal, seismic, wind or any other loading.

Commenter's Reason: This code change proposal clarifies that joints between fire resistance rated assemblies exist not only for the purposes of relative movement, but due to other reasons as well. The joint protection methods apply equally to all such gaps, regardless of why they exist. The term "Joint", as utilized in Chapter 7, relates to the protective systems installed in gaps, joints, voids, or other discontinuities between (or bounded by) two or more supporting elements even when the opening is created due to building tolerances. Joints are present in buildings by design, to accommodate various movements induced by thermal differentials, seismicity, and wind loads, but they also exist as a clearance separation, or due to acceptable dimensional tolerances between two or more building elements, for example, between non-loadbearing walls and floors. Inadequate design, inaccurate assembly, repairs or damage to the building can also create a need to install joint systems. All of these are still required to be protected when they are located in or between fire-resistance rated assemblies

The proposed language presented here is consistent with the test standards used to test fire-resistant joint systems.

Final Action: AS AM AMPC____ D

FS4-09/10
703.4

Proposed Change as Submitted

Proponent: Tony Crimi, AC Consulting Solutions Inc., representing International Firestop Council

Add new text as follows:

703.4 Automatic sprinklers. The fire resistance rating of a building element, component or assembly shall be established without the use of automatic sprinklers or any other fire suppression system being incorporated as part of the assembly tested in accordance with the fire exposure, procedures, and acceptance criteria specified in ASTM E119 or UL 263.

(Renumber subsequent sections)

Reason: There is a potential for misuse of established fire-resistance test Standards relied upon in the Code to determine performance of elements and assemblies, wherein the established consensus test method are modified outside the scope of the test standard to include a flow of cooling water during the fire exposure portion of the test.

Since some material manufacturers have begun to submit test reports to Authorities Having Jurisdiction with fire-resistance ratings obtained using a flow of cooling water during the fire test, it now becomes important to clarify that the code-required fire resistance rating is in fact a property that is meant to represent the inherent resistance to fire without the assistance of cooling flows. In countless instances, the code already incorporates the risk-reducing effect of a cooling flow from an extinguishing system by reducing the fire-resistance requirements, or by reducing other required safety measures.

The possibility of reducing some code requirements based on the improved behavior of an assembly when subjected to a cooling water flow can already be done via Alternative protection methods as allowed by Section 104.11, or by evaluation as a performance-based option. Thus, the only impact of this code change is to prevent a manufacturer of products from claiming an inflated fire resistance rating. The code change would not restrict anyone from proving that the addition of a cooling and/or extinguishing water flow can reduce some other requirement in the code.

It has never been the intent of either the Codes or the fire resistance testing Standards to incorporate the fire suppression system as part of the fire resistance rating of a building element, component or assembly. It would not be acceptable to have a fire-resistance rating that is determined during a test using a cooling flow, since the need for a fire resistive assembly is usually required by the Code in order to provide a an inherent passive level of fire protection. The notion of multiple safeguards and “Balanced Fire Protection” is not new to the Codes. It has long been a basic tenet that the design of every building or structure intended for human occupancy shall be such that reliance for safety to life does not depend solely on any single safeguard. Additional safeguards are provided for life safety in case any single safeguard is ineffective due to inappropriate human actions or system failure.

The resulting cooling-enhanced fire resistance rating then provides a result that would be incompatible with the required fire resistance ratings specified throughout the I-Codes. The various fire resistance ratings mandated throughout dozens of articles in the Code have been established based on an assumption of the type of construction that would pass the standardized tests without the aid of water cooling during fire exposure. For example, a relatively thin and un-insulated metal panel wall with suitable water cooling could potentially be arranged to pass a 1-hour standardized fire-resistance test, and possibly even longer duration fire-resistance tests. However, where the Code specifies the need for a 1-hour assembly, the intent in the development of that code provision would have clearly been to have an assembly that could survive a fire without being breached and without losing any load-bearing capabilities all by itself, without relying on an external water source for continued cooling. If sprinkler protection was also required for such an occupancy, then the overall intent of the Code is to have these two systems act independently, but in concert with each other.

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: Standards ASTM E119 and UL 263 are currently referenced in the I-codes.

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

ICCFILENAME: CRIMI-FS3-703.4

Public Hearing Results

Committee Action: Approved as Submitted

Committee Reason: The committee agreed that passive and active fire protection should not be used together, specific to ASTM E119 and UL263 testing. Further, code officials should not be attempting to determine if a proposed test completely meets the requirements of test methods ASTM E119 or UL263. Lastly, adhoc tests that combine active and passive systems are not prohibited and can be reviewed and approved by the code official as alternative methods under Section 104.11 of the code.

Assembly Action: None

Individual Consideration Agenda

These items are on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Jeffrey M. Shapiro, P. E., International Code Consultants, representing TYCO Fire Suppression and Building Products, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

703.4 Automatic sprinklers. Under the prescriptive fire resistance requirements of the *International Building Code*, ~~T~~the fire resistance rating of a building element, component or assembly shall be established without the use of automatic sprinklers or any other fire suppression system being incorporated as part of the assembly tested in accordance with the fire exposure, procedures, and acceptance criteria specified in ASTM E119 or UL 263. However, this section shall not prohibit or limit the duties and powers of the *building official* allowed by Sections 104.10 and 104.11.

Commenter's Reason: The additional text is a necessary clarification of the new section, and it is consistent with the committee's stated intent to not limit use of Section 104 for approving alternative methods on a case by case basis. The proponent of this code proposal also stated at the hearing that the addition of this section was clarification of the existing prescriptive code requirements for established fire-resistance test standards, and was not intended to usurp the ultimate authority of the code official's powers under Section 104, "Duties and Powers of Building Official".

Nevertheless, as the section is currently written, use of Section 104 would not be permissible since it would directly violate the requirements in Section 704.3. If the code says "you can't use sprinklers as part of the test criteria…period," then one can't simply go to Section 104 and count sprinklers. It is understood that having the code simply accept the use of fire sprinklers as a consideration in any fire resistance test is inappropriate, except on a case-by-case basis when approved by the Code Official, and for that reason, we are not opposing the intent of the proposal, just the text. With the recommended modifications, code application will be clarified in a manner that seems to satisfy all interests that were expressed in Baltimore.

Public Comment 2:

Gene Boecker, Code Consultants, representing The National Association of Theatre Owners, requests Disapproval.

Commenter's Reason: Although not mentioned by name in the reason statement, the obvious subject of this proposal is ICC ESR-2397. No official is forced to accept ESR-2397, because it does not constitute a listed assembly. It is a tested assembly that can be submitted to the code official for approval as an alternative method in accordance with Section 104.11. Section 104.11 specifically requires the submittal of research reports to assist the official in making a decision on the approval of a material or assembly.

The decision for many years was, appropriately, the code official's. Now the ability to selectively apply this alternative, at the official's discretion, will be taken away, despite the proponent's argument to the contrary.

Note that the proposal included no actual data regarding failures of this type of system. Also, note that the code itself allows sprinklered glazing in a number of applications (atrium enclosures, pedestrian walkway separations) as a direct equivalent method for fire resistive rated assemblies. These allowances have been in the codes for years and have not proven to be present an undue hazard.

This change, if allowed to move forward, will place a prohibition on a system that has been used successfully in jurisdictions across the country for many years. It will also create confusion for systems where sprinklers are specifically addressed, as noted above. Based on the language of ESR-2397and Section 104.11, in every case where this system has been used it was ultimately the official's decision that this system constituted an equivalent method for the protection of whatever building separation element the ESR-2397 compliant system was being proposed to protect.

Appropriate limitations on its use are therefore based on the reasonable consideration of the building official, regardless of the proposed use. Unfortunately, what this code change will do is take this decision away from the building official, and add language to the code that will inhibit any future development of this type of technology.

Final Action: AS AM AMPC____ D

FS5–09/10

703.4.1

Proposed Change as Submitted

Proponent: Richard Porter and Robert Sullivan, cfiFOAM, Inc., representing themselves

Revise as follows:

703.4.1 Elementary materials. Materials required to be noncombustible shall be tested in accordance with ASTM E 136.

Exception: Where foam plastic insulation is encased within either the core cells of concrete masonry wall assemblies or within the core spaces of precast hollow core concrete panel wall assemblies, the potential heat of the foam plastic insulation shall be determined in accordance with NFPA 259 and the results shall be expressed in Btu per square feet (MJ/m^2).

Reason: Section 2603 FOAM PLASTIC INSULATION makes no reference to ASTM E 136 but instead points to the significance of testing in accordance with NFPA 259 to measure the potential heat contribution of the foam plastic insulation incorporated into a wall or panel.

On one hand, NFPA 259 data shows that foam plastic insulation contributes very little fuel per square foot (MJ/W) of wall or panel area by virtue of its very low density; therefore, the presence of foam plastic insulation has little or no impact upon the fire resistance performance of a wall or panel assembly.

In measuring fuel contribution per wall or panel area, NFPA 259 data provides superior information vs. ASTM E 136 which provides only pass/fail criteria having to do with temperature rise and the fragility of foam plastic insulation.

On the other hand, foam plastic insulation offers resistance to heat flow as does any insulating material. By virtue of its encased presence within concrete masonry wall and precast concrete panel assemblies, the initial heat-up of assemblies exposed to fire is slightly retarded up to or until the point where the foam plastic insulation thermally degrades. This slight heat flow delay contributes slightly to the fire-rating of the wall assembly.

The positive contribution on the one hand is off-set by the negative contribution on the other hand.

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: Standard NFPA 259 is currently referenced in the I-codes.

ICCFILENAME: PORTER-SULLIVAN-FS1-703.4.1

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee agreed that Chapter 26 sufficiently deals with the requirements for foam plastic materials. Further, neither the proposed text nor the proposed test standard (NFPA 259) contains pass fail criteria. Therefore there is no guidance on what to do with the test results. Lastly, these requirements are in the wrong location as foam plastic materials are combustible materials.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Michael J. Wolfe, CE, M.J. Wolfe & Associates, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

703.4.1 Elementary materials. Materials required to be noncombustible shall be tested in accordance with ASTM E 136.

Exception: Where foam plastic insulation is encased within a wall assembly by noncombustible materials such as concrete and steel ~~either the core cells of concrete masonry wall assemblies or within the core spaces of precast hollow core concrete panel wall assemblies~~, the potential heat of the wall assembly ~~foam plastic insulation~~ shall be determined in accordance with NFPA 259 and the results shall be expressed in Btu per pound (kJ/kg). ~~square feet (MJ/m^2)~~

Commenter's Reason: This commenter agrees that the NFPA 259 test protocol should be used to determine the Potential Heat released by a building material and included under section 703.4 as an additional means of qualifying a building material as either a non-combustible, limited-combustible or combustible material. The NFPA 259 test expresses the Potential Heat of a particular material in btu/lb. and is a superior test method for proving combustibility and fire performance characteristics than the ASTM E-136 test, which provides only pass/fail criteria.

However, the commenter recommends that the test results be expressed in btu/lb, as per the NFPA 259 Standard Test Method for Potential Heat of Building Materials, which can then be converted to btu/sq. ft. by mathematical calculation.

Final Action: AS AM AMPC____ D

FS7-09/10
703.6

Proposed Change as Submitted

Proponent: Valarie Loper, City of North Las Vegas Building Safety

Revise as follows:

703.6 Marking and identification. Fire walls, fire barriers, fire partitions, smoke barriers, and smoke partitions or any other wall required to have protected openings or penetrations shall be effectively and permanently identified with signs or stenciling. Such identification shall:

1. Be located in accessible concealed floor floor-ceiling or attic spaces;
2. Be ~~repeated~~ located with in 15 feet (4572 mm) of the end of each wall and at intervals not exceeding 30 feet (9144mm) measured horizontally along the wall or partition; and
3. Included lettering not less than 3 inches (76 mm) ~~0.5 inch (12.7mm)~~ in height in a contrasting color incorporating the suggested wording. "FIRE AND/OR SMOKE BARRIER—PROTECT ALL OPENINGS" or other wording.

> **Exception:** Walls in Group R-2 occupancies that do not have a removable decorative ceiling allowing access to the concealed space.

Reason: I believe this is a needed code to assist in maintaining the integrity of fire resistive construction. The change to a larger size of3 Inches will better ensure that the lettering will be seen by the contractors and subcontractors that will be creating unprotected openings in protected assemblies. The contrasting color will regulate that the lettering be installed in a color that will contrast the base color of the assembly also ensuring a better chance of this identification being achieved. To install this lettering within 15 feet of the end of each wall will also aid in the ability of the persons remodeling the existing wall to be informed of the need to protect any openings made. The maintaining of a fire resistive assembly is as important as the creating of the assembly was to begin with.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: LOPER-FS1-703.6.doc

Public Hearing Results

Committee Action: **Approved as Modified**

Modify the proposal as follows:

703.6 Marking and identification. Fire walls, fire barriers, fire partitions, smoke barriers, and smoke partitions or any other wall required to have protected openings or penetrations shall be effectively and permanently identified with signs or stenciling. Such identification shall:

1. Be located in accessible concealed floor floor-ceiling or attic spaces;
2. Be located with in 15 feet (4572 mm) of the end of each wall and at intervals not exceeding 30 feet (9144mm) measured horizontally along the wall or partition; and
3. Included lettering not less than 3 inches (76 mm) in height with a minimum 3/8 inch (9.5 mm) stroke in a contrasting color incorporating the suggested wording. "FIRE AND/OR SMOKE BARRIER—PROTECT ALL OPENINGS" or other wording.

Exception: Walls in Group R-2 occupancies that do not have a removable decorative ceiling allowing access to the concealed space.

Committee Reason: The committee agreed that the closer spacing and larger letter height would aid in enforcement of these provisions. The modification provides for consistent letter sizing, which again will aid in enforcement of these provisions.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Lawrence G. Perry, AIA, representing Building Owners and Managers Association (BOMA) International requests Approval as Modified.

Further modify the proposal as follows:

703.6 Marking and identification. Fire walls, fire barriers, fire partitions, smoke barriers, and smoke partitions or any other wall required to have protected openings or penetrations shall be effectively and permanently identified with signs or stenciling. Such identification shall:

1. Be located in accessible concealed floor floor-ceiling or attic spaces;
2. Be located within 15 feet (4572 mm) of the end of each wall and at intervals not exceeding 30 feet (9144mm) measured horizontally along the wall or partition; and
3. Include lettering not less than <u>1 inch (25 mm)</u> ~~3 inches (76 mm)~~ in height ~~with a minimum 3/8" (9.5 mm) stroke~~ in a contrasting color incorporating the suggested wording. "FIRE AND/OR SMOKE BARRIER—PROTECT ALL OPENINGS" or other wording.

Exception: Walls in Group R-2 occupancies that do not have a removable decorative ceiling allowing access to the concealed space.

Commenter's Reason: The current code provision, new to the 2009 edition, requires 1/2" high characters. This code change increased the minimum height to 3". While this might make sense on a wall where the marking would be observed from a distance away (such as high on an exposed wall, or on a large exposed wall in an equipment room), the provision does not require the markings in locations likely to be viewed from any significant distance. The markings are required only in concealed spaces, where someone is likely to be poking their head up through an opening into a small space. The proposed modification for minimum 1" characters is more than adequate for the short viewing distance that will occur for these markings. With shorter character height, the stroke width issue is less critical, and becomes an unnecessary complication for what is supposed to be a simple marking.

Final Action: AS AM AMPC____ D

FS9-09/10
704.2, 704.3, 704.4

Proposed Change as Submitted

Proponent: Sam Francis representing American Forest & Paper Association

Revise as follows:

704.2 Column protection. Where columns are required to be fire-resistance rated, the entire column shall be provided individual encasement protection by protecting it on all sides for the full column length, including connections to other structural members, with materials having the required fire-resistance rating. Where the column extends through a ceiling, the encasement protection shall be continuous from the top of the foundation or floor/ceiling assembly below through the ceiling space to the top of the column.

<u>**Exception:** Columns complying with Section 602.4, 721.1 or 721.6.3</u>

704.3 Protection of the primary structural frame other than columns. Members of the primary structural frame other than columns that are required to have a fire-resistance rating and support more than two floors or one floor and roof, or support a load-bearing wall or a nonload-bearing wall more than two stories high, shall be provided individual encasement protection by protecting them on all sides for the full length, including connections to other structural members, with materials having the required fire-resistance rating.

Exception<u>s</u>:

<u>1.</u> Individual encasement protection on all sides shall be permitted on all exposed sides provided the extent of protection is in accordance with the required fire-resistance rating, as determined in Section 703.
<u>2.</u> <u>Members complying with Section 602.4, 721.1 or 721.6.3</u>

704.4 Protection of secondary members. Secondary members that are required to have a fire-resistance rating shall be protected by individual encasement protection, by the membrane or ceiling of a horizontal assembly in accordance with 712, or by a combination of both

704.4.1 Light-frame protection. King studs and boundary elements that are integral elements in load- bearing walls of light-framed construction shall be permitted to have required fire-resistance ratings provided by the membrane protection provided for the load-bearing wall.

<u>**704.4.2 Alternative protection.** Structural elements complying with Section 602.4, 721.1 or 721.6.3 shall not be required to comply with Section 704.4.</u>

Reason: Wood members of sufficiently large section to be considered heavy timber have never been required to be protected with a membrane in order to be considered heavy timber. There has been some confusion about the fire resistive properties of heavy timber as compared to the fire resistance of large members determined by the calculation methodology in Section 721. This confusion has led to a misapplication of Section 714 and its provision for protecting the member on all sides by materials having the required fire resistance. In the case of large wood members used in Type IV Construction as defined in Section 602.4, there is an inherent protection afforded the member by the char layer that forms as the timber is pyrolized. Table 601 recognizes this unique characteristic and distinguishes it from a fire resistance by utilizing the term “heavy timber” to describe this type of construction.

Moreover, the calculation methodology in Section 721 also relies on the insulating qualities of the char layer in order to calculate the size of member which will afford a sufficient sacrificial layer and still have adequate section to resist 100% of the required loads imposed on it. Accordingly, neither members complying with Section 602 nor members complying with Section 721 require further protection as required in Section 704. This code change is intended to make it clear that large wood members conforming to 602 or to 721 are not required to have this additional and redundant layer of protection.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: FRANCIS-FS2-704.2

<u>Public Hearing Results</u>

Committee Action: Disapproved

Committee Reason: The committee felt that these provisions were confusing and should be located in charging text rather than in an exception. Further, it would be more appropriate for the provisions to be located where the code addresses heavy timber construction.

Assembly Action: None

<u>Individual Consideration Agenda</u>

These items are on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Sam Francis, representing the American Wood Council/AF&PA, requests Approval as Modified by this Public Comment.

Replace the proposal as follows:

602.4.1 Columns. Wood columns shall be sawn or glued laminated and shall not be less than 8 inches nominal, in any dimension where supporting floor loads and not less than 6 inches nominal in width and not less than 8 inches nominal in depth where supporting roof and ceiling loads only. Columns shall be continuous or superimposed and connected in an approved manner. <u>Protection in accordance with Section 704.2 is not required</u>.

Commenter’s Reason: It is widely understood that heavy timber does not require the encapsulation required of columns in Section 704 in order to achieve its inherent fire performance. The committee believed that the notation that such protection was not required would be better placed in the Heavy Timber section. This comment proposes to place the language in the location and in the manner suggested by the Fire Safety Code Development Committee.

Public Comment 2:

Jonathan Humble, AIA, representing the American Iron & Steel Institute, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

704.2 Column protection. Where columns are required <u>to have protection</u> to be fire-resistance rated, the entire column shall be provided individual encasement protection by protecting it on all sides for the full column length, including connections to other structural members, with materials having the required fire-resistance rating. Where the column extends through a ceiling, the encasement protection shall be continuous from the top of the foundation or floor/ceiling assembly below through the ceiling space to the top of the column.

~~**Exception:** Columns complying with Section 602.4, 721.1 or 721.6.3~~

704.3 Protection of the primary structural frame other than columns. Members of the primary structural frame other than columns that are required to have protection to achieve a fire-resistance rating and support more than two floors or one floor and roof, or support a load-bearing wall or a nonload-bearing wall more than two stories high, shall be provided individual encasement protection by protecting them on all sides for the full length, including connections to other structural members, with materials having the required fire-resistance rating.

Exception~~s~~:

~~1.~~ Individual encasement protection on all sides shall be permitted on all exposed sides provided the extent of protection is in accordance with the required fire-resistance rating, as determined in Section 703.
~~2. Members complying with Section 602.4, 721.1 or 721.6.3~~

704.4 Protection of secondary members. Secondary members that are required to have a fire-resistance rating shall be protected by individual encasement protection, by the membrane or ceiling of a horizontal assembly in accordance with 712, or by a combination of both

704.4.1 Light-frame protection. King studs and boundary elements that are integral elements in load- bearing walls of light-framed construction shall be permitted to have required fire-resistance ratings provided by the membrane protection provided for the load-bearing wall.

~~**704.4.2 Alternative protection**. Structural elements complying with Section 602.4, 721.1 or 721.6.3 shall not be required to comply with Section 704.4.~~

Commenter's Reason: This public comment addresses the concerns of the Code Committee in terms of eliminating the confusing language, and placing the provisions in the charging text rather than in an exception.

The pubic comment also generalizes the original proposal FS9-09/10 to cover not only heavy timber structural members, but all structural members that do not need protection in order to achieve a fire-resistance rating. This would correct an existing conflict within the code language that requires encasement, membrane or ceiling protection regardless of whether the fire resistance rated design required any protection or not.

Approval of this modification would address many types of tested and fire-resistance rated constructions that achieve fire resistance ratings without protection, such as:

Unprotected heavy timber members, rated in accordance with IBC section 721,
Unprotected reinforced concrete members, rated in accordance with IBC section 721,
Steel columns complying with IBC Table 720.1(1) item 1-9.1,
Unprotected concrete-filled tubular steel columns complying with ASCE-29, Section 5.2.3,
Unprotected concrete over steel deck floors, tested and rated in accordance with ASTM E119, and listed by testing agencies.

Final Action: AS AM AMPC____ D

FS11–09/10
705.2, TABLE 705.2 (New)

Proposed Change as Submitted

Proponent: Gary Lampella, City of Redmond, OR, representing Oregon Building Officials Association

1. Revise as follows:

SECTION 705
EXTERIOR WALLS

705.2. Projections. Cornices, eave overhangs, exterior balconies and similar projections extending beyond the exterior wall shall conform to the requirements of this section and Section 1406. Exterior egress balconies and exterior exit stairways shall also comply with Sections 1019 and 1026, respectively. Projections shall not extend beyond the distance determined by the following ~~three~~ two methods, whichever results in the lesser projection:

1. A point one-third the distance ~~from the exterior face of the wall~~ to the lot line ~~where protected openings or a combination of protected and unprotected openings are required in the exterior wall~~ from an assumed vertical plane in accordance with Table 705.2.
~~2. A point one-half the distance from the exterior face of the wall to the lot line where all openings in the exterior wall are permitted to be unprotected or the building is equipped throughout with an automatic sprinkler system installed under the provisions of Section 705.8.2.~~
2 ~~3.~~ More than 12 inches (305 mm) into areas where openings are prohibited.
3. For the purposes of determining allowable projections from buildings, the assumed vertical plane shall be measured at right angles from the lot line or, for buildings on the same lot, an imaginary line in accordance

with Section 705.3. Buildings on the same lot and considered as portions of one building in accordance with Section 705.3 are not required to comply with this Section. The assumed vertical plane shall be parallel with the lot line or imaginary line.

2. Add new table as follows:

TABLE 705.2
ASSUMED VERTICAL PLANE (feet)

GROUP	TYPE I, II[a]	TYPE III, IV, V[a]
A, B, E, F-2, I, R, S-2, U	3	5[b]
M, S-1, F-1	5	10
H	15	20[c]

a. Based on type of construction in Chapter 6
b. I-2 occupancies are not permitted in Type VB construction
c. H-1 occupancies are not permitted in Type VB construction

3. Revise as follows:

705.2.3 Combustible projections. Combustible projections located ~~where openings are not permitted or where protection of openings is required~~ within 5 feet (1524 mm) of a lot line or imaginary line shall be of at least 1-hour fire-resistance-rated construction, Type IV construction, fire-retardant-treated wood or as required by Section 1406.3.

Exception: Type V construction shall be allowed for R-3 occupancies.

Reason: This code change is necessary to clarify how far projections from a building can extend into the fire separation distance. The purpose is to completely disassociate this section from Table 705.8. The proposal returns this section to its original intent to regulate projections based on occupancy and construction type that was a provision of a legacy code. This is recognizing that different occupancies of differing construction types present different levels of hazards. For instance, projections from an H-2 occupancy present a higher risk than projections from an S-1 occupancy and should be regulated as such. This section has been widely interpreted and misapplied.

The provision for projections in Section 705.2 is language from a legacy code that had definite measurements for when openings were required to be protected and when they were prohibited based on occupancy and construction type. With Section 705.8 and Table 705.8, the absolute measurement that was used in the previous legacy code is no longer present. This makes it very difficult to apply and has created inconsistency in application. There is different terminology between the IBC and the legacy code that does not allow the user to adequately apply this section.

The legacy code also stated that the assumed vertical plane for protection of openings was when they were "first" required to be protected. IBC Table 704.8 does not have a provision where you can definitely apply this assumed vertical plane. Utilizing the provisions of Equation 7-2 in Section 704.8.4 for a non-sprinklered M occupancy of IIIB construction 7 feet from the lot line if the combination of protected and unprotected was less than or equal to 1, there would be some required protected openings in the wall. But looking at the Table 704.8, protected openings could be required at 10 feet from the lot line using the same equation. Does one measure the distance from wall and its location in relation to the lot line or from the point at 10 feet where openings would have been required if they would have used the same equation? Or from some other assumed vertical plane?

The philosophy of this code change is to line up with the recent code changes that have occurred with the Table 508.4, Table 602 and other sections of the code that have based their merit on similar and dissimilar risks as well as similar fuel loads of occupancies. We have taken the approach of using Table 508.4, Table 602 and Table 706.4 to develop this language. As you can see, we tried to fit the occupancies and their exterior wall fire rating from Table 602 into this new table.

By putting some actual measurements into the code, we believe that this will vastly improve the application and consistency in which projections are regulated.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: LAMPELLA-FS1-705.2

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee felt that this proposal did not clarify the requirements for allowable projections. Further, the committee was concerned about the use of the term fire separation distance in that it seemed to conflict with the code-defined term.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Gary Lampella, City of Redmond, representing Oregon Building Officials Association, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

705.2. Projections. Cornices, eave overhangs, exterior balconies and similar projections extending beyond the exterior wall shall conform to the requirements of this section and Section 1406. Exterior egress balconies and exterior exit stairways shall also comply with Sections 1019 and 1026, respectively. Projections shall not extend beyond the distance determined by one of the following ~~two~~ three methods. ~~, whichever results in the lesser projection:~~

1. In buildings not equipped throughout with an automatic sprinkler system installed under the provisions of Section 705.8.2, ~~A~~ a point one-third the distance from the exterior face of the wall to the lot line where protected openings or a combination of protected and unprotected openings are required in the exterior wall. ~~from an assumed vertical plane in accordance with Table 705.2.~~
2. In buildings equipped throughout with an automatic sprinkler system installed under the provisions of Section 705.8.2, or where all openings in the exterior wall are permitted to be protected, a point one-half the distance from the exterior face of the wall to the lot line.

~~2.~~ 3. More than 12 inches (305 mm) into areas where openings are prohibited.

~~3. For the purposes of determining allowable projections from buildings, the assumed vertical plane shall be measured at right angles from the lot line or, for buildings on the same lot, an imaginary line in accordance with Section 705.3. Buildings on the same lot and considered as portions of one building in accordance with Section 705.3 are not required to comply with this Section. The assumed vertical plane shall be parallel with the lot line or imaginary line.~~

~~TABLE 705.2~~
~~ASSUMED VERTICAL PLANE (feet)~~

~~GROUP~~	~~TYPE I, II[a]~~	~~TYPE III, IV, V[a]~~
~~A, B, E, F-2, I, R, S-2, U~~	~~3~~	~~5[b]~~
~~M, S-1, F-1~~	~~5~~	~~10~~
~~H~~	~~15~~	~~20[c]~~

~~a. Based on type of construction in Chapter 6~~
~~b. I-2 occupancies are not permitted in Type VB construction~~
~~c. H-1 occupancies are not permitted in Type VB construction~~

705.2.3 Combustible projections. Combustible projections located where openings are not permitted or where protection of openings is required ~~within 5 feet (1524 mm) of a lot line or imaginary line~~ shall be of at least 1-hour fire-resistance-rated construction, Type IV construction, fire-retardant-treated wood or as required by Section 1406.3.

Exception: Type V construction shall be allowed for R-3 occupancies.

Commenter's Reason: I was the original proponent of the current code language in this section that was approved in Palm Springs, CA in 2008. I purposely put in the provision for buildings that had an automatic sprinkler system throughout under the provisions of Section 508.2. That section gave credit to buildings that where equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 and the exterior openings are protected by a water curtain using automatic sprinklers approved for that use. After reading the current code provisions and the requirement that projections are determined by the three methods, whichever results in the lesser projection, the second method could never be applicable because one-third is always going to be a lesser projection than one-half. This Public Comment is just to clarify the original intent of the code change.

The first method is applicable to buildings without the water curtains and sprinkler system and the second method is applicable to water curtains and sprinklers. The Table has been deleted and Section 705.2.3 has been returned to its original verbiage.

Analysis: Public comments to FS11 and FS12 propose differing revisions to Sections 705.2. The membership needs to make its preference clear with respect to these provisions. Further, public comments to FS11, FS12, and FS13 propose differing revisions to 705.2.3. The membership needs to make its preference clear with respect to these provisions.

Final Action: AS AM AMPC____ D

FS12-09/10
705.2, Table 705.2 (New), 705.2.3

Proposed Change as Submitted

Proponent: Stephen Thomas, Colorado Code Consulting, LLC representing the Colorado Chapter ICC

1. Revise as follows:

705.2 Projections. Cornices, eave overhangs, exterior balconies and similar projections extending beyond the exterior wall shall conform to the requirements of this section and Section 1406. Exterior egress balconies and exterior exit stairways shall also comply with Sections 1019 and 1026, respectively. ~~Projections shall not extend beyond the distance determined by the following three methods, whichever results in the lesser projection:~~ Projections shall not extend any closer to a lot line than permitted in Table 705.2.

Exception: Buildings on the same lot and considered as portions of one building in accordance with Section 705.3 are not required to comply with this section.

1. ~~A point one-third the distance from the exterior face of the wall to the *lot line* where protected openings or a combination of protected and unprotected openings are required in the *exterior wall*.~~
2. ~~A point one-half the distance from the exterior face of the wall to the *lot line* where all openings in the *exterior wall* are permitted to be unprotected or the building is equipped throughout with an *automatic sprinkler system* installed under the provisions of Section 705.8.2.~~
3. ~~More than 12 inches (305 mm) into areas where openings are prohibited. Buildings on the same lot and considered as portions of one building in accordance with Section 705.3 are not required to comply with this section.~~

2. Add new Table as follows:

Table 705.2
Minimum Distance of Projection from Lot Lines

Fire Separation Distance	Minimum distance from lot line
0 feet to less than 2 feet	Not Permitted
2 feet to less than 5 feet	24 inches
5 feet or greater	40 inches

3. Revise as follows:

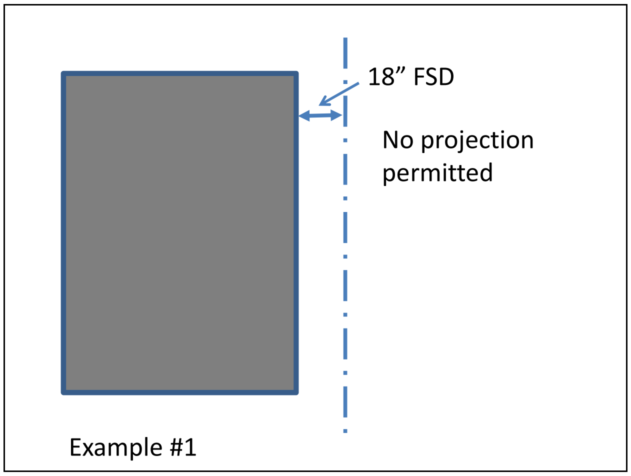
705.2.3 Combustible projections. Combustible projections ~~located where openings are not permitted or where protection of openings is required~~ extending to within 5 feet of the lot line shall be of at least 1-hour fire-resistance-rated construction, Type IV construction, fire-retardant-treated wood or as required by Section 1406.3.

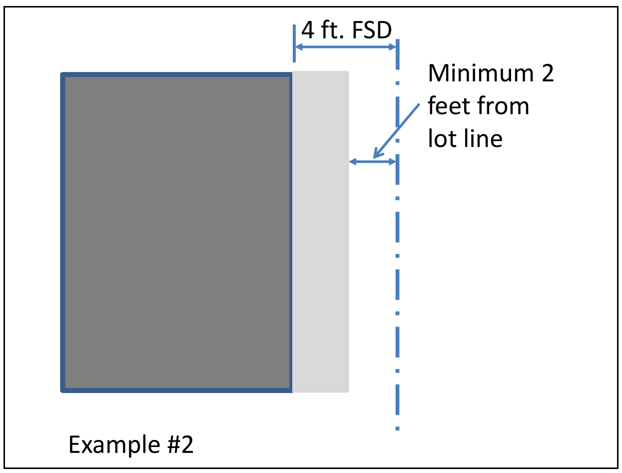
Exception: Type V construction shall be allowed for R-3 occupancies.

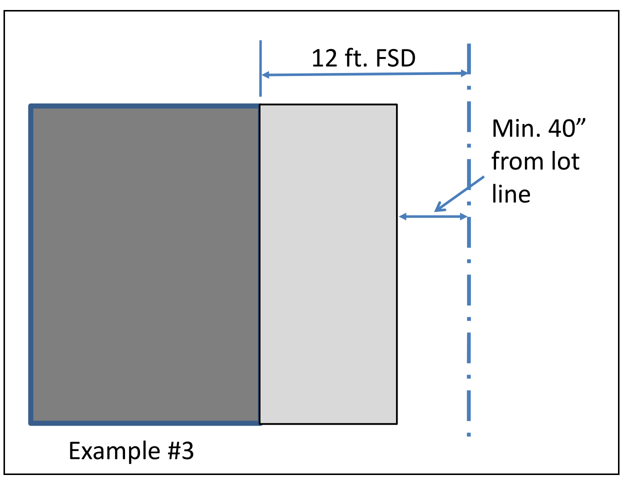
Reason: The current language outlining the requirements for projections is very confusing . Table 704.8 appears to have different distances where openings are required to be protected. However, when you really evaluate the table, the first option in Section 704.2 would occur at 5 feet (where openings are required to be protected) and the third option occurs at 3 feet (where openings are not permitted). The intent of this proposal is to simplify the requirement for determining the location of projections and when combustible projections are required to be protected. The proposal takes the language of the current first and third items and specifies the distance in a table format. The extent of the projection is now related to the fire separation distance. The 24-inch requirement is based on item 3 of the current language and the 40-inch requirement is based on option 1 of the current requirement.

Item 2 in the current language is confusing and actually makes the code more restrictive than the language in the 2006 IBC. For example if a building is located 22 feet from the lot line, the projection would only be allowed to extend to within 11 feet from the lot line. The 2006 IBC and this proposal would allow the projection to extend to a point no closer than 40 inches from the lot line. Therefore, the item has been deleted and not addressed in the table.

Examples of how this table would work are shown below.







Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: Code change proposals FS12, FS13 and FS14 propose revisions to Section 705.2.3. The committee needs to make its intent clear with respect to these revisions.

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: This proposal seems to allow for projections where the fire separation distance is 24 inches with no substantiation. Further, the committee was concerned about the use of the term fire separation distance in that it seemed to conflict with the code-defined term.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Stephen Thomas representing Colorado Chapter ICC, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

705.2 Projections. Cornices, eave overhangs, exterior balconies and similar projections extending beyond the exterior wall shall conform to the requirements of this section and Section 1406. Exterior egress balconies and exterior exit stairways shall also comply with Sections 1019 and 1026, respectively. ~~Projections shall not extend any closer to a lot line than permitted in Table 705.2.~~ Projections shall not extend any closer to the line used to determine the fire separation distance than shown in Table 705.2

> **Exception:** Buildings on the same lot and considered as portions of one building in accordance with Section 705.3 are not required to comply with this section.

Table 705.2 Minimum Distance of Projection ~~from Lot Lines~~

Fire Separation Distance (FSD)	Minimum distance from ~~lot line~~ line used to determine FSD
0 feet to less than 2 feet	Projections not permitted
2 feet to less than 5 feet	24 inches
5 feet or greater	40 inches

705.2.1 Type I and II construction. Projections from walls of Type I or II construction shall be of noncombustible materials or combustible materials as allowed by Sections 1406.3 and 1406.4.

705.2.2 Type III, IV or V construction. Projections from walls of Type III, IV or V construction shall be of any approved material.

705.2.3 Combustible projections. Combustible projections extending to within 5 feet of the ~~lot line~~ line used to determine the fire separation distance shall be of at least 1-hour fire-resistance-rated construction, Type IV construction, fire-retardant-treated wood or as required by Section 1406.3.

> **Exception:** Type V construction shall be allowed for R-3 occupancies.

Commenter's Reason: The intent of this proposal is to simplify the projection requirements in the code. Every time I meet with an architect or teach seminars on this subject, there is enormous confusion on what the projection section is saying. The current language is based on a legacy code that based the protection of exterior walls and associated openings on the occupancy and type of construction. The distances changed from occupancy to occupancy. The IBC does not base the protection on either. It bases it on the fire separation distance. Table 705.8 in the 2009 IBC makes the provisions even more confusing since it incorporates the sprinkler provisions in the code. The question that always comes up is "When are openings required to be protected?" and "When are openings not permitted?" The answer is they are required to be protected at 3-5 feet fire separation distance and prohibited at a 3 feet fire separation distance. So, if you use that premise, the current language allows the projection to extend 12 inches into the 3 foot fire separation distance or 1/3 the distance into the 5 foot separation distance which is 1 foot, 8 inches. That means that a projection cannot be any closer than 2 feet from or 3 feet, 4 inches (40 inches) from the interior lot line, the center of the street or the imaginary line between two buildings. What I did was take these answers an put them into a table.

The revision to Section 705.2.3 is the same. The current language states combustible projections have to be protected when openings are either not permitted or required to be protected. Again, where is that? The answer is again 5 feet because that is where openings are required to be protected. Therefore, the proposed language just states what the dimension is where the projection must be protected.

The committee was concerned that the provision would allow projections within 2 feet of a property line. The current language in the 2009 IBC does not permit projections within 2 feet of a property line. There was no intent of changing the requirements for these projections, only to clarify the current requirements. The table has been revised to specifically say that projections are not permitted when a building has a fire separation distance of less than 2 feet.

The committee was also confused about the use of the term fire separation distance in the table. The current code requirements are based on where opening are either prohibited or required to be protected in Section 705.8.1 and Table 705.8. The requirements in table 705.8 are based on the fire separation distance. Therefore, it seems logical that the dimension used in Table 705.8 be brought back into the projection section and the proposed table.

Analysis: Public comments to FS11 and FS12 propose differing revisions to Sections 705.2. The membership needs to make its preference clear with respect to these provisions. Further, public comments to FS11, FS12, and FS13 propose differing revisions to 705.2.3. The membership needs to make its preference clear with respect to these provisions.

Final Action: AS AM AMPC____ D

FS13-09/10
705.2.3

Proposed Change as Submitted

Proponent: Ali M. Fattah, City of San Diego, representing SD Area Chapter ICC Code Committee

Revise as follows:

705.2.3 Combustible projections. Combustible projections located where openings are not permitted, or where protection of openings is required or where a combination of protected and unprotected openings are required shall be of at least 1-hour fire-resistance-rated construction, Type IV construction, fire-retardant-treated wood or as required by Section 1406.3.

> **Exception:** Type VB construction shall be allowed for combustible projections in R-3 occupancies with a fire separation distance greater than or equal to 5 ft (1524 mm).

Reason: The proposed change adds clarity to the IBC. Code change FS14-07/08 amended Section 704.2 to improve the code section to make clear when the length of projections is to be limited due to fire separation; the section was brought to the IBC from a legacy Code that did not include table like Table 704.8 where the area of openings is limited and protected openings are an option to include more openings in a an exterior wall based on fire separation distance within ranges of distance. The initial portion of the code change merely continues the effort that was started in the prior code change cycle and extends the same logic to this Section. Using the word "location" makes clear that if the projection falls within the distance range it is subject to the requirement.

ICC has indicated that they believe that Code intends only portions of the eave extending into the regulated area to be protected since the protection is intended to prevent ignition; additionally the IBC in Table 602 requires measurement of fire separation perpendicular to the face of a wall so it is possible for portions of a wall at an angle to be connected to portions of a wall that are not protected. The proposed code change does not seek to make a change to current practice insofar as the extent of the protection along the projection is concerned.

The exception has been amended to require the same level of protection as the IRC and eliminates ambiguity as to whether rated or non rated projections are required. Table R302.1 of the 2009 IRC requires eaves located at a fire separation distance less than 5 ft to be protected with one-hour construction on the underside. Both the 2009 IRC ad 2009 IBC require sprinkler protection in R-3 occupancies so the codes should be comparable.

Without changing the exception, the code user could conclude that an exposed 12 inch long wood eave located within 24 inches from a lot line and supported on an exterior one hour rated wall located 3 ft from a lot line is permissible which makes no sense. The IBC and IRC have increased the level of exterior fire protection due to fire separation distance recognizing the vulnerability of least protected occupancies such R-3 from conflagration hazards.

Cost Impact: This proposal will minimally impact the cost of construction.

Analysis: Code change proposals FS12, FS13 and FS14 propose revisions to Section 705.2.3. The committee needs to make its intent clear with respect to these revisions.

ICCFILENAME: FATTAH-FS1-705.2.3

Public Hearing Results

Committee Action: **Approved as Modified**

Modify the proposal as follows:

705.2.3 Combustible projections. Combustible projections located where openings are not permitted, or where protection of openings is required or where a combination of protected and unprotected openings are permitted ~~required~~ shall be of at least 1-hour fire-resistance-rated construction, Type IV construction, fire-retardant-treated wood or as required by Section 1406.3.

> **Exception:** Type VB construction shall be allowed for combustible projections in R-3 occupancies with afire separation distance greater than or equal to 5 ft (1524 mm).

Committee Reason: The committee agreed that the proposal provides for coordination with Section 705.3 and Section 705.2.3 by including projections located where a combination of protected and unprotected openings are permitted. Further, the revisions to the exception clarify that the intent of the exception is not to allow a combustible projection within 24 inches of a lot line. Lastly, the modification provides for consistent code terminology.

Assembly Action: **None**

Individual Consideration Agenda

These items are on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Ali M. Fattah, P.E, City of San Diego, Development Services Department, representing San Diego Area Chapter of ICC, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

705.2.3 Combustible projections. Combustible projections located where openings are not permitted, or where protection of openings is required or where a combination of protected and unprotected openings are permitted shall be of at least 1-hour fire-resistance-rated construction, Type IV construction, *fire-retardant-treated wood* or as required by Section 1406.3.

Exception: Type VB construction shall be allowed for combustible projections in R-3 <u>and U</u> occupancies with a fire separation distance greater than or equal to 5 ft.

Commenter's Reason: The original code change inadvertently omitted Group U occupancies. The committee approved the code change with a modification to correct an error in the second sentence. Changes shown in double underline or double strike through were made by the committee or as a result of the correction shown in this public comment. We urge the voting governmental members support for this public comment. The "or where protection of openings is required or where a combination of protected and unprotected openings are permitted" had been added in the original code change as approved by the committee for consistency with the prior Section.

Public Comment 2:

Name: Maureen Traxler, representing City of Seattle Department of Planning & Development, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

705.2.3 Combustible projections. Combustible projections located where openings are not permitted~~,~~ or where protection of <u>some</u> openings is required ~~or where a combination of protected and unprotected openings are permitted~~ shall be of at least 1-hour fire-resistance-rated construction, Type IV construction, fire-retardant-treated wood or as required by Section 1406.3.

Exception: Type VB construction shall be allowed for combustible projections in R-3 occupancies with a fire separation distance greater than or equal to 5 ft (1524 mm).

Commenter's Reason:
Because protected openings are permitted wherever openings are allowed, the phrase "where a combination of protected and unprotected openings are permitted" actually means "where some percentage of openings are required to be protected and some unprotected openings are permitted." In the case of such a combination, some amount of protected openings are required so the second condition (where protection of openings is required) would apply. Therefore there is no need to indicate the combination as a separate condition.

Analysis: Public comments to FS11, FS12, and this public comment propose differing revisions to 705.2.3. The membership needs to make its preference clear with respect to these provisions.

Final Action: AS AM AMPC____ D

FS17–09/10
705.6

Proposed Change as Submitted

Proponent: Sam Francis representing American Forest & Paper Association

Revise as follows:

705.6 Structural stability. The wall shall extend to the height required by Section 705.11 and shall have sufficient structural stability such that it will remain in place for the duration of time indicated by the required fire-resistance rating. <u>Interior structural elements which brace the exterior wall but are not within the plane of the exterior wall nor on the outside of it shall have the fire resistance rating required by Table 601.</u>

Reason: This section of the code is a direct descendent of the following section of the BOCA National Building Code which read in part:

Section 302.2.3 Method 3: The fire resistance rated wall shall be so constructed that it will remain structurally in place against an exterior exposing fire, for the duration of time indicated by the required fire resistance rating.

The 2006 IBC, Section 714.5, required all load-bearing structural members located within an exterior wall or exterior to it (outside of the exterior wall meaning outdoor side, not the enclosed side) to have the higher of the fire resistance ratings required for that element in:

(1) Table 601;
(2) Table 601 for the exterior bearing wall; or,
(3) Table 602 based upon fire separation distance.

It may be inferred from this requirement that load-bearing structural members located internally within the building need only have the fire resistance rating required of them in Table 601. The fire resistance ratings for exterior walls are based upon exterior exposure or conflagration. Thus, it is not reasonable to assume that because an interior element braces, to any extent, an exterior wall that it follows that the bracing element interior to that exterior wall must then have the same fire resistance rating as the exterior wall. The 2009 IBC has this requirement relocated to 705.6 and the base fire resistance requirements were "mixed with fire separation distance requirements" so the base requirement is not so readily discernable.

This proposal would clarify the intent of Section 705.6. It is clear that the code has a long standing provision which permits the various elements of a building for a given construction type to have differing fire resistance ratings based upon the function of the individual element and the duration of time deemed necessary for that element to continue to perform that function.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: FRANCIS-FS1-705.6

Public Hearing Results

Committee Action: Disapproved

Committee Reason: The committee felt that referencing only Table 601 could lead to confusion, in that Table 602 should also be considered and may result in a higher fire resistance rating.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Sam Francis representing American Wood Council, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

705.6 Structural stability. The wall shall extend to the height required by Section 705.11 and shall have sufficient structural stability such that it will remain in place for the duration of time indicated by the required fire-resistance rating. Where exterior walls have a minimum fire separation distance of not less than 30 feet, interior structural elements which brace the exterior wall but which are not located within the plane of the exterior wall ~~nor on the outside of it~~ shall have the minimum fire resistance rating required in Table 601 for that structural element. Structural elements which brace the exterior wall but are located outside of the exterior wall or within the plane of the exterior wall shall have the minimum fire resistance rating required in Table 601 and Table 602 for the exterior wall.

Commenter's Reason: This section of the code is a direct descendent of the following section of the BOCA National Building Code which read in part:

Section 302.2.3 Method 3: The fire resistance rated wall shall be so constructed that it will remain structurally in place against an exterior exposing fire, for the duration of time indicated by the required fire resistance rating.

The 2006 IBC, Section 714.5 (now section 704.10 in IBC 2009) required all load-bearing structural members located within an exterior wall or exterior to it (outside of the exterior wall meaning outdoor side, not the enclosed side) to have the higher of the fire resistance ratings required for that element in:

(1) Table 601;
(2) Table 601 for the exterior bearing wall; or,
(3) Table 602 based upon fire separation distance.

It may be inferred from this requirement that load-bearing structural members located internally within the building need only have the fire resistance rating required of them in Table 601. The fire resistance ratings for exterior walls are based upon exterior exposure or conflagration. Thus, it is not reasonable to assume that because an interior element braces, to any extent, an exterior wall that it follows that the bracing element interior to that exterior wall must then have the same fire resistance rating as the exterior wall. The 2009 IBC has this requirement relocated to 705.6 and the base fire resistance requirements were "mixed with fire separation distance requirements" so the base requirement is not so readily discernable.

Following immediately in the 2009 IBC is 705.7 Unexposed surface temperature and then, later 705.11 Parapets. 705.7 specifically addresses the limitation on temperature rise on the unexposed surface of the exterior wall based on equivalent unprotected openings OR on fire separation distance. Fire separation distance is a response to exposure as indicated in the NBC section302.2.3 cited above. The conditions for parapets on exterior walls in 705.11 also is based on exposure.

This proposal would clarify the intent of Section 705.6. It is clear that the code has a long standing provision which permits the various elements of a building for a given construction type to have differing fire resistance ratings based upon the function of the individual element and the duration of time deemed necessary for that element to continue to perform that function. This means that any structural element interior to the exterior wall need only have the fire resistance rating of Table 601, Table 602 or an exterior wall for elements outside of the "unexposed face of the exterior wall".

Final Action: AS AM AMPC____ D

FS18–09/10
705.6

Proposed Change as Submitted

Proponent: Dennis Richardson PE, dbr group inc. representing self

Revise as follows:

705.6 Structural stability. The wall shall extend to the height required by Section 705.11 and shall have sufficient structural stability such that it will remain in place for the duration of time indicated by the required *fire-resistance rating*.

Exceptions:

1. Building elements providing out of plane structural stability for fire-resistance rated exterior walls shall be considered to remain in place for 2 hours if they are one hour fire resistance rated or heavy timber construction and the building is equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1.
2. Building elements providing out of plane structural stability for fire-resistance rated exterior walls shall be considered to remain in place for 2 hours if they are one hour fire resistance rated or heavy timber construction and the building is equipped with an automatic sprinkler system in accordance with Section 903.3.1.2 or 903.3.1.3 and the fire-resistance rated exterior wall conforms with any of the conditions listed in the exception to Section 705.11 for parapets.
3. Building elements providing out of plane structural stability for fire-resistance rated exterior walls shall be considered to remain in place for 1 hour in construction that is not otherwise fire-resistance rated if the building is equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1.
4. Building elements providing out of plane structural stability for fire-resistance rated exterior walls shall be considered to remain in place for 1 hour in construction that is not otherwise fire-resistance rated if the building equipped with an automatic sprinkler system in accordance with Section 903.3.1.2 or 903.3.1.3 and the fire-resistance rated exterior wall conforms with any of the conditions listed in the exception to Section 705.11 for parapets.

Reason: Section 705.6 which requires structural stability of exterior fire resistance rated walls is rarely, if ever, enforced because it provides no criteria for "sufficient structural stability" and does not consider protection to supporting elements provided in part by automatic sprinkler systems and partially by passive fire resistance. An informal phone survey of a number of building officials and code consultants including review of numerous interpretation manuals did little to shed light on the application of this section. Lack of enforcement and a wide range of interpretations justifies this section needs to be clarified or removed from the code.

The proposed exceptions are superior to the existing code language because they provide a prescriptive way to address the intent of this code section giving credit to the combination of fire sprinklers and passive fire resistance of one hour fire restive or heavy timber construction. Credit is given for NFPA 13 systems referenced in 903.3.1.1 and NFPA 13R or 13D systems referenced in 903.3.1.2 or 903.3.1.3 of the IBC.

Footnote c. of Table 601 refers to heavy timber construction as an equivalent to one hour fire resistance rated construction.

Footnote d. of table 601 allows non rated construction with a NFPA 13 sprinkler system throughout to be substituted for 1-hour fire-resistance rated construction provided the system is not otherwise required by the other provisions of the code or used for an allowable area increase in accordance with Section 506.3 or an allowable height increase in accordance with Section 504.2. Footnote c. goes on to state the 1-hour substitution for the fire resistance of exterior walls is not permitted.

This proposed code change does not provide an exception to the fire resistance rating for the exterior wall itself or for the elements providing vertical support of the wall. The code proposal only clarifies the anticipated effectiveness and required protection of secondary structural elements providing out of plane stability for the fire resistance rated exterior wall. As such the proposed use of the proposed exceptions would not disqualify the use of sprinklers for allowable area or height increases.

This proposed code change relies on NFPA 13R and 13D sprinkler systems when used for residential construction. It is acknowledged these systems are based on lower water flow than a NFPA 13 system and do not require sprinkler heads in attic areas. However residential construction typically is highly compartmentalized typically with one hour construction between multi-family units and noncombustible interior finish materials and a great deal of structural redundancy. Because of the lack of sprinkler heads in attic areas, the proposed exceptions as written for 13R and 13D systems only apply if the fire-resistance rated exterior wall conforms with any of the conditions listed in the exception to Section 705.11 for elimination of parapets. These exceptions for parapets either rely on additional passive fire resistance in lieu of a parapet or are limited by size or location of the structure.

In addition to this change, a proposal is also being submitted to add Section 1604.14 to establish out of plane structural design criteria for the instances where these exceptions would not apply.

The author of this proposed code change acknowledges there is little data or full scale research to specifically address this issue however the current code language provides absolutely no basis or guidance whatsoever as to the intent or application of this code section. Because of the wide variety of configurations materials and conditions and the need to show performance of structural stability during a wide variety of fire conditions, it is not clear how a structural engineer would provide a rational analysis if requested under the present code language.

Because of this Section 705.6 appears to be almost universally ignored by designers and code officials alike. At a minimum, this code change proposal is intended to provide a reasonable basis (or at minimum a starting point for a healthy discussion) for consistent application and enforcement acknowledging the contributions of both active systems and passive fire-resistance construction.

Cost Impact: Since the proposed code change incorporates exceptions to be utilized if desired by the designer, it is anticipated this change would result in a cost savings.

ICCFILENAME: RICHARDSON-FS1-705.6

Public Hearing Results

Committee Action: Disapproved

Committee Reason: The committee felt more substantiation was required to justify this sprinkler trade-off and to clarify why in some cases an NFPA 13R or NFPA 13D system are considered appropriate protection to allow the trade-off.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Dennis Richardson PE, CBO, Building Official, City of Salinas, representing self, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

705.6 Structural stability. The wall shall extend to the height required by Section 705.11 and shall have sufficient structural stability such that it will remain in place for the duration of time indicated by the required *fire-resistance rating*.

Exceptions:

1. Building elements providing out of plane structural stability for fire-resistance rated exterior walls shall be considered to remain in place for 2 hours if they are one hour fire resistance rated or heavy timber construction and the building is equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1.
~~2. Building elements providing out of plane structural stability for fire-resistance rated exterior walls shall be considered to remain in place for 2 hours if they are one hour fire resistance rated or heavy timber construction and the building is equipped with an automatic sprinkler system in accordance with Section 903.3.1.2 or 903.3.1.3 and the fire-resistance rated exterior wall conforms with any of the conditions listed in the exception to Section 705.11 for parapets.~~
2. ~~3.~~ Building elements providing out of plane structural stability for fire-resistance rated exterior walls shall be considered to remain in place for 1 hour in construction that is not otherwise fire-resistance rated if the building is equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1.
~~4. Building elements providing out of plane structural stability for fire-resistance rated exterior walls shall be considered to remain in place for 1 hour in construction that is not otherwise fire-resistance rated if the building equipped with an automatic sprinkler system in accordance with Section 903.3.1.2 or 903.3.1.3 and the fire-resistance rated exterior wall conforms with any of the conditions listed in the exception to Section 705.11 for parapets.~~

Commenter's Reason: Section 705.6 requires exterior fire resistance rated walls to have sufficient structural stability to keep the exterior wall in place for the duration of the fire resistance rating of the wall. The code gives no criteria for "sufficient structural stability" and does not consider protection to supporting elements provided in part by automatic sprinkler systems and partially by passive fire resistance.

Since horizontal floor and roof diaphragms and perpendicular structural walls or frames typically provide out of plane structural stability for exterior walls, Section 705.6 would require them to continue to provide out of plane bracing for the wall for the same duration as the wall. In the case of two hour exterior walls, these elements providing out of plane bracing would need to be themselves rated for two hours or the wall would need to be designed to stand on it's own and remain stable out of plane for the duration of the rating of the exterior wall.

An informal phone survey of a number of building officials and code consultants including review of numerous interpretation manuals did little to shed light on the application of this section. Lack of enforcement and a wide range of interpretations justifies this section needs to be clarified in the code or practical alternatives identified. In cases where the building department did enforce the letter of the code, the staff at the department described a difficult argument and typically some sort of alternate method being utilized. This is especially true with multiple story buildings with two hour exterior walls.

A strict reading of this code section would practically prohibit Type II and III construction since one hour or non rated roof-ceiling and floor-ceiling assemblies would not remain in place for the duration of the two hour exterior wall rating.

A similar situation would affect exterior fire resistance rated walls parallel to the property line and perpendicular to the storefront for infill construction in any city. Table 602 requires the exterior fire rated wall within five feet of the property line to be 2 hour fire resistant rated for M, F1 and S1 occupancies regardless of the type of construction.

How many jurisdictions are requiring the floor-ceiling and roof-ceiling assembly providing out of plane support to be rated 2 hours in this condition?

This code change proposal would deem a one hour rated roof-ceiling assembly and/or floor-ceiling to be acceptable in a building that is protected throughout by a NFPA 13 sprinkler system. It would also accept non-rated framing providing out of plane support to a one hour wall if the building is protected throughout by a NFPA 13 sprinkler system.

Similar exceptions utilizing NFPA 13R and 13D systems (with limitations) have been removed from this proposal due to concerns about water supply and the placement of head in these life-safety systems.

The proposed exceptions are superior to the existing code language because they provide a prescriptive way to address the intent of this code section giving credit to the combination of fire sprinklers working together with passive fire resistance of one hour fire restive or heavy timber construction.

Footnote c. of Table 601 refers to heavy timber construction as an equivalent to one hour fire resistance rated construction.

Footnote d. of table 601 allows non rated construction with a NFPA 13 sprinkler system throughout to be substituted for 1-hour fire-resistance rated construction provided the system is not otherwise required by the other provisions of the code or used for an allowable area increase in accordance with Section 506.3 or an allowable height increase in accordance with Section 504.2. Footnote c. goes on to state the 1-hour substitution for the fire resistance of exterior walls is not permitted.

This proposed code change does not provide an exception to the fire resistance rating for the exterior wall itself or for the elements providing vertical support of the wall. The code proposal only clarifies the anticipated effectiveness and required protection of secondary structural elements providing out of plane stability for the fire resistance rated exterior wall. As such the use of the proposed exceptions would not disqualify the use of sprinklers for allowable area or height increases.

The author of this proposed code change acknowledges there is little data or full scale research to specifically address this issue however the current code language provides absolutely no basis or guidance whatsoever as to the intent or application of this code section. The requirement of 705.6 was not found in two of the three legacy codes and it appears no justification or testing was utilized to put this in the code. Common sense and reason by code officials should conclude that a two hour wall braced out of plane by a one hour roof-ceiling assembly in a fully sprinklered building does not pose a threat of collapse to fire fighters or a threat to the adjacent building.

In Summary this code change as modified by public comment provides reasonable relief from an unreasonable and often ignored code requirement that had its origins in only one of three legacy codes.

Final Action: AS AM AMPC____ D

FS20-09/10
705.8.6

<u>Proposed Change as Submitted</u>

Proponent: Homer Maiel, PE, CBO, City of San Jose**,** representing ICC Tri-Chapter (Peninsula, East Bay, Monterey Bay)

Revise as follows:

705.8.6 Vertical exposure. <u>Opening protectives of buildings shall comply with this section.</u>

<u>705.8.6.1</u> Vertical exposure <u>for buildings on the same lot</u>. For buildings on the same lot, opening protectives having a *fire protection rating* of not less than 3/4 hour shall be provided in every opening that is less than 15 feet (4572 mm) vertically above the roof of an adjacent building or structure based on assuming an imaginary line between them. The opening protectives are required where the *fire separation distance* between the imaginary line and the adjacent building or structure is less than 15 feet (4572 mm).

Exceptions:

1. Opening protectives are not required where the roof assembly of the adjacent building or structure has a fire-resistance rating of not less than 1 hour for a minimum distance of 10 feet (3048 mm) from the exterior wall facing the imaginary line and the entire length and span of the supporting elements for the fire-resistance-rated roof assembly has a fire-resistance rating of not less than 1 hour.
2. Buildings on the same lot and considered as portions of one building in accordance with Section 705.3 are not required to comply with Section 705.8.6<u>.1</u>.

<u>**705.8.6.2 Vertical exposure for buildings on separate lots.** When a new building or an addition is to be erected adjacent to an existing building, all openings in the exterior wall of the new building or addition are required to be not less than ¾ hour protectives when these openings are less than 15' vertically above the roof of the existing building or structure. The opening protectives are required where the distance between buildings or structures is less than 15' feet. When the roof of the new building or an addition is at lower elevation from the existing building, the roof construction of the new building or the addition shall have fire-resistance rating of not less than 1 hour for a minimum distance of 10 feet (3048 mm) from the exterior wall facing the existing building and the entire length and span of the</u>

supporting elements for the fire-resistance-rated roof assembly shall have a fire-resistance rating of not less than 1 hour. The roof protections are required where the distance between the buildings or structures is less than 15' feet.

Reason: A fire in a lower building that is adjacent to a taller building can be a source of fire exposure to openings in the taller building. Since fire does not differentiate between buildings on same lot or separate adjacent lots, the existing provisions for buildings on the same lot need to be expanded to cover buildings on separate lots too. The requirements for the buildings on the separate lots should not be different from those on the same lot. The buildings on the same lots are under one ownership and the imaginary property lines can be moved so that it will serve all buildings in the most efficient way.

On the other hand, the buildings on separate lots are under different ownerships. The property lines are legal property lines and can not be moved around. An existing building on one site should not dictate the design and construction of the future building nor a future building should not alter the design and construction of an existing building. In other words, between two neighboring buildings, whichever is built last will need to comply with requirements of this section. The 15-foot separation requirement between buildings on the separate lots, is consistent with the same requirement for buildings on the same lot.

Also not to leave out the additions to existing buildings, additions are also included in these requirements. So for the sake of argument, imagine that there are two existing buildings, with same height, on separate lots. If one building is adding more stories, then these requirements could apply to the windows of new stories.

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: Code change proposals FS20 and FS21 propose similar requirements for vertical exposure for buildings on separate lots. The committee needs to make its intent clear with respect to these revisions.

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The proposal is impractical to enforce based on verification of the conditions of an existing building. Further, the language is confusing in that it could be interpreted to be more restrictive for buildings on the same lot than for buildings on separate adjacent lots.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Homer Maiel, PE, CBO, City of San Jose, representing ICC Tri-Chapter (Peninsula, East Bay, Monterey Chapters), requests Approval as Submitted.

Commenter's Reason: In Baltimore, the committee disapproved the proposal stating; "The proposal is impractical to enforce based on verification of the conditions of an existing building." It is unfortunate that this misconception was not clarified during the testimony before the committee, but the way the proposal is written there is NO requirement to obtain or verify ANY information regarding the construction of the neighboring existing building. Instead, only dimensional information is necessary. The two pieces of information needed to apply this provision are the horizontal distance between the new and existing buildings, and a vertical distance between the roof of the lower building (new or existing) and openings in the exterior wall of the neighboring building (new or existing). In addition, only the new building or new addition to an existing building must comply with the construction requirements of this provision.

If the new building or the addition is taller than the neighboring existing building, then the windows of the new building or the addition will need to be rated; irregardless of the type of the roof the existing neighboring building has. If the new building or the addition to an existing building is lower in height than the neighboring existing building, then the roof of the new building or the roof of the addition to an existing building will have to comply with these requirement; irregardless of the ratings of the windows on the existing neighboring building. No verification of the construction of the roof or windows, or any other portion of an existing building are necessary to apply these provisions.

To explain the paragraph above, a graphical illustration is presented. In Fig. 1, a multi story building is erected adjacent to a property which has an existing one-story building. A real, legal property line is shown as "PL". In this situation if L is less than 15', any openings in the new building (wall facing the PL) that are less than 15' (dimension H) above the roof of the existing building, are required to be rated not less than ¾ hour. In Fig. 2, a new one-story building is erected next to an existing multi-story building. If L is less than 15'and there are openings in the existing building that are less than 15' (H dimension) above the roof of the new building, the roof of the new building is required to be minimum 1 hour construction for at least 10' from the exterior wall (X dimension). In Fig. 3, an addition, in form of more stories, is made to an existing building. This creates the same situation as Fig 1. In Fig. 4, an addition is made to a single story building that is adjacent to an existing multi-story building. This creates the same situation as Fig. 2.

As it can be seen from these cases, at no time verification of the conditions of an existing building is warranted. Only dimensions L and H need to be established.

Analysis: Public comments to FS20 and FS21 contain similar provisions for vertical exposure for buildings on the same lot. The membership needs to make its preference clear with respect to these provisions.

Final Action: AS AM AMPC____ D

FS21-09/10
705.8.6, 705.8.6.1 (New), 705.8.6.2 (New)

Proposed Change as Submitted

Proponent: Gary Lampella, City of Redmond, Oregon, representing: Oregon Building Officials Association

Revise as follows:

705.8.6 Vertical exposure. <u>Opening protectives of buildings shall comply with this section.</u>

<u>705.8.6.1</u> Vertical exposure <u>for buildings on the same lot</u>. For buildings on the same lot, opening protectives having a fire protection rating of not less than 3/4 hour shall be provided in every opening that is less than 15 feet (4572 mm) vertically above the roof of an adjacent building or structure based on assuming an imaginary line between them. The opening protectives are required where the ~~fire separation~~ distance between the ~~imaginary line and the adjacent~~ building**<u>s</u>** or structure**<u>s</u>** is less than 15 feet (4572 mm).

Exceptions:

1. Opening protectives are not required where the <u>lower</u> roof assembly of the adjacent building or structure has a fire-resistance rating of not less than 1 hour for a minimum distance of 10 feet (3048 mm) from the exterior wall facing the imaginary line and the entire length and span of the supporting elements for the fire-resistance-rated roof assembly has a fire-resistance rating of not less than 1 hour.
2. Buildings on the same lot and considered as portions of one building in accordance with Section 704.3 are not required to comply with Section 704.8.6.

<u>705.8.6.2 Vertical exposure for buildings on separate lots.</u> <u>When a new building is to be erected adjacent to an existing building, all openings in the exterior wall of the new building are required to be not less than ¾ hour when these openings are less than 15 feet (4572 mm) vertically above the roof of existing building or structure. The opening protectives are required where the distance between the buildings or structures is less than 15 (4572 mm) feet. When the roof of the new building is at lower elevation from the existing building, the roof construction of the new building shall have fire-resistance rating of not less than 1 hour for a minimum distance of 10 feet (3048 mm) from the exterior wall facing the new building and the entire length and span of the supporting elements for the fire-resistance-rated roof assembly shall have a fire-resistance rating of not less than 1 hour. The roof protections are required where the distance between the buildings or structures is less than 15 feet (4572 mm).</u>

Reason: I was the original proponent in Palm Springs of a similar proposal that was approved by the Fire Safety Committee. The Committee agreed that buildings with a real property line should be treated the same as two buildings on the same lot in regards to vertical fire exposure. In Minneapolis there was a Public Comment submitted pointing out some flaws in the code change. Rather than attempt to keep it in the code I opted to ask ICC staff to simply withdraw it and I would work with the author of the Public Comment and come back with a new proposal in Baltimore.

The purpose of this submittal is clean up inconsistent provisions between buildings on the same lot with an imaginary line for fire separation distance and the lack of the same provision for buildings on adjacent lots with real property lines. The purpose of assuming an imaginary line between buildings on the same lot is to mirror the fire separation distance of those buildings with actual property lines and determining opening and wall protection. Currently, the provisions of buildings on the same lot with an imaginary line have more restrictive requirements than those buildings with a real line.

If one is concerned about fire spread from one building to another, should the provisions be the same for a real lot line as opposed to an imaginary one? Yes, we believe so. The probability of a fire spreading from one building to another via openings and fire separation distance to other buildings is the same regardless of real or imaginary lines. Based on the current code language, we can only assume that a recorded property line somehow adds an additional level of protection over and above an imaginary one.

We have divided this Section into three parts now. We are proposing to delete the language “imaginary line and the adjacent” in the Section 704.8.6.1 because it only addresses the fire separation for one building and ignores the other. There are many reasons to have fire separation from an imaginary line at different place and one building may have less than 15 feet of fire separation distance and the other may have 20. In this case the lower roof would be required to have a 1 hour roof assembly, which doesn’t make sense. The reference to “fire separation” is being deleted because we believe the crucial distance is the true distance between the buildings, which clears up the confusion over where the measurement is taken. We have also added the word “lower” in the first exception to make it clear that it is the lower roof that is required to be of 1 hour fire-resistive construction. Lastly, we have created a new Subsection 704.8.6.2 to address buildings and structures with real property lines.

Cost Impact: The code change proposal will not increase the cost of construction. There could be some minimal costs in providing the 1 hour roof assemblies.

Analysis: Code change proposals FS20 and FS21 propose similar requirements for vertical exposure for buildings on separate lots. The committee needs to make its intent clear with respect to these revisions.

ICCFILENAME: LAMPELLA-FS2-704.8.6

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The proposal is impractical to enforce based on verification of the conditions of an existing building. Further, the language is confusing in that it could be interpreted to be more restrictive for buildings on the same lot than for buildings on separate adjacent lots. Also, Section 705.8.6.1 appears to reduce the distance between buildings from 30 feet to 15 feet without technical justification.

Assembly Action: **None**

Individual Consideration Agenda

These items are on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Gary Lampella, City of Redmond, representing Oregon Building Officials Association, requesting Approval as Modified by Public Comment.

Modify the proposal as follows:

~~**705.8.6 Vertical exposure.** Opening protectives of buildings shall comply with this section.~~

705.8.6.~~1~~ Vertical exposure for buildings on the same lot. For buildings on the same lot, opening protectives having a fire protection rating of not less than 3/4 hour shall be provided in every opening that is less than 15 feet (4572 mm) vertically above the roof of an adjacent building or structure based on assuming an imaginary line between them. The opening protectives are required where the aggregate fire separation distance between the imaginary line and the adjacent buildings or structures is less than ~~15~~ 30 feet (~~4572~~ 9144 mm).

Exceptions:

1. Opening protectives are not required where the lower roof assembly of the adjacent building or structure has a fire-resistance rating of not less than 1 hour for a minimum distance of 10 feet (3048 mm) from the exterior wall facing the imaginary line and the entire length and span of the supporting elements for the fire-resistance-rated roof assembly has a fire-resistance rating of not less than 1 hour.
2. Buildings on the same lot and considered as portions of one building in accordance with Section 704.3 are not required to comply with Section 704.8.6.

705.8.6.1 ~~2~~ Vertical exposure for buildings on separate lots. When a new building is to be erected adjacent to an existing building on a separate lot, opening protectives having a fire protection rating of not less than 3/4 hour shall be provided in every opening that is less than 15 feet (4572 mm) vertically above the roof of the existing building. ~~all openings in the exterior wall of the new building are required to be not less than ¾ hour when these openings are less than 15 feet (4572 mm) vertically above the roof of existing building or structure.~~ The opening protectives are required where the aggregate fire separation distance between the buildings or structures and the lot line is less than ~~15~~ 30 (~~4572~~ 9144 mm) feet. When the roof of the new building is at lower elevation from the existing building, the roof construction of the new building shall have fire-resistance rating of not less than 1 hour for a minimum distance of 10 feet (3048 mm) from the exterior wall facing ~~the new building~~ the lot line and the entire length and span of the supporting elements for the fire-resistance-rated roof assembly shall have a fire-resistance rating of not less than 1 hour. The roof and supporting element protection~~s~~ are required where the aggregate fire separation distance between the buildings or structures and the lot line is less than ~~15~~ 30 feet (~~4572~~ 9144 mm).

Commenter's Reason: The Fire Safety Committee in Baltimore disapproved this code change based on three concerns.
1) was that it was impractical to enforce based on verification of the conditions of an existing building; and
2) the language is confusing in that it could be interpreted to be more restrictive for buildings on the same lot than for buildings on separate adjacent lots; and,
3) Section 705.8.6.1 appears to reduce the distance between buildings from 30 feet to 15 feet without technical justification.

The purpose of this submittal is clean up inconsistent provisions between buildings on the same lot with an imaginary line for fire separation distance and the lack of the same provision for buildings on adjacent lots with real property lines. The purpose of assuming an imaginary line between buildings on the same lot is to mirror the fire separation distance of those buildings with actual property lines and determining opening and wall protection. Currently, the provisions of buildings on the same lot with an imaginary line have more restrictive requirements than those buildings with a real line.

If one is concerned about fire spread from one building to another, should the provisions be the same for a real lot line as opposed to an imaginary one? Yes, we believe so. The probability of a fire spreading from one building to another via openings and fire separation distance to other buildings is the same regardless of real or imaginary lines. Based on the current code language, we can only assume that a recorded property line somehow adds an additional level of protection over and above an imaginary one.

The change to Section 705.8.6 is to clean up very confusing language. The change makes the fire separation distance determination by measuring the aggregate or total of the distances of the two buildings to the imaginary line, regardless of where that imaginary line is placed. Currently, you could have the buildings separated by 40 plus feet but because of design considerations and site constraints, you could have the imaginary line less than 15 feet from the adjacent building and the other building 30 feet from the imaginary line, and you would still have to rate the windows or roof without the proposed type of measurement, simply because the code only requires measurement of one building. If you read the code carefully, you realize that the lower elevation building is always the adjacent building. Changing the way you determine the fire separation distance to the aggregate of both buildings, meets the intent of what we believe this section intended. Currently, we believe the code could be overly restrictive in some cases (See Examples 1, 2 and 3)

The new modified language in Section 705.8.6.1 addresses the committee's concerns (See Examples 4 and 5).

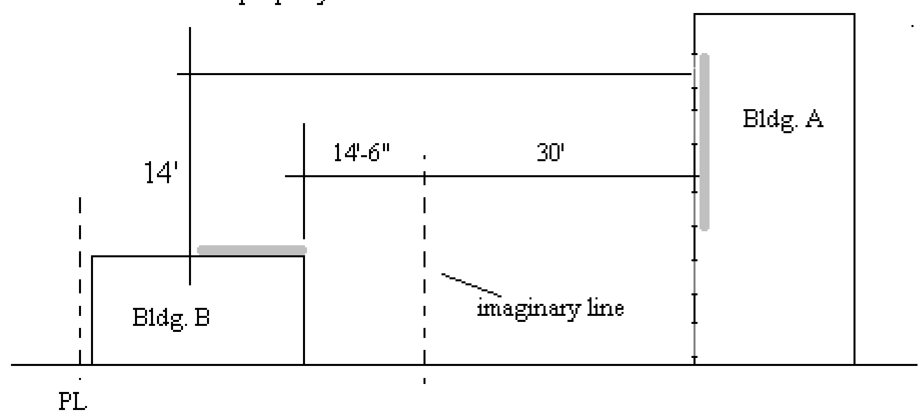
1) The code change as written is not impractical to enforce based on verification of the conditions of an existing building.
The code change identifies the fire resistive application is only applicable to the proposed newer building. It does not require the existing building to be upgraded in any way. The first part of Section 705.8.6.1 tells the user that if a new building is proposed and has openings that are less than 15 feet (4572 mm) vertically above the roof of existing building or structure on an adjacent lot, and the aggregate fire separation distance to the lot line of both buildings is less than 30 feet, then opening protectives are required. If the proposed building is has a roof height lower that the existing building, then roof protection and supporting elements are required for 10 feet from the wall facing the lot line. Both of these conditions use the same criteria as buildings on the same lot in Section 705.8.6.

2) The modification cleans up the language and is clear that provisions for buildings on the same lot are identical to those of buildings on separate adjacent lots.

3) The distance between buildings was indeed reduced to 15 feet in the initial proposal. We have modified the code change to clearly indicate that the fire separation distance should be 30 feet. We have modified the way it is measured to make easier to enforce and easier to interpret and apply. The measure between the buildings is now the <u>aggregate</u> or <u>total</u> of the measurements between the two buildings, which is 30 feet.

Of course, other provisions of the code may require protected openings other than these section.

Bldg. A is non-sprinklered and needs 30 feet of separation to keep glazing. Building B has site constraints because of a property line.

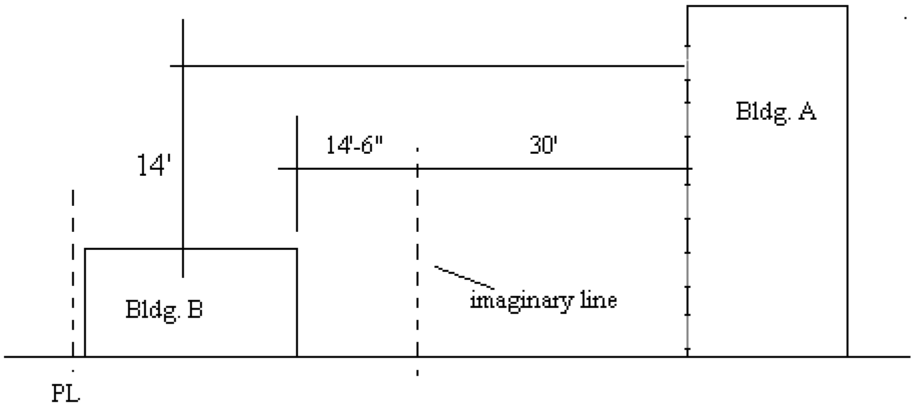


Current code language would require either to opnings in Building A, or the roof of Building B to be protected because Building B is the adjacent building.

Current code language has only one measurement, that of the separation distance to the adjacent building. So since the measurement to Bldg. B (adjacent building) is less than 15 feet, then the code provisions apply regardless of how far Bldg. A is from the imaginary line.

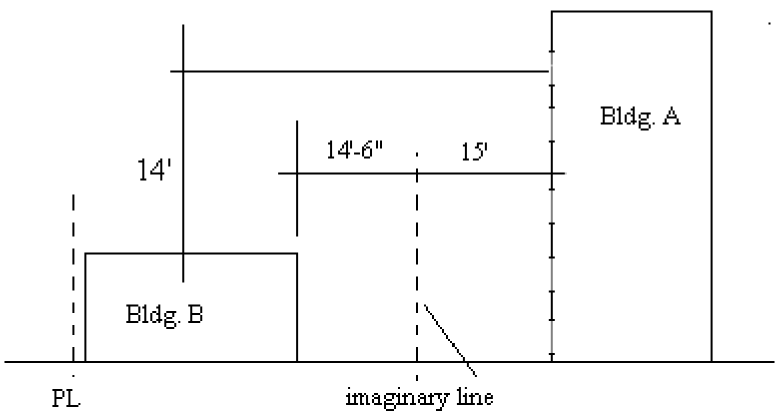
EXAMPLE 1
BUILDINGS ON THE SAME LOT
CURRENT LANGUAGE

Bldg. A is non-sprinklered and needs 30 feet of separation to keep glazing. Building B has site constraints because of a property line.



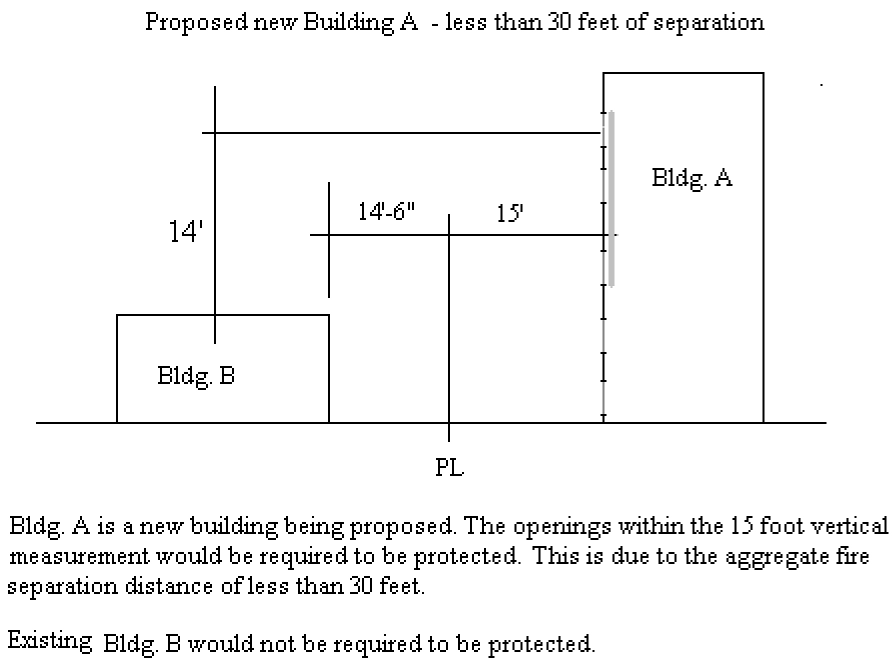
Proposed code language would have no requirements for protection of either the galzing or the roof under Section 705.8.6. This is because the aggregate fire separation distance of the two buildings is not less than 30 feet.

EXAMPLE 2
BUILDINGS ON THE SAME LOT
PROPOSED LANGUAGE
30 FEET OR MORE OF SEPARATION

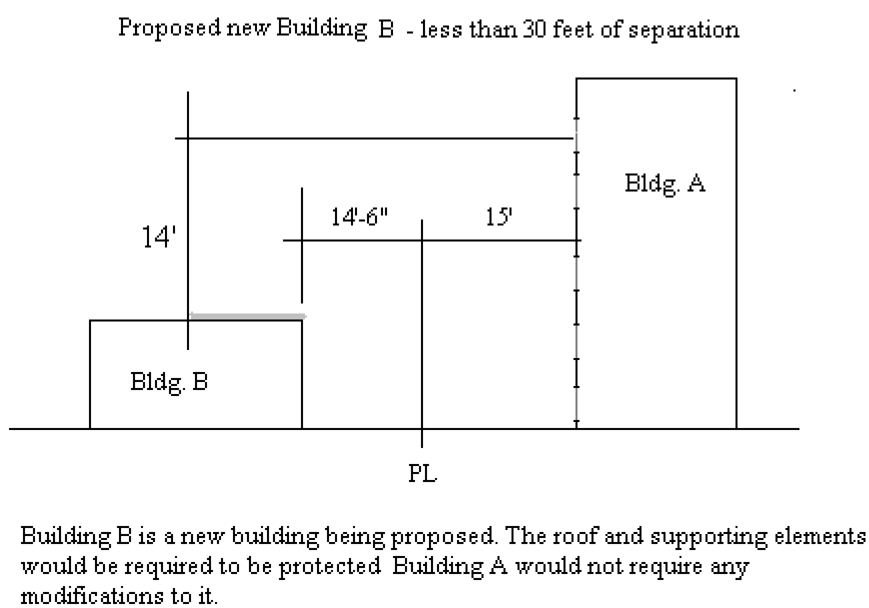


With the proposed new language, either the openings in Bldg. A or the roof of Bldg. B would be required to be protected since the aggregate of the two separation distances is less than 30 feet. Again, this is consistent with what we believe this section intended.

EXAMPLE 3
BUILDINGS ON THE SAME LOT
PROPOSED LANGUAGE
LESS THAN 30 FEET OF SEPARATION



EXAMPLE 4
BUILDINGS ON SEPARATE LOTS
BUILDING A IS PROPOSED



EXAMPLE 5
BUILDINGS ON SEPARATE LOTS
BUILDING B IS PROPOSED

Analysis: Public comments to FS20 and FS21 contain similar provisions for vertical exposure for buildings on the same lot. The membership needs to make its preference clear with respect to these provisions.

Public Comment 2:

Thomas S. Zaremba, Roetzel & Andress, representing Glazing Industry Code Committee (GICC), a committee of the Glass Association of North America (GANA) requests Approval as Submitted.

Commenter's Reason: Property lines are invisible, non-physical boundary lines that run between adjoining lots. They, simply, have no ability to protect buildings on one lot from fire spread from nearby buildings on an adjoining lot. However, as currently written, Section 705.8.6 only applies to "buildings on the same lot." Accordingly, in the absence of a provision of the code providing protection from fire spread across lot lines, one can only conclude that if a lot line happens to exist between two buildings, that line alone will somehow stop fire from spreading from a building on one side of the line to a building on the other side.

FS21 fixes this problem by proposing new and clear fire protection requirements intended to protect buildings from fire spread across lot lines. Final Action Agenda voters are urged to vote against the standing motion to disapprove FS21 and to vote in favor of a motion to adopt it "As Submitted."

Analysis: Public comments to FS20 and FS21 contain similar provisions for vertical exposure for buildings on the same lot. The membership needs to make its preference clear with respect to these provisions.

Final Action: AS AM AMPC____ D

FS23-09/10
706.2, Chapter 35

Proposed Change as Submitted

Proponent: Sarah A. Rice, CBO, representing self

706.2 Structural stability. Fire walls shall have sufficient structural stability under fire conditions to allow collapse of construction on either side without collapse of the wall for the duration of time indicated by the required fire-resistance rating <u>or shall be double fire walls constructed in accordance with NFPA 221</u>.

2. Add new standard to Chapter 35 as follows:

NFPA
<u>221-09</u> <u>Standard for High Challenge Fire Walls, Fire Walls, and Fire Barrier Walls, 2009 Edition</u>

Reason: To allow what today would be considered a design using 2 exterior walls to be classified as a fire wall and thus also allowed to have openings when the wall is not located on a lot line (party wall).

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: A review of the standard proposed for inclusion in the code, NFPA 221-09, for compliance with ICC criteria for referenced standards given in Section 3.6 of Council Policy #CP 28 will be posted on the ICC website on or before September 24, 2009.

Public Hearing:	Committee:	AS	AM	D
	Assembly:	ASF	AMF	DF

ICCFILENAME: RICE-FS4-706.2

Public Hearing Results

Analysis: The standard was not received by ICC staff.

Committee Action: **Disapproved**

Committee Reason: Disapproval was based on the proponents request for disapproval. Further, the proposed standard NFPA 221-09 has not been submitted.

Assembly Action: **None**

Individual Consideration Agenda

These items are on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Sarah A. Rice, CBO, The Preview Group, representing self, requesting Approval as Submitted.

Commenter's Reason: For years both the legacy codes and the now the IBC, have struggled with how to erect a new building right next to an existing building when they are both situated on the same lot (no lot line between them). Each building meets the all the code requirements. The answer seems simple enough, just erect your new building right next to the existing building (they are not structurally tied together) and then if you want to have communications between the two building punch some holes in the walls. This design seems to works great – by putting two exterior walls right next to each the design has achieved the same level of "independence as a single "firewall" would, e.g., should one wall collapse the other wall will remain standing.

But the code does not regulate this design as a "firewall," rather the code looks at this design as two (2) exterior walls situated right next to each other. The code requires there be an imaginary line created between the walls from which the fire resistance ratings and opening limitations can be established – fundamentally there is 0-feet of fire separation distance from the imaginary line to each of the walls. And It is at this point where the provisions for exterior walls and firewalls diverge immensely.

If there had been a firewall that met Section 7____, Section 7____ would allow there to be openings as long as they don't occupy more than 25% of the length of the wall. But in Table 70____ (which regulates openings in exterior walls) it very clearly states that where the fire separation distance is less than 3 feet, NO openings are permitted in that wall.

It is simple- Firewall (no lot line) – openings allowed, two exterior walls (no lot line) – NO openings allowed.

The arguments, and there have been plenty, are mostly directed at how would you ensure that the two exterior walls would be built to function the same as a fire wall. Well there is a way – build the two exterior walls so that they comply with the provisions in NFPA 221 for "double fire walls."

In NFPA 221 contains the construction details that will ensure that two exterior walls will provide the same level of independence between buildings that a firewall would.

Public Comment 2:

Jason Thompson, National Concrete Masonry Association (NCMA), representing Masonry Alliance for Codes and Standards (MACS), requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

706.2 Structural stability. Fire walls shall have sufficient structural stability under fire conditions to allow collapse of construction on either side without collapse of the wall for the duration of time indicated by the required fire-resistance rating or shall be <u>constructed as</u> double fire walls ~~constructed~~ in accordance with NFPA 221.

NFPA

221-09 Standard for High Challenge Fire Walls, Fire Walls, and Fire Barrier Walls, 2009 Edition

Commenter's Reason: This Public Comment has made a slight editorial modification to the original code change proposal to help clarify the intent. We believe the original intent of this code change proposal is to allow double fire walls designed and constructed in accordance with NFPA 221 Standard for High Challenge Fire Walls, Fire Walls, and Fire Barriers Walls (2009) to be used to satisfy the requirements of Section 706 for fire walls separating buildings.

Unfortunately, the new 2009 edition of NFPA 221 was not provided to the IBC Fire Safety Code Development Committee for their review prior to the hearings in Baltimore last year. Thus, the proponent requested that the code change proposal be disapproved. However, the standard has now been available for public review and, in our opinion, is acceptable as a referenced standard for use by the IBC in determining the design and construction requirements for double fire walls which will serve the same purpose of subdividing buildings into separate buildings as required in Section 706 for fire walls. In fact, one of the members of MACS, as well as our code consultant, are voting members of the NFPA Technical Committee on Building Construction which is responsible for the development and maintenance of NFPA 221.

Double wall assemblies constructed to serve as a fire wall are regulated by Section 4.5 Double Wall Assemblies of NFPA 221, as well as Section 6.5 Double Fire Walls. These sections allow two independent walls to serve as the required fire wall separation where the fire-resistance rating of each wall is allowed to be reduced to 1-hour less than the required fire-resistance rating for a single fire wall. For example, where a 3-hour fire-resistance-rated single fire wall is required by the IBC, two 2-hour fire-resistance rated (double) fire walls could be utilized based on NFPA 221. Similarly, for a 2-hour fire-resistance-rated single fire wall, two walls serving as a double fire wall could each have a 1-hour fire-resistance rating.

In conclusion, we believe that the use of double fire walls designed and constructed in accordance with NFPA 221 should be allowed as comparable construction to that specified in Section 706 for fire walls in the IBC. Therefore, we respectfully request that the Class A voting members overturn the Committee recommendation for disapproval and vote to approve this Public Comment for approved as modified for Code Change FS23-09/10.

Final Action: AS AM AMPC____ D

FS24–09/10

702.1, 705.6, 706.2, 706.2.1 (New), 706.2.2 (New), 706.2.3 (New), 706.4, Table 706.X (New)

Proposed Change as Submitted

Proponent: Marshall P. Carman, Structural Engineers Association of Ohio

Revise as follows:

702.1 Definitions

FIRE WALL. A fire-resistance rated wall having protected openings, which restricts the spread of fire and extends continuously from the foundation to or through the roof ~~with sufficient structural stability under fire conditions to allow.~~ designed to safely support loads as required by Chapter 16 following collapse of construction on either side. ~~without collapse of the wall.~~

Fire wall, cantilevered. Self supporting fire wall which is independent from construction on either side of the fire wall.

Fire wall, double. Two independent parallel walls meeting the exterior wall requirements of section 705 and having an equivalent combined assembly fire-resistance rating equal to the required fire-resistance rating.

Fire wall, tied. Fire wall connected to a diaphragm on both sides of the wall, with the fire wall relying on the diaphragm on either side for structural support, but not at the same time.

705.6 Structural ~~stability~~ requirements. The wall shall extend to the height required by Section 705.11 and shall ~~have sufficient structural stability such that it will remain in place for~~ be designed to safely support loads as required by Chapter 16 for the duration of time indicated by the required fire-resistance rating

706.2 Structural ~~stability~~ requirements. ~~Fire walls shall have sufficient structural stability under fire conditions to allow collapse of construction on either side without collapse of the wall for the duration of time indicated by the required fire-resistance rating.~~ *Fire walls* shall be designed to safely support loads as required by Chapter 16 for the duration of time indicated by the required fire-resistance rating, assuming collapse of construction due to fire on either side of the wall. For application of wind loads and lateral live loads, it is permitted to consider the portions of the fire wall that are interior prior to assumed collapse as interior walls after assumed collapse. Load combinations with earthquake loading need not be considered after assumed collapse. Fire walls shall meet the additional requirements of 706.2.1, 706.2.2, or 706.2.3.

706.2.1 Tied fire walls. Tied fire walls and supporting structure opposite of the assumed collapse of construction, shall resist an applied lateral load induced by collapse of construction on either side of the wall. Lateral loads applied to the wall and supporting structure due to collapse are permitted to be determined in accordance with equation 7-2 provided both of the following conditions are met.

1. Framing supported by the fire wall is detailed to permit rotation of the framing element at the fire wall support.
2. Framing, other than tension ties, is not continuous through the fire wall

$$h_f = 1.5 \omega l \qquad \textbf{(Equation 7-2)}$$

Where:

h_f = lateral load applied at framing support
l = span of framing perpendicular to fire wall
ω = equivalent uniform applied gravity load to framing member

The applied lateral load due to collapse need not exceed the maximum force that can be developed in the system.

Construction on both sides of the fire wall shall be considered a single structure for structural design and analysis.

(Renumber subsequent equations)

706.2.2 Cantilevered fire walls. Separation between a cantilevered fire wall and building elements on all sides shall meet the requirements of 1613.6.7.

706.2.3 Double fire walls. Each wall of a double fire wall shall be considered an exterior wall as required by section 705. Construction on either side of the fire wall shall be considered separate structures and shall meet the building separation requirements of 1613.6.7.

706.4 Fire-resistance rating. *Fire walls* shall have a fire-resistance rating of not less than that required by table 706.4(1). Double fire walls shall be considered to have an equivalent combined fire resistance rating as specified in table 706.4(2).

TABLE 706.4(1)
FIRE WALL FIRE-RESISTANCE RATINGS

GROUP	FIRE-RESISTANCE RATING (hours)
A, B,E, H-4, I, R-1, R-2, U	3[a]
F-1, H-3[b], H-5, M, S-1	3
H-1, H-2	4[b]
F-2, S-2, R-3, R-4	2

a. In Type II or V construction, walls shall be permitted to have a 2-hour fire–resistance rating
b. For Group H-1, H-2 or H-3 buildings, also see Sections 415.4 and 415.5

Add new Table as follows:

TABLE 706.4(2)
EQUIVALENT COMBINED FIRE-RESISTANCE RATING FOR DOUBLE FIRE WALLS.

Required fire-resistance rating for each wall of a double fire wall (hours)	Equivalent single wall fire-resistance rating (hours)
3	4
2	3
1	2

Reason: The language of Section 706.2 requires that fire walls have sufficient structural stability to prevent collapse of the fire wall under fire conditions. However, there is no definition of *sufficient structural stability* or design loads provided for fire conditions. While this provides a legitimate performance goal, it is inconsistent with typical structural code requirements which require specific resistance against defined loading.

This code change proposal attempts to clearly define loading and resistance requirements for fire walls, reference already defined strength and stability requirements in chapter 16, as well as clarify / define types of firewalls.

A provision has been added permitting the application of interior lateral live loads on fire walls based upon their condition prior to collapsed construction on either side of the wall. NFPA 221 applies 5psf for the lateral design load on fire walls, which is also the typical lateral live load applied to interior walls per 1607.13.

The types of fire walls are typical walls defined in NFPA 221. NFPA 221 provides an equation for determining the lateral load applied to a tied fire wall, which is based upon a catenary action due to sagging of the member. The equation provided in this proposal is based upon the horizontal reaction due the centripetal force of a swinging member that lost support at the far end. While lateral loads due to catenary action are possible, the horizontal reaction due to centripetal force provides a larger horizontal load than the catenary action equation provided in NFPA 221.

Reference:
NFPA 221, Standard for High Challenge Fire Walls, Fire Walls and Fire Barrier Walls (2009 Edition). National Fire Protection Association (NFPA)

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: CARMAN-FS1-702.1

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee felt that current language is clear and describes appropriate performance requirements for fire walls. Further, there are apparent differences between the proposed requirements and NFPA 221, which may be of concern. Lastly, reference to Secton 705 in Section 706.2.3 would trigger weather resistance and exterior finishes requirements, which do not appear to be applicable.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Edwin Huston, National Council of Structural Engineers Association, NCSEA Code Advisory Subcommittee, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

702.1 Definitions

FIRE WALL. A fire-resistance rated wall having protected openings, which restricts the spread of fire and extends continuously from the foundation to or through the roof ~~designed to safely support loads as required by Chapter 16 following collapse of construction on either side~~.

> ~~**Fire wall, cantilevered.** Self supporting fire wall which is independent from construction on either side of the fire wall.~~
>
> ~~**Fire wall, double.** Two independent parallel walls meeting the exterior wall requirements of section 705 and having an equivalent combined assembly fire-resistance rating equal to the required fire-resistance rating.~~
>
> ~~**Fire wall, tied.** Fire wall connected to a diaphragm on both sides of the wall, with the fire wall relying on the diaphragm on either side for structural support, but not at the same time.~~

705.6 Structural requirements. The wall shall extend to the height required by Section 705.11 and shall be designed to safely support loads as required by Chapter 16 for the duration of time indicated by the required fire-resistance rating

706.2 Structural requirements. *Fire walls* shall be designed to safely support loads as required by Chapter 16 for the duration of time indicated by the required fire-resistance rating, assuming collapse of construction due to fire on either side of the wall. ~~For application of wind loads and lateral live loads, it is permitted to consider the portions of the fire wall that are interior prior to assumed collapse as interior walls after assumed collapse. Load combinations with earthquake loading need not be considered after assumed collapse. Fire walls shall meet the additional requirements of 706.2.1, 706.2.2, or 706.2.3.~~

~~**706.2.1 Tied fire walls.** Tied fire walls and supporting structure opposite of the assumed collapse of construction, shall resist an applied lateral load induced by collapse of construction on either side of the wall. Lateral loads applied to the wall and supporting structure due to collapse are permitted to be determined in accordance with equation 7-2 provided both of the following conditions are met.~~

1. ~~Framing supported by the fire wall is detailed to permit rotation of the framing element at the fire wall support.~~
2. ~~Framing, other than tension ties, is not continuous through the fire wall~~

$$\cancel{h_f = 1.5\omega l}$$ (~~**Equation 7-2**~~)

~~Where:~~

~~h_f~~	=	~~lateral load applied at framing support~~
~~l~~	=	~~span of framing perpendicular to fire wall~~
~~ω~~	=	~~equivalent uniform applied gravity load to framing member~~

~~The applied lateral load due to collapse need not exceed the maximum force that can be developed in the system.~~

~~Construction on both sides of the fire wall shall be considered a single structure for structural design and analysis.~~

~~**706.2.2 Cantilevered fire walls.** Separation between a cantilevered fire wall and building elements on all sides shall meet the requirements of 1613.6.7.~~

~~**706.2.3 Double fire walls.** Each wall of a double fire wall shall be considered an exterior wall as required by section 705. Construction on either side of the fire wall shall be considered separate structures and shall meet the building separation requirements of 1613.6.7.~~

706.4 Fire-resistance rating. *Fire walls* shall have a fire-resistance rating of not less than that required by table 706.4~~(1). Double fire walls shall be considered to have an equivalent combined fire resistance rating as specified in table 706.4(2)~~.

TABLE 706.4~~(1)~~
FIRE WALL FIRE-RESISTANCE RATINGS

GROUP	FIRE-RESISTANCE RATING (hours)

a. In Type II or V construction, walls shall be permitted to have a 2-hour fire–resistance rating
b. For Group H-1, H-2 or H-3 buildings, also see Sections 415.4 and 415.5

~~**TABLE 706.4(2)**~~
~~**EQUIVALENT COMBINED FIRE-RESISTANCE RATING FOR DOUBLE FIRE WALLS.**~~

~~Required fire-resistance rating for each wall of a double fire wall (hours)~~	~~Equivalent single wall fire-resistance rating (hours)~~
~~3~~	~~4~~
~~2~~	~~3~~
~~1~~	~~2~~

Commenter's Reason: In lieu of the original code change proposal which attempted to add requirements for specific types of firewalls and provide guidance for various firewall systems, this modification is more editorial in nature. It still removes the undefined term Structural Stability, and references chapter 16 for loading requirements. It also leaves the statement regarding *"safely support loads as required by Chapter 16 for the duration of time indicated by the required fire-resistance rating, assuming collapse of construction due to fire on either side of the wall"* out of the definition of Fire Wall, since it is restated in section 706.2 as a requirement for Fire Walls.

There are potential conflicts between commonly employed firewall design methodologies and the requirements of sections 12.1.3 and 12.11 of ASCE 7-10 which require the interconnectivity of structural elements and minimum wall to diaphragm connection capacities. Referencing chapter 16 for the loading / support criteria, as opposed to having undefined stability criteria within section 706, is a 1st step towards addressing these conflicts.

Final Action: AS AM AMPC____ D

FS31-09/10
TABLE 707.3.9

Proposed Change as Submitted

Proponent: Rick Thornberry, PE, The Code Consortium, Inc., representing self

Revise as follows:

TABLE 707.3.9
FIRE-RESISTANCE RATING REQUIREMENTS FOR FIRE BARRIER ASSEMBLIES OR HORIZONTAL ASSEMBLIES BETWEEN FIRE AREAS

OCCUPANCY GROUP	FIRE-RESISTANCE RATING (hours)
H-1, H-2	4
F-1, H-3, S-1	3
A, B, E, F-2, H-4, H-5, I, M[a], R, S-2	2
U	1

a. For Group M occupancies containing display shelves or storage racks where the top of the merchandise is greater than 12 feet (3658 mm) in height above the floor, the minimum fire-resistance rating shall be 3 hours.

Reason: The purpose of this proposed code change is to increase the required fire-resistance rating from 2-hours to 3-hours for fire barriers and horizontal assemblies used to separate fire areas of Group M occupancies where the Group M occupancy contains display shelves and/or storage racks where the top of the merchandise is greater than 12 ft in height. This is intended to recognize the fact that the fire load will be significantly greater in those Group M occupancies where the heights of the merchandise on display or on storage racks in the retail sales area exceed 12 ft. For the most part where Group M occupancies have display racks less than 8 ft in height, the fire load will generally not exceed 20 pounds per sq ft which is roughly equivalent to a 2-hour fire duration. However, for those stores where the display shelving and storage racks allow for merchandise to be placed greater than 12 ft above the floor such as in the typical "big box" stores where the fire load is significantly greater, the fire load can greatly exceed 20 pounds per sq ft and can be as high as 30 to 40 pounds per sq ft. A 30 pound per sq ft fire load is roughly equivalent to a 3-hour fire duration.

We believe this is especially important since fire areas are used to avoid the requirements triggering automatic sprinkler system protection in accordance with Section 903.2.7 for Group M occupancies. If a Group M occupancy building is separated into fire areas of 12,000 sq ft or less, then the building is not required to be sprinklered unless the combined fire areas exceed 24,000 sq ft. In reality, this means that a 1-story building could be divided into two 12,000 sq ft fire areas without having to provide for automatic sprinkler protection. Similarly, a 3-story Group M occupancy limited to 8,000 sq ft per story with the floors (horizontal assemblies) having the required fire-resistance rating to create the fire area separations would also not be required to be sprinklered. In those nonsprinklered cases, it is very important to limit the fire load for the Group M occupancies based on the height of the merchandise displayed and stored in the building. So for those cases which generally encompass most retail sales situations, the 2-hour fire-resistance rating would be suitable. But for those cases such as the "big box" stores where the display shelves and storage racks are greater than 12 ft in height, the fire-resistance rating of the fire barriers and horizontal assemblies should be increased to a minimum of 3-hours.

The proposed 12 ft height limit is also consistent with Chapter 23 of the International Fire Code for high-piled combustible storage which is defined as "storage of combustible materials in closely packed piles or combustible materials on pallets, in racks or on shelves where the top of the storage is greater than 12 ft (3658 mm) in height…" Chapter 23 recognizes that high-piled combustible storage creates a much greater fire hazard than storage of lesser heights. Thus, there are more restrictive fire safety requirements incorporated into Chapter 23 as enumerated in Table 2306.2 General Fire Protection and Life Safety Requirements. This recognizes the fact that the fire load is significantly greater in these types of storage occupancies.

Increasing the minimum fire-resistance rating from 2-hours to 3-hours for these Group M occupancies would also be consistent with the minimum 3-hour fire-resistance rating specified for Group F-1, H-3, and S-1 occupancies in the table based on the relative fire load and fire hazard. And it is also consistent with Table 706.4 Fire Wall Fire-Resistance Ratings.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: Thornberry-FS3-707.3.9

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The committee agreed that high merchandise display in Group M occupancies is a fire safety concern, which warrants the 3 hour separation regardless of the display area or the presence of automatic sprinklers.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Rob Geislinger representing the Fire Marshals Association of Colorado, and Tim Pate, representing the Colorado Chapter of ICC, requests Disapproval.

Commenter's Reason: Chapter 23 of the International Fire Code adequately addresses concerns with high piled combustible storage. This proposal creates some confusion and conflict with that Code. In some cases, the proposal would be overly restrictive. For example, the proposal would require an increase in the fire resistance rating if only one display shelf in an occupancy exceeded twelve feet in height. The Fire Code does not require any special protection for small high-piled combustible storage areas under 500 square feet. This provision would also apply regardless of the commodity class being displayed, even for noncombustible items such as metal work or similar items. The Fire Code does not regulate high-piled noncombustible storage.

While the proposal is sometimes over restrictive, in other cases, it may not be restrictive enough. Chapter 23 of the Fire Code recognizes that, "certain high-hazard commodities, such as rubber tires, Group A plastics, flammable liquids, idle pallets, and similar commodities…," may be considered high-piled storage at heights above six, not twelve feet.

The Fire Code adequately addresses the hazards of high-piled combustible storage. This proposal is not necessary.

Final Action: AS AM AMPC____ D

FS35–09/10
708.5

Proposed Change as Submitted

Proponent: Sharon Halpert, representing self

Revise as follows:

708.5 Continuity. Shaft enclosures shall be constructed as *fire barriers* in accordance with Section 707 or *horizontal assemblies* constructed in accordance with Section 712, or both, and shall have continuity in accordance with Section 707.5 for *fire barriers* or Section 712.4 for *horizontal assemblies* as applicable. <u>Joints created at every intersection between the bottom of a shaft wall assembly and the top of the floor or slab shall also comply with Section 714.</u>

Reason: Where used, shafts are critical building elements in preventing the passage of heat, flame and toxic gases to stories beyond the floor of fire origin. While the requirements for continuity of vertical and horizontal shafts through floors and walls are quite detailed, there is a lack of specific information for the construction detail required when the shaft wall is not a continuous membrane, but rather is interrupted at one or more floors by the floor slab.

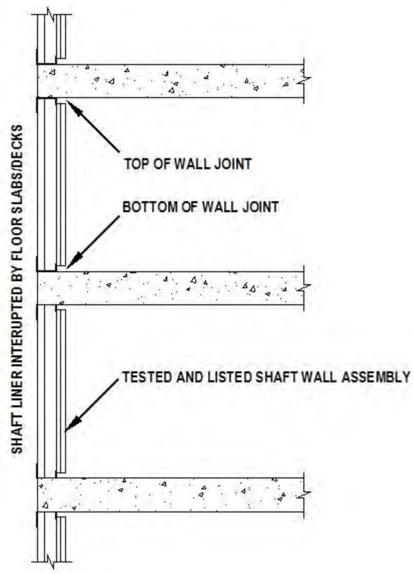
Substantiation: A shaft is intended to be a continuous assembly (fire barrier) from its lowest point to its highest point, with all openings, joints and penetrations suitably protected or sealed. This revision serves simply to clarify the intent of how this protection will be maintained.

When a shaft is hung entirely from the floors it traverses and is constructed of wall materials (e.g. gypsum boards, concrete masonry units) that are joined one to another from top to bottom, there would normally not be any intermediate floor slabs that would bisect the shaft wall, and therefore no fire resistive joint systems within the wall.

On the other hand, when a shaft enclosure is constructed of independent wall segments that rest on top of each floor slab/deck that the shaft traverses, there will be a joint between the wall segments and the floor slab/deck above, as well as between the wall and the floor slab/deck below it. Clearly both types of joints will occur at each level this shaft wall assembly is intended to protect. Shaft construction is unique in that the joint at the top of the wall and at the bottom of wall are equally important in maintaining the anticipated protection.

Since the code already maintains provisions for the continuity of shaft wall construction, this proposed clarification will simply serve to enhance this intent. Smoke and fire inside a shaft, in a multi-story building, will not delineate between the head of wall joint on the underside of a deck and the bottom of wall joint on the top side of this same deck. Once the pressure builds and the temperatures rise, fire and smoke will find its way through any unprotected areas. An illustration of this condition is enclosed.

There are dozens of bottom-of-wall fire resistance rated joint systems that have been tested by nationally recognized testing organizations and have been listed in their directories. Information concerning these details is described in the individual systems. Bottom-of-wall joint systems have been investigated using the general methods and conditions of acceptance specified for the four defined types of joint systems in ANSI/UL 2079 and ASTM E1966.



Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: HALPERT-FS1-708.5

Public Hearing Results

Committee Action: Disapproved

Committee Reason: The committee felt that these requirements did not belong in the requirements for shafts and that this particular concern was already covered in the portion of the code dealing with joint requirements.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Tony Crimi, A.C. Consulting Solutions, representing International Firestop Council, request Approval as Modified by this Public Comment.

Modify the proposal as follows:

708.5 Continuity. Shaft enclosures shall be constructed as *fire barriers* in accordance with Section 707 or *horizontal assemblies* constructed in accordance with Section 712, or both, and shall have continuity in accordance with Section 707.5 for *fire barriers* or Section 712.4 for *horizontal assemblies* as applicable. Joints created at the ~~every~~ intersection between the bottom of every segment of the ~~a~~ shaft enclosure ~~wall assembly~~ and the top of the floor or slab shall also comply with Section 714.

Commenter's Reason: While the need to ensure proper protection of bottom-of-wall joints exists for most fire rated wall assemblies, shafts are particularly critical because they are designed to contain both fire and smoke. They are intended to be continuous assemblies (fire barriers) from their lowest point to their highest point, with all openings, joints and penetrations suitably protected or sealed. Shafts are critical building elements used to prevent the passage of fire and pressurized smoke to stories beyond the floor of fire origin. While the requirements for continuity of vertical and horizontal shafts through floors and walls are quite detailed, there is a lack of clarity in the construction detail required when the shaft wall is not continuous through the floor, but rather is interrupted at one or more floors by the floor slab.

During its deliberations, the Committee pointed out that this is currently required based on the fire barrier continuity requirements in section 709. Nonetheless, the bottom-of-wall joint is often overlooked. When a shaft enclosure is constructed of independent wall segments that rest on top of each floor slab/deck that the shaft traverses, there will be a joint between the wall segments and the floor slab/deck above, as well as between the wall and the floor slab/deck below it, at each level.

During a fire, stack effect is often responsible for the side distribution of smoke through a building. Stack effects are present to varying degrees in all multi-storey buildings. They normally occur when the indoor air temperature is greater than the outdoor air temperature. They are characterized by a strong draft from the ground floor to the roof of the building. However, they can also occur when the reverse is true, but in the opposite direction. The magnitude of the stack effect depends on how large the temperature difference is, and the height of the building, but can be very large in colder months. The following Table illustrates some simple examples of building stack effects (assuming normal barometric pressures and air density, and an approximate height of 10 ft per storey):

Building Height* (ft)(No. of Storeys)	Temperature Difference (indoor/outdoor) (^oF)	Stack Effect Pressure[1] (In. of Water) (Pa)
100 (10)	30	5.7 (1,425)
100 (10)	70	66.8 (16,624)
300 (30)	30	17.1 (4,275)
300 (30)	70	200 (49,872)

1 Fire Protection Handbook, NFPA, Nineteenth Edition, Volume 2, 2003.
* "Building Height" in this example actually denotes vertical height between the inlet and outlet pressure measurement.

At these pressures, smoke is driven through the bottom-of-wall joints in each segment of the vertical shaft that rests on the floor or slab, both inward and outward, with the amount of smoke and products of combustion driven through an unsealed joint being a function of the story (height) at which each such joint is located.

There are dozens of bottom-of-wall fire resistance rated joint systems that have been tested by nationally recognized testing organizations for this purpose and have been listed in their directories. Information concerning these details is described in the individual systems. Bottom-of-wall joint systems have been investigated using the general methods and conditions of acceptance specified for the four defined types of joint systems in ANSI/UL 2079 and ASTM E1966 for several years.

Final Action: AS AM AMPC____ D

FS36-09/10
708.8

Proposed Change as Submitted

Proponent: David S. Collins, FAIA, The Preview Group, Inc. representing The American Institute of Architects

Revise as follows:

708.8 Penetrations. Penetrations in a shaft enclosure shall be protected in accordance with Section 713 as required for fire barriers. <u>Structural elements, such as beams or joists, where they and their supporting construction are protected in accordance with Section 713 shall be permitted to penetrate a shaft enclosure.</u>

Reason: It is virtually impossible to design a shaft enclosure over a few stories tall without some support from adjoining structural elements. This change will allow a beam or other structural member to penetrate a shaft as long as it is also protected as required.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: Collins-FS2-708.8

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee was concerned about the phrase "…and their supporting construction…" in that they were not clear on how this related to penetration protection.

Assembly Action: **None**

Individual Consideration Agenda

These items are on the agenda for individual consideration because public comments were submitted.

Public Comment:

William E. Koffel, P.E, Koffel Associates, Inc., representing Firestop Contractors International Association (FCIA), requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

708.8 Penetrations. Penetrations in a shaft enclosure shall be protected in accordance with Section 713 as required for fire barriers. Structural elements, such as beams or joists, where ~~they and their supporting construction are~~ protected in accordance with Section 713 shall be permitted to penetrate a shaft enclosure.

Commenter's Reason: The proposed language meets the intent of the original Public Proposal. The language in the proposal was confusing to the Code Development Committee due to the reference to "supporting construction."

The proposed language clarifies that structural members may penetrate a shaft enclosure in addition to those that are already permitted because they are necessary for the purpose of the shaft enclosure. Recently, several manufacturers have obtained listings for structural members penetrating fire barriers and protected in accordance with Section 713. In addition, some recent testing conducted by Southwest Research Institute and Koffel Associates, Inc., for a specific construction project, has demonstrated that not only will the through penetration firestop system obtain an F-rating but the system is also very effective at limiting the temperature of the steel on the unexposed surface.

Final Action: AS AM AMPC____ D

FS40-09/10
708.14.1

Proposed Change as Submitted

Proponent: Rick Thornberry, PE, The Code Consortium, Inc., representing self

Revise as follows:

708.14.1 Elevator lobby. An enclosed elevator lobby shall be provided at each floor where an elevator shaft enclosure connects more than ~~three~~ <u>two</u> stories. The lobby enclosure shall separate the elevator shaft enclosure doors from each floor by fire partitions. In addition to the requirements in Section 709 for fire partitions, doors protecting openings in the elevator lobby enclosure walls shall also comply with Section 715.4.3 as required for corridor walls and penetrations of the elevator lobby enclosure by ducts and air transfer openings shall be protected as required for corridors in accordance with Section 716.5.4.1. Elevator lobbies shall have at least one means of egress complying with Chapter 10 and other provisions within this code.

Exceptions:

(Exceptions to remain unchanged)

Reason: This proposed code change is a follow up to Code Change FS46-07/08 which was submitted by Cal Chiefs. During the public hearings in Palm Springs, the Cal Chiefs representative at the hearings requested that the Fire Safety Committee disapprove the code change since it needed further development. No other testimony was offered on that code change proposal. It is not clear as to why this position was taken, especially since a Public Comment was never developed to follow up. At any rate, the following text in the remainder of this supporting statement is taken from that original code change submittal.

Currently, this Section triggers the requirement for enclosed elevator lobbies when the elevator shaft enclosure connects more than three stories. The purpose of this code change proposal is to reduce that threshold to where the elevator shaft enclosure connects more than two stories.

This is generally consistent with Section 708 Shaft Enclosures which requires shaft enclosures for openings that pass through floor/ceiling assemblies but allows specific exceptions for two consecutive stories to be interconnected with floor openings without a shaft enclosure. Refer to Exceptions 7 and 11 to Section 708.2. Thus, for those cases smoke will be able to readily migrate from one story to the next through the unenclosed floor openings. In that case it seems reasonable that it would not be critical to require the elevator lobby to protect elevator hoistway enclosures from smoke migration. However, we believe that once the elevator shaft interconnects three or more stories, it should be protected against smoke movement through the shaft so as to prevent smoke spread from floor to floor.

It has been well documented that smoke spreads readily throughout the building via the elevator shafts even though the elevator hoistway doors are protected with fire protection rated fire doors. The fact is that such doors are very loose fitting. Even though they pass the fire door test, they will still allow significant quantities of smoke to pass around the edges of the door. Since stack effect occurs in multi-story buildings, the natural tendency for smoke is to migrate toward the elevator shafts. Then the smoke will move either upward or downward, depending upon where the origin of smoke is in relationship to the neutral pressure plane within the building. And then the smoke will leak out of the elevator shafts and spread onto floors remote from the fire floor.

Therefore, we believe that it is important to provide protection for the elevator shaft hoistway doors against the movement of smoke from floor to floor once the elevator intercommunicates more than two stories.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: Thornberry-FS2-708.14.1

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee felt that reducing the elevator lobby threshold from 3 stories to 2 stories was not technically justified. Also the code currently allows a two story unprotected opening to be directly adjacent to what is proposed to be an enclosed elevator lobby, so it is unclear what is being achieved with this proposal.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Rick Thornberry PE, The Code Consortium Inc, representing self, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

708.14.1 Elevator lobby. An enclosed elevator lobby shall be provided at each floor where an elevator shaft enclosure connects more than two stories. The lobby enclosure shall separate the elevator shaft enclosure doors from each floor by fire partitions. In addition to the requirements in Section 709 for fire partitions, doors protecting openings in the elevator lobby enclosure walls shall also comply with Section 715.4.3 as required for corridor walls and penetrations of the elevator lobby enclosure by ducts and air transfer openings shall be protected as required for corridors in accordance with Section 716.5.4.1. Elevator lobbies shall have at least one means of egress complying with Chapter 10 and other provisions within this code.

Exceptions:

1. Enclosed elevator lobbies are not required at the street floor, provided the entire street floor is equipped with an *automatic sprinkler system* in accordance with Section 903.3.1.1.
2. Elevators not required to be located in a shaft in accordance with Section 708.2 are not required to have enclosed elevator lobbies.
3. Where additional doors are provided at the hoistway opening in accordance with Section 3002.6. Such doors shall be tested in accordance with UL 1784 without an artificial bottom seal.
4. Enclosed elevator lobbies are not required where the building is protected by an *automatic sprinkler system* installed in accordance with Section 903.3.1.1 or 903.3.1.2. This exception shall not apply to the following:
   4.1. Group I-2 occupancies,
   4.2. Group I-3 occupancies, and
   4.3. High-rise buildings.
5. Smoke partitions shall be permitted in lieu of *fire partitions* to separate the elevator lobby at each floor where the building is equipped throughout with an *automatic sprinkler system* installed in accordance with Section 903.3.1.1 or 903.3.1.2. In addition to the requirements in Section 711 for smoke partitions, doors protecting openings in the smoke partitions shall also comply with Sections 711.5.2, 711.5.3, and 715.4.8 and duct penetrations of the smoke partitions shall be protected as required for *corridors* in accordance with Section 716.5.4.1.
6. Enclosed elevator lobbies are not required where the elevator hoistway is pressurized in accordance with Section 708.14.2.
7. Enclosed elevator lobbies are not required where the elevator serves only *open parking garages* in accordance with Section 406.3.
8. Enclosed elevator lobbies are not required at floors where a shaft enclosure is not required by Exceptions 7 or 11 to Section 708.2.

Commenter's Reason: We believe the revision proposed in this Public Comment to add a new Exception 8 responds to the IBC Fire Safety Committee's main concern for disapproving this code change proposal. New Exception 8 indicates that enclosed elevator lobbies would not be required at floors where a shaft enclosure is not required by either Exception 7 or Exception 11 to Section 708.2 Shaft Enclosure Required. Basically, these are the only two Exceptions to the requirements for shaft enclosures that allow a shaft enclosure to be omitted on two adjacent floors (stories) meeting the conditions described in the Exceptions. Thus, there would be no need to provide special elevator lobby enclosures to protect against smoke movement between those two adjacent floors since they would be allowed to have open shafts between those floors.

Approving this Public Comment will make the elevator lobby enclosure requirements for the protection of smoke movement through elevator hoistway shafts consistent with the requirements for shaft enclosures which protect against fire spread in shafts connecting multiple stories in a building. For good and consistent fire protection it follows that where the spread of fire is to be limited and controlled, the spread of smoke should also be limited and controlled. Therefore, we urge the ICC Class A voting members to approve this Public Comment to modify our original Code Change Proposal FS40-09/10.

Final Action: AS AM AMPC____ D

FS44-09/10
708.14.1

Proposed Change as Submitted

Proponent: Bob Eugene, representing Underwriters Laboratories Inc

Revise as follows:

708.14.1 Elevator lobby. An enclosed elevator lobby shall be provided at each floor where an elevator shaft enclosure connects more than three *stories*. The lobby enclosure shall separate the elevator shaft enclosure doors from each floor by *fire partitions*. In addition to the requirements in Section 709 for fire partitions, doors protecting openings in the elevator lobby enclosure walls shall be also comply with Section 715.4.3 as required for *corridor* walls with the UL 1784 test conducted without an artificial bottom seal. ~~and p~~Penetrations of the elevator lobby enclosure by ducts and air transfer openings shall be protected as required for *corridors* in accordance with Section 716.5.4.1. Elevator lobbies shall have at least one *means of egress* complying with Chapter 10 and other provisions within this code.

Exceptions:

(Exceptions to remain unchanged)

Reason: This proposal clarifies that the air leakage rating of smoke and draft control doors protecting openings in elevator lobby enclosure walls shall be determined without an artificial bottom seal in order to replicate the stack effect present in an elevator shaft and hence the elevator lobby. This proposal is consistent with the artificial bottom seal requirements for smoke and draft control doors protecting the lobby of the new Fire Services Access Elevator found in Section 3007.4.3.
Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: Code change proposals FS43 and FS44 address lobby fire door testing without an artificial bottom seal. The committee needs to make its intent clear with respect to these provisions. Standard UL 1784 is currently referenced in the I-codes.

ICCFILENAME: EUGENE-FS1-708.14.1

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee did not agree that the proposed language was a coordination issue with Section 3007.4 and that the requirements for testing fire doors in fire partitions currently in the code were sufficient.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jon Siu representing Washington Association of Building Officials Technical Code Development Committee, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

708.14.1 Elevator lobby. An enclosed elevator lobby shall be provided at each floor where an elevator shaft enclosure connects more than three *stories*. The lobby enclosure shall separate the elevator shaft enclosure doors from each floor by *fire partitions*. In addition to the requirements in Section 709 for fire partitions, doors protecting openings in the elevator lobby enclosure walls, other than the door to the hoistway, shall be also comply with Section 715.4.3 as required for *corridor* walls with the UL 1784 test conducted without an artificial bottom seal. Penetrations of the elevator lobby enclosure by ducts and air transfer openings shall be protected as required for *corridors* in accordance with Section 716.5.4.1. Elevator lobbies shall have at least one *means of egress* complying with Chapter 10 and other provisions within this code.

Exceptions:

(Exceptions to remain unchanged)

Commenter's Reason: UL 1784 for the testing of fire door assemblies is well referenced in Section 715 for smoke and draft control fire door assemblies. The test records the data from the testing and the manufacturer with may test doors assemblies or without an artificial bottom seal- most commonly a layer of duct tape is used for the undercut. The responsibility for the referencing of design or result data from testing is with the Code that references UL 1784. If it simply states testing according to UL 1784, then any door tested with or without an artificial bottom seal can be utilized. Listed fire doors can have as much as ¾ inch undercut to allow for door swing and uneven floors. Heat and smoke flow from the underside of the door can be significant, placing both the occupants and the fire responders at risk.

In the case of elevator lobbies, the fire rated elevator shaft protected by fire rated doors in 708.14.1 requires an additional box or lobby in front of it to stall the impact of heat or smoke upon the elevator shaft or in certain cases the movement of heat and smoke from the elevator shaft to upper floors based upon the heat stratification. Pressure differentials between the fire floor, non-fire floors, elevator shafts, interior HVAC operation, and wind loads upon the exterior of the building can all contribute to pressure differences at the elevator lobby. The lobby doors logically should be able to restrict the passage of smoke on all four sides of the door opening- to include the undercut. This recommended restriction is best achieved by requiring the door assembly to be tested without the duct tape across the bottom of the door assembly.

This would be consistent with the existing requirements where a supplemental hoistway door is used in lieu of an elevator lobby as currently allowed by Exception 3.

Final Action: AS AM AMPC____ D

FS45-09/10
708.14.1

<u>Proposed Change as Submitted</u>

Proponent: Bill Ziegert, representing Smoke Guard, Inc.

Revise as follows:

708.14.1 Elevator lobby. An enclosed elevator lobby shall be provided at each floor where an elevator shaft enclosure connects more than three *stories*. The lobby enclosure shall separate the elevator shaft enclosure doors from each floor by *fire partitions*. In addition to the requirements in Section 709 for *fire partitions*, doors protecting openings in the elevator lobby enclosure walls shall also comply with Section 715.4.3 as required for *corridor* walls and penetrations of the elevator lobby enclosure by ducts and air transfer openings shall be protected as required for *corridors* in accordance with Section 716.5.4.1. Elevator lobbies shall have at least one *means of egress* complying with Chapter 10 and other provisions within this code. <u>Access to an exit through an elevator lobby shall be permitted provided that access to at least one other required exit does not require passing through the elevator lobby.</u>

Exceptions:

(Exceptions to remain unchanged)

Reason: Currently there is no prohibition in the code for occupied spaces exiting directly into an elevator lobby. Irrespective of whether the corridors leading to the elevator lobby are rated or not, the elevator lobby is a potentially hazardous area that can be filled with smoke. This change would insure that building occupants would have access to at least one exit without being forced to pass through the elevator lobby. Note that this language is already part of the current New York City Building Code which is based upon the IBC.

Cost Impact: No additional costs, since it is possible with the beginning design to structure the corridor system to provide direct access to at least one exit.

ICCFILENAME: ZIEGERT-FS3-708.14.1

<u>Public Hearing Results</u>

Committee Action: **Approved as Modified**

Modify the proposal as follows:

708.14.1 Elevator lobby. An enclosed elevator lobby shall be provided at each floor where an elevator shaft enclosure connects more than three *stories*. The lobby enclosure shall separate the elevator shaft enclosure doors from each floor by *fire partitions*. In addition to the requirements in Section 709 for *fire partitions*, doors protecting openings in the elevator lobby enclosure walls shall also comply with Section 715.4.3 as required for *corridor* walls and penetrations of the elevator lobby enclosure by ducts and air transfer openings shall be protected as required for *corridors* in accordance with Section 716.5.4.1. Elevator lobbies shall have at least one *means of egress* complying with Chapter 10 and other provisions within this code. Access to an exit through an <u>enclosed</u> elevator lobby shall be permitted provided that access to at least one other required exit does not require passing through the elevator lobby.

Exceptions:

(Exceptions to remain unchanged)

Committee Reason: The committee agreed that the proposed language clarified the intent of the code by allowing egress through an elevator lobby as long as one other required exit was available without having to egress through the lobby.

Assembly Action: **None**

Individual Consideration Agenda

These items are on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Dave Frable, representing U.S. General Services Administration, requests Disapproval.

Commenter's Reason: We are opposed to this proposed code change based on the fact that the Fire Safety Committee stated in their reason statement that the subject new text clarified the intent of the Code. On the contrary, if in fact this was an egress issue, it should have been heard by the Means of Egress Code Committee and not the Fire Safety Committee. Regardless, no technical justification has been provided by the proponent that supports his hypothesis that all enclosed elevator lobbies are a potentially hazardous area and therefore occupants need at least one exit available without passing through an enclosed elevator lobby. It should be noted that based on past National of Institute of Standards and Technology (NIST) research, smoke travel through enclosed or unenclosed elevator lobbies has not been a contributing factor to fire deaths in buildings protected throughout by automatic sprinklers. This has also been documented in the NIST research that showed that such flows will **NOT** result in untenable conditions beyond the fire floor with operating sprinklers regardless of whether elevator lobbies are provided. Therefore, we believe this requirement is unwarranted since the risk is minimal and also will cause unintended design considerations when trying to meeting exit stair remoteness and travel distance requirements and therefore should be removed. For example, a design such that an office space is located south of an elevator lobby with both exits on the north side of the elevator lobby would no longer be permitted. In addition, we also disagree with the proponent that this code change will not increase the cost of construction as the proponent has stated in his reason statement. We believe there will be extra construction costs associated with this requirement to meet all means of egress requirements.

Public Comment 2:

Lawrence G. Perry, AIA, representing Building Owners and Managers Association (BOMA) International, requests Disapproval.

Commenter's Reason: This code change should be disapproved for the following reasons:

1. "The lobby is a potentially hazardous area that can be filled with smoke." That is the full extent of technical substantiation offered for this significant change.
2. If adding lobbies has created a hazard that did not previously exist, perhaps lobbies themselves should be reconsidered. The modification that was approved to clarify what the intent of the proposal only points to the questionable rationale. One building is not required to provide any elevator separation or protection; that building can have egress travel directly past the elevator doors. Another building chooses to provide 'additional doors' in front of the elevator hoistway openings; that building can have egress travel directly past the elevator doors. A third building that provides enclosed elevator lobbies now has created a condition in front of the elevator doors that warrants prohibiting passing by them for egress purposes?
3. Where is the hazard coming from? If the lobby is enclosed on a lower floor where a fire is occurring, the lobby at that floor provides separation from the fire and smoke.
4. The extent of building area that could be arranged with the only egress through the elevator lobby is already limited due to dead end limits.
5. This is an egress issue, not an elevator lobby issue. If such a provision is to be included in the code, it should be in Chapter 10, not in Chapter 7.
6. The Committee statement indicates the proposal 'clarifies the intent of the code', which clearly is not what the intent of the IBC has ever been. In fact, there is even an ICC interpretation that addresses egress through elevator lobbies. Interpretation 01-07, reads as follows:

   1017.5 Corridor continuity. Fire-resistance-rated corridors shall be continuous from the point of entry to an exit, and shall not be interrupted by intervening rooms.

   Exception: Foyers, lobbies or reception rooms constructed as required for corridors shall not be construed as intervening rooms.

   Q: Where an elevator lobby is required by the provisions of Section 707.14.1 of the *International Building Code*, is egress to the exits permitted through the lobby?

   A: Yes. The provisions in Section 707.14.1 require an elevator lobby to be enclosed and separated from an exit access corridor with fire-resistance-rated construction equal to the fire-resistance rating of the corridor, but does not prohibit egress through the enclosed elevator lobby.

Final Action: AS AM AMPC____ D

FS48-09/10
708.14.1

<u>Proposed Change as Submitted</u>

Proponent: Gregory J. Cahanin, Cahanin Fire & Code Consulting representing the Smoke Safety Council

Revise as follows:

708.14.1 Elevator lobby. An enclosed elevator lobby shall be provided at each floor where an elevator shaft enclosure connects more than three *stories*. The lobby enclosure shall separate the elevator shaft enclosure doors from each floor by *fire partitions*. In addition to the requirements in Section 709 for *fire partitions*, doors protecting openings in the elevator lobby enclosure walls shall also comply with Section 715.4.3 as required for *corridor* walls and penetrations of the elevator lobby enclosure by ducts and air transfer openings shall be protected as required for *corridors* in accordance with Section 716.5.4.1. Elevator lobbies shall have at least one *means of egress* complying with Chapter 10 and other provisions within this code.

Exceptions:

1. Enclosed elevator lobbies are not required at the street floor, provided the entire street floor is equipped with an *automatic sprinkler system* in accordance with Section 903.3.1.1.
2. Elevators not required to be located in a shaft in accordance with Section 708.2 are not required to have enclosed elevator lobbies.
3. Enclosed elevator lobbies are not required where additional doors are provided at the hoistway opening in accordance with Section 3002.6. Such doors shall be tested in accordance with UL 1784 without an artificial ~~bottom~~ <u>horizontal or vertical</u> seal.
4. Enclosed elevator lobbies are not required where the building is protected by an *automatic sprinkler system* installed in accordance with Section 903.3.1.1 or 903.3.1.2. This exception shall not apply to the following:
   4.1. Group I-2 occupancies,
   4.2. Group I-3 occupancies, and
   4.3. High-rise buildings.
5. Smoke partitions shall be permitted in lieu of *fire partitions* to separate the elevator lobby at each floor where the building is equipped throughout with an *automatic sprinkler system* installed in accordance with Section 903.3.1.1 or 903.3.1.2. In addition to the requirements in Section 711 for smoke partitions, doors protecting openings in the smoke partitions shall also comply with Sections 711.5.2, 711.5.3, and 715.4.8 and duct penetrations of the smoke partitions shall be protected as required for *corridors* in accordance with Section 716.5.4.1.
6. Enclosed elevator lobbies are not required where the elevator hoistway is pressurized in accordance with Section 708.14.2.
7. Enclosed elevator lobbies are not required where the elevator serves only *open parking garages* in accordance with Section 406.3.

Reason: UL 1784 for the testing of fire door assemblies is well referenced in Section 715 for smoke and draft control fire door assemblies. Newer applications of in-the-field or aftermarket seals may not have been tested in the orientation utilized on elevator doors they are being installed upon. This change by its simple removal or either artificial horizontal or vertical bottom seals (duct tape) from material tested will insure that the as-installed assembly is an as-tested assembly consistent with IBC Section 715.4.3.1 intent.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: Cahanin-FS1-708.14.1

<u>Public Hearing Results</u>

Committee Action: **Approved as Submitted**

Committee Reason: The committee agreed replacing bottom seal with "horizontal of vertical seal" is more appropriate in that it reflects current testing practices.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

John Woestman, Kellen Company, representing Builders Hardware Manufacturers Association (BHMA), requests Disapproval.

Commenter's Reason: BHMA members agree with the proponent of FS48 that these doors are to be tested in accordance with UL 1784 without artificial seals.

However, BHMA members recommend disapproval of FS48 as the proposed changes of FS48 are addressed in UL1784 and including this language in the code will require revising door assembly test reports to unnecessarily affirm test conditions explicitly required by UL 1784.

UL 1784 states, in Section 1.3, "These requirements apply to complete door assemblies or to gasketing systems intended for use with specific door assemblies."

Section 5.4.5 of UL 1784 permits the air leakage testing of door assemblies using an artificial seal along the bottom edge only. There are no provisions in UL 1784 for testing with artificial vertical edge seals. As such, this code change is not needed. In addition, a provision in the code which is inconsistent with the referenced test standard and resulting listings will be confusing to code users.

Final Action: AS AM AMPC____ D

FS51–09/10
708.14.1-708.14.2.11

Proposed Change as Submitted

Proponent: Mike Ashley, CBO, representing Alliance for Fire & Smoke Containment & Control, Inc.

Revise as follows:

708.14.1 Elevator lobby. An enclosed elevator lobby shall be provided at each floor where an elevator shaft enclosure connects more than three *stories*. The lobby enclosure shall separate the elevator shaft enclosure doors from each floor by *fire partitions*. In addition to the requirements in Section 709 for *fire partitions*, doors protecting openings in the elevator lobby enclosure walls shall also comply with Section 715.4.3 as required for *corridor* walls and penetrations of the elevator lobby enclosure by ducts and air transfer openings shall be protected as required for *corridors* in accordance with Section 716.5.4.1. Elevator lobbies shall have at least one *means of egress* complying with Chapter 10 and other provisions within this code.

Exceptions:

1. Enclosed elevator lobbies are not required at the street floor, provided the entire street floor is equipped with an *automatic sprinkler system* in accordance with Section 903.3.1.1.
2. Elevators not required to be located in a shaft in accordance with Section 708.2 are not required to have enclosed elevator lobbies.
3. Enclosed elevator lobbies are not required where additional doors are provided at the hoistway opening in accordance with Section 3002.6. Such doors shall be tested in accordance with UL 1784 without an artificial bottom seal.
4. Enclosed elevator lobbies are not required where the building is protected by an *automatic sprinkler system* installed in accordance with Section 903.3.1.1 or 903.3.1.2. This exception shall not apply to the following:
   4.1. Group I-2 occupancies;
   4.2. Group I-3 occupancies; and
   4.3. High-rise buildings.
5. Smoke partitions shall be permitted in lieu of *fire partitions* to separate the elevator lobby at each floor where the building is equipped throughout with an *automatic sprinkler system* installed in accordance with Section 903.3.1.1 or 903.3.1.2. In addition to the requirements in Section 711 for smoke partitions, doors protecting openings in the smoke partitions shall also comply with Sections 711.5.2, 711.5.3, and 715.4.8 and duct penetrations of the smoke partitions shall be protected as required for *corridors* in accordance with Section 716.5.4.1.

~~6. Enclosed elevator lobbies are not required where the elevator hoistway is pressurized in accordance with Section 708.14.2.~~

~~7~~ 6. Enclosed elevator lobbies are not required where the elevator serves only *open parking garages* in accordance with Section 406.3.

Delete without substitution:

~~**708.14.2 Enclosed elevator lobby.** Where elevator hoistway pressurization is provided in lieu of required enclosed elevator lobbies, the pressurization system shall comply with this section.~~

~~**708.14.2.1 Pressurization requirements.** Elevator hoistways shall be pressurized to maintain a minimum positive pressure of 0.10 inches of water (25 Pa) and a maximum positive pressure of 0.25 inches of water (67 Pa) with respect to adjacent occupied space on all floors. This pressure shall be measured at the midpoint of each hoistway door, with all elevator cars at the floor of recall and all hoistway doors on the floor of recall open and all other hoistway doors closed. The opening and closing of hoistway doors at each level must be demonstrated during this test. The supply air intake shall be from an outside, uncontaminated source located a minimum distance of 20 feet (6096 mm) from any air exhaust system or outlet.~~

~~**708.14.2.2 Rational analysis.** A rational analysis complying with Section 909.4 shall be submitted with the *construction documents*.~~

~~**708.14.2.3 Ducts for system.** Any duct system that is part of the pressurization system shall be protected with the same *fire-resistance rating* as required for the elevator shaft enclosure.~~

~~**708.14.2.4 Fan system.** The fan system provided for the pressurization system shall be as required by this section.~~

~~**708.14.2.4.1 Fire resistance.** When located within the building, the fan system that provides the pressurization shall be protected with the same *fire-resistance rating* required for the elevator shaft enclosure.~~

~~**708.14.2.4.2 Smoke detection.** The fan system shall be equipped with a smoke detector that will automatically shut down the fan system when smoke is detected within the system.~~

~~**708.14.2.4.3 Separate systems.** A separate fan system shall be used for each elevator hoistway.~~

~~**708.14.2.4.4 Fan capacity.** The supply fan shall either be adjustable with a capacity of at least 1,000 cfm (.4719 m3/s) per door, or that specified by a *registered design professional* to meet the requirements of a designed pressurization system.~~

~~**708.14.2.5 Standby power.** The pressurization system shall be provided with standby power from the same source as other required emergency systems for the building.~~

~~**708.14.2.6 Activation of pressurization system.** The elevator pressurization system shall be activated upon activation of the building fire alarm system or upon activation of the elevator lobby smoke detectors. Where both a building fire alarm system and elevator lobby smoke detectors are present, each shall be independently capable of activating the pressurization system.~~

~~**708.14.2.7 Special inspection.** *Special inspection* for performance shall be required in accordance with Section 909.18.8. System acceptance shall be in accordance with Section 909.19.~~

~~**708.14.2.8 Marking and identification.** Detection and control systems shall be marked in accordance with Section 909.14.~~

~~**708.14.2.9 Control diagrams.** Control diagrams shall be provided in accordance with Section 909.15.~~

~~**708.14.2.10 Control panel.** A control panel complying with Section 909.16 shall be provided.~~

~~**708.14.2.11 System response time.** Hoistway pressurization systems shall comply with the requirements for smoke control system response time in Section 909.17.~~

Reason: This proposed change deletes the option to provide for pressurization of the elevator shaft as an equivalent solution to the use of the enclosed elevator lobby and other alternatives described in Section 708.14.1. The intent of this section is to define compliance alternatives that provide equivalent protection of the elevator shaft from vertical smoke migration. In the case of the elevator shaft pressurization option defined in Section 708.14.2, questions have been raised as to the effective equivalency of this option with the others. If elevator shaft pressurization is chosen as an alternative solution, it must work effectively in conjunction with other building systems, and particularly with stair shaft pressurization which is a requirement for buildings as required in Sections 403.5, 1022.9 and 909.20.5. Stair shaft pressurization must maintain a minimum pressure differential of 0.10 inches of water (25 Pa) (Section 909.20.5) and a maximum pressure differential of 0.35 inches of water (87 Pa). Section 708.14.2.1 requires a pressurization differential of between 0.10 (minimum) and 0.25 (maximum) inch water gauge. This can cause interference between the two pressurization systems as the two systems must be balanced so that they can operate simultaneously. This balance is difficult to attain as the stair shaft pressurization system operates with only one leakage point per floor at the egress door into the stair shaft. The elevator shaft pressurization system must maintain the designated pressure differential across a much larger leakage area, usually multiple elevator door and frame systems at each floor. The leakage at the stair shaft at the door will typically be 200 cfm or less, while the leakage across a standard two leaf 3.5 ft by 7 ft elevator door and frame will be 600 – 900 cfm. Most floors will have two to three openings per floor, providing for a much larger leakage area to be overcome by the elevator shaft pressurization system.

A recent study published in *Building and Environment Journal* raised this question of competing pressurization systems. The study, “On stairwell and elevator shaft pressurization for smoke control in tall buildings”, by Dr. Richard S. Miller and Dr. Don Beasley, with the Department of Mechanical Engineering at Clemson University, studied three scenarios: operation of the stair shaft pressurization system alone, operation of the elevator shaft pressurization system alone, and operation of the two systems simultaneously. They used the CONTAM simulation software to model these three scenarios in both a residential and commercial building thirty stories in height. The two occupancy types selected used data driven exterior leakage rates from documented sources. CONTAM is one of the key tools developed and used by NIST in modeling computational fluid dynamics scenarios for smoke travel in building fires.

The study found that stair shaft pressurization was feasible because the stair shaft has only one entry point per floor, and the single gasketed swing door at that point of entry represents a relatively small leakage area. When elevator shaft pressurization air flow was analyzed, the study found that (quoting for the abstract section) “…elevator shaft pressurization systems are found to produce prohibitively large pressure differences across both the elevator and stairwell doors if (1) minimum pressure differences must be maintained at both open and closed elevator doors, and (2) if the system must function properly when the ground floor exterior building doors are closed.” This was found to be true even with the revised positive pressure limits provided in Section 708.14.2.1 (minimum positive pressure of 0.10 inches of water (25 Pa) and a maximum positive pressure of 0.25 inches of water (67 Pa) with respect to adjacent occupied space on all floors.

The study concluded that this was due primarily to the much larger leakage rates at the elevator door and frame, and the substantially added leakage that occurs on the Phase I recall floor where the doors are parked in the open position. Because the ground floor exterior doors (typically the Phase I recall floor) are normally closed, this results in over pressurization of this floor. The effect is that “the across elevator door pressure difference is increased substantially on the second floor (as well as on all the remaining floors). The elevator shaft pressurization system also interfered with the stair shaft pressurization system in the modeling scenarios due to the high pressures that were needed to provide positive pressure in the elevator shaft. The study also found that “fan location, vents, and louvers were all found to be ineffective as means of controlling the shaft pressures.” In addition, the study found that “…substantially different fan flow rates are required based on the exterior temperature (Table 3). Therefore, a system calibrated and tested during one season may have significantly different behavior during other seasons.”

The data generated by this study raises the question as to whether or not elevator shaft pressurization should be considered as a functionally equivalent solution to the other code compliant solutions defined in Section 707.18.1 for protecting the elevator shaft from vertical smoke migration. It is also generally known that testing and commissioning elevator shaft pressurization systems is difficult and susceptible to daily variations in atmospheric temperature.

For these reasons, we urge the membership to approve this code change as submitted.

Miller, Richard S. and Beasley, D. On stairwell and elevator shaft pressurization for smoke control in tall buildings, Building and Environment (2008), doi:10.1016/j.buildenv.2008.09.015

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: Code change proposals FS51, FS52 and FS53 address elevator lobby pressurization requirements. FS51 deletes the requirements and FS52 and FS53 revise the requirements. The committee needs to make its intent clear with respect to these provisions.

ICCFILENAME: ASHLEY-FS1-708.14.1.doc

Public Hearing Results

Committee Action: Disapproved

Committee Reason: The committee agreed that the deletion hoistway pressurization option was not warranted based on the feasibility of designing a pressurization system as currently provided for in the code.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Bill Ziegert, Smoke Guard, Inc., representing self, requests Approval as Modified by this Public Comment.

Replace the proposal as follows:

708.14.2 Enclosed elevator lobby. Where elevator hoist-way pressurization is provided in lieu of required enclosed elevator lobbies, the pressurization system shall comply with this section.

708.14.2.1 Pressurization requirements.
Elevator hoistways shall be pressurized to maintain a minimum positive pressure of 0.10 inches of water (25 Pa) and a maximum positive pressure of 0.25 inches of water (67 Pa) with respect to adjacent occupied space on all floors. This pressure shall be measured at the midpoint of each hoistway door, with all elevator cars at the floor of recall and all hoistway doors on the floor of recall open and all other hoistway doors closed. <u>The pressure differentials shall be measured between the hoistway and the adjacent area. In residential buildings the pressure differential is permitted to be measured between the hoistway and the dwelling unit.</u> The opening and closing of hoistway doors at each level must be demonstrated during this test. The supply air intake shall be from an outside, uncontaminated source located a minimum distance of 20 feet (6096 mm) from any air exhaust system or outlet.

<u>**Exception:** The pressure differential is permitted to be measured relative to the outdoor atmosphere on floors other than the following</u>

1. <u>The fire floor</u>
2. <u>The two floors immediately below the fire floor, and</u>
3. <u>The floor immediately above the fire floor</u>

<u>**708.14.2.1.1 Use of Ventilation Systems** Ventilation systems, other than hoistway supply air systems, are permitted to be used to exhaust air from adjacent spaces on the fire floor, two floors immediately below, and one floor immediately above the fire floor to the building exterior when necessary to maintain the positive pressure relationships as required in 708.14.2.1 during the operation of the elevator shaft pressurization system.</u>

Commenter's Reason: FS 51 09/10 originally was submitted for the Committee hearings to remove the alternative to an enclosed elevator lobby if elevator shaft pressurization was employed under Exception 6 of 708.14.1 due to concerns that the prescriptive requirements of 708.14.2 were exceptionally difficult to achieve in most high rise buildings. The FS committee voted to Disapprove the change and during their comments, suggested that options be proposed to make this design option acceptable. This modification is based upon work by the City of Seattle that should accomplish those goals of maintaining elevator shaft pressurization as an option to enclosed elevator lobbies.

The issue with the current requirements of 708.14.2 are primarily due to the requirement to meet a minimum differential pressure requirement across hoistway doors of 0.10 inches of water <u>including the recall floor hoistway doors</u>. Achieving the required minimum pressure across the open hoistway doors on the recall floor required such a large volume of pressurization air, that all other floors will be over pressurized. In addition, it is believed that these high volumes in the elevator shaft negatively impact the performance of the pressurization systems for the exit stairs.

The City of Seattle has been at the forefront of allowing elevator shaft pressurization systems for many years and has done significant research with noted smoke control experts on the issues of pressuring elevator shafts. They have developed an approach that allows differential pressures for most of the shaft to be measured to the outside of the building and utilizes a venting approach to increase the differential pressure on the floors closest to the fire incident. Specifically, allowing the differential pressure to be measured to the outside on most floors substantially reduces the pressurization volumes required. In addition, in Seattle they also allow the fire floor and three adjacent floors be vented (exhausted) to the exterior. This venting / exhausting serves to substantially increase the differential pressure across the hoistway doors on the most critical floors which keeps smoke from entering the elevator shaft. The combination of measuring to ambient on most floors, and the option of venting the floors in the vicinity of the fire floor allows all floors to achieve the minimum / maximum pressures with substantially lower pressurization volumes.

Dr. Miller of Clemson University has done extensive modeling of different elevator shaft pressurization designs using the CONTAM model and has concluded that the "Seattle approach" does indeed meet all the prescriptive requirements of the IBC 2009.

Final Action: AS AM AMPC____ D

FS53-09/10
708.14.2.3 (New)

Proposed Change as Submitted

Proponent: Bill Ziegert, representing Smoke Guard, Inc.

Add new text as follows:

<u>**708.14.2.3. Exit Discharge door position**. When elevator hoistway pressurization is activated at least two exit discharge doors to the outside of the building shall be automatically opened and shall remain open for the duration of the operation of the pressurization system. The open exit discharge doors shall be in addition to other doors required to be open for atrium air flow or smoke control systems.</u>

(Renumber subsequent sections)

Reason: Recent computer modeling by experts has called into question the ability of an elevator pressurization system to meet the differential pressure requirements of Section 708.14.2.1 across the hoistway doors. The difficulty is caused by the necessity to design the system to work properly during Elevator Phase 1 Recall where the elevators return to the recall floor and park with the hoistway doors open for the duration of the emergency or until the Fire Service commandeers them under Phase 2.

Unless other precautions are undertaken, the models suggest that if the minimum differential pressure is achieved across the hoistway door openings on the recall floor, all other floors above this will see excessive pressures beyond the code limits and beyond the ability of the elevator doors to operate properly.

Two solutions were proposed including a) opening doors to the outside, or alternately b) providing an enclosed elevator lobby at the recall floor. Only the option of opening doors to the outside is viable however since elevator lobbies at the recall floor would serve minimal benefit as occupants would continually be opening the lobby doors during evacuation thereby defeating the intended purpose.

For additional information see http://www.ces.clemson.edu/~rm/PDF/BandE.pdf

Cost Impact: Minimal cost impact for automatic door opener systems

Analysis: Code change proposals FS51, FS52 and FS53 address elevator lobby pressurization requirements. FS51 deletes the requirements and FS52 and FS53 revise the requirements. The committee needs to make its intent clear with respect to these provisions.

ICCFILENAME: ZIEGERT-FS5-708.14.2.3

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee felt that this proposal was not technically justified as being a problem in current practice. Further, requiring these exterior doors to open during the operation of the pressurization system could be a health and safety risk to the occupants of the building.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Bill Ziegert, Smoke Guard, Inc., representing self, requests Approval as Submitted.

Commenter's Reason: Recent computer modeling by experts has called into question the ability of an elevator pressurization system to meet the (expanded) differential pressure requirements of IBC 2009 - Section 708.14.2.1 across the hoistway doors (minimum of 0.10 inches of water to a maximum of 0.25 inches of water). The difficulty is caused by the mandate in the elevator code that during Phase 1 elevator recall, all elevator cabs return to the exit discharge floor, park with the hoistway doors open, and remain in this position throughout the emergency (unless the Fire Service commandeers them for Phase 2 use). Achieving the minimum differential pressure across the open hoistway doors on the recall floor requires such a substantial volume of pressurization air, that all the upper floors end up being over pressurized. Alternately if the maximum differential pressure is not exceeded on the upper floors, the minimum differential pressure cannot be achieved on the recall floor.

Additional modeling has suggested three solutions including a) leaving the hoistway doors closed during Phase 1 recall (in violation of ASME A17.1), b) providing an enclosed lobby on the ground floor, and c) opening multiple doors to the outside.

For additional information see http://www.ces.clemson.edu/~rm/PDF/BandE.pdf

Final Action: AS AM AMPC____ D

FS54-09/10
708.14.1

Proposed Change as Submitted

Proponent: Dave Frable, U.S. General Services Administration, representing the U.S. General Services Administration

Revise as follows:

708.14.1 Elevator lobby. An enclosed elevator lobby shall be provided at each floor where an elevator shaft enclosure connects more than three *stories*. The lobby enclosure shall separate the elevator shaft enclosure doors from each floor by *fire partitions*. In addition to the requirements in Section 709 for *fire partitions*, doors protecting openings in the elevator lobby enclosure walls shall also comply with Section 715.4.3 as required for *corridor* walls and penetrations of the elevator lobby enclosure by ducts and air transfer openings shall be protected as required for *corridors* in accordance with Section 716.5.4.1. Elevator lobbies shall have at least one *means of egress* complying with Chapter 10 and other provisions within this code.

Exceptions:

1. Enclosed elevator lobbies are not required at the street floor, provided the entire street floor is equipped with an *automatic sprinkler system* in accordance with Section 903.3.1.1.
2. Elevators not required to be located in a shaft in accordance with Section 708.2 are not required to have enclosed elevator lobbies.
3. Enclosed elevator lobbies are not required where additional doors are provided at the hoistway opening in accordance with Section 3002.6. Such doors shall be tested in accordance with UL 1784 without an artificial bottom seal.
4. Enclosed elevator lobbies are not required where the building is protected by an *automatic sprinkler system* installed in accordance with Section 903.3.1.1 or 903.3.1.2. This exception shall not apply to the following:
   4.1. Group I-2 occupancies;
   4.2. Group I-3 occupancies; and
   4.3. High-rise buildings<u>, except as permitted in exception 5</u>.

<u>5.</u> <u>Enclosed elevator lobbies are not required in Group B occupancies with an occupied floor not greater than 420 feet in height above the lowest level of fire department vehicle access that are protected throughout by an automatic fire sprinkler system designed and installed in accordance with Section 903.3.1.1 and maintained in accordance with Section 903.5.</u>

<u>6</u> ~~5.~~ Smoke partitions shall be permitted in lieu of *fire partitions* to separate the elevator lobby at each floor where the building is equipped throughout with an *automatic sprinkler system* installed in accordance with Section 903.3.1.1 or 903.3.1.2. In addition to the requirements in Section 711 for smoke partitions, doors protecting openings in the smoke partitions shall also comply with Sections 711.5.2, 711.5.3, and 715.4.8 and duct penetrations of the smoke partitions shall be protected as required for *corridors* in accordance with Section 716.5.4.1.

<u>7.</u> ~~6.~~ Enclosed elevator lobbies are not required where the elevator hoistway is pressurized in accordance with Section 708.14.2.

<u>8.</u> ~~7.~~ Enclosed elevator lobbies are not required where the elevator serves only *open parking garages* in accordance with Section 406.3.

Reason: The intent of this code change is to acknowledge that Group B occupancies with an occupied floor not greater than 420 feet in height above the lowest level of fire department vehicle access that are protected by an operational automatic fire sprinkler system provide an acceptable level of safety for building occupants and therefore do not warrant the need for enclosed elevator lobbies.

During the 2006/2007 ICC Code Development Hearings in Orlando, the Fire Safety Code Committee approved a similar code change proposal (FS54-06/07) that acknowledged that Group B occupancies of any height that are protected by an operational automatic fire sprinkler system provided an acceptable level of safety for building occupants and therefore did not warrant the need for enclosed elevator lobbies for the following reasons:

1. The proposal ties the exception to a specific occupancy which has a good fire record.
2. The NIST analysis is new technical data that shows a justification for this proposal.
3. The NIST study did address smoke flow in both winter and summer for this low hazard occupancy. When combined with the excellent fire safety record for high-rise buildings, both sprinklered and unsprinklered, this exception appears justified and will help to eliminate this contentious issue which has come before the committee for several years.

However, at the Final Action Hearings of the ICC in May 2007, the ICC membership voted to overturn the Fire Safety Code Committee's recommendation and disapproved the subject code change. At the Hearings, no new technical information was provided to discount any of the Fire Safety Committee's aforementioned rationale for approval as submitted other than several opponents were concerned that it would apply to high-rise office buildings of any height; even those super high-rise office buildings greater than 420 feet in height, where the potential for stack effect in certain areas of the country may be greater and result in the vertical smoke migration through the elevator hoistways.

Therefore, to address this concern, we have limited exception 5 to only apply to Group B occupancies with an occupied floor not more than 420 feet in height above the lowest level of fire department vehicle access.

In addition, the previous research conducted by the National Institute of Standards and Technology (NIST) has shown that sprinklered fires do not represent a significant hazard to the building occupants because the automatic sprinklers activated and extinguished the fire prior to releasing a significant energy or mass. Little or no smoke or gases entered the hoistways, and none reached remote locations in any building regardless of height or other conditions examined[1]. Therefore, it can be concluded that smoke spread in shafts and elevator hoistways is not a problem in Group B occupancies protected throughout with an operational fire sprinkler system since the fire sprinklers both control the burning rate (and thus limit smoke production) and maintain near ambient temperature which limits the buoyancy forces that drive smoke to the shafts where stack affect may cause smoke spread to other floors. It is also widely accepted that operating fire sprinklers will prevent room flashover and full floor fires, and will limit the size of room fires[2]. This conclusion can also be substantiated from a paper presented by Dr. John Klote at the Elevator Symposium on Emergency Use of Elevators in March 2004 and in an article titled "Is There A Need to Enclose Elevator Lobbies In Tall Buildings?", written by Richard Bukowski in the August 2005 *Building Safety Journal*.

In addition, all high-rise fires where smoke spread has been a problem have either been in unsprinklered buildings or partially sprinklered buildings. A recent comprehensive analysis in 2005 of high-rise fires by NFPA identified that no fatalities had occurred for more than a decade in any U.S. high-rise occupancy (> 10 story) other than the 6 fatalities in the unsprinklered Cook County Office Building (2003); the 1 fatality in the unsprinklered First Interstate Bank Building (1991); and 3 firefighter fatalities in the partially sprinklered (unsprinklered on floor of fire origin and several floors above) Meridan Plaza Building (1991). The Murrah Federal Building (1995) and the World Trade Center (1993 & 2001) bombings were excluded from this analysis.

Fire sprinklers control the burning rate (and thus limit smoke production) and maintain near ambient temperature which limits the buoyancy forces that drive smoke to the shafts where stack affect may cause smoke spread to other floors. It is also widely accepted that operating fire sprinklers will prevent room flashover and full floor fires, and will limit the size of room fires. The reliability of sprinklers should not be called into question as an NFPA report issued in 2005 indicated that automatic fire sprinklers successfully operating in reported structural fires was an exemplary 93%. This same report indicated that two-thirds of the automatic fire sprinkler system failures were because the automatic fire sprinkler systems were shut off, an unlikely scenario where jurisdictions adopt the IBC since the IBC requires the supervision of the automatic fire sprinkler system. Hence, the successful operation of an automatic fire sprinkler system designed and installed in compliance with the IBC requirements could be reasonably estimated at 98% (or better, since NFPA indicated that a number of fire incidents extinguished by sprinklers may not even be reported).

In addition to fire sprinklers in these buildings, the 2009 edition of the IBC now requires a number of additional safety enhancements such as: enclosed elevator lobbies for fire service access elevators in buildings greater than 120 feet; enclosed elevator lobbies for occupant evacuation elevators where utilized; two way communication at all elevator landings; an increase of 50% in egress capacity for exit stairs in all buildings; increased cohesive/adhesive bond strength for sprayed fire resistive materials; exit stair path markings in all high rise buildings; etc.

Given the aforementioned protection coupled with the excellent track record for sprinklered B occupancies, and keeping in mind that the purpose of the IBC is to provide minimum requirements to safeguard occupants of buildings from fire and other hazards attributed to the built environment based on sound technical documentation. Also keep in mind that fatalities are very rare in office buildings, even rarer in high-rise office buildings, and surpassingly rare in high-rise office buildings protected with an operational fire sprinkler system.

Last but not least, it should be noted that a similar proposal regarding the enclosure of elevator lobbies was also addressed by the National Fire Protection Association (NFPA) 101 Technical Committee on Industrial, Storage, and Miscellaneous (e.g., High-rise) Occupancies. The NFPA Technical Committee did not approve the proposal to separate elevator hoistways with smoke barriers in sprinkler high-rise buildings based on a lack of technical substantiation. In addition, on June 9, 2005 the NFPA membership approved the 2006 edition of NFPA 101 and supported the Technical Committee's decision to not include a requirement to separate elevator hoistways with smoke barriers in sprinkler high-rise buildings.

Based on all these points stated above, we strongly believe that it is reasonable to state that Group B occupancies that are not more than 420 feet in height, and protected throughout with automatic fire sprinkler system is not a rationale alternative to enclosed elevator lobbies and that automatic fire sprinklers are not an effective method for slowing or stopping the spread of smoke throughout a building protected throughout with an operational automatic fire sprinkler system. In addition, we believe the current requirement for enclosing elevator lobbies in Group B occupancies not more than 420 feet in height, protected throughout by an operational automatic fire sprinkler system has not been based on sound technical documentation and will significantly increase building construction and maintenance costs without increasing the overall safety to the building occupants.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: Frable-FS3-708.14.1-2

Public Hearing Results

Committee Action: Disapproved

Committee Reason: The wording is confusing in that it is not clear if the sprinkler system is required for the building or only the B occupancy. Further, sprinkler systems can fail and redundant safety features in a highrise building are needed.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Dave Frable, representing U.S. General Services Administration, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

708.14.1 Elevator lobby. An enclosed elevator lobby shall be provided at each floor where an elevator shaft enclosure connects more than three *stories*. The lobby enclosure shall separate the elevator shaft enclosure doors from each floor by *fire partitions*. In addition to the requirements in Section 709 for *fire partitions*, doors protecting openings in the elevator lobby enclosure walls shall also comply with Section 715.4.3 as required for *corridor* walls and penetrations of the elevator lobby enclosure by ducts and air transfer openings shall be protected as required for *corridors* in accordance with Section 716.5.4.1. Elevator lobbies shall have at least one *means of egress* complying with Chapter 10 and other provisions within this code.

Exceptions:
1. Enclosed elevator lobbies are not required at the street floor, provided the entire street floor is equipped with an *automatic sprinkler system* in accordance with Section 903.3.1.1.
2. Elevators not required to be located in a shaft in accordance with Section 708.2 are not required to have enclosed elevator lobbies.
3. Enclosed elevator lobbies are not required where additional doors are provided at the hoistway opening in accordance with Section 3002.6. Such doors shall be tested in accordance with UL 1784 without an artificial bottom seal.
4. Enclosed elevator lobbies are not required where the building is protected by an *automatic sprinkler system* installed in accordance with Section 903.3.1.1 or 903.3.1.2. This exception shall not apply to the following:
   - 4.1. Group I-2 occupancies;
   - 4.2. Group I-3 occupancies; and
   - 4.3. High-rise buildings, except as permitted in exception 5.

5. Enclosed elevator lobbies are not required in Group B occupancies with an occupied floor not greater than 420 feet in height above the lowest level of fire department vehicle access that are ~~protected~~ <u>equipped throughout the entire building</u> by an automatic fire sprinkler system designed and installed in accordance with Section 903.3.1.1 and maintained in accordance with Section 903.5.

(re-number remaining text accordingly)

Commenter's Reason: The intent of this code change is to acknowledge that high-rise Group B occupancies protected by an operational fire sprinkler system throughout the entire building provides an acceptable level of safety for building occupants and therefore does not warrant the need for enclosed elevator lobbies in buildings < 420 feet in height.

The proposed modifications to G54 have addressed the two concerns raised by the Fire Safety Code Committee regarding this code change proposal. We have revised the text so that it is now clear that the entire building would need to be protected throughout by automatic sprinkler system. In addition, we have included the NFPA website to view the complete 2009 NFPA report on "U.S. Experience With Sprinklers and Other Automatic Fire Extinguishing Equipment" which includes statistics on sprinkler performance. This report can be viewed at:

http://www.nfpa.org/itemDetail.asp?categoryID=521&itemID=18245&URL=Research%20&%20Reports/Fire%20reports/Fire%20protection%20 systems

In essence, we strongly believe that the reliability of sprinklers for office buildings should not be called into question as the subject NFPA report issued in 2009 indicates that automatic wet-pipe fire sprinklers successfully operating in reported structural fires large enough to activate fire sprinklers was an exemplary 96%. This same report indicated that two-thirds of the automatic fire sprinkler system failures were because the automatic fire sprinkler systems were shut off, an unlikely scenario where jurisdictions adopt the IBC since the IBC requires the supervision of the automatic fire sprinkler system. Hence, the successful operation of an automatic fire sprinkler system designed and installed in compliance with the IBC requirements could be reasonably estimated at 98% (or better, since NFPA indicated that a number of fire incidents extinguished by sprinklers may not even be reported). In addition, the report also indicated that in office buildings with wet-pipe fire sprinklers that operated were 99% effective.

It should also be noted that fire sprinklers control the burning rate (and thus limit smoke production) and maintain near ambient temperature which limits the buoyancy forces that drive smoke to the shafts where stack affect may cause smoke spread to other floors. It is also widely accepted that operating fire sprinklers will prevent room flashover and full floor fires, and will limit the size of room fires. Therefore, we believe it is reasonable to state that Group B occupancies that are not more than 420 feet in height, and protected throughout with automatic fire sprinkler system is a rationale alternative to enclosing elevator lobbies in office buildings.

Proposed Change as Submitted

Proponent: Paul K. Heilstedt, PE, FAIA, Chair, representing ICC Code Technology Committee (CTC)

Revise as follows:

SECTION 702
DEFINITIONS

702.1 Definitions. The following words and terms shall, for the purposes of this chapter, and as used elsewhere in this code, have the meanings shown herein.

JOINT. The linear opening in or between adjacent ~~fire resistance rated~~ assemblies that is designed to allow independent movement of the building in any plane caused by thermal, seismic, wind or any other loading.

L RATING. The air leakage rating of a through penetration firestop system or a fire-resistant joint system when tested in accordance with UL 1479 or UL 2079, respectively.

MEMBRANE PENETRATION. ~~An opening made through one side (wall, floor or ceiling membrane) of an assembly.~~ . A breach in one side of a floor-ceiling, roof-ceiling or wall assembly to accommodate an item installed into or passing through the breach.

MEMBRANE-PENETRATION FIRESTOP. A material, device or construction installed to resist for a prescribed time period the passage of flame and heat through openings in a protective membrane in order to accommodate cables, cable trays, conduit, tubing, pipes or similar items.

MEMBRANE-PENETRATION FIRESTOP SYSTEM. An assemblage consisting of a fire-resistance-rated floor-ceiling, roof-ceiling or wall assembly, one or more penetrating items installed into or passing through the breach in one side of the assembly and the materials or devices, or both, installed to resist the spread of fire into the assembly for a prescribed period of time.

PENETRATION FIRESTOP. A through-penetration firestop or a membrane-penetration firestop.

THROUGH PENETRATION. ~~An opening that passes through an entire assembly.~~ A breach in both sides of a floor, floor-ceiling or wall assembly to accommodate an item passing through the breaches.

THROUGH-PENETRATION FIRESTOP SYSTEM. ~~An assemblage of specific materials or products that are designed, tested and fire-resistance rated to resist for a prescribed period of time the spread of fire through penetrations. The F and T rating criteria for penetration fire stop systems shall be in accordance with ASTM E814 or UL 1479. See definition of "F" rating and "T" rating".~~ An assemblage consisting of a fire-resistance-rated floor, floor-ceiling, or wall assembly, one or more penetrating items passing through the breaches in both sides of the assembly and the materials or devices, or both, installed to resist the spread of fire through the assembly for a prescribed period of time.

(Relocate Section 708 to Section 712 and 713. Renumber subsequent sections)

SECTION ~~709~~ 708
FIRE PARTITIONS

SECTION ~~710~~ 709
SMOKE BARRIERS

SECTION ~~711~~ 710
SMOKE PARTITIONS

SECTION ~~712~~ 711
HORIZONTAL ASSEMBLIES

~~712.4~~ 711.4 Continuity. Assemblies shall be continuous without openings, penetrations or joints except as permitted by this section and Sections ~~708.2~~ 712.1, ~~713.4~~ 714.4, ~~714~~ 715 and 1022.1. Skylights and other penetrations through a fire-resistance-rated roof deck or slab are permitted to be unprotected, provided that the structural integrity of the fire-resistance-rated roof construction is maintained. Unprotected skylights shall not be permitted in roof assemblies required to be fire-resistance rated in accordance with Section 704.10. The supporting construction shall be protected to afford the required fire-resistance rating of the horizontal assembly supported.

> **Exception:** In buildings of Type IIB, IIIB or VB construction, the construction supporting the *horizontal assembly* is not required to be fire-resistance-rated at the following:
>
> 1. Horizontal assemblies at the separations of incidental uses as specified by Table 508.2.5, provided the required *fire-resistance rating* does not exceed 1 hour.
> 2. Horizontal assemblies at the separations of *dwelling units* and *sleeping units* as required by Section 420.3.
> 3. Horizontal assemblies at *smoke barriers* constructed in accordance with Section ~~710~~ 709.

711.4.1 Nonfire-resistance-rated assemblies. ~~Linear openings~~ Joints in or between floors assemblies without a required fire-resistance rating shall comply with one of the following:

1. The linear opening shall be concealed within the cavity of a wall.
2. The linear opening shall be located above a ceiling.
3. The linear opening shall be sealed, treated or covered with an approved material or system to resist the free passage of flame and the products of combustion.

   Exception: Joints meeting one of the joint exceptions listed in 715.1

~~712.5~~ 711.5 Penetrations. Penetrations of horizontal assemblies, whether concealed or unconcealed, shall comply with Section ~~713~~ 714.

SECTION ~~708~~ 712
~~SHAFT ENCLOSURES~~ VERTICAL OPENINGS

~~708.1~~ 712.1 General. The provisions of this section shall apply to the vertical opening applications listed in Sections 712.1.1 through 712.1.18. ~~shafts required to protect openings and penetrations through floor/ceiling and roof/ceiling assemblies. Shaft enclosures shall be constructed as fire barriers in accordance with Section 707 or horizontal assemblies in accordance with Section 712, or both.~~

~~**708.2 Shaft enclosure required.** Openings through a floor/ceiling assembly shall be protected by a shaft enclosure complying with this Section.~~

> ~~**Exceptions:**~~

712.1.1 Smoke compartments. Vertical openings contained entirely within a shaft enclosure complying with Section 709 shall be permitted.

~~1.~~ 712.1.2 Individual dwelling unit. ~~A shaft enclosure is not required for~~ Unconcealed vertical openings totally within an individual residential dwelling unit and connecting four stories or less shall be permitted.

~~2.~~ 712.1.3 Escalator and Stairway Openings. ~~A shaft enclosure is not required in~~ Where a building is equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1, ~~for~~ an escalator opening or stairway that is not a portion of the means of egress shall be protected according to Item ~~2.1 or 2.2~~ 712.1.3.1 or 712.1.3.2:

~~2.1~~ 712.1.3.1 Opening size. Where the area of the ~~floor~~ vertical opening between stories does not exceed twice the horizontal projected area of the escalator or stairway and the opening is protected by a draft curtain and closely spaced sprinklers in accordance with NFPA 13. In other than Groups B and M, this application is limited to openings that do not connect more than four stories.

~~2.2~~ 712.1.3.2 Automatic shutters. Where the vertical opening is protected by approved power-operated automatic shutters at every penetrated floor. The shutters shall be of noncombustible construction and have a fire-resistance rating of not less than 1.5 hours. The shutter shall be so constructed as to close immediately upon the actuation of a smoke detector installed in accordance with Section 907.11 and shall completely shut off the well opening. Escalators shall cease operation when the shutter begins to close. The shutter shall operate at a speed of not more than 30 feet per minute (152.4 mm/s) and shall be equipped with a sensitive leading edge to arrest its progress where in contact with any obstacle, and to continue its progress on release there from.

~~3.~~ 712.1.4 Penetrations. ~~A shaft enclosure is not required for~~ Penetrations by pipe, tube, conduit, wire, cable and vents shall be protected in accordance with Section ~~713.4~~ 712.4.

~~4.~~ 712.1.5 Ducts. ~~A shaft enclosure is not required for~~ Penetrations by ducts shall be protected in accordance with Section 716.6. Grease ducts shall be protected in accordance with the *International Mechanical Code*.

~~5.~~ 712.1.6 Atriums. In other than Group H occupancies, ~~a shaft enclosure is not required for floor openings complying with the provisions for~~ atriums ~~in~~ complying with Section 404 shall be permitted.

~~6.~~ 712.1.7 Masonry chimney. ~~A shaft enclosure is not required for~~ Approved masonry chimneys shall be permitted where the annular space is fireblocked at each floor level in accordance with Section 717.2.5.

~~7.~~ 712.1.8 Two story openings. In other than Groups I-2 and I-3~~, a shaft enclosure is not required for~~ a floor opening that is not used as one of the applications listed in this section shall be permitted if it complies with all the items below ~~or an air transfer opening that complies with the following:~~

- ~~7.1~~ 1. Does not connect more than two stories.
- ~~7.2~~ 2. Does not contain a stairway or ramp required by Chapter 10. ~~Is not part of the required means of egress system~~.
- 3. Does not penetrate a horizontal assembly that separates fire areas or smoke barriers that separate smoke compartments.
- ~~7.3~~ 4. Is not concealed within the construction of a wall or a floor/ceiling assembly.
- ~~7.4~~ 5. Is not open to a corridor in Group I and R occupancies.
- ~~7.5~~ 6. Is not open to a corridor on nonsprinklered floors ~~in any occupancy~~.
- ~~7.6~~ 7. Is separated from floor openings and air transfer openings serving other floors by construction conforming to required shaft enclosures.
- ~~7.7.~~ ~~Is limited to the same smoke compartment~~.

~~8.~~ 712.1.9 Parking garages. ~~A shaft enclosure is not required for~~ Automobile ramps in open and enclosed parking garages shall be permitted where constructed in accordance with Sections 406.3 and 406.4, respectively.

~~9.~~ **712.1.10 Mezzanine.** ~~A shaft enclosure is not required for~~ Vertical ~~floor~~ openings between a mezzanine complying with Section 505 and the floor below shall be permitted. ~~and the floor below.~~

~~10.~~ 712.1.11 Joints. ~~A shaft enclosure is not required for~~ Joints shall be permitted where complying ~~protected by a fire-resistant joint system in accordance~~ with Section ~~714~~ 715.

~~11.~~ 712.1.12 Unenclosed stairs and ramps. A ~~shaft enclosure shall not be required for~~ vertical floor openings created by unenclosed stairs or ramps in accordance with Exception 3 or 4 in Section 1016.1 shall be permitted.

~~12.~~ 712.1.13 Floor Fire Doors. ~~Floor~~ Vertical openings shall be permitted where protected by floor fire doors in accordance with Section ~~712.8~~ 711.8.

~~13.~~ 712. 1.14. Group I-3. In Group I-3 occupancies, ~~a shaft enclosure is not required for floor~~ vertical openings shall be permitted in accordance with Section 408.5.

~~14.~~ 712.1.15 Elevators in parking garages. ~~A shaft enclosure is not required for e~~ vertical openings for elevator hoistways in open or enclosed parking garages that serve only the parking garage, and complying with 406.3 and 406.4 respectively, shall be permitted..

~~15.~~ **712.1.16 Duct systems in parking garages.** Vertical openings for mechanical exhaust or supply duct systems in open or enclosed parking garages ~~a shaft enclosure is not required to enclose mechanical exhaust or supply duct systems~~ complying with 406.3 and 406.4 respectively, shall be permitted to be unenclosed where ~~when~~ such duct system is contained within and serves only the parking garage.

712.1.17 Nonfire-resistance-rated joints. Joints in or between floors without a required fire-resistance rating shall be permitted in accordance with section 711.4.1.

~~16.~~ **712.1.18 Openings otherwise permitted.** Vertical openings shall be ~~Where~~ permitted where allowed by other sections of this code.

SECTION 713
SHAFT ENCLOSURES

713.1 General. The provisions of this section shall apply to shafts required to protect openings and penetrations through floor/ceiling and roof/ceiling assemblies. Shaft enclosures shall be constructed as fire barriers in accordance with Section 707 or horizontal assemblies in accordance with Section 711, or both.

SECTION ~~713~~ <u>714</u>
PENETRATIONS

~~713.3~~ <u>714.3</u> Fire-resistance-rated walls. Penetrations into or through fire walls, fire-barrier walls, smoke-barrier walls and fire partitions shall comply with Sections ~~713.3.1~~ <u>714.3.1</u> through ~~713.3.4~~ <u>714.3.4</u>. Penetrations in smoke barrier walls shall also comply with Section ~~713.5~~ <u>714.5</u>.
~~713.3.1~~ <u>714.3.1</u> Through penetrations. *(No change to text)*

~~713.3.1.1~~ <u>714.3.1.1</u> Fire resistance rated assemblies. *(No change to text)*

~~713.3.1.2~~ <u>714.3.1.2</u> Through penetration firestop system. *(No change to text)*

~~713.3.2~~ <u>714.3.2</u> Membrane penetrations. *(No change to text)*

~~713.3.3~~ <u>714.3.3</u> Dissimilar materials. *(No change to text)*

~~713.4~~ <u>714.4</u> Horizontal assemblies. Penetrations of a floor, floor/ceiling assembly or the ceiling membrane of a roof/ceiling assembly not required to be enclosed in a shaft by Section 708.2 shall be protected in accordance with Sections ~~713.4.1~~ <u>714.4.1</u> through ~~713.4.2.2~~ <u>714.4.2.2</u>.

~~713.4.1~~ <u>714.4.1</u> Fire-resistance rated assemblies. Penetrations of the fire-resistance rated floor, floor/ceiling assembly or the ceiling membrane of a roof/ceiling assembly shall comply with Sections ~~714.4.1.1~~ <u>713.4.1.1</u> through ~~713.4.1.4~~ <u>714.4.1.4</u>. Penetrations in horizontal smoke barriers shall also comply with ~~713.5~~ <u>714.5</u>.

~~713.4.1.1~~ <u>714.4.1.1</u> Through penetrations. *(No change to text)*

~~713.4.1.1.1~~ <u>714.4.1.1.1</u> Installation. *(No change to text)*

~~713.4.1.1.2~~ 714.4.1.1.2 Through penetration firestop system. *(No change to text)*

~~713.4.1.2~~ 714.4.1.2 Membrane penetrations. Penetrations of membranes that are part of a horizontal assembly shall comply with Section ~~713.4.1.1.1~~ 714.4.1.1.1 or ~~713.4.1.1.2~~ 714.4.1.1.2. Where floor/ceiling assemblies are required to have a fire-resistance rating, recessed fixtures shall be installed such that the required fire resistance will not be reduced.

Exceptions:

1. *Membrane penetrations* by steel, ferrous or copper conduits, pipes, tubes or vents, or concrete or masonry items where the *annular space* is protected either in accordance with Section 713.4.1.1 or to prevent the free passage of flame and the products of combustion. The aggregate area of the openings through the membrane shall not exceed 100 square inches (64 500 mm2) in any 100 square feet (9.3 m2) of ceiling area in assemblies tested without penetrations.
2. Ceiling membrane penetrations of maximum 2-hour *horizontal assemblies* by steel electrical boxes that do not exceed 16 square inches (10 323 mm2) in area, provided the aggregate area of such penetrations does not exceed 100 square inches (44 500 mm2) in any 100 square feet (9.29 m2) of ceiling area, and the annular space between the ceiling membrane and the box does not exceed 1/8 inch (3.2 mm).
3. Membrane penetrations by electrical boxes of any size or type, which have been *listed* as part of an opening protective material system for use in *horizontal assemblies* and are installed in accordance with the instructions included in the listing.
4. *Membrane penetrations* by *listed* electrical boxes of any material, provided such boxes have been tested for use in fire-resistance-rated assemblies and are installed in accordance with the instructions included in the listing. The *annular space* between the ceiling membrane and the box shall not exceed 1/8 inch (3.2 mm) unless *listed* otherwise.
5. The *annular space* created by the penetration of a fire sprinkler, provided it is covered by a metal eschutcheon plate.
6. Noncombustible items that are cast into concrete building elements and that do not penetrate both top and bottom surfaces of the element.

~~**713.4.1.3 Ducts and air transfer openings.** Penetrations of horizontal assemblies by ducts and air transfer openings shall comply with Section 716.~~

~~713.4.1.4~~ 714.4.1.4 Disimilar materials. *(No change to text)*

~~713.4.2~~ 714.4.2 Nonfire-resistance-rated assemblies. Penetrations of nonfire-resistance rated floor or floor/ceiling assemblies or the ceiling membrane of a nonfire-resistance rated roof/ceiling assembly shall meet the requirements of Section 708 or shall comply with Section ~~713.4.2.1~~ 714.4.2.1 or ~~713.4.2.2~~. 714.4.2.2

~~713.4.2.1~~ 714.4.2.1 Noncombustible penetrating items. Noncombustible penetrating items that connect not more than ~~three~~ five stories are permitted, provided that the annular space is filled to resist the free passage of flame and the products of combustion with an approved noncombustible material or with a fill, void or cavity material that is tested and classified for use in through-penetration firestop systems.

~~713.4.2.2~~ 714.4.2.2 Penetrating items. Penetrating items that connect not more than two stories are permitted, provided that the annular space is filled with an approved material to resist the free passage of flame and the products of combustion.

~~713.5~~ 714.5 Penetrations in smoke barriers. Through-penetration firestop systems in *smoke barriers* shall be tested in accordance with the requirements of UL 1479 for air leakage. The ~~air leakage rate~~ L rating of the system measured at 0.30 inch (7.47 Pa) of water in both the ambient temperature and elevated temperature tests, shall not exceed:
5.0 cfm per square foot (0.025m^3/ s m^2) of penetration opening for each *through-penetration firestop system*; or
A total cumulative leakage of 50 cfm (0.024m^3/s) for any 100 square feet (9.3 m^2) of wall area, or floor area.

Section ~~714~~ 715
FIRE RESISTANT JOINT SYSTEMS

~~714.6~~ 715.6 Fire-resistant joint systems in smoke barriers. Fire-resistant joint systems in smoke barriers, and joints at the intersection of a horizontal *smoke barrier* and an exterior curtainwall, shall be tested in accordance with the requirements of UL 2079 for air leakage. The ~~air leakage rate~~ L rating of the joint system shall not exceed 5 cfm per lineal foot (0.00775 m^3/s m) of joint at 0.30 inch (7.47 Pa) of water for both the ambient temperature and elevated temperature test.

Reason: The ICC Board established the ICC Code Technology Committee (CTC) as the venue to discuss contemporary code issues in a committee setting which provides the necessary time and flexibility to allow for full participation and input by any interested party. The code issues are assigned to the CTC by the ICC Board as "areas of study". Information on the CTC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CTC effort can be downloaded from the following website: http://www.iccsafe.org/cs/cc/ctc/index.html <http://www.iccsafe.org/cs/cc/ctc/index.html> . Since its inception in April/2005, the CTC has held seventeen meetings - all open to the public.

This proposed change is a result of the CTC's investigation of vertical openings through the Vertical Opening Study Group, which is part of the area of study, entitled "Balanced Fire Protection." The scope of the activity is noted as:

"To investigate what constitutes an acceptable balance between active fire protection and passive fire protection measures with respect to meeting the fire and life safety objectives of the IBC."

The ICC Vertical Opening Study Group re-grouped after the last ICC code development cycle and again looked at the problems and inconsistencies with Chapter 7 of the 2009 IBC. This statement provides a comprehensive explanation of the code proposals drafted and supported by the study group.

Rather than scrap the affected sections and re-write new text, the study group approached this task using mainly surgical fixes. After careful review we felt that the current content in Chapter 7 is fundamentally sound and familiar to all. We believe the inconsistencies that have developed in Chapter 7are mainly due to the initial drafting of the IBC, where language from each of the three legacy code was used, as is. As concepts in the IBC changed, some of these sections became in conflict with one another, obsolete or created "do loops" where the user never finds the correct requirement.

Most of the changes proposed by the study group are editorial in nature and will not change how the code is applied or used. However, as you will see, the study group has also proposed changes separately that are technical in nature. During the review, we felt there are areas in code that, based on fire statistics, should be improved. The study group was very focused on getting a basic proposal in front of the committee and membership that fixes the code editorially. Our main proposal includes only amendments that this group feels are editorial or very minor changes. In addition to the main proposal, we are also proposing technical changes. The study group is in support of both of these; however we did not want to jeopardize the entire effort because of the technical change debate.

Several of the definitions in Section 702 containing specific terms used in Chapter 7 were modified. Mainly the group wanted to emphasize the difference between openings, penetrations and membrane penetrations, although they are all defined globally as vertical openings. The definitions include the term breach to describe the entry into an assembly. This term was currently used in one of the existing definitions and we expanded its use. Our focus was to properly define the terms so that they can be dealt with in a prescriptive manner regarding vertical openings. In addition, the definition of joints was expanded to include linear openings in both rated or non-rated horizontal assemblies. This amendment was needed to be able to guide the code user to what is needed for non-rated assemblies. Other terms were discussed but the term "joint" was already defined in a way that familiar to all. The term L rating was also defined in a manner consistent with the existing standards and listings.

Section 711.4.1 was added to provide the user with guidance for non-rated assemblies in terms of what to do with open joints between the floor assemblies that allow for independent movement of the building in any plane caused by thermal, seismic, wind or any other loading. Basically, if the joint is not concealed within a cavity of a wall or not covered by a floor topping, then it must be sealed or treated with an approved material. Typically, they are covered by a decorative metal or something similar. This proposal will still allow for that method plus many other methods of sealing the vertical opening that this creates.

Section 711.5 was amended to clarify it applies to concealed and unconcealed penetrations. The study group felt that all penetrations needed to be sealed in some fashion, to reduce accelerated structural damage due to a breach in the assembly. Vertical openings should be protected in some way, whether the assembly is rated or non-rated. The added exception provides for joints that meet the exceptions in 715.1 and do not required additional measures.

Section 708 was changed to Section 712 to come after Horizontal Assemblies. The 2009 currently states that all vertical openings require a shaft and then give 17 exceptions to providing that shaft. Realizing that in today's built environment a shaft enclosure is only one of many ways to deal with a vertical opening, we re-named Section 712 (previously Section 708) to Vertical Openings and re-wrote the exceptions to become available options for dealing with the multitude of various vertical openings encountered within a building. Additionally, we felt that the code should be specific on where to go to find the requirements for each application. And finally we felt users should not be able to use sections that are out of context, such as the example of using current Exception 7 for penetrations.

Section 712.1.8 was further modified to clarify the meaning "required means of egress" and to remind the user that smoke and fire barriers cannot be penetrated with an unprotected vertical opening. Additionally "limited to the same smoke compartment" was removed because the charging statement eliminates I-2 and I-3 occupancies from consideration.

A new sections were added under Section 712.1.17 that provides guidance for joints in non-rated assemblies, previously discussed.
The term "vertical" was added where the current 2009 Code section 708 used just the term "opening". We felt this clarification is consistent with our overall goal to emphasize the difference between vertical openings used for convenience and those vertical openings which are used as penetrations, joint and other applications where the vertical opening is breached by an object and intended to be sealed.

An exception was added to Section 714.4.1.2 Membrane Penetrations that exempts membrane penetrations by non-combustible items in concrete floors. Membrane penetration requirements were not intended to address embedded or cast non-combustible items within concrete floors. This condition has never been shown to be a problem. Reports from fires show that this application performs very well in real fire conditions without compromising the integrity of the structure or allowing fire spread.

The study group believes that these amendments, explained so far are all very minor or editorial in nature and do reflect any new technical requirements.

Definitions: Reason for change

These terms were either added or modified based on previous and current VO study group work.

711.4.1: Reason for change

This section was proposed to address holes in unrated floor ceiling assemblies. After a conference call on 3/31, it was determined that the term "linear opening" needed a definition or change the term.
Further work to address the term is needed. To be completed by the CTC meeting.

712:Reason for changes

Section 708 was identified as being a problem.

This proposal removes the exceptions to providing a shaft a makes them options for vertical openings. No technical changes occurred.
Alternate code change 708.1.8 is a technical change that is being proposed for discussion.

714: Reason for change.

Indentified as a problem at the Balt. MD CTC meeting.

No guidance was given as to how the measurement is to be taken.
This proposal mandates the full height of the wall as one dimension when calculating the 100 sq. ft. This was determined to be the area most affected

A 10 ft. x 10 ft. square was chosen as an easy visual reference for inspectors in the field. This was determined to be area most affected.
An exception was added to stipulate that penetrations (membrane) in solid concrete floors was not considered a membrane penetration.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: HEILSTEDT-FS1-702.1

Public Hearing Results

Committee Action: Approved as Submitted

Committee Reason: The committee agreed that the proposal was a good reorganization of the requirements for vertical openings. The committee did recognize that there were also some minor technical changes and felt that these were appropriate and reasonable.

Note: The following modification was considered editorial:

712.1.4 Penetrations. Penetrations by pipe, tube, conduit, wire, cable and vents shall be protected in accordance with Section 714 ~~712.4~~.

(Portions of the proposal not shown remain unchanged)

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Gregory R. Keith, Professional heuristic Development, representing the Boeing Company, requests Approval as Modified by Public Comment.

Modify the proposal as follows:

~~**711.4.1 Nonfire-resistance-rated assemblies.** Joints in or between floors assemblies without a required fire-resistance rating shall comply with one of the following:~~

1. ~~The linear opening shall be concealed within the cavity of a wall.~~
2. ~~The linear opening shall be located above a ceiling.~~
3. ~~The linear opening shall be sealed, treated or covered with an approved material or system to resist the free passage of flame and the products of combustion.~~

~~**Exception:** Joints meeting one of the joint exceptions listed in 715.1~~

711.5 Penetrations. Penetrations of horizontal assemblies~~, whether concealed or unconcealed,~~ shall comply with Section 714.

~~**712.1.17 Nonfire-resistance-rated joints.** Joints in or between floors without a required fire-resistance rating shall be permitted in accordance with section 711.4.1.~~

(portions of the proposal not shown remain unchanged)

Commenter's Reason: In its published reason statement, the proponent of FS56-09/10 stated, "Most of the changes proposed by the study group are editorial in nature and will not change how the code is applied or used. However, as you will see, the study group has also proposed changes separately that are technical in nature. During the review, we felt there are areas in code that, based on fire statistics, should be improved. The study group was very focused on getting a basic proposal in front of the committee and membership that fixes the code editorially. Our main proposal includes only amendments that this group feels are editorial or very minor changes. In addition to the main proposal, we are also proposing technical changes. The study group is in support of both of these; however we did not want to jeopardize the entire effort because of the technical change debate."

It is acknowledged that much of FS56-09/10 reorganizes existing Chapter 7 provisions. Although the proponent suggests that the proposal "includes only amendments that this group feels are editorial or very minor changes," certain more stringent technical requirements have been introduced that have not been debated in the code development process to this point. Specifically, the proposal creates requirements for the protection of joints in nonfire-resistance rated floor assemblies. Additionally, it expands the scope of penetration requirements in horizontal assemblies to include those concealed within the assembly. Although the proponent states that these changes are based on fire statistics, no such statistics or other technical substantiation was offered for the inclusion of either one of these more stringent requirements in the IBC.

Section 711 (current Section 712) applies to "horizontal assemblies." The definition of horizontal assembly in Section 702.1 states, "A fire-resistance rated floor or roof assembly of materials designed to restrict the spread of fire in which continuity is maintained." 2009 Section 712.1 states, "Floor and roof assemblies required to have a fire-resistance rating shall comply with this section." Additionally, it states, "Nonfire-resistance-rated floor and roof assemblies shall comply with Section 713.4.2." Section 713.4.2 prescribes penetration protection in nonfire-resistance rated floor and roof assemblies under certain conditions. Although additional requirements have been created for non-fire resistance rated assemblies, they are not referenced in the section charging language (Section 711.1). As previously stated, there has been absolutely no technical justification or fire statistics that would demonstrate the need for additional joint protection in nonfire-resistance rated floor or roof assemblies. Additionally, the proposed requirements are more stringent in scope than the current penetration protection requirements for nonfire-resistance rated floor and roof assemblies based on the number of interconnected stories.

Also, Section 717 currently provides requirements for the protection of concealed spaces. Increasing the scope of Section 711.5 to include concealed spaces, is without precedence, without technical substantiation, without loss history and is entirely inappropriate.

These two provisions intended to increase protection requirements in nonfire-resistance rated construction are significant technical changes that deserve proper technical debate. To disguise these requirements as "editorial or very minor" is an insult to the objective code development process. The proponent indicated that technical changes were separately submitted. These questioned provisions that increase opening protection requirements for nonrated floor and roof assemblies should have been individually considered by the ICC Fire Safety Code Committee and the ICC membership. If the format provided by FS56-09/10 is preferred over current provisions, then it is recommended that the item be approved as modified by deleting the noted significant technical changes that were not even addressed during discussion of the proposal in Baltimore.

Public Comment 2:

Sarah A. Rice, CBO, representing self, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

SECTION 711
HORIZONTAL ASSEMBLIES

711.4 Continuity. Assemblies shall be continuous without openings, penetrations or joints except as permitted by this section ~~and Sections 712.1, 714.4, 715 and 1022.1.~~ Skylights and other penetrations through a fire-resistance-rated roof deck or slab are permitted to be unprotected, provided that the structural integrity of the fire-resistance-rated roof construction is maintained. Unprotected skylights shall not be permitted in roof assemblies required to be fire-resistance rated in accordance with Section 704.10. The supporting construction shall be protected to afford the required fire-resistance rating of the horizontal assembly supported.

Exception: In buildings of Type IIB, IIIB or VB construction, the construction supporting the *horizontal assembly* is not required to be fire-resistance-rated at the following:

1. Horizontal assemblies at the separations of incidental uses as specified by Table 508.2.5, provided the required *fire-resistance rating* does not exceed 1 hour.
2. Horizontal assemblies at the separations of *dwelling units* and *sleeping units* as required by Section 420.3.
3. Horizontal assemblies at *smoke barriers* constructed in accordance with Section 709.

711.8 Vertical openings. Vertical openings in horizontal assemblies shall be enclosed in a shaft constructed in accordance with Section 713 or comply with Section 712.

711.9 Means of egress stairs and ramps. Vertical openings in horizontal assemblies containing stairs or ramps required to comply with Chapter 10 shall comply with Section 1022.1.

(Renumber subsequent sections)

(Portions of proposal not shown remain unchanged)

Commenter's Reason:
711.4 – The modification eliminates the laundry list of section numbers as with the incorporation of new section 711.8, each is already referenced within the body of Section 711. Section 712 are addressed through references in new Sections 711.8 and 711.9, Section 714.4 is referenced in current 2009 IBC Section 712.6, Section 715 is referenced in current 2009 IBC 712.5

711.8 & 711.9 – The addition of these 2 sections brings consistency into the section. Currently all types of "holes" are addressed except for those that qualify as "vertical openings" and those that contain stairs or ramps required by Chapter 10. With the changes made through FS56-09/10 we now have a section on "vertical openings." The revisions add references to that new section and current 2009 IBC Section 1022.

Public Comment 3:

Sarah A. Rice, CBO, representing self, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

SECTION 712
VERTICAL OPENINGS

712.1 General. <u>In accordance with Section 711.4, vertical openings through floor and roof assemblies shall comply with the provision of this section or be enclosed in a shaft constructed in accordance with Section 713</u> ~~The provisions of this section shall apply to the vertical opening applications listed in Sections 712.1.1 through 712.1.18.~~

<u>Exception:</u> <u>Vertical openings that comply with Section 714.4, 715 or 1022.1.</u>

712.1.1 Smoke compartments. Vertical openings contained entirely within a <u>smoke compartment</u> ~~shaft enclosure~~ complying with Section <u>407 or 408</u> ~~709~~ shall be permitted.

(Portions of proposal not shown remain unchanged)

Commenter's Reason:

712.1 - The charging section has been revised to make it clear that there are two paths that the designer may choose for protecting a vertical opening – enclose it in a shaft (Section 713) or meet one of the parameters found in new Section 712.

712.1.1 - In Section 712.1.1, the language has been modified to clarify the original intent – vertical openings in smoke compartments (only found in hospitals & penal facilities) are allowed within the parameters outlined in Sections 407 and 408.

Public Comment 4:

Sarah A. Rice, CBO, representing self, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

712.1.8 Two story openings. In other than Groups I-2 and I-3, a floor opening that is not used as one of the applications listed in this section shall be permitted if it complies with all the items below:

1. Does not connect more than two stories.
2. Does not contain a<u>n exit</u> stairway or ramp required by Chapter 10.
3. Does not penetrate a horizontal assembly that separates fire areas or smoke barriers that separate smoke compartments.
4. Is not concealed within the construction of a wall or a floor/ceiling assembly.
5. Is not open to a corridor in Group I and R occupancies.
6. Is not open to a corridor on nonsprinklered floors.
7. Is separated from floor openings and air transfer openings serving other floors by construction conforming to required shaft enclosures.

712.1.10 Mezzanine. Vertical floor openings between a mezzanine<u> or mezzanines,</u> complying with Section 505 and the floor below shall be permitted.

712.1.11 <u>Fire-resistance rated</u> Joints. Joints shall be permitted where complying with Section 715.

(Portions of proposal not shown remain unchanged)

Commenter's Reason:

712.1.8 - The modification is needed to make it clear that the stair or ramp limitation in new Section 712.1.8, Item 3 is only for "exit" stairs. Given the revisions proposed for Chapter 10 in code change E5-09/10 (which was Approved as Submitted by the MOE Code Development Committee) some may interpret the limitation to apply to any stair or ramp covered by Chapter 10 – which is ALL stairs and ramps but this provision is only applicable to those that are "exits." Should E5-09/10 not be successful the proposed modification is still appropriate as it then emphasizes which stairs and ramps are being limited. Stairs and ramps that provide only intercommunication and are not required for the means of egress system would acceptable.

712.1.10 – The modification is needed to recognized that there may be more than one mezzanine in a story.

712.1.11 – The modification is needed so as to distinguish clearly this section from the provisions in new section 712.1.17 "nonfire-resistance rated joints."

Public Comment 5:

Gregory R. Keith, Professional heuristic Development, representing the Boeing Company, requests Disapproval

Commenter's Reason: The ICC Code Technology Committee (CTC) appointed a Vertical Openings Study Group on December 13, 2006. The CTC recognized that there were technical inconsistencies in IBC Chapter 7 requirements for the protection of openings in horizontal assemblies intended to restrict the vertical movement of fire. There were also concerns that opening and penetration requirements for horizontal assemblies were difficult for users to properly determine. It was suggested that there needs to be a vertical migration strategy and that technical requirements should support that strategy in concert, as opposed to being a collection of abstract requirements that perhaps achieve no practical end. Specifically, there were concerns that certain provisions required the protection of openings or penetrations in a given horizontal assembly while exceptions permitted unprotected openings in the same assembly.

FS56-09/10 was the second Vertical Opening Study Group attempt to achieve the CTC's stated goals. Upon close analysis, FS56 does very little to improve Chapter 7 provisions. The proponent's published reason statement explains, "Most of the changes proposed by the study group are editorial in nature and will not change how the code is applied or used. However, as you will see, the study group has also proposed changes separately that are technical in nature. During the review, we felt there are areas in code that, based on fire statistics, should be improved. The study group was very focused on getting a basic proposal in front of the committee and membership that fixes the code editorially. Our main proposal includes only amendments that this group feels are editorial or very minor changes. In addition to the main proposal, we are also proposing technical changes. The study group is in support of both of these; however we did not want to jeopardize the entire effort because of the technical change debate."

To gain a sense as to how FS56-09/10 actually impacts Chapter 7, the ICC staff has posted a document on the ICC website that shows how the proposal will overlay current Chapter 7 requirements. It can be found as follows: codes, standards and guidelines > Technical Committees > Other Code Committees > Code Technology Committee > Balanced Fire Protection > Study Groups: Vertical Openings > Impact of FS56-09/10. FS 56 provisions appear in red.

• Six definitions were either modified or created.

• Beginning with Section 708, several sections have been renumbered with no technical changes whatsoever.

• Sections 711.4.1 and 711.5 contain significant technical changes, contrary to the proponent's claims. Section 711 (current Section 712) applies to "horizontal assemblies." The definition of horizontal assembly in Section 702.1 states, "A fire-resistance rated floor or roof assembly of materials designed to restrict the spread of fire in which continuity is maintained." 2009 Section 712.1 states, "Floor and roof assemblies required to have a fire-resistance rating shall comply with this section." Additionally, it states, "Nonfire-resistance-rated floor and roof assemblies shall comply with Section 713.4.2." Section 713.4.2 prescribes penetration protection in nonfire-resistance rated floor and roof assemblies under certain conditions. Although additional joint protection requirements have been created for non-fire resistance rated assemblies, they are not referenced in the section charging language (Section 711.1). As previously stated, there has been absolutely no technical justification or fire statistics that would demonstrate the need for additional joint protection in nonfire-resistance rated floor or roof assemblies. Additionally, the proposed requirements are more stringent in scope than the current penetration protection requirements for nonfire-resistance rated floor and roof assemblies based on the number of interconnected stories. Currently, Section 717 provides requirements for the protection of concealed spaces. Increasing the scope of Section 711.5 to include concealed spaces, is without precedence, without technical substantiation, without loss history and is entirely inappropriate.

• A new Section 712 (Vertical Openings) has been created. It essentially represents a laundry list of potential opening protection requirements that potentially apply to floor and roof construction. The new section restates many provisions contained elsewhere in the Chapter 7. For instance, Sections 711.6 and 712.1.11 state essentially the same thing. The various opening protection requirements should be placed in the context of the assembly that they protect.

• Section 713 shaft enclosure provisions have been reformatted. What were formally exceptions are now stated as positive requirements. The requirements themselves, are virtually unchanged.

FS56-09/10 does little to improve continuity or understandability of Chapter 7 vertical opening protection requirements. It resolves none of the technical conflicts that currently exist and were the reason that the CTC appointed the Vertical Openings Study Group in the first place. In fact, through the inclusion of new technical requirements applicable to nonfire-resistance rated floor and roof construction, more technical and philosophical inconsistencies have been created. The technical ramifications or fire loss justification of these significant changes were never discussed at any point during the committee hearings. The proposal contains change for change's sake and accomplishes very little except for creating unreasonable, more stringent requirements for nonrated construction and concealed openings within horizontal assemblies. The result of approval of FS56-09/10 will be to only further confuse fundamental provisions that are in need of repair. FS56 should be disapproved and the CTC Vertical Openings Study Group should be instructed to produce a proposal that responds to the CTC's original concerns and actually improves the IBC.

Final Action: AS AM AMPC____ D

FS63-09/10

711.5, 711.6, 711.7

Proposed Change as Submitted

Proponent: Sarah A. Rice, CBO, representing self

Add new text as follows:

711.5 Openings. Openings in smoke partitions shall comply with Sections 711.5.1 and 711.5.2.

711.5.1 Windows. Windows in smoke partitions shall be sealed to resist the free passage of smoke or be automatic-closing upon detection of smoke. ~~Doors in smoke partitions shall comply with this section.~~

711.5.2 Doors. Doors in smoke partitions shall comply with Sections 711.5.2.1 through 711.5.2.3.

711.5.2.1 ~~**711.5.1**~~ **Louvers.** Doors in smoke partitions shall not include louvers.

711.5.2.2 ~~**711.5.2**~~ **Smoke and draft control doors.** Where required elsewhere in the code, doors in smoke partitions shall meet the requirements for a smoke and draft control door assembly tested in accordance with UL 1784. The air leakage rate of the door assembly shall not exceed 3.0 cubic feet per minute per square foot (0.015424m3/(s m2)) of door opening at 0.10 inch (24.9 Pa) of water for both the ambient temperature test and the elevated temperature exposure test. Installation of smoke doors shall be in accordance with NFPA 105.

711.5.2.3 ~~**711.5.3**~~ **Self- or automatic-closing doors.** Where required elsewhere in the code, doors in smoke partitions shall be self- or automatic-closing by smoke detection in accordance with Section 715.4.8.3.

711.6 Penetrations ~~**and joints**~~**.** The space around penetrating items ~~and in joints~~ shall be filled with an *approved* material to limit the free passage of smoke.

711.7 Joints. Joints shall be filled with an *approved* material to limit the free passage of smoke.

~~711.7~~ 711.8 Ducts and air transfer openings. *(No change to text)*

Reason: The proposed changes create uniformity with how openings, joints, penetrations and air-transfer and duct openings are addressed in other sections.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: RICE-FS1F-711

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The committee agreed that this was a good reorganization of the opening requirements for smoke partitions. The committee did recognize the technical change in Section 711.7 and indicated that it was appropriate.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Sarah A. Rice, CBO, The Preview Group, representing self, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

711.5.1 Windows. Where required elsewhere in the code, windows in smoke partitions shall be sealed to resist the free passage of smoke or be automatic-closing upon detection of smoke.

711.5.2 Doors. Where required elsewhere in the code, doors in smoke partitions shall comply with Sections 711.5.2.1 through 711.5.2.3.

711.7 Joints. Where required elsewhere in the code, joints shall be filled with an *approved* material to limit the free passage of smoke.

(portions of proposal not shown, remain unchanged)

Commenter's Reason: The proposal is intended to clarify when the opening protective provisions in Section 711 have to be installed in a smoke partition. Without the proposed language the intended application of the smoke partition section starts to become unclear.

Let's not forget that the smoke partition section, when originally put into the code, was an orphan – we had a classification of a wall, i.e., smoke partition, but no requirements for there ever to be smoke partitions. It was also put for when "smoke partitions" were introduced that should there ever become a requirement for a smoke partition that each installation would need to be examined to see what function the smoke partition might play and therefore that when it came to "opening protectives" each requirement for a smoke partition would need to assess how openings should be addressed. Not all smoke partitions would need to provide the same level of protection to its openings, thus the concept that was agreed to was to have the section in the code call out what types and level of opening protectives would be needed. The language being added, just reaffirms that the opening protective provisions contained in Section 711 don't kick in unless they are "required elsewhere in the code.

Final Action: AS AM AMPC____ D

FS64–09/10

712 (New)

Proposed Change as Submitted

Proponent: Sarah A. Rice, CBO, representing self

Add new text as follows:

Section 712
NONFIRE-RESISTANCE RATED INTERIOR PARTITIONS AND BARRIERS

<u>**712.1 General.** Nonfire-resistance rated interior partitions shall comply with this section.</u>

<u>**712.2 Materials.** The walls shall be of materials permitted by the building type of construction.</u>

<u>**712.3 Openings.** Unless serving as a smoke partition or required by other sections of this code, openings in nonfire-resistance rated interior partitions shall be not be required to be protected.</u>

<u>**712.4 Penetrations.** Unless serving as a smoke partition or required by other sections of this code, penetrations into or through a nonfire-resistance rated interior partitions shall be not be required to be protected.</u>
<u>**712.5 Joints.** Unless serving as a smoke partition or required by other sections of this code, joints between nonfire-resistance rated interior partitions shall be not be required to be protected.</u>

<u>**712.6 Ducts and air transfer openings.** Unless serving as a smoke partition or required by other sections of this code, ducts and air-transfer openings in nonfire-resistance rated interior partitions shall be not be required to be protected.</u>

(Renumber subsequent sections)

Reason: This proposal introduces a new section on nonfire-resistance rated interior partitions. Often questions regarding construction and levels of protection arise when the wall of a corridor is allowed to not be fire rated because the building is spinklered. When the wall is fire rated it is considered to be a fire partition and has to be constructed as such, but how are the walls that are not fire rated to be constructed? And when an exit stairway is allowed to unenclosed, such as in an open parking garage, but the designer chooses to enclose the stair (maybe for weather purposes) what now are the requirements for the walls around that stair?

This proposal seeks to provide the answer to these questions.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: RICE FS1e NEW 712

<u>Public Hearing Results</u>

Committee Action: Disapproved

Committee Reason: The proposed wording is confusing in that most of the proposal tells the code user what is not required. The code is typically written to indicate what is required.

Assembly Action: None

<u>Individual Consideration Agenda</u>

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Sarah A. Rice, CBO, representing self, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

Section 712

NONFIRE-RESISTANCE RATED INTERIOR PARTITIONS AND BARRIERS

712.1 General. Nonfire-resistance rated interior partitions<u>, both loadbearing and non-loadbearing,</u> shall comply with this section.

<u>**Exception:** Smoke barriers shall comply with Section 711.</u>

712.2 Materials. The walls shall be of materials permitted by the building type of construction.

712.3 Openings. Unless serving as a smoke partition or required by other sections of this code, openings in nonfireresistance rated interior partitions shall ~~be~~ not be required to be protected.

712.4 Penetrations. Unless ~~serving as a smoke partition or~~ required <u>elsewhere in the</u> ~~by other sections of this~~ code, penetrations into or through a nonfire-resistance rated interior partitions shall ~~be~~ not be required to be protected.

712.5 Joints. Unless ~~serving as a smoke partition or~~ required <u>elsewhere in the</u> ~~by other sections of this~~ code, joints between nonfireresistance rated interior partitions shall ~~be~~ not be required to be protected.

712.6 Ducts and air transfer openings. Unless ~~serving as a smoke partition or~~ required elsewhere in the ~~by other sections of this~~ code, ducts and air-transfer openings in nonfire-resistance rated interior partitions shall ~~be~~ not be required to be protected.

(Renumber subsequent sections)

Commenter's Reason: While I agree in concept with the Committees reason for disapproving this proposal, the overwhelming history of interpretations on this topic drives the need for this section. The Committee stated that "The proposed wording is confusing in that most of the proposal tells the code user what is not required. The code is typically written to indicate what is required."

But ask a Code Official or one of ICC staff how oftern they get asked if doors in non-fireresistance-rated walls have to be fire doors, if closers are required on doors in non-fireresistance-rated walls or if duct openings need dampers. The questions go on and on. And for this topic the need for a section that tells the code user how to address openings in non-fireresistance-rated walls outweighs the negatives.

The references to "Smoke Partiions" have been removed within the body of the section and replaced with a general exception sending the code user to the appropriate section.

Final Action: AS AM AMPC____ D

FS65-09/10
712.3

Proposed Change as Submitted

Proponent: Lee Kranz representing Washington Association of Building Officials (WABO), Technical Code Development Committee

Revise as follows:

SECTION 712
FIRE-RESISTANCE RATED HORIZONTAL ASSEMBLIES

712.1 General. Floor and roof assemblies required to have a fire-resistance rating shall comply with this section. Nonfire-resistance-rated floor and roof assemblies shall comply with Section 713.4.2

712.2 Materials. The floor and roof assemblies shall be of materials permitted by the building type of construction.

712.3 Fire-resistive rating. The fire-resistance rating of floor and roof assemblies shall be a minimum of 1-hour fire-resistance rated construction but not be less than that required by the building type of construction. Where the floor assembly separates mixed occupancies, the assembly shall have a fire-resistance rating of not less than that required by Section 508.3.3 based on the occupancies being separated. Where the floor assembly separates a single occupancy into different fire areas, the assembly shall have a fire-resistance rating of not less than that required by Section 707.3.9. ~~Horizontal assemblies separating dwelling units in the same building and horizontal assemblies separating sleeping units in the same building shall be a minimum of 1-hour fire-resistance-rated construction.~~

> **Exception:** Dwelling unit and sleeping unit separations in buildings of Type IIB, IIIB and VB construction shall have fire-resistance ratings of not less than ½ hour in buildings equipped throughout with an approved automatic sprinkler system in accordance with Section 903.3.1.1.

Reason: Adding "Fire Resistance Rated" to the title clarifies that this section only applies to rated horizontal assemblies. The changes in 712.3 are needed to provide coordination with Section 420.3. Currently, Section 420.3 refers to Section 712 for horizontal assemblies but Section 712 does not include scoping for "floor assemblies separating dwelling or sleeping units from other occupancies contiguous to them in the same building" but does include the scoping for "horizontal assemblies separating dwelling units in the same building and horizontal assemblies separating sleeping units in the same building". Deleting the scoping text from 712.3 eliminates the redundancy with Section 420.3. Adding the minimum 1-hour fire-resistance rated construction to Section 712.3 provides clarity similar to that provided in Section 709.3 for Fire Partitions which is also referenced in Section 420.2.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: KRANZ-FS1-712.3

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee felt that the proposed change would conflict with Section 712.1 where you would need to go to Table 601 to determine the requirements for fireresistance. Further, Section 102.1 of the code differentiates between general and specific requirements sufficiently so coordination with 420 is not required and in fact might cause confusion instead of clarity.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Lee Kranz representing Washington Association of Building Officials Technical Code Development Committee, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

SECTION 712
FIRE-RESISTANCE RATED HORIZONTAL ASSEMBLIES

712.1 General. Floor and roof assemblies required to have a fire-resistance rating shall comply with this section. Nonfire-resistance-rated floor and roof assemblies shall comply with Section 713.4.2

712.2 Materials. The floor and roof assemblies shall be of materials permitted by the building type of construction.

712.3 Fire-resistive rating. The fire-resistance rating of floor and roof assemblies shall ~~be a minimum of 1-hour fire-resistance rated construction but~~ not be less than that required by the building type of construction. Where the floor assembly separates mixed occupancies, the assembly shall have a fire-resistance rating of not less than that required by Section 508.3.3 based on the occupancies being separated. Where the floor assembly separates a single occupancy into different fire areas, the assembly shall have a fire-resistance rating of not less than that required by Section 707.3.9. <u>Horizontal assemblies separating dwelling units or sleeping units from other dwelling units or sleeping units or from other occupancies contiguous to them in accordance with Section 420 shall have a minimum fire-resistance rating of 1-hour.</u>

> **Exception:** Dwelling unit and sleeping unit separations in buildings of Type IIB, IIIB and VB construction shall have fire-resistance ratings of not less than ½ hour in buildings equipped throughout with an approved automatic sprinkler system in accordance with Section 903.3.1.1.

Commenter's Reason: As advised by the Fire Safety Committee in Baltimore, the language for this proposal has been modified to resolve potential conflicts with Table 601 for type of construction. The language has also been revised to clarify that horizontal assemblies must be not less than 1-hour rated when separating dwelling or sleeping units from other dwelling or sleeping units <u>or from other occupancies contiguous to them</u>. This modification is needed to provide coordination with Section 420.3. Currently, Section 420.3 refers to Section 712 for horizontal assemblies but Section 712 does not specify an hourly rating for floor assemblies separating dwelling or sleeping units from other occupancies contiguous to them in the same building.

Final Action: AS AM AMPC____ D

FS70-09/10
713.3.1.1, 713.4.1.1.2, 716.3.1 (IMC 607.3.1)

Proposed Change as Submitted

Proponent: Julius Ballanco, PE, JB Engineering and Code Consulting, PC, representing In-O-Vate Technologies, Inc.

Revise as follows:

713.3.1.2 Through-penetration firestop system. Through penetrations shall be protected by an approved penetration firestop system installed as tested in accordance with ASTM E 814 or UL 1479, with a minimum positive pressure differential of 0.01 inch (2.49 Pa) of water and shall have an F <u>and T</u> rating of not less than the required fire-resistance rating of the wall penetrated.

713.4.1.1.2 Through-penetration firestop system. Through penetrations shall be protected by an approved through-penetration firestop system installed and tested in accordance with ASTM E 814 or UL 1479, with a minimum positive pressure differential of 0.01 inch of water (2.49 Pa). The system shall have an F-rating and a T-rating of not less than 1 hour but not less than the required rating of the floor penetrated.

~~Exception:~~ ~~Floor penetrations contained and located within the cavity of a wall do not require a T- rating.~~

716.3.1 (IMC 607.3.1) Damper testing. Dampers shall be listed and bear the label of an approved testing agency indicating compliance with the standards in this section. Fire dampers shall comply with the requirements ofUL555. <u>In addition, fire dampers shall be tested in accordance with ASTM E 814 or UL 1479, with a minimum positive pressure differential of 0.01 inch of water (2.49 Pa). The system shall have a T-rating of not less than rating of the penetrating assembly</u>. Only fire dampers labeled for use in dynamic systems shall be installed in heating, ventilation and air-conditioning systems designed to operate with fans on during a fire. Smoke dampers shall comply with the requirements of UL 555S. Combination fire/smoke dampers shall comply with the requirements of both UL 555 and UL 555S. Ceiling radiation dampers shall comply with the requirements of UL 555C.

Reason: During the last code change cycle, I attempted to remove the requirement for a "T rating" on a horizontal penetration of a membrane by a box. The opposition provided a compelling argument supporting the inclusion of a "T rating" that the membership supported.

While I did not agree with the testimony supporting a "T rating," I do support consistency in the code. If the arguments for "T ratings" are compelling for a box membrane penetration, then the same argument would support a "T rating" for a full horizontal penetration and a duct penetration.

If a duct penetrated a membrane, there is currently no requirement for a "T rating." How can this be allowed in the code when a smaller box penetration of a membrane must have a "T rating?" This does not make sense. Both membrane penetrations present the same hazard.

The same can be said for any full penetration. How can we ignore the "T rating?" Clearly, without a "T rating" the penetration is not equivalent to an ASTM E119 assembly. Again, this was the argument used during the last code change cycle.

There needs to be consistency in the Building Code. I have an alternative change to Section 713.3.2 that removes the "T rating" for horizontal penetration of a membrane by a box. Either this change or that change must be accepted for the code to be consistent.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: BALLANCO-FS1-713.3.1.2

<u>Public Hearing Results</u>

Committee Action: Disapproved

Committee Reason: The committee felt that there was no technical justification for the T-rating requirement to be added for all through penetration firestop systems. The committee also felt that the exception to 713.4.1.1.2 has been well established and should not be removed.

Assembly Action: None

<u>Individual Consideration Agenda</u>

This item is on the agenda for individual consideration because a public comment was submitted.

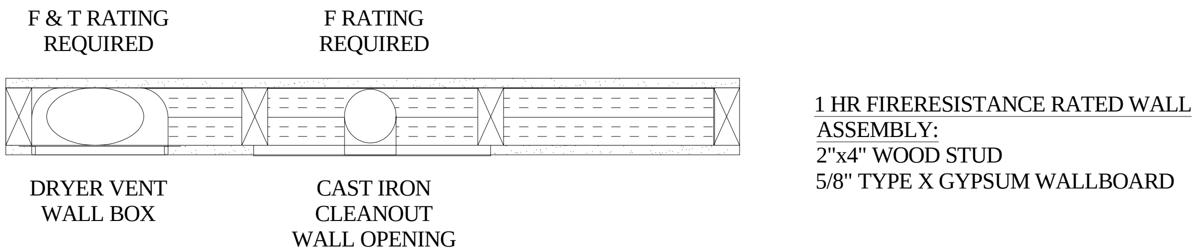
Public Comment:

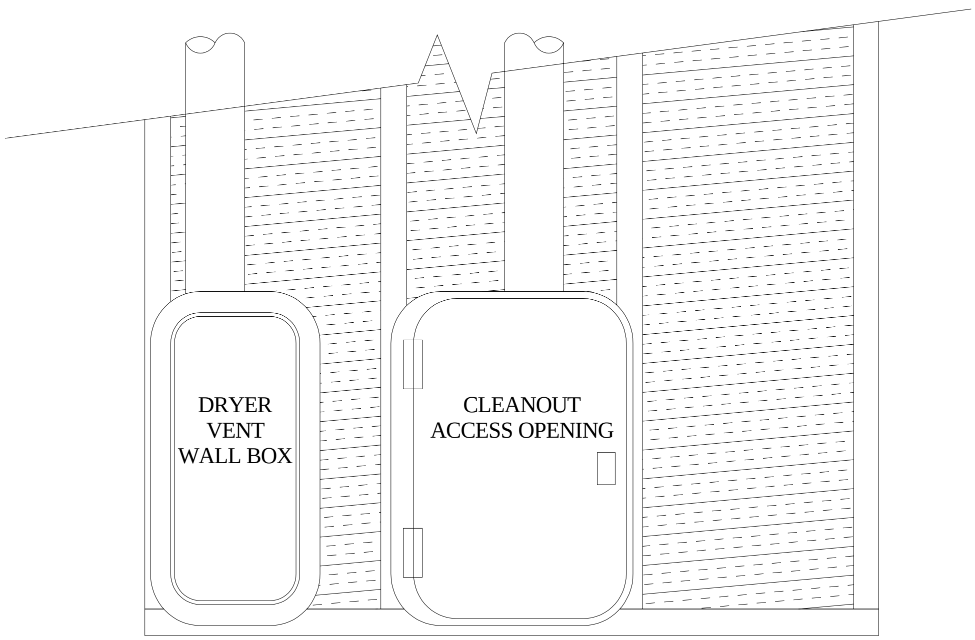
Julius Ballanco, PE, JB Engineering and Code Consulting, PC, representing In-O Vate Technologies, requests Approval as Submitted.

Commenter's Reason: The Committee failed to address the single concern that I raised with Code Change F70-09/10. That concern is, "Why does the code require a "T" rating for a box penetrating a wall while not requiring a "T" rating for any other wall penetration?

Either a "T" rating is appropriate or it is not. I have included a drawing of the absurdity of the current code requirement. If a dryer vent box is located in a 1 hour wall, the box penetration must have an F and T rating. Right alongside the dryer vent box, a cleanout wall opening to a cast iron pipe is shown. That opening only requires an F rating. Yet, the hazard is the same for both openings. Anything you say about the one opening, you can say about the other opening. This is true for so many other wall penetrations that are not boxes.

So, the real question is, do we need a T rating (in addition to an F rating) for wall penetrations? I do not believe we do. That is why I would encourage the membership to vote to approve Code Change F71-09/10. If the membership believes a T rating is necessary, then I have provided that opportunity with Code Change F70-09/10.





Commenter's Reason:

Final Action: AS AM AMPC____ D

FS71-09/10
713.3.2

Proposed Change as Submitted

Proponent: Julius Ballanco, PE, JB Engineering and Code Consulting, PC, representing In-O-Vate Technologies, Inc.

Revise as follows:

713.3.2 Membrane penetrations. Membrane penetrations shall comply with Section 713.3.1. Where walls or partitions are required to have a fire-resistance rating, recessed fixtures shall be installed such that the required fire-resistance will not be reduced.

Exceptions:

(Exceptions not shown remain unchanged)

4. Membrane penetrations by boxes, other than electrical boxes, provided such penetrating items and the annular space between the wall membrane and the box, are protected by an approved membrane penetration firestop system installed as tested in accordance with ASTM E 814 or UL 1479, with a minimum positive pressure differential of 0.01 inch (2.49 Pa) of water, and shall have an F ~~and T~~ rating of not less than the required fire-resistance rating of the wall penetrated and be installed in accordance with their listing.

Reason: I submitted this change to the last cycle when the “T rating” was added to the membrane box penetration. This was not a requirement in the 2006 edition of the IBC. Traditionally, the IBC has never required a “T rating” for horizontal penetrations. This is the first requirement for such a rating.

It is my opinion that the code should be consistent. I have submitted another change that adds the “T rating” for all horizontal penetrations. Either all horizontal penetrations or no horizontal penetrations should be required to have a “T rating.” The code cannot be inconsistent.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: BALLANCO-FS2-713.3.2.doc

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee felt that the T-rating for the items described in item 4 of 713.3.2 was appropriate and was cost effective to achieve during the testing of the boxes and therefore should remain as a requirement.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Julius Balance, PE, JB Engineering and Code Consulting, PC, representing In-O-Vate Technologies, requests Approval as Submitted.

Commenter's Reason: The Committee failed to address the single concern that I raised with Code Change F71-09/10. That concern is, “Why does the code require a “T” rating for a box penetrating a wall while not requiring a “T” rating for any other wall penetration?

Either a “T” rating is appropriate or it is not. I have included a drawing of the absurdity of the current code requirement. If a dryer vent box is located in a 1 hour wall, the box penetration must have an F and T rating. Right alongside the dryer vent box, a cleanout wall opening to a cast iron pipe is shown. Final Action: AS AM AMPC____ D

FS72-09/10
713.2 (New)

Proposed Change as Submitted

Proponent: William E. Koffel, Koffel Associates, Inc, representing Firestop Contractors International Association

Add new text as follows:

713.2 Contractor Qualifications. In buildings having occupied floors located more than 75 feet (22860 mm) above the lowest level of fire department vehicle access, through-penetration firestop systems shall be installed by contractors that are approved or qualified for such installations under programs administered by approved agencies, such as FM Approvals or Underwriters Laboratories.
(Renumber subsequent sections)

Reason: Proper Design, Installation, Inspection and Maintenance of Firestop Systems is critical to fire and life safety in buildings because firestopping is used in everything from egress corridors to separation of spaces. Firestopping is a highly technical industry, requiring specialized knowledge at the firestop contracting firm in the office and field to analyze conditions on construction documents and / or on-site, select the appropriate firestop system(s) from UL, FM, Intertek and other directories, then match the systems to penetrating items and annular spaces as they exist in the field, with no variances from the systems allowed. If the system is not installed to the parameters in the design, the 'system' may or may not work when called upon by fire. This code change proposal addresses installation of through penetration and membrane firestop systems to zero-tolerance parameters of the classified and listed firestop design. The concept has been proposed in the past and some felt the scope was too broad. Therefore, the scope of the proposed requirement has been limited to high-rise buildings.

There are approval or qualification programs administered by approved agencies such as FM Approvals and Underwriters Laboratories for contractors who install materials that become firestop systems. Any contractor (trade or specialty firestop contractor) installing firestop systems can be approved or qualified to the programs administered by these agencies. The programs are similar to ISO 9000 that is used for the manufacturing environment, but adjusted for the construction environment. Successful completion means that the company has policies and procedures in place sufficient to control operations resulting in installations conforming to the listed firestop system.

Any firm is eligible to obtain FM Approval and or UL Qualification. With costs ranging from $6000 to $10000 for the initial audit and about $3000 annually for ongoing audits by UL & FM, the cost is less than many contractors would spend on advertising in the "Blue Book" or in entertainment. Experience shows that the cost can be recovered through the benefits of improved processes and reduced errors on firestopping projects.

Firestopping by a contractor firm who has been approved or qualified means that the firm has the processes in place in the company culture to handle the zero tolerance installation program needed for firestop systems for fire and life safety. The audits by FM & UL test the company's ability to install fire and life safety through penetration firestop systems to these requirements, through extensive review of the company procedures.

Below is a summary of what it takes for a contractor company to become FM 4991 Approved and / or UL Qualified:

-Designated Responsible Individual (DRI) – Each firm employs a DRI who has passed an industry exam based on the Firestop Contractors International Association's Firestop Industry Manual of Practice, FM Standard FM 4991, Standard for the Approval of Firestop Contractors, and - or the UL Qualified Firestop Contractor Program requirements, as well as selection of firestop systems from directories matched to field conditions.

-Quality Audits – FM & UL then audit the firestop processes of the company:

--Initial Audit - The process to install firestopping is very technical, and needs attention to detail. The specialty firestop contractor firm or trade contractor firm has their company quality manual audited and approved or qualified by an auditor from either FM Approvals or Underwriters Laboratories to be recognized by the approved agency as a 'certified contractor'. This is a very robust, truly independent inspection of the contractors' firestop systems selection, submittal, and installation and inspection processes by FM & UL Auditors. Auditors also visit a project site to verify that the procedures are actually in place throughout the company. Audits of the company include every discipline from training of employees, systems selection and communications to – from the field.

--Annual Audit – FM and or UL visit the firm to review the company's procedures annually to verify continued compliance to the FM 4991 Standard or UL Qualified Firestop Contractor Program. These visits are key to continued success of the firm's quality management system.

Firestopping is a vital part of effective compartmentation. When installation is not performed correctly, it can cause delays of certificate of occupancy, reducing building owners' revenue streams and create a fire and life safety risk. FM Approved and UL Qualified Firestop Contractors can lower the risk of non compliant firestopping through a company culture that has embraced the quality management system approach through their company culture.

Firestopping installation is a process that is knowledge sensitive, and requires a company (not just a worker) that has the quality management systems culture ingrained in it's operations and, more importantly, it's people. Plus, the production of the quality assurance manual at the company helps them gather important insight into company operations through self assessment followed up by a full audit by a credible, independent organization, FM & UL

There are many contractor firms who have been approved or qualified, that cover most of the US, Dubai, with many more in process of becoming approved or qualified throughout the world. Since firestopping is lightweight, and knowledge travels, so too can FM Approved and UL Qualified Firestop Contractor Firms travel to serve local needs competitively, throughout North America. Contractors have even exported the process know how to the Middle East including the United Arab Emirates, and beyond. For more information, visit http://www.fcia.org to view Specialty Firestop Contractor Firms who have become FM 4991 Approved or UL Qualified, and see the approval and qualification documents to understand how the contractor company can get involved in the programs.

Cost Impact: The code change proposal will not increase the costs of construction.

ICCFILENAME: KOFFELL-FS5-713.2 NEW

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee felt that there was a concern over the availability of approved contractors to provide these installations nation-wide. Further, the term "approved agency" puts the responsibility on the code official to approve these agencies, which in many cases they are not qualified to do.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

William E. Koffel, PE, Koffel Associates, Inc., representing Firestop Contractors International Association (FCIA), requests Approval as Modified by this Public Comment.

Replace the proposal as follows:

<u>**713.2 Contractor Qualifications.** In buildings having a building height of 420 feet (128 m) or more, through-penetration firestop systems shall be installed by contractors qualified by an approved agency.</u>

<u>Exception: Where the work is of a minor nature as approved by the building official.</u>

Commenter's Reason: The language of the proposed Public Comment addresses the issues and concerns of the Code Development Committee

1. Availability of contractors – The application of the section has been restricted to special high-rise buildings and the Code has already established special requirements for such buildings. As such, there is a higher probability of access to multiple "qualified contractors." Even if a "qualified contractor" is not immediately available in close proximity to the project, such large projects typically involve special construction teams that draw from a larger geographic area.
2. References to specific qualification programs – The proposed language in the Public Comment eliminates the references to UL and FM and instead used the phrase "approved agency" as defined in Chapter 17 of the Code.
3. Small projects – Just as Chapter 17 allows for special inspections, the proposed exception permits the Building Official to exempt small projects and minor work from the requirement.

Proper design, installation, inspection, and maintenance of Firestop Systems is critical to fire and life safety in buildings because firestopping is used in everything from egress corridors to separation of spaces. Firestopping is a highly technical industry, requiring specialized knowledge at the firestop contracting firm in the office and field to analyze conditions on construction documents and/or on-site, select the appropriate firestop system(s) from UL, FM, Intertek and other directories, then match the systems to penetrating items and annular spaces as they exist in the field, with no variances from the systems allowed. If the system is not installed to the parameters in the design, the 'system' may or may not work when called upon by fire. This Public Comment addresses installation of through penetration and membrane firestop systems to zero-tolerance parameters of the classified and listed firestop design. The concept has been proposed in the past and some felt the scope was too broad. Therefore, the scope of the proposed requirement has been limited to certain high-rise buildings.

There are approval or qualification programs administered by approved agencies such as FM Approvals and Underwriters Laboratories for contractors who install materials that become firestop systems. Any contractor (trade or specialty firestop contractor) installing firestop systems can be approved or qualified to the programs administered by these agencies. The programs are similar to ISO 9000 that is used for the manufacturing environment, but adjusted for the construction environment. Successful completion means that the company has policies and procedures in place sufficient to control operations resulting in installations conforming to the listed firestop system.

Any firm is eligible to obtain FM Approval and or UL Qualification. With costs ranging from $6000 to $10000 for the initial audit and about $3000 annually for ongoing audits by UL & FM, the cost is less than many contractors would spend on advertising in the "Blue Book" or in entertainment. Experience shows that the cost can be recovered through the benefits of improved processes and reduced errors on firestopping projects.

Firestopping by a contractor firm who has been approved or qualified means that the firm has the processes in place in the company culture to handle the zero tolerance installation program needed for firestop systems for fire and life safety. The audits by FM & UL test the company's ability to install fire and life safety through penetration firestop systems to these requirements, through extensive review of the company procedures.

Final Action: AS AM AMPC____ D

FS74-09/10
713.2.1 (New)

Proposed Change as Submitted

Proponent: William E. Koffel, Koffel Associates, Inc, representing Firestop Contractors International Association

Add new text as follows:

713.2 Installation details. Where sleeves are used, they shall be securely fastened to the assembly penetrated. The space between the item contained in the sleeve and the sleeve itself and any space between the sleeve and the assembly penetrated shall be protected in accordance with this section. Insulation and coverings on or in the penetrating item shall not penetrate the assembly unless the specific material used has been tested as part of the assembly in accordance with this section.

713.2.1 Alternative Methods. Where the configuration of a penetrating item or group of items is such that listed penetration firestop system tested in accordance with ASTM E 814 or UL 1479 is determined to be non-existent and reconfiguration of the penetrations or fire resistance rated assembly is determined to be impractical or impossible, alternative methods for maintaining the integrity of the required fire–resistance rating of the assembly shall be permitted to be established by any of the following methods or procedures.

1. Designs documented in approved sources but not in public directories.
2. Calculations performed in an approved manner.
3. Engineering analysis based on a comparison of approved penetration firestop systems tested in accordance with ASTM E 814 or UL 1479 that extrapolate specific similar features from these systems and combine them to formulate an equivalent fire resistant rated assembly as specifically designated by the manufacturer's technical representative of the systems specified within the referenced approved penetration firestop system.
4. Alternative protection methods as allowed by Section 104.11

Reason: The purpose of this code change proposal is to clarify a part of the code that is confusing in the field to enforce. Although there are over 8000 classified systems in the Underwriters Laboratories Fire Resistance Directory and thousands more in Intertek, FM Approvals and other laboratories listings, there are still configurations that appear at project sites that have no qualified system listed in a directory. This is when our firestop contracting industry searches for advice from the manufacturers headquarters technical personnel to seek a determination that a combination of systems that closely resembles the situation be suggested for approval from the manufacturer, that is documented by the manufacturer for submittal.

This service is performed by manufacturer's qualified technical personnel who understand the fire performance of these products in systems, and use characteristics found in similar systems to make a determination about suitability for use of the products in the specific application. These suggestions are submitted by firestop manufacturer's technical staff through the contractor for approval. Using knowledge from those who fire test the products frequently and understand their limitations, these manufacturer's technical personnel reference the closest possible tested system(s) to determine an appropriate method that provides a system closest to the field condition.

This code language is needed to set minimum requirements for how these determinations, (also known as Engineering Judgments, or Equivalent Fire Resistance Rated Assemblies) are created, and who at the company should be responsible for writing these determinations of suitability for use in specific applications.

Companies are structured different ways, with many titles for field sales people. Those with the most experience with fire testing products at companies, and the most removed from the sales process seems to be the manufacturer's technical personnel at headquarters locations. This code language is needed to provide the building official transparency in the process when presented engineering judgments from the industry…only if a listed system cannot be found in the directories from any manufacturer…even if it means switching manufacturers for a few applications.

Cost Impact: The code change proposal will not increase the costs of construction.

Analysis: Standards ASTM E814 and UL 1479 are currently referenced in the I-codes.

ICCFILENAME: KOFFELL-FS2-713.2.1 NEW

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee felt some of the terms, such as "impractical" and "impossible" were too subjective and difficult to determine. Further, the phrase "calculations performed in an approve manner" is difficult to determine and perhaps unenforceable. Lastly, Section 104.11 already allows for alternative methods.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

William E. Koffel, PE, Koffel Associates, Inc., representing Firestop Contractors International Association (FICA), requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

713.2 Installation details. Where sleeves are used, they shall be securely fastened to the assembly penetrated. The space between the item contained in the sleeve and the sleeve itself and any space between the sleeve and the assembly penetrated shall be protected in accordance with this section. Insulation and coverings on or in the penetrating item shall not penetrate the assembly unless the specific material used has been tested as part of the assembly in accordance with this section.

713.2.1 Alternative Methods. Where the configuration of a penetrating item or group of items is such that listed penetration firestop system tested in accordance with ASTM E 814 or UL 1479 is determined to be non-existent and reconfiguration of the penetrations or fire resistance rated assembly is determined to be impractical or impossible, alternative methods for maintaining the integrity of the required fire–resistance rating of the assembly shall be permitted to be established ~~by any of the following methods or procedures.~~ using an engineering analysis based on a comparison of listed penetration firestop systems and prepared by a manufacturer's technical representative of the systems specified or prepared by the laboratory that conducted the original test.

1. ~~Designs documented in approved sources but not in public directories.~~
2. ~~Calculations performed in an approved manner.~~
3. ~~Engineering analysis based on a comparison of approved penetration firestop systems tested in accordance with ASTM E 814 or UL 1479 that extrapolate specific similar features from these systems and combine them to formulate an equivalent fire resistant rated assembly as specifically designated by the manufacturer's technical representative of the systems specified within the referenced approved penetration firestop system.~~
4. ~~Alternative protection methods as allowed by Section 104.11~~

Commenter's Reason: The purpose of this Public Comment is to clarify a part of the Code that is confusing in the field to enforce. Although there are over 8000 classified systems in the Underwriters Laboratories Fire Resistance Directory and thousands more in Intertek, FM Approvals and other laboratories listings, there are still configurations that appear at project sites that have no qualified system listed in a directory. This is when the firestop contracting industry searches for advice from the manufacturer's headquarters technical personnel to seek a determination that a combination of systems that closely resembles the situation be suggested for approval from the manufacturer.

This service is to be performed by manufacturer's qualified technical personnel who understand the fire performance of these products in systems or a representative of the testing laboratory, and use characteristics found in similar systems to make a determination about suitability for use of the products in the specific application. These suggestions are submitted by firestop manufacturer's technical staff through the contractor for approval. Using knowledge from those who fire test the products frequently and understand their limitations, the manufacturer's technical personnel reference the closest possible tested system(s) to determine an appropriate method that provides a system closest to the field condition.

This Code language is needed to set minimum requirements for when these determinations are permitted to be used, how these determinations (also known as Engineering Judgments, or Equivalent Fire Resistance Rated Assemblies) are created, and who should be responsible for writing these determinations of suitability for use in specific applications.

Companies are structured different ways, with many titles for field sales people. Those with the most experience with fire testing products at companies, and the most removed from the sales process seems to be the manufacturer's technical personnel at headquarters locations. This Code language is needed to provide the building official transparency in the process when presented engineering judgments from the industry…only if a listed system cannot be found in the directories from any manufacturer…even if it means switching manufacturers for a few applications.

During the Public Hearings various comments were raised ranging from this is desperately needed in the field to such language will encourage the further use of engineering judgments. By restricting the application to instances for which a listed system does not exist and who may prepare the engineering judgment we do not believe that the further use of engineering judgments will be encouraged. Although the Code will now specifically permit engineering judgments, something permitted today by the Code as an alternative method, most manufacturers will continue to test applications that are commonly used in the field since there is still a cost involved in preparing engineering judgments and the use of engineering judgments has the potential to increase the construction time due to the specific approval required for an engineering judgment.

In summary, the Public Comment simplifies the verbiage that was originally proposed in the Public Proposal. Furthermore, the verbiage of the Public Comment restricts the use of engineering judgments to those instances for which a listed system does not exist by any manufacturer. Lastly, the Public Comment retains the original concept that the engineering judgment must be prepared by someone who is familiar with the testing that has been performed.

Final Action: AS AM AMPC____ D

FS75-09/10
713.4.1.2

Proposed Change as Submitted

Proponent: Tim Pate, City and County of Broomfield, representing the Colorado Chapter ICC Code Change Committee

Revise as follows:

713.4.1.2 Membrane penetrations. Penetrations of membranes that are part of a horizontal assembly shall comply with Sections 713.4.1.1.1 or 713.4.1.1.2. Where floor/ceiling assemblies are required to have a fire resistance rating, recessed fixtures shall be installed such that the required fire resistance will not be reduced.

Exceptions:

(Exceptions 1-5 remain unchanged)

6. The ceiling membrane of 1 and 2 hour fire resistance rated horizontal assemblies is permitted to be interrupted with the double wood top plate of a fire resistance wall assembly provided that all penetrating items through the double top plates are protected in accordance with Section 713.4.1.1.1 or 713.4.1.1.2.

Reason: This code change will add a new exception to section 712.4.1.2 which will allow the ceiling membrane of a 1 or 2 hour fire rated floor/ceiling or roof/ceiling assembly to be interrupted by a double wood top plate of a fire rated wall. All penetrations of the top plates would have to be protected by approved through penetration firestop systems. This would codify the typical construction that we see with Type VA construction where the wood framed walls extend up and attach directly to the underside of wood floor joists/trusses or roof joists/trusses for structural requirements. Non fire rated wall top plates would not be allowed to interrupt the drywall membrane of the floor/ceiling or roof/ceiling.
Section 711.4 would technically require this ceiling membrane to be continuous in these areas but it would be impossible to install this drywall on top of load bearing walls since the drywall would end up being crushed when building is fully loaded. This code change would get the IBC in line with the UL testing criteria and general notes. This code change would allow what we already see on every Type VA building.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: PATE-FS1-713.4.1.2

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee felt that the ceiling membrane should be continuous and uninterrupted; however if this proposal were to be considered it should be limited to nonfireresistance rated partitions or fire partitions.

Assembly Action: **None**

Individual Consideration Agenda

These items are on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

George Kellogg, Rocklin, CA, representing Sacramento Valley Association of Building Officials, requests Approval as Submitted.

Commenter's Reason: The proposed code change would codify the practical application of the code by clarifying that ceiling membrane of 1 and 2 hour fire-rated ceilings may be interrupted by the double top-plate of a supporting wall so long as penetrations are treated with appropriate fire stop assemblies. This proposal would allow for continuity of structural systems with the proper application of Section 713.4.1.1.1 or 713.4.1.1.2.

Public Comment 2:

Tim Pate representing the Colorado Chapter of ICC, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

713.4.1.2 Membrane penetrations. Penetrations of membranes that are part of a horizontal assembly shall comply with Sections 713.4.1.1.1 or 713.4.1.1.2. Where floor/ceiling assemblies are required to have a fire resistance rating, recessed fixtures shall be installed such that the required fire resistance will not be reduced.

Exceptions:

(Exceptions 1-5 remain unchanged)

6. The ceiling membrane of 1 and 2 hour fire resistance rated horizontal assemblies is permitted to be interrupted with the double wood top plate of a fire resistance wall assembly, provided that all penetrating items through the double top plates are protected in accordance with Section 713.4.1.1.1 or 713.4.1.1.2. <u>The fire resistance rating of the wall shall not be less than the rating of the horizontal assembly.</u>

Commenter's Reason: There was testimony in opposition to the original code change that this new exception could potentially allow a fire barrier to not be continuous through the fire resistance rated horizontal assembly. We respectfully disagree since Section 707.5 Continuity of Fire Barriers specifically requires these assemblies to be continuous to the under side of the floor or roof sheathing, slab or deck above. This would super cede this new exception since it is the more restrictive requirement.

Section 709.4 Continuity of Fire Partitions has same language but allows them to stop at bottom membrane of horizontal assembly as long as there is adequate fire blocking or draftstopping above and within the interstitial space.

As described in the original reason statement this code change will allow the two top plates to become equivalent to the ceiling membranes of either the one or two hour rated assembly. I have added language to clarify that the rating of the wall would need to match the rating of the horizontal – one hour wall for one hour assembly and two hour wall for two hour assembly. This exception would then only deal with the fire partitions and interior bearing walls based on the Table 601 requirements.

Public Comment 3:

Bruce Dimmig and Tom Hedges, Mesa, AZ, representing the Arizona Building Officials, requests Approved as Modified by this public comment.

Modify the proposal as follows:

713.4.1.2 Membrane penetrations. Penetrations of membranes that are part of a horizontal assembly shall comply with Section~~s~~ 713.4.1.1.1 or 713.4.1.1.2. Where floor/ceiling assemblies are required to have a fire resistance rating, recessed fixtures shall be installed such that the required fire resistance will not be reduced.

Exceptions:

(Exceptions 1-5 remain unchanged)

6. The ceiling membrane of ~~1 and~~ <u>maximum</u> 2-hour ~~fire resistance rated~~ horizontal assemblies is permitted to be interrupted with the ~~double wood~~ top plate of a fire resistance <u>rated</u> wall assembly<u>, having an equal or greater fire resistance rating than the horizontal assembly,</u> provided that all penetrating items through the ~~double~~ top plates are protected in accordance with Section 713.4.1.1.1 or 713.4.1.1.2.

Commenter's Reason: The committee reason that the ceiling membrane should be continuous and uninterrupted is not practical or possible as the existing exceptions demonstrate. Section 711.4 would technically require this ceiling membrane to be continuous in these areas but it would be impossible to install this drywall on top of load bearing walls or shear walls since the drywall would end up being crushed when building is fully loaded. A fire resistance rated wall could be of wood, masonry or steel. By stipulating a rating for the walls that can penetrate the ceiling membrane, a safe level of fire resistance will be provided.

If the ceiling membrane is not permitted to be interrupted by walls, the following Fig. 1 and 2 examples of typical construction would no longer be permitted.

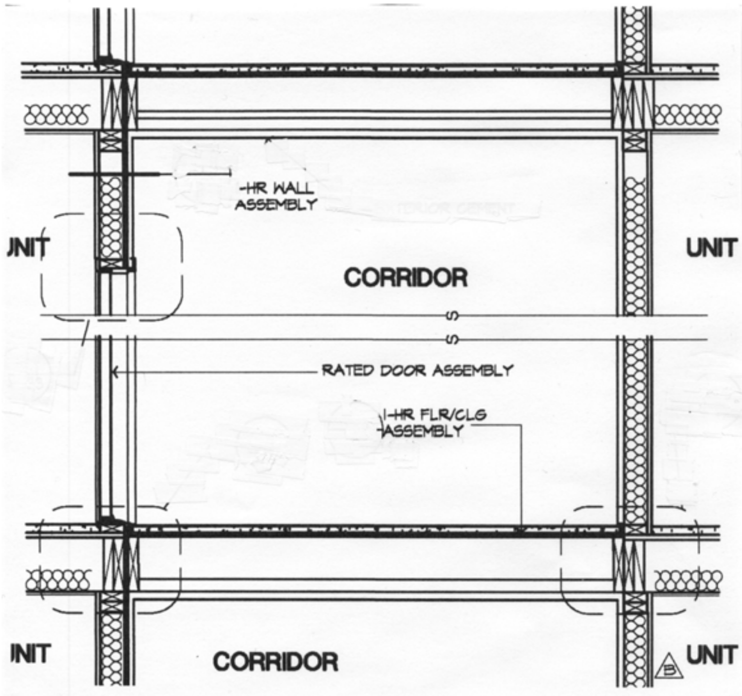

FIG. 1

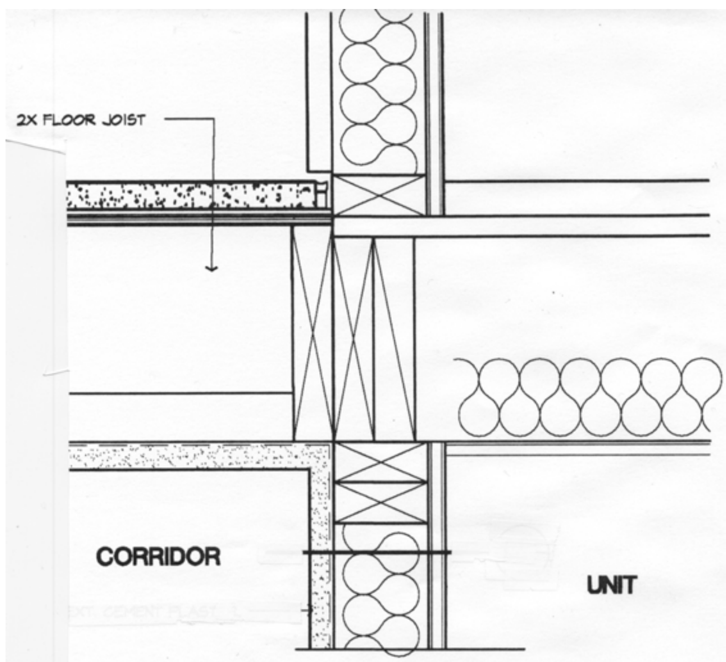

FIG. 2

Final Action: AS AM AMPC____ D

FS76-09/10
713.4.2.3 (New)

Proposed Change as Submitted

Proponent: William E. Koffel, Koffel Associates, Inc, representing Firestop Contractors International Association

1. Revise as follows:

713.4.2 Nonfire-resistance-rated assemblies. Penetrations of nonfire-resistance-rated floor or floor/ceiling assemblies or the ceiling membrane of a nonfire-resistance-rated roof/ceiling assembly shall meet the requirements of Section 708 or shall comply with Section 713.4.2.1 ~~or~~ , 713.4.2.2., or 713.4.2.3.

713.4.2.1 Noncombustible penetrating items. Noncombustible penetrating items that connect not more than three *stories* are permitted, provided that the *annular space* is filled to resist the free passage of flame and the products of combustion with an *approved* noncombustible material or with a fill, void or cavity material that is tested and classified for use in through-penetration firestop systems.

712.4.2.2 Penetrating items. Penetrating items that connect not more than two stories are permitted, provided that the annular space is filled with an approved material to resist the free passage of flame and the products of combustion.

2. Add new text as follows:

713.4.2.3 Unlimited stories. Penetrating items shall be permitted provided the annular space is filled with a fill, void, cavity material, or device that is tested and classified for use in through-penetration firestop systems.

Reason: Currently the Code limits the number of stories connected without a shaft when the floor is not required to have a fire resistance rating. The Code currently permits the use of approved materials. While fill, void, or cavity materials and devices tested for use in through penetration firestop systems would likely be approved materials, the proposed language clearly states that such materials shall be permitted without specific approval. The proposed language will also allow such materials without a height restriction. However, Table 503 limits most buildings with non-rated floor assemblies to heights less than three stories unless an automatic sprinkler system is provided.

A void or cavity material that is tested and classified for use in through penetration firestop systems is an effective method for preventing the passage of fire and toxic gas. Very often this limitation in the code relating to the number of stories of penetrating items is overlooked because the floor is not required to be fire resistant and as a result penetrations are left inadequately protected.

To require a shaft enclosure for what could be a very limited quantify of penetrations of a non-rated floor assembly is excessive when other acceptable means to protect the penetrations are available.

Cost Impact: Much more cost effective methodology.

ICCFILENAME: KOFFELL-FS8-713.4.2 NEW

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: Disapproval was requested by the proponent based on the committee's action on FS56-09/10.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

William E. Koffel, PE, Koffel Associates, Inc., representing Firestop Contractors International Association (FCIA), requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

713.4.2 Nonfire-resistance-rated assemblies. Penetrations of nonfire-resistance-rated floor or floor/ceiling assemblies or the ceiling membrane of a nonfire-resistancerated roof/ceiling assembly shall meet the requirements of Section 708 or shall comply with Section 713.4.2.1 or 713.4.2.2, or 713.4.2.3.

713.4.2.1 Noncombustible penetrating items. Noncombustible penetrating items that connect not more than ~~three~~ five stories are permitted, provided that the annular space is filled to resist the free passage of flame and the products of combustion with an approved noncombustible material or with a fill, void, or cavity material, or device that is tested and classified for use in through-penetration firestop systems.

713.4.2.2 Penetrating items. Penetrating items that connect not more than two stories are permitted, provided that the annular space is filled with an approved material to resist the free passage of flame and the products of combustion.

713.4.2.3 ~~Unlimited stories~~ Combustible penetrating items. Combustible penetrating items that connect not more than five stories shall be permitted, provided the annular space is filled with a fill, void, or cavity material, or device that is tested and classified for use in through-penetration firestop systems.

Commenter's Reason: With the action taken on FS56-09/10, noncombustible penetrating items are permitted to connect up to five stories without a shaft enclosure when the horizontal assembly is not required to have a fire resistance rating. Combustible and noncombustible penetrations are permitted to connect two stories and only be protected by an approved material to fill the annual space. The Code makes no reference to the use of a fill, void, or cavity material or a device for combustible penetrations other than to presume they would be an "approved material" as required in 713.4.2.2.

The FCIA submitted proposal FS76-09/10 that would also allow the use of a fill, void, or cavity material or device for combustible penetrations. FS76-09/10 was recommended for Disapproval based upon the action taken on FS56-09/10. However, FS56-09/10 did not address combustible penetrations connecting more than two stories. The purpose of this Public Comment is to extend the permitted use of fill, void, or cavity materials materials or devices to protect non-rated floors for both combustible and noncombustible penetrations.

A fill, void or cavity material or a device that is tested and classified for use in through penetration firestop systems is an effective method for preventing the passage of fire and toxic gas. Very often this limitation in the code relating to the number of stories of combustible penetrating items is overlooked because the floor is not required to be fire resistant and as a result penetrations are left inadequately protected.

To require a shaft enclosure for what could be a very limited quantity of penetrations of a non-rated floor assembly is excessive when other acceptable means to protect the penetrations are available.

The change from three stories to five stories in 713.4.2.1 is consistent with the action taken on FS56-09/10. Although we would agree that the three paragraphs could be sequenced better, the language in the Public Comment has been formatted so that it can be incorporated into the action on FS56-09/10 by only changing the section numbers from 713.4.2 to 714.4.2.

Final Action: AS AM AMPC____ D

FS81–09/10
714.1

Proposed Change as Submitted

Proponent: Jesse J. Beitel, Hughes Associates, Inc., representing Metal Building Manufacturers Association

Revise as follows:

714.1 General. Joints installed in or between fire-resistance-rated walls, floor or floor/ceiling assemblies and roofs or roof/ceiling assemblies shall be protected by an *approved fire-resistant joint system* designed to resist the passage of fire for a time period not less than the required *fire-resistance rating* of the wall, floor or roof in or between which it is installed. *Fire-resistant joint systems* shall be tested in accordance with Section 714.3. The void created at the intersection of a floor/ceiling assembly and an exterior curtain wall assembly shall be protected in accordance with Section 714.4.

Exceptions:

1. *Fire-resistant joint systems* shall not be required for joints in all of the following locations:
   1.1. Floors within a single *dwelling unit*.
   1.2. Floors where the joint is protected by a shaft enclosure in accordance with Section 708.
   1.3. Floors within atriums where the space adjacent to the atrium is included in the volume of the atrium for smoke control purposes.
   1.4. Floors within malls.
   1.5. Floors and ramps within open and enclosed parking garages or structures constructed in accordance with Sections 406.3 and 406.4, respectively.
   1.6. *Mezzanine* floors.
   1.7. Walls that are permitted to have unprotected openings.
   1.8. Roofs where openings are permitted.
   1.9. Control joints not exceeding a maximum width of 0.625 inch (15.9 mm) and tested in accordance with ASTM E 119 or UL 263.
2. The voids created at the intersection of a fire-resistance-rated wall assembly and a non-fire-resistance-rated roof assembly shall be filled, but are not required to comply with the requirements of this section. The material or system used to fill the void shall be securely installed in or on the intersection for its entire length so as not to dislodge, loosen or otherwise impair its ability to accommodate expected building movements and to retard the passage of fire and hot gases.

Reason: The IBC defines joints as being an opening that occurs between two fire-resistance rated assemblies. However, in many instances there are openings/void spaces that occur between a fire-resistance rated assembly and a non-fire resistance rated assembly. One very common type of this situation occurs when a fire-resistance rated wall assembly terminates at the underside of a non-fire-resistance rated roof assembly in a low-rise metal building. This code change proposal has been submitted so as to clarify the requirements for these types of situations.

The Metal Building Manufacturers Association requested a formal interpretation on this matter. Interpretation 34-08 dated February 20, 2009 states that Section 713.1 (2006 edition) did not apply to these intersections. Thus, this Code proposal is just adding new language to address the findings of the Code interpretation and therefore enhance the code.

It is understood that this new Exception does not remove the continuity requirements for these types of assemblies as specified in the appropriate Sections of the Code.

Also, the industry has specifically inserted the requirements for installation so as to address the proper installation of the materials and systems used in this application.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: BEITEL-FS3-714.1.doc

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee felt that the exception was in the wrong place and would be better located in the continuity provisions. Also, the committee felt there should be some referenced to an acceptable material to used to fill the void in question.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jesse J. Beitel, Hughes Associates, Inc., representing Metal Building Manufacturers Association, requests Approval as Modified by this Public Comment.

Replace the proposal as follows:

707.5 Continuity. Fire barriers shall extend from the top of the floor/ceiling assembly below to the underside of the floor or roof sheathing, slab or deck above and shall be securely attached thereto. Such fire barriers shall be continuous through concealed space, such as the space above a suspended ceiling. Joints and voids at intersections shall comply with Section 707.8 and 707.9.

707.8 Joints. Joints made in or between fire barriers and joints at the intersection of fire barriers with the underside of a fire-resistance-rated ~~the~~ floor or roof sheathing, slab or deck above, shall comply with Section 714.

707.9 Voids At Intersections. The voids created at the intersection of a fire barrier and a non-fire-resistance-rated roof assembly shall be filled. An approved material or system shall be used to fill the void, shall be securely installed in or on the intersection for its entire length so as not to dislodge, loosen or otherwise impair its ability to accommodate expected building movements and to retard the passage of fire and hot gases.

(Renumber subsequent section)

Commenter's Reason: This modified language addresses comments made by the Committee and others at the CDH. The basic language from our Proposal remains but the modification to the proposal addresses the concern of the appropriate location for this provision that addresses voids at the intersection of fire barriers and non-fire-resistance-rated roofs. The new Section 707.9 will provide the requirements. The additional language in Section 707.5 provides a pointer to the new Section and the new language in section 707.8 provides clarification.
Additionally, the proposal requires that the material or system be approved. Thus, documentation to show that material or system will meet the performance requirements to retard the passage of fire and hot gases must be provided. The Metal Building Manufacturers Association (MBMA) has performed this type of testing and the information including UL's test reports can be found at MBMA.com and follow the links to Technical Library, Fire Resistance, Head of Wall.

Note to Staff: If FS56-09/10 is approved, wording of "voids at intersections" could be changed to 'joints".

Final Action: AS AM AMPC____ D

FS83-09/10
714.1.1 (New)

Proposed Change as Submitted

Proponent: William E. Koffel, Koffel Associates, Inc, representing Firestop Contractors International Association

Add new text as follows:

714.1 General. Joints installed in or between fire-resistance- rated walls, floor or floor/ceiling assemblies and roofs or roof/ceiling assemblies shall be protected by an *approved fire-resistant joint system* designed to resist the passage of fire for a time period not less than the required *fire-resistance rating* of the wall, floor or roof in or between which it is installed. *Fire-resistant joint systems* shall be tested in accordance with Section 714.3. The void created at the intersection of a floor/ceiling assembly and an exterior curtain wall assembly shall be protected in accordance with Section 714.4.

Exception: *Fire-resistant joint systems* shall not be required for joints in all of the following locations:

1. Floors within a single *dwelling unit*.
2. Floors where the joint is protected by a shaft enclosure in accordance with Section 708.
3. Floors within atriums where the space adjacent to the atrium is included in the volume of the atrium for smoke control purposes.
4. Floors within malls.
5. Floors and ramps within open and enclosed parking garages or structures constructed in accordance with Sections 406.3 and 406.4, respectively.
6. *Mezzanine* floors.
7. Walls that are permitted to have unprotected openings.
8. Roofs where openings are permitted.
9. Control joints not exceeding a maximum width of 0.625 inch (15.9 mm) and tested in accordance with ASTM E 119 or UL 263.

714.1.1 Alternative Methods. Where the configuration of a joint is such that a listed joint firestop system or perimeter fire containment system tested in accordance with ASTM E 1966 or UL 2079 or ASTM E 2307, is determined to be non-existent alternative methods for maintaining the integrity of the required fire–resistance rating of the assembly shall be permitted to be established by any of the following methods or procedures.

1. Designs documented in approved sources but not in public directories.
2. Calculations performed in an approved manner.
3. Engineering analysis based on a comparison of approved penetration firestop systems tested in accordance with ASTM E 1966 or UL 2079 and or ASTM E 2307 that extrapolate specific similar features from these systems and combine them to formulate an equivalent fire resistant rated assembly as specifically designated by the manufacturer's technical representative of the systems specified within a referenced approved penetration firestop system
4. Alternative protection methods as allowed by Section 104.11

Reason: The purpose of this code change proposal is to clarify a part of the code that is confusing in the field to enforce. Although there are over 8000 classified systems in the Underwriters Laboratories Fire Resistance Directory and thousands more in Intertek, FM Approvals and other laboratories listings, there are still configurations that appear at project sites that have no qualified system listed in a directory. This is when the firestop contracting industry searches for advice from the manufacturer's technical personnel to seek a determination that a combination of systems that closely resembles the situation be suggested for approval based upon documentation from the manufacturer.

This service is performed by manufacturer's qualified technical personnel who understand the fire performance of these products in systems, and use characteristics found in similar systems to make a determination about suitability for use of the products in the specific application. These suggestions are submitted by firestop manufacturer's technical staff through the contractor for approval. Using knowledge from those who fire test the products frequently and understand their limitations, these manufacturers technical personnel reference the closest possible tested system(s) to determine an appropriate method that provides a system closest to the field condition.

This code language is needed to set minimum requirements for how these determinations, (also known as Engineering Judgments, or Equivalent Fire Resistance Rated Assemblies) are created, and who at the company should be responsible for writing these determinations of suitability for use in specific applications.

Companies are structured different ways, with many titles for field sales people. Those with the most experience with fire testing products at companies, and the most removed from the sales process seem to be the manufacturers technical personnel often located at headquarter locations. This code language is needed to provide the building official transparency in the process when presented engineering judgments from the industry…only if a listed system cannot be found in the directories from any manufacturer…even if it means switching manufacturers for a few applications.

Cost Impact: The code change proposal will not increase the costs of construction.

ICCFILENAME: KOFFELL-FS3-714.1.1 NEW

Public Hearing Results

Committee Action: Disapproved

Committee Reason: The committee felt the phrase "calculations performed in an approve manner" is difficult to determine and perhaps unenforceable. Further, Section 104.11 already allows for alternative methods.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

William E. Koffel, PE, Koffel Associates, representing Firestop Contractors International Association (FCIA), requests Approved as Modified by this Public Comment.

Modify the proposal as follows:

714.1.1 Alternative Methods: Where the configuration of a joint is such that a listed joint firestop system or perimeter fire containment system tested in accordance with ASTM E 1966 or UL 2079 or ASTM E 2307 is determined to be non-existent, alternative methods for maintaining the integrity of the required fire–resistance rating of the assembly shall be permitted to be established ~~by any of the following methods or procedures~~ using an engineering analysis based on a comparison of listed systems that is prepared by a manufacturer's technical representative of the systems specified or prepared by the laboratory that conducted the original test.

1. ~~Designs documented in approved sources but not in public directories.~~
2. ~~Calculations performed in an approved manner.~~
3. ~~Engineering analysis based on a comparison of approved penetration firestop systems tested in accordance with ASTM E 1966 or UL 2079 and or ASTM E 2307 that extrapolate specific similar features from these systems and combine them to formulate an equivalent fire resistant rated assembly as specifically designated by the manufacturer's technical representative of the systems specified within a referenced approved penetration firestop system~~
4. ~~Alternative protection methods as allowed by Section 104.11~~

Commenter's Reason: The purpose of this Public Comment is to clarify a part of the Code that is confusing in the field to enforce. Although there are over 8000 classified systems in the Underwriters Laboratories Fire Resistance Directory and thousands more in Intertek, FM Approvals and other laboratories listings, there are still configurations that appear at project sites that have no qualified system listed in a directory. This is when the firestop contracting industry searches for advice from the manufacturer's headquarters technical personnel to seek a determination that a combination of systems that closely resembles the situation be suggested for approval from the manufacturer.

This service is to be performed by manufacturer's qualified technical personnel who understand the fire performance of these products in systems or a representative of the testing laboratory, and use characteristics found in similar systems to make a determination about suitability for use of the products in the specific application. These suggestions are submitted by firestop manufacturer's technical staff through the contractor for approval. Using knowledge from those who fire test the products frequently and understand their limitations, the manufacturer's technical personnel reference the closest possible tested system(s) to determine an appropriate method that provides a system closest to the field condition.

This Code language is needed to set minimum requirements for when these determinations are permitted to be used, how these determinations (also known as Engineering Judgments, or Equivalent Fire Resistance Rated Assemblies) are created, and who should be responsible for writing these determinations of suitability for use in specific applications.

Companies are structured different ways, with many titles for field sales people. Those with the most experience with fire testing products at companies, and the most removed from the sales process seems to be the manufacturer's technical personnel at headquarters locations. This Code language is needed to provide the building official transparency in the process when presented engineering judgments from the industry…only if a listed system cannot be found in the directories from any manufacturer…even if it means switching manufacturers for a few applications.

During the Public Hearings various comments were raised ranging from this is desperately needed in the field to such language will encourage the further use of engineering judgments. By restricting the application to instances for which a listed system does not exist and who may prepare the engineering judgment we do not believe that the further use of engineering judgments will be encouraged. Although the Code will now specifically permit engineering judgments, something permitted today by the Code as an alternative method, most manufacturers will continue to test applications that are commonly used in the field since there is still a cost involved in preparing engineering judgments and the use of engineering judgments has the potential to increase the construction time due to the specific approval required for an engineering judgment.

In summary, the Public Comment simplifies the verbiage that was originally proposed in the Public Proposal. Furthermore, the verbiage of the Public Comment restricts the use of engineering judgments to those instances for which a listed system does not exist by any manufacturer. Lastly, the Public Comment retains the original concept that the engineering judgment must be prepared by someone who is familiar with the testing that has been performed.

Final Action: AS AM AMPC____ D

FS86-09/10
714.2.1 (New)

Proposed Change as Submitted

Proponent: William E. Koffel, Koffel Associates, Inc., representing Firestop Contractors International Association

Add new text as follows:

714.2 Installation. *Fire-resistant joint systems* shall be securely installed in or on the joint for its entire length so as not to dislodge, loosen or otherwise impair its ability to accommodate expected building movements and to resist the passage of fire and hot gases.

<u>**714.2.1 Installation details, field installation.** In buildings having occupied floors located more than 75 feet (22860 mm) above the lowest level of fire department vehicle access, fire-resistant joint systems shall be installed by contractors that are approved or qualified for such installations under programs administered by approved agencies, such as FM Approvals or Underwriters Laboratories.</u>

Reason: Proper Design, Installation, Inspection and Maintenance of Joint Systems is critical to fire and life safety in building. This is a highly technical industry, requiring specialized knowledge at the firestop contracting firm in the office and field to analyze conditions on construction documents and / or on-site, select the appropriate firestop system(s) from UL, FM, Intertek and other directories, then match the systems to penetrating items and annular spaces as they exist in the field, with no variances from the systems allowed. If the system is not installed to the parameters in the design, the 'system' may or may not work when called upon by fire. This code change proposal addresses installation of joint systems to zero-tolerance parameters of the classified and listed design. And, *fire-resistant joint systems* are very complicated systems, where the contractor firm installing must have special qualifications to accomplish the goal of limiting fire and smoke spread from the compartment of origin. The concept has been proposed in the past and some felt the scope was too broad. Therefore, the scope of the proposed requirement has been limited to high-rise buildings.

There are approval or qualification programs administered by approved agencies such as FM Approvals and Underwriters Laboratories for contractors who install materials that become firestop systems. Any contractor (trade or specialty firestop contractor) installing firestop systems can be approved or qualified to the programs administered by these agencies. The programs are similar to ISO 9000 that is used for the manufacturing environment, but adjusted for the construction environment. Successful completion means that the company has policies and procedures in place sufficient to control operations resulting in installations conforming to the listed firestop system.

Any firm is eligible to obtain FM Approval and or UL Qualification. With costs ranging from $6000 to $10000 for the initial audit and about $3000 annually for ongoing audits by UL & FM, the cost is less than many contractors would spend on advertising in the "Blue Book" or in entertainment. Experience shows that the cost can be recovered through the benefits of improved processes and reduced errors on firestopping projects.

Firestopping by a contractor firm who has been approved or qualified means that the firm has the processes in place in the company culture to handle the zero tolerance installation program needed for firestop systems for fire and life safety. The audits by FM & UL test the company's ability to install fire and life safety through penetration firestop systems to these requirements, through extensive review of the company procedures.

Below is a summary of what it takes for a contractor company to become FM 4991 Approved and / or UL Qualified:

-Designated Responsible Individual (DRI) – Each firm employs a DRI who has passed an industry exam based on the Firestop Contractors International Association's Firestop Industry Manual of Practice, FM Standard FM 4991, Standard for the Approval of Firestop Contractors, and - or the UL Qualified Firestop Contractor Program requirements, as well as selection of firestop systems from directories matched to field conditions.

-Quality Audits – FM & UL then audit the firestop processes of the company:

--Initial Audit - The process to install firestopping is very technical, and needs attention to detail.The specialty firestop contractor firm or trade contractor firm has their company quality manual audited and approved or qualified by an auditor from either FM Approvals or Underwriters Laboratories to be recognized by the approved agency as a 'certified contractor'. This is a very robust, truly independent inspection of the contractors' firestop systems selection, submittal, and installation and inspection processes by FM & UL Auditors. Auditors also visit a project site to verify that the procedures are actually in place throughout the company. Audits of the company include every discipline from training of employees, systems selection and communications to – from the field.

--Annual Audit – FM and or UL visit the firm to review the company's procedures annually to verify continued compliance to the FM 4991 Standard or UL Qualified Firestop Contractor Program These visits are key to continued success of the firm's quality management system.

Firestopping is a vital part of effective compartmentation. When installation is not performed correctly, it can cause delays of certificate of occupancy, reducing building owners' revenue streams and create a fire and life safety risk. FM Approved and UL Qualified Firestop Contractors can lower the risk of non compliant firestopping through a company culture that has embraced the quality management system approach through their company culture.

Firestopping installation is a process that is knowledge sensitive, and requires a company (not just a worker) that has the quality management systems culture ingrained in it's operations and, more importantly, it's people. Plus, the production of the quality assurance manual at the company helps them gather important insight into company operations through self assessment followed up by a full audit by a credible, independent organization, FM & UL

There are many contractor firms who have been approved or qualified, that cover most of the US, Dubai, with many more in process of becoming approved or qualified throughout the world. Since firestopping is lightweight, and knowledge travels, so too can FM Approved and UL Qualified Firestop Contractor Firms travel to serve local needs competitively, throughout North America. Contractors have even exported the process know how to the Middle East including the United Arab Emirates, and beyond. For more information, visit http://www.fcia.org to view Specialty Firestop Contractor Firms who have become FM 4991 Approved or UL Qualified, and see the approval and qualification documents to understand how the contractor company can get involved in the programs.

Cost Impact: There is no cost impact to this code change proposal. Approved or qualified firms assign the correct value to firestopping systems installed to the listed system.

ICCFILENAME: KOFFELL-FS9-714.1

Public Hearing Results

Committee Action: Disapproved

Committee Reason: As with FS85-09/10, the committee felt there was a concern over the availability of approved contractors to provide these installations nation-wide. Further, the term "approved agency" puts the responsibility on the code official to approve these agencies, which in many cases they are not qualified to do.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

William E. Koffel, PE, Koffel Associates, Inc., representing Firestop Contractors International Association (FCIA), requests Approval as Modified by this Public Comment.

Replace the proposal as follows:

<u>**714.2 Contractor Qualifications.** In buildings having a building height of 420 feet (128 m) or more, fire resistant joint systems shall be installed by contractors qualified by an approved agency.</u>

<u>Exception: Where the work is of a minor nature as approved by the building official.</u>

Commenter's Reason: The language of the proposed Public Comment addresses the issues and concerns of the Code Development Committee

1. Availability of contractors – The application of the section has been restricted to special high-rise buildings and the Code has already established special requirements for such buildings. As such, there is a higher probability of access to multiple "qualified contractors." Even if a "qualified contractor" is not immediately available in close proximity to the project, such large projects typically involve special construction teams that draw from a larger geographic area.
2. References to specific qualification programs – The proposed language in the Public Comment eliminates the references to UL and FM and instead used the phrase "approved agency" as defined in Chapter 17 of the Code.
3. Small projects – Just as Chapter 17 allows for special inspections, the proposed exception permits the Building Official to exempt small projects and minor work from the requirement.

Proper design, installation, inspection and maintenance of joint systems is critical to fire and life safety in building. This is a highly technical industry, requiring specialized knowledge at the firestop contracting firm in the office and field to analyze conditions on construction documents and / or on-site, select the appropriate fire resistant joint system(s) from UL, FM, Intertek and other directories, then match the systems to conditions as they exist in the field, with no variances from the systems allowed. If the system is not installed to the parameters in the design, the 'system' may or may not work when called upon by fire. This Public Comment addresses installation of joint systems to zero-tolerance parameters of the classified and listed design. And, *fire-resistant joint systems* are very complicated systems, where the contractor firm installing must have special qualifications to accomplish the goal of limiting fire and smoke spread from the compartment of origin. The concept has been proposed in the past and some felt the scope was too broad. Therefore, the scope of the proposed requirement has been limited to high-rise buildings.

There are approval or qualification programs administered by approved agencies such as FM Approvals and Underwriters Laboratories for contractors who install materials that become fire resistant joing systems. Any contractor (trade or specialty firestop contractor) installing fire resistant joing systems can be approved or qualified to the programs administered by these agencies. The programs are similar to ISO 9000 that is used for the manufacturing environment, but adjusted for the construction environment. Successful completion means that the company has policies and procedures in place sufficient to control operations resulting in installations conforming to the listed fire resistant joint system.

Any firm is eligible to obtain FM Approval and or UL Qualification. With costs ranging from $6000 to $10000 for the initial audit and about $3000 annually for ongoing audits by UL & FM, the cost is less than many contractors would spend on advertising in the "Blue Book" or in entertainment. Experience shows that the cost can be recovered through the benefits of improved processes and reduced errors on projects.

Installation by a contractor firm who has been approved or qualified means that the firm has the processes in place in the company culture to handle the zero tolerance installation program needed for fire resistant joint systems for fire and life safety. The audits by FM & UL test the company's ability to install fire and life safety fire resistant joint systems to these requirements, through extensive review of the company procedures.

Final Action: AS AM AMPC____ D

FS87-09/10
714.4

Proposed Change as Submitted

Proponent: Jesse J. Beitel, Hughes Associates, Inc., representing self

Revise as follows:

714.4 Exterior curtain wall/floor intersection. Where fire resistance-rated floor or floor/ceiling assemblies are required, voids created at the intersection of the exterior curtain wall assemblies and such floor assemblies shall be sealed with an *approved* system to prevent the interior spread of fire. Such systems shall be securely installed and tested in accordance with ASTM E 2307 to provide an F rating ~~prevent the passage of flame~~ for ~~the~~ a time period at least equal to the *fire-resistance rating* of the floor assembly ~~and prevent the passage of heat and hot gases sufficient to ignite cotton waste~~. Height and fire-resistance requirements for curtain wall spandrels shall comply with Section 705.8.5.

Reason: This Code change provides a better clarification of the requirements for the materials. The "F" rating as determined in ASTM E 2307 evaluates the material or assembly for passage of flame and passage of heat and hot gases sufficient to ignite cotton waste.

This change just clarifies that the requirements are only for an "F" rating and a "T" rating is not required.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: BEITEL-FS2-714.4.doc

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The committee agreed that since the criteria for F rating includes passage of heat and hot gasses that this change was editorial and ultimately easier to enforce.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Tony Crimi, A.C. Consulting Solutions Inc., representing North American Insulation Manufacturers Association (NAIMA), requests Disapproval.

Commenter's Reason: The proposed change makes enforcement of 714.4 more difficult in that it gives the false impression of removing a long-standing IBC performance requirement, thereby reducing the level of performance of perimeter fire barrier joints from what has traditionally been required. The language in Section of 714.4 has been in the IBC prior to inclusion of ASTM E2307. The IBC has always established the desired level of performance of exterior curtain wall and floor intersections as being both preventing the passage of flame and "… prevent the passage of heat and hot gases sufficient to ignite cotton waste." The inclusion of ASTM E2307 led to a clear requirement that the F-Rating determined by ASTM E2307 was to prevent the passage of flame for the time period at least equal to the *fire-resistance rating* of the floor assembly. The additional text clearly stated that the installed system also needed to prevent the passage of heat and hot gases sufficient to ignite cotton waste. This is very similar to the definition of "F"-Rating in ASTM E2307, which states that the rating of the perimeter fire barrier shall be determined as the time at which either fire penetrates through the perimeter joint protection or around its boundaries, or the passage of flames or hot gases are sufficient to ignite the cotton waste. The existing IBC text in 714.4 accurately identifies and separates these 2 requirements within 714.4. The proposed change has the effect of burying the second component of the requirement in the test standard.

While the committee felt that, since the criteria for F rating includes passage of heat and hot gasses, this change was editorial and ultimately easier to enforce. Our concern is that, without sufficient knowledge of the test method, the component of the performance requirement that limits the rate of passage of heat through the system is less apparent to Code users.

What ASTM E2307 measures is the performance of the perimeter joint system and its ability to maintain a barrier to prevent fire spread during the deflection and deformation of the exterior wall assembly and floor assembly during the fire test, while resisting fire exposure from an interior compartment fire as well as from the flame plume emitted from the window burner below.

Final Action: AS AM AMPC____ D

FS88-09/10
714.4

Proposed Change as Submitted

Proponent: James P. Stahl Jr., representing Specified Technologies, Inc.

Revise as follows:

714.4 Exterior curtain wall/floor intersection. Where fire resistance-rated floor or floor/ceiling assemblies are required, voids created at the intersection of the exterior curtain wall assemblies and such floor assemblies shall be sealed with an *approved* system to prevent the interior spread of fire. Such systems shall be securely installed and tested in accordance with ASTME 2307 to prevent the passage of flame for the time period at least equal to the *fire-resistance rating* of the floor assembly and prevent the passage of heat and hot gases sufficient to ignite cotton waste. Height and fire-resistance requirements for curtain wall spandrels shall comply with Section 705.8.5.

> **Exception**: Voids created at the intersection of the exterior curtain wall assemblies and such floor assemblies where the vision glass extends down to the finished floor level shall be permitted to be sealed with an approved material to prevent the interior spread of fire. Such material shall be securely installed and cable of preventing the passage of flame and hot gases sufficient to ignite cotton waste where subjected to ASTM E119 time-temperature fire conditions under a minimum positive pressure differential of 0.01 inch (0.254 mm) of water column (2.5 Pa) for the time period at least equal to the fire-resistance rating of the floor assembly.

Reason: The purpose of the proposed change is to reinstate the allowance for testing at least some curtain wall assemblies, specifically those which incorporate full height vision glass, based on fire exposure to an ASTM E119 time-temperature curve.

Justification: The proposed language in the exception existed in the Code until the 2009 edition of the IBC. While ASTM E2307 was specifically developed to test perimeter fire barrier systems, there is a problem for certain types of assemblies in terms of being able to meet the new performance criteria. The proposed exception would permit the continued use of full height vision glass curtain wall assemblies based on compliance with the traditional ASTM E119 testing.

Cost Impact: This code change will not increase the cost of construction.

ICCFILENAME: STAHL-FS1-714.4

Public Hearing Results

Committee Action: **Approved as Modified**

Modify the proposal as follows:

714.4 Exterior curtain wall/floor intersection. Where fire resistance-rated floor or floor/ceiling assemblies are required, voids created at the intersection of the exterior curtain wall assemblies and such floor assemblies shall be sealed with an *approved* system to prevent the interior spread of fire. Such systems shall be securely installed and tested in accordance with ASTME 2307 to prevent the passage of flame for the time period at least equal to the *fire-resistance rating* of the floor assembly and prevent the passage of heat and hot gases sufficient to ignite cotton waste. Height and fire-resistance requirements for curtain wall spandrels shall comply with Section 705.8.5.

> **Exception**: Voids created at the intersection of the exterior curtain wall assemblies and such floor assemblies where the vision glass extends ~~down~~ to the finished floor level shall be permitted to be sealed with an approved material to prevent the interior spread of fire. Such material shall be securely installed and capable ~~cable~~ of preventing the passage of flame and hot gases sufficient to ignite cotton waste where subjected to ASTM E119 time-temperature fire conditions under a minimum positive pressure differential of 0.01 inch (0.254 mm) of water column (2.5 Pa) for the time period at least equal to the fire-resistance rating of the floor assembly.

Committee Reason: The committee agreed that this proposal appropriately allows for assemblies that are commonly used in current building practice to be approved based on ASTM E119 time-temperature exposure conditions. The modification recognizes that the glass could extend up or down. Changing cable to capable was considered editorial.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Maureen Traxler, representing the City of Seattle Department of Planning & Development, requests Disapproval.

Commenter's Reason: The reason given for introducing the exception is "there is a problem for certain types of assemblies in terms of being able to meet the new performance criteria". In other words, the assembly shouldn't be required to be tested because it can't pass the test. Testing according to ASTM E 2307 is required because there is a danger of fire lapping from floor to floor on the interior side of curtain walls. That danger is no less when glass extends to the floor. This code change proposal should be disapproved because no technical justification was provided to show why this construction should not be required to comply with the ASTM standard.

In the 2009 IBC the requirements for exterior curtain wall/floor intersections were revised to recognize the newly-developed ASTM E 2307 standard. ASTM E 2307 was developed specifically to determine the fire resistance of perimeter fire barrier systems when subjected to standard fire exposure conditions using the intermediate scale, multistory test apparatus. The scope of ASTM E 2307 does not suggest that the test standard should not apply to situations where the vision glass extends to the finished floor level, and the risk of fire compromising these intersections is the same whether the curtain wall has vision glass that extend to the finished floor or not. In addition, since the proposed exception only references the time-temperature fire conditions from ASTM E 119, there is nothing which defines the minimum test sample size, the sample configuration and the acceptance criteria for how the assembly needs to perform during and after the fire exposure.

Final Action: AS AM AMPC____ D

FS90-09/10
714.4, 714.4.1, 714.4.2 (New)

Proposed Change as Submitted

Proponent: Jesse J. Beitel, Rick Thornberry, Hughes Associates, Inc., The Code Consortium, representing Centria, Trespa North America, Inc., Alcan Composites USA, Inc.

Revise as follows:

714.4 Exterior curtain wall/floor intersections. The intersections of exterior curtain wall assemblies and floor or floor/ceiling assemblies shall be protected against interior fire spread in accordance with Sections 714.4.1 through 714.4.3 as applicable. Height and fire-resistance requirements for curtain wall spandrels shall comply with Section 705.8.5.

714.4.1 Fire-resistance-rated exterior curtain wall/fire-resistance-rated floor intersections. Where fire resistance-rated floor or floor/ceiling assemblies are required, ~~voids created at~~ the intersection of ~~the~~ fire-resistance-rated exterior curtain wall assemblies and such floor assemblies shall be sealed with an approved system. ~~to prevent the interior spread of fire.~~ Such systems shall be securely installed and tested in accordance with ASTM E 2307 to ~~prevent the passage of flame~~ provide an "F" rating and a "T" rating for ~~the~~ a time period at least equal to the fire-resistance rating of the floor assembly. ~~and prevent the passage of heat and hot gases sufficient to ignite cotton waste. Height and fire-resistance requirements for curtain wall spandrels shall comply with Section 705.8.5.~~

714.4.2 Nonfire-resistance-rated exterior curtain wall/fire-resistance-rated floor intersections. Voids created at the intersection of nonfire-resistance-rated exterior curtain wall assemblies and fire-resistance-rated floor assemblies shall be sealed with an approved system. Such systems shall be securely installed and tested in accordance with ASTM E2307 to provide an "F" rating when tested with the nonfire-resistance-rated exterior curtain wall assembly. The "F" rating shall be the greater of 30 minutes or the time at which one of the following occurs .

1. The "F" rating is determined in the ASTM E2307 test, or
2. A through-crack, hole or other opening is observed in the exterior exposed face of the curtain wall assembly at a location above the upper surface of the floor assembly during the ASTM E2307 test.

714.4.~~1~~ 3 Exterior curtain wall/nonfire-resistance-rated floor assembly intersections. Voids created at the intersection of exterior curtain wall assemblies and nonfire-resistance-rated floor or floor/ceiling assemblies shall be sealed with an approved material or system to retard the interior spread of fire and hot gases between stories.

Reason: This code change is a revision to Section 714.4. This revision addresses several issues with respect to the existing wording and provides in some cases, new requirements. The proposed reorganization of Section of 714.4 now provides requirements based on the fire-resistance ratings of the types of wall assemblies and floors or floor/ceiling assemblies that intersect. This reorganization greatly simplifies the use of this section of the Code.

One new item is the requirement for the seal when a fire-resistance-rated wall meets a fire-resistance-rated floor or floor/ceiling assembly. In this case, the seal must exhibit an "F" rating and a "T" rating equivalent to the fire-resistance rating of the floor or floor ceiling assembly. This change is appropriate for this application and incorporates the reported results of ASTM E2307 ('F" and "T" ratings) and thus clarifies the requirements.

Another change is the addition of a section to address the intersection of a nonfire-resistance-rated wall assembly and a fire-resistance-rated floor or floor/ceiling assembly. This is a very common type of intersection when curtain walls are used. In this case, the wall assembly does not have a fire-resistance rating and when tested in the ASTM E2307, the wall may not remain intact for the fire-resistance-rating period of the floor or floor/ceiling assembly. This new section recognizes this fact but still requires ASTM E2307 testing with the nonfire-resistance-rated wall assembly and requires a minimum fire-resistance rating for the seal material. The time period of 30 minutes was selected as providing a significant but yet realistic fire performance criteria for this condition.

The current 714.4.1 which addresses the issue of nonfire-resistance-rated floors is unchanged.

This reorganization provides significant clarity to this section of the Code and provides appropriate requirements based on the fire-resistance ratings of the intersecting walls and floors or floor ceiling assemblies.

Cost Impact: This code change will not increase the cost of construction.

Analysis: Code change proposals FS90 and FS91 address fire-resistance rated curtain wall/floor intersection requirements. The committee needs to make its intent clear with respect to these provisions.

ICCFILENAME: BEITEL-FS13-714.4

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee felt that these changes should be done in the development of the referenced standard rather than in the code. Further, the limit of 30 minutes in Section 714.4.2 may not be appropriate for situations where the floor fireresistance rating is greater than this.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Rick Thornberry, PE, The Code Consortium and Jesse Beitel, Hughes Associates, Inc., representing Alcan Composites USA, Inc./Centria/Trespa North American, Ltd, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

714.4 Exterior curtain wall/floor intersections. The intersections of exterior curtain wall assemblies and floor or floor/ceiling assemblies shall be protected against interior fire spread in accordance with Sections 714.4.1 through 714.4.3 as applicable. Height and fire-resistance requirements for curtain wall spandrels shall comply with Section 705.8.5.

714.4.1 Fire-resistance-rated exterior curtain wall/fire-resistance-rated floor intersections. Where fire-resistance-rated floor or floor/ceiling assemblies are required, the intersection of fire-resistance-rated exterior curtain wall assemblies and such floor assemblies shall be sealed with an approved system. Such systems shall be securely installed and tested in accordance with ASTM E 2307 to provide an "F" rating and a "T" rating for a time period at least equal to the <u>required</u> fire-resistance rating of the floor assembly.

714.4.2 Nonfire-resistance-rated exterior curtain wall/fire-resistance-rated floor intersections. Voids created at the intersection of nonfire-resistance-rated exterior curtain wall assemblies and fire-resistance-rated floor assemblies shall be sealed with an approved system. Such systems shall be securely installed and tested in accordance with ASTM E2307 to provide an "F" rating when tested with the nonfire-resistance-rated exterior curtain wall assembly. <u>A "T" rating shall not be required.</u> The "F" rating shall be ~~the greater of 30 minutes or the time at which one of the following occurs:~~ <u>for a time period at least equal to the required fire-resistance rating of the floor assembly.</u>

~~1. The "F" rating is determined in the ASTM E2307 test, or~~

<u>Exception: Where the time at which</u> ~~2.~~a through-crack, hole or other opening is observed in the exterior exposed face of the curtain wall assembly at a location above the upper surface of thefloor assembly during the ASTM E2307 test <u>is less than the required "F" rating but not less than 30 minutes, the system shall not be required to have an "F" rating at least equal to the required fire-resistance rating of the floor assembly, provided the void created at the intersection of the exterior curtain wall assembly and the floor assembly is sealed with an approved material to prevent the interior spread of fire. Such material shall be securely installed and capable of preventing the passage of flame and hot gases sufficient to ignite cotton waste where subjected to ASTM E119 time-temperature fire conditions under a minimum positive pressure differential of 0.01 inch (0.254 mm) of water column (2.5 Pa) for the time period at least equal to the required fire-resistance rating of the floor assembly</u>.

(Portions of proposal not shown remain unchanged.)

Commenter's Reason: The Committee Reason Statement for disapproval of this Code Change focused mainly on Section 714.4.2 Nonfire-Resistance-Rated Exterior Curtain Wall/Fire-Resistance-Rated Floor Intersections since the Committee felt it contained criteria that more appropriately belonged within the referenced standard ASTM E 2307 rather than the code. However, this code change proposal actually consists of a reformatting of Section 714.4 Exterior Curtain Wall/Floor Intersections to break it down into logical subsections that address the different configurations and fire-resistance ratings of the building elements that make up the intersection that occurs at the exterior curtain wall and the floor in multistory buildings. We believe that the reformatting will definitely make this section more user friendly and enforceable. The Committee also expressed concerns about the minimum F rating only being required to be 30 minutes in Section 714.4.2 since the fire-resistance rating of the floor assembly will most likely be either 1-hour or 2-hours.

The revisions we have incorporated into our original code change submittal, we believe, help to further clarify the intent of the code change while also making it consistent with actions taken on other code changes during this cycle that impact this section such as FS87-09/10 and FS88-09/10. In fact, Section 714.4.2 has been revised in this Public Comment to eliminate the minimum F rating of 30 minutes and instead allow for the use of a new Exception to current Section 714.4 that was approved as modified by the Committee in Code Change FS88-09/10. The Committee agreed that the Exception was necessary to accommodate exterior curtain wall assemblies containing vision glass that extends to the finished floor level. That is because such assemblies cannot be effectively tested in accordance with ASTM E 2307 as the glass will break out early in the fire test. We believe that the Exception is also appropriate for other exterior curtain wall assemblies that will also not remain fully intact during the duration of the ASTM E 2307 fire test. Such exterior curtain wall assemblies are generally constructed of aluminum or are supported by aluminum extrusions and brackets used as attachments to the structural subframe that supports the curtain wall system away from the edge of the floor slab. Such systems cannot resist direct fire exposure for significant periods of time and thus do not remain intact in place during the full fire exposure for the ASTM E 2307 fire test for cases where there are 1-hour or 2-hour fire-resistance rated floors.

The Exception is invoked when a through-crack, hole, or other opening is observed in the exterior exposed face of the exterior curtain wall assembly at a location above the upper surface of the floor assembly during the ASTM E 2307 fire test. This would represent the loss of integrity of the curtain wall assembly similar to the breaking of visions glass. But the Exception is also conditional on the fact that such a failure of the exterior curtain wall assembly must not occur prior to 30 minutes of exposure during the ASTM E 2307 fire test. Thus, the curtain wall design must have some minimum substantial integrity for the first 30 minutes of fire exposure. Obviously, this limitation is more restrictive than for vision glass which breaks out of the curtain wall assembly generally within the first 15 minutes of the fire test. If those conditions are met, then the Exception approved by FS88-09/10 for vision glass can be applied. This Exception will still require the void at the intersection of the exterior curtain wall assembly and the fire-resistance rated floor assembly to be filled with a material that will resist the passage of flames and hot gases for a period of not less than that required by the fire-resistance rating of the floor assembly when tested to ASTM E 119 time-temperature conditions under a minimum positive pressure differential of 0.01 inches of water column. It should be noted that until the 2009 International Building Code (IBC), this method of testing the perimeter fire barrier protection at that void was either required or allowed as an alternative to the ASTM E 2307 fire test.

We believe that this Public Comment adequately responds to the Committee's concerns regarding our original code change proposal while meeting the intent of our original code change proposal for providing reasonable means for achieving the protection of the void created at the intersection of the exterior curtain wall assembly and the floor in multistory buildings, while not causing undue hardship on the installation of curtain wall assemblies that have traditionally been successfully used in multistory buildings for many years prior to the development of the ASTM E 2307 fire test method.

Therefore, we respectfully request that the Class A voting members support our Public Comment by overturning the Committee's recommendation for disapproval and voting for approval as modified in accordance with this Public Comment.

Analysis: Public comments to FS90 and FS91 address fire-resistance rated curtain wall/floor intersection requirements. The membership needs to make their preference clear with respect to these provisions.

Final Action: AS AM AMPC____ D

FS91-09/10

702, 714.4, 714.4.1, 714.4.1.1 (New), 714.4.3 (New)

Proposed Change as Submitted

Proponent: Rick Thornberry, PE, The Code Consortium, Inc., representing Alcan Composites USA, Inc.

1. Add new text as follows:

702 DEFINITIONS

<u>**PERIMETER FIRE BARRIER.** The perimeter joint protection installed between the exterior curtain wall assembly and the floor assembly to resist the passage of fire and hot gases between stories within the building at the voids created at the intersection of the exterior curtain wall assembly and the floor assembly.</u>

2. Revise as follows:

714.4 Exterior curtain wall/floor intersection. <u>Exterior curtain wall/floor intersections shall comply with Sections 714.4.1 and 714.4.2 as applicable.</u>

<u>**714.4.1 Exterior curtain wall/fire-resistance rated floor assembly intersections.**</u> Where fire-resistance-rated floor or floor/ceiling assemblies are required, voids created at the intersection of the exterior curtain wall assemblies and such floor assemblies shall be <u>protected by</u> ~~sealed with~~ an *approved* <u>perimeter fire barrier designed to resist</u> ~~system to~~

~~prevent~~ the interior spread of fire and hot gases between stories. ~~Such systems~~ The perimeter fire barrier shall be ~~securely installed and~~ tested in accordance with ASTM E 2307 ~~to prevent the passage of flame~~ for the time period at least equal to the *fire-resistance rating* of the floor assembly ~~and prevent the passage of heat and hot gases sufficient to ignite cotton waste. Height and fire-resistance requirements for curtain wall spandrels shall comply with Section 705.8.5~~.

714.4.1.1 Installation. The perimeter fire barrier shall be securely installed so as not to dislodge, loosen or otherwise impair its ability to accommodate expected building movements and to resist the passage of fire and hot gases.

714.4.~~1~~2 Exterior curtain wall/nonfire-resistance-rated floor assembly intersections. Voids created at the intersection of exterior curtain wall assemblies and nonfire-resistance-rated floor or floor/ceiling assemblies shall be sealed with an *approved* material or system to retard the interior spread of fire and hot gases between *stories*.

714.4.3 Curtain wall spandrels. Height and fire-resistance requirements for curtain wall spandrels shall comply with Section 705.8.5.

Reason: This section was revised during the last code cycle to eliminate the alternate method of testing which was utilized prior to the development of ASTM E 2307. So now the protection of the voids created at the intersection of exterior curtain wall assemblies and floor assemblies is required to be tested in accordance with ASTM E 2307. We believe it is appropriate to further revise this section to clarify that fact. Therefore, we have deleted some of the unnecessary terminology since that is already covered within the test method itself or within the new definition for "Perimeter Fire Barrier" which we are also including as a part of this code change proposal.

The definition for "Perimeter Fire Barrier" being proposed is similar to that contained in ASTM E 2307 and is the term contained in the title of the standard which is "Standard Test Method for Determining Fire Resistance of Perimeter Fire Barriers Using Intermediate-Scale, Multi-story Test Apparatus." So we have incorporated the term "Perimeter Fire Barrier" within this code change to make it very clear what protection the section prescribes based on tests conducted in accordance with ASTM E 2307. Some of the other terminology we have substituted parallels that in Section 714.1 General for fire-resistant joint systems so that they are consistent since Section 714.4 is a subsection of Section 714 Fire-Resistant Joint Systems.

We have also reformatted Section 714.4 and subdivided it into two additional subsections. Subsection 714.4.1 specifically deals with the installation of the perimeter fire barrier where the floor assembly is required to have a fire-resistance rating and utilizes terminology based on Section 714.2 Installation for fire-resistant joint systems for consistency. Subsection 714.4.3 is simply the last sentence of Section 714.4 relocated. Current Subsection 714.4.1 has been renumbered as 714.4.2 to fit into this reformatting. We believe that this will provide for better clarity, interpretation, and enforcement of these provisions for exterior curtain wall/floor intersection protection utilizing perimeter fire barriers.

In summary, no technical changes have been made to this section. It has simply been editorially revised to be consistent with the referenced test method ASTM E 2307 and similar requirements in Section 714 for fire-resistant joint systems of which this Section 714.4 is a subsection.

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: Code change proposals FS90 and FS91 address fire-resistance rated curtain wall/floor intersection requirements. The committee needs to make its intent clear with respect to these provisions.

ICCFILENAME: THORNBERRY-FS7-714.4.1

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee felt that the term "perimeter fire barrier" was not needed and could cause confusion rather than clarity.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Rick Thornberry, PE, The Code Consortium, Inc., representing Alcan Composites USA, Inc., requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

702 DEFINITIONS

F RATING. The time period that the through-penetration firestop system limits the spread of fire through the penetration when tested in accordance with ASTM E 814 or UL 1479; the time period that the perimeter fire barrier limits the spread of flames or hot gases through the intersection of the exterior curtain wall assembly and the fire-resistance-rated floor or floor/ceiling assembly when tested in accordance with ASTM E 2307.

PERIMETER FIRE BARRIER. The perimeter joint protection installed between the exterior curtain wall assembly and the floor assembly to resist the passage of fire and hot gases between stories within the building at the voids created at the intersection of the exterior curtain wall assembly and the floor assembly.

T RATING. The time period that the penetration firestop system, including the penetrating item, limits the maximum temperature rise to 325°F (163°C) above its initial temperature through the penetration on the nonfire side when tested in accordance with ASTM E814 or UL 1479; the time period that the perimeter fire barrier limits the maximum temperature rise to 325°F (181°C) above its initial temperature on the nonfire side when tested in accordance with ASTM E 2307.

714.4 Exterior curtain wall/floor intersection. Exterior curtain wall/floor intersections shall comply with Sections 714.4.1 and 714.4.2 as applicable.

714.4.1 Exterior curtain wall/fire-resistance rated floor assembly intersections. Where fire-resistance-rated floor or floor/ceiling assemblies are required, voids created at the intersection of the exterior curtain wall assemblies and such floor assemblies shall be protected by an approved perimeter fire barrier designed to resist the interior spread of fire and hot gases between stories. The perimeter fire barrier shall be tested in accordance with ASTM E2307 to provide an "F" rating for ~~the~~ a time period at least equal to the required fire-resistance rating of the floor assembly. A "T" rating shall not be required.

714.4.1.1 Installation. The perimeter fire barrier shall be securely installed so as not to dislodge, loosen or otherwise impair its ability to accommodate expected building movements and to resist the passage of fire and hot gases.

714.4.2 Exterior curtain wall/nonfire-resistance-rated floor assembly intersections. Voids created at the intersection of exterior curtain wall assemblies and nonfire-resistance-rated floor or floor/ceiling assemblies shall be sealed with an approved material or system to retard the interior spread of fire and hot gases between stories.

714.4.3 Curtain wall spandrels. Height and fire-resistance requirements for curtain wall spandrels shall comply with Section 705.8.5.

Commenter's Reason: The main reason the Committee voted to disapprove this Code Change was that they felt the proposed new definition for "Perimeter Fire Barrier" could cause confusion with the currently defined term "Fire Barrier." We respectfully disagree with the Committee's reason since defined terms are shown in italics in the code text, so any user of the code would be able to determine that the phrase "perimeter fire barrier" is different than the term "fire barrier." Furthermore, the term "perimeter fire barrier" as noted in the Reason Statement to the original Code Change is the identical terminology used in the referenced test method ASTM E 2307. It concisely defines the protection that is required to be installed between the exterior curtain wall assembly and the floor assembly in order to resist the passage of fire and hot gases between stories. By providing this defined term, it will no longer be necessary to have a long descriptive phrase to identify the perimeter joint protection required by the code. We have also revised Section 714.4.1 to reflect changes made to Section 714.4 by Code Change FS87-09/10 which was recommended for approval by the Committee.

And one final important point, we have added second definitions to the current definitions for "F Rating" and "T Rating" to recognize the F rating and T rating determined in accordance with ASTM E 2307 so as not to confuse them with the currently defined terms for those ratings based on ASTM E 814/UL 1479 for through-penetration firestop systems.

With the revisions proposed in this Public Comment, we believe that Section 714.4 will be more user friendly and enforceable, as well as more closely correlated with the ASTM E 2307 fire test required by this section. Therefore, we respectfully request that the Class A voting members in attendance at the hearings to overturn the Committee recommendation for disapproval and vote for approval as modified for Code Change FS91-09/10 based on this Public Comment.

Analysis: Public comments to FS90 and FS91 address fire-resistance rated curtain wall/floor intersection requirements. The membership needs to make their preference clear with respect to these provisions.

Final Action: AS AM AMPC____ D

FS96-09/10
715.4.3.1

Proposed Change as Submitted

Proponent: Bill Ziegert, representing Smoke Guard, Inc.

Revise as follows:

715.4.3.1 Smoke and draft control. *Fire door* assemblies including elevator hoistway doors opening into fire-resistance rated corridors shall also meet the requirements for a smoke and draft control door assembly tested in accordance with UL 1784. The air leakage rate of the door assembly shall not exceed 3.0 cubic feet per minute per square foot ($0.01524\ m^3/s \cdot m^2$) of door opening at 0.10 inch (24.9 Pa) of water for both the ambient temperature and elevated temperature tests. Louvers shall be prohibited. Installation of smoke doors shall be in accordance with NFPA 105.

Reason: Just as it is important that room to corridor doors in fire rated corridors meet not only the fire-resistance rating requirements, but also the requirements for smoke and draft control, it is equally if not more important that the elevator hoistway doors which are fire- resistance rated meet the same smoke leakage requirements when they open into fire resistance rated corridors. Fires on one floor can potentially overcome the corridor doors, filling the corridor with smoke and then enter the elevator shaft where the stack effect would force the smoke out onto non affected floors. If the hoistway doors resist the passage of smoke, occupants on other floors would not be as likely to be exposed to the smoke hazard.

Cost Impact: Moderate cost increase that would apply only to occupancies without elevator lobbies.

ICCFILENAME: ZIEGERT-FS2-715.4.3.1

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee felt that these provisions were not necessary to enforce the code. Elevator manufacturers have indicated that they cannot achieve smoke and draft control requirements, therefore the option is to provide an enclosed elevator lobby, which are clearly provided for in the code.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Thomas Meyers, City of Central City, Colorado, representing Colorado Chapter of ICC, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

715.4.3.1 Smoke and draft control. *Fire door* assemblies including elevator hoistway doors opening directly into fire-resistance rate corridors shall also meet the requirements for a smoke and draft control door assembly tested in accordance with UL 1784. The air leakage rate of the door assembly shall not exceed 3.0 cubic feet per minute per square foot (0.01524 m3/s · m2) of door opening at 0.10 inch (24.9 Pa) of water for both the ambient temperature and elevated temperature tests. Louvers shall be prohibited. Installation of smoke doors shall be in accordance with NFPA 105.

Commenter's Reason: The modification adds the word "directly" within the original proponent's change to include elevator hoistway doors as being required to provide for smoke protection in accordance with the testing procedure contained in UL 1784. This is intended to clarify the committee's concerns that the hoistway doors would be required to be protected in circumstances where a smoke protected elevator lobby is already provided with smoke and draft control door assemblies. Using the term "directly" indicates that the hoistway door is in direct communication with a corridor and not isolated via lobby or additional (3002.6) swinging doors.

The change is needed to address inconsistency in enforcement of smoke and draft door provisions in fire resistance rated corridor applications penetrated with leaky elevator hoistway openings. Currently, some enforcing agencies require any elevator hoistway door to have smoke and draft control capacity whenever the corridor is rated, consistent with the requirement for other door assemblies in the corridor fire partition. Other jurisdictions interpret the 708.14 elevator lobby provisions as providing the draft and smoke control provisions specific to the elevator hoistway opening for all circumstances, including corridor applications referencing 715.4.3.1. Approval as modified would provide clear resolution to this inconsistency.

Elevators are known for their ability to convey smoke from level to level in a building. If the code insists on smoke and draft control at normal door openings, it is only logical to require it at the elevator hoistway opening.

Final Action: AS AM AMPC____ D

FS97–09/10
715.4.3.2, Table 715.4

Proposed Change as Submitted

Proponent: William F. O'Keeffe, representing SAFTIFirst

1. Revise as follows:

715.4.3.2 Glazing in door assemblies. Where Table 715.4 identifies 1-hour rated corridor walls or 1-hour rated smoke barriers, ~~I~~in a 20-minute fire door assembly, the glazing material in the door itself shall have a minimum fire-protection rating of 20 minutes and shall be exempt from the hose stream test. Glazing material in any other part of the door assembly including transom lites and sidelites, shall be tested for 45-minutes in accordance with NFPA ~~257~~ 252 or UL ~~9~~ 10C, including the hose stream test~~, in accordance with Section 715.5~~.Where Table 715.4 identifies 0.5-hour rated corridor walls or other fire partitions, in a 20-minute fire door assembly, the glazing material in the door vision panel, sidelights and transoms shall have a minimum fire-protection rating of 20 minutes when tested to NFPA 252 or UL 10C, and shall be exempt from the hose stream test.

2. Revise as follows:

TABLE 715.4
FIRE DOOR AND FIRE SHUTTER FIRE PROTECTION RATINGS

TYPE OF ASSEMBLY	REQUIRED ASSEMBLY RATING (hours)	MINIMUM FIRE DOOR AND FIRE SHUTTER ASSEMBLY RATING (hours)
Fire walls and fire barriers having a required fire-resistance rating greater than 1 hour	4	3
	3	3[a]
	2	$1\frac{1}{2}$
	$1\frac{1}{2}$	$1\frac{1}{2}$
Fire barriers having a required fire-resistance rating of 1 hour:		
Shaft, exit enclosure and exit passageway walls	1	1
Other fire barriers	1	$\frac{3}{4}$
Fire partitions:		
Corridor walls	1	$\frac{1}{3}$ [b]
	0.5	$\frac{1}{3}$ ~~b~~
Other fire partitions	1	$\frac{3}{4}$
	0.5	$\frac{1}{3}$
Exterior walls	3	$1\frac{1}{2}$
	2	$1\frac{1}{2}$
	1	$\frac{3}{4}$
Smoke barriers	1	$\frac{1}{3}$ [b]

a. Two doors, each with a fire protection rating of 11/2 hours, installed on opposite sides of the same opening in a firewall, shall be deemed equivalent in fire protection rating to one 3-hour fire door.
b. For testing requirements, see Section 715.4.3.

Reason: This code change provides for testing of a 20-minute door assembly, including the sidelight and transom panels, to NFPA 252 without hose stream, when the assembly is in a half-hour rated corridor or fire partition. Since a half hour wall tested to ASTM E119 is not required to be hose stream tested, there is no fire safety reason to require the door assembly component in that wall to meet a hose stream test.

In past code cycle testimony it has been suggested that there is a reason to treat sidelights and transoms differently than the glazing in the vision panel of the door, because combustibles can be stacked next to a sidelight (of course, that argument doesn't apply to the transom, because it is above the door). It has also been suggested that 20-minute tempered products are subject to "disintegration."

The first point is not a hose stream issue, but a radiant heat issue, and applying a hose stream test to products does not assure that they will block radiant heat from passing through the glazing and spreading the fire. Indeed, as seen by the test data in the supporting fire test video, http://www.safti.com/video/resist/resistive.html, one type of fire protection material, ceramic, transmits enough radiant heat in the first 20-minutes of fire exposure to cause spontaneous combustion. Wired glass, another fire protection product that can pass the hose stream test, likewise transmits dangerous levels of radiant heat during the early stages of a fire.

The second point simply isn't true, and was not substantiated by any test data showing alleged "disintegration." Specialty tempered products have undergone rigorous fire testing, and have proven to be effective fire protection materials by fire case history. Millions of square feet of these products have been used worldwide without any reports of the alleged "disintegration" alleged by opponents to this code change. Significantly, opponents of this code change have never come forward with any reported instances of failure.
The fact is, products not tested to the hose stream protect against fire equally as well as those that are tested.

This change also changes the test standard for sidelights and transoms back to NFPA 252 and UL 10C, which is the standard historically applied to door assemblies that include sidelights and transoms, and is consistent with the test protocol specified in NFPA 80. The application of NFPA 257 under the existing provision has caused confusion and impractical test methods for testing one door assembly to two different test standards.

In 20-minute window applications in half hour walls, there is no legitimate fire safety reason for requiring one element of the fire resistive construction to pass the hose stream test, where the half hour wall assembly and 20-minute door components do not pass that same test.

Cost Impact: The code change proposal will reduce the cost of construction.

ICCFILENAME: OKEEFFE-FS6-715.4.3.2

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee felt that the proposed wording was confusing with respect to door requirements and door vision panel requirements. Further, NFPA 257 is the appropriate standard and should not be eliminated.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Jeff Inks, Window and Door Manufacturers Association, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

715.4.3.2 Glazing in door assemblies. ~~Where Table 715.4 identifies 1-hour rated corridor walls or 1-hour rated smoke barriers,~~ In a 20-minute fire door assembly, the glazing material in the door itself shall have a minimum fire-protection rating of 20 minutes and shall be exempt from the hose stream test. Glazing material in any other part of the door assembly including transom lites and sidelites, shall be tested ~~for 45-minutes~~ in accordance with NFPA 252 or UL 10C, including the hose stream test, in accordance with Section 715.5.~~Where Table 715.4 identifies 0.5-hour rated corridor walls or other fire partitions, in a 20-minute fire door assembly, the glazing material in the door vision panel, sidelights and transoms shall have a minimum fire-protection rating of 20 minutes when tested to NFPA 252 or UL 10C, and shall be exempt from the hose stream test.~~

TABLE 715.4
FIRE DOOR AND FIRE SHUTTER FIRE PROTECTION RATINGS

TYPE OF ASSEMBLY	REQUIRED ASSEMBLY RATING (hours)	MINIMUM FIRE DOOR AND FIRE SHUTTER ASSEMBLY RATING (hours)
Fire walls and fire barriers having a required fire-resistance rating greater than 1 hour	4	3
	3	3[a]
	2	$1\frac{1}{2}$
	$1\frac{1}{2}$	$1\frac{1}{2}$
Fire barriers having a required fire-resistance rating of 1 hour:		
Shaft, exit enclosure and exit passageway walls	1	1
Other fire barriers	1	$\frac{3}{4}$
Fire partitions:		
Corridor walls	1	$\frac{1}{3}$ [b]
	0.5	$\frac{1}{3}$ [b]
Other fire partitions	1	$\frac{3}{4}$
	0.5	$\frac{1}{3}$
Exterior walls	3	$1\frac{1}{2}$
	2	$1\frac{1}{2}$
	1	$\frac{3}{4}$
Smoke barriers	1	$\frac{1}{3}$ [b]

a. Two doors, each with a fire protection rating of 11/2 hours, installed on opposite sides of the same opening in a firewall, shall be deemed equivalent in fire protection rating to one 3-hour fire door.
b. For testing requirements, see Section 715.4.3.

Commenter's Reason: WDMA concurs with the intent of the initial proposal and with the proponent's supporting statements regarding the appropriate test standards transom lights and sidelights in 20-minute fire door assemblies which is the bases for this comment. We do not believe the testimony in opposition to this proposal or the Fire Safety Committee provided an adequate reason for rejecting it. .

Both NFPA 252 – *Standard Methods of Fire Tests of Door Assemblies*, and UL 10 *Standard for Positive Pressure Fire Tests of Door Assemblies*, expressly include glazing as an integral part of the entire door assembly to be tested, while the NFPA 257 *Standard on Fire Test for Window and Glass Block Assemblies,* and UL 9 *Fire Tests of Window Assemblies* are limited only to glazing in window assemblies and do not include glazing in door assemblies. Requiring glazing in fire door assemblies to be tested to NFPA 257 or UL 9C therefore results in a very significant conflict in section 715.4.3 that is further exacerbated by requiring the hose stream for glazing in 20-minute rated fire door assemblies. This creates an impractical and unreasonable testing protocol by requiring different components in the same assembly to be tested to two different standards.

Section 715.4.3. requires fire door assemblies, including side and transom lights and glazing in the door to have minimum fire rating of 20-minutes, tested to NFPA 252 or UL 10 without the hose stream test which is then followed by Section 715.4.3.2, that requires the same sidelight and transom light glazing to be tested to NFPA 257 or UL 9, including the hose stream test, for the same rating. In effect, this means taking glazing that was tested separately from the assembly, per NFPA 257, including the hose stream test, and installing it in a door assembly that was tested without the hose stream test per NFPA 252. This cannot be reasonably accomplished in a lab and makes little sense. This is also inconsistent with the protocols specified by NFPA 80, which together with the conflict in 715.4.3 is causing unnecessary confusion and as noted, an impractical and unreasonable testing protocol for testing requirements that have never been adequately justified in the first place. This public comment eliminates the fire testing conflicts currently created by the section.

Public Comment 2:

Jeff Inks, Window and Door Manufacturers Association, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

715.4.3.2 Glazing in door assemblies. ~~Where Table 715.4 identifies 1-hour rated corridor walls or 1-hour rated smoke barriers,~~ In a 20-minute fire door assembly, the glazing material in the door itself shall have a minimum fire-protection rating of 20 minutes and shall be exempt from the hose stream test. Glazing material in any other part of the door assembly including transom lites and sidelites, shall be tested ~~for 45-minutes~~ in accordance with NFPA 257 ~~252~~ or UL 9 ~~10C~~, including the hose stream test, in accordance with Section 715.5. ~~Where Table 715.4 identifies 0.5-hour rated corridor walls or other fire partitions, in a 20-minute fire door assembly, the glazing material in the door vision panel, sidelights and transoms shall have a minimum fire-protection rating of 20 minutes when tested to NFPA 252 or UL 10C, and shall be exempt from the hose stream test.~~

> **Exception:** Glazing material in any other part of the door assembly including transom lights and sidelights, in fire partitions required to be 1/2 hour rated by Table 715.4, shall be exempt from the hose stream test.

TABLE 715.4
FIRE DOOR AND FIRE SHUTTER FIRE PROTECTION RATINGS

TYPE OF ASSEMBLY	REQUIRED ASSEMBLY RATING (hours)	MINIMUM FIRE DOOR AND FIRE SHUTTER ASSEMBLY RATING (hours)
Fire walls and fire barriers having a required fire-resistance rating greater than 1 hour	4 3 2 1 1/2	3 3[a] 1 1/2 1 1/2
Fire barriers having a required fire-resistance rating of 1 hour: Shaft, exit enclosure and exit passageway walls Other fire barriers	 1 1	 1 3/4
Fire partitions: Corridor walls Other fire partitions	 1 0.5 1 0.5	 1/3[b] 1/3[b] 3/4 1/3
Exterior walls	3 2 1	1 1/2 1 1/2 3/4
Smoke barriers	1	1/3[b]

a. Two doors, each with a fire protection rating of 11/2 hours, installed on opposite sides of the same opening in a firewall, shall be deemed equivalent in fire protection rating to one 3-hour fire door.
b. For testing requirements, see Section 715.4.3.

Commenter's Reason: WDMA concurs with the intent of the initial proposal and with the proponent's supporting statements regarding application of the hose stream test requirement on transom lights and sidelights in 20-minute fire door assemblies which is the bases for this comment. The proposal as amended by this comment addresses the Committee's reason for disapproval by removing the proposed language the Committee felt was confusing, and clarifying it by adding a limited exception to accomplish the same objective.

WDMA believes that the exception as proposed is wholly justified because of the continued lack of data, actual incidents of failure, or any other justification for requiring a hose stream test for the sidelight and transom light glazing in a 20-minute door assembly, especially when there is no hose stream test requirement for any other component of the assembly or partition because such a test is not necessary to assure the required performance. Having no requirement for a hose stream test in 20-minute assemblies is also consistent with the requirements in NFPA 101.

The only bases for maintaining a requirement for the hose stream test for sidelight and transom light glazing in 20-minute door assemblies in the IBC continues to be unsubstantiated assertions by opponents to removing the requirement that fuel loads can be stacked by sidelight glazing, and tempered glass can fail when experiencing a significant temperature delta. Those assertions are not disputed in and of themselves. However, as noted, they have not been substantiated by data, actual incidents or any other sound technical information to establish that they are in fact the risk they are asserted to be in order to justify the need for the hose stream test for glazing in these assemblies.

The argument that the potential for fuel loads to be stacked in front of a sidelight and that that potential poses a significant risk to these assemblies is subjective and unsupported. The other argument that glazing in these assemblies is vulnerable to failure due to thermal shock caused by water from an activated sprinkler is equally unsupported by data or documented failures under those circumstances. There is no record of reported incidents of failure due to thermal shock from fire sprinklers in the U.S. or anywhere in the world indicating a fire safety problem. In fact, specialty tempered products have undergone rigorous fire testing, and have proven to be effective fire protection materials by fire case history. Millions of square feet of these products have been used worldwide without any reports of the failures opponents have asserted that there is a too great a risk of.

Final Action: AS AM AMPC____ D

FS100-09/10
715.4.4.1

<u>Proposed Change as Submitted</u>

Proponent: William F. O'Keeffe, representing SAFTIFirst

Revise as follows:

715.4.4 Doors in exit enclosures and exit passageways. Fire door assemblies in exit enclosures and exit passageways shall have a maximum transmitted temperature end point of not more than 450° F (250° C) above ambient at the end of 30 minutes of standard fire test exposure.

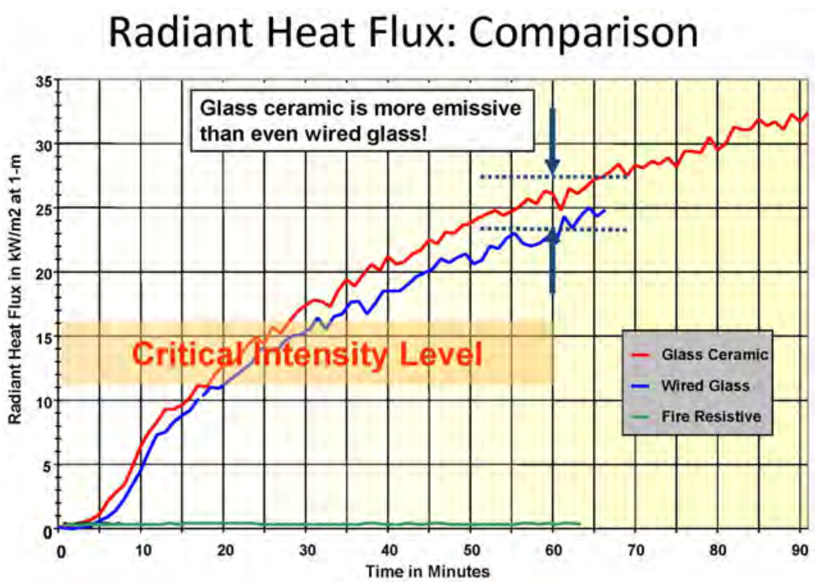
> **Exception:** The maximum transmitted temperature rise is not required in buildings equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.1.2.

715.4.4.1 Glazing in doors. Fire-protection-rated glazing in excess of 100 sq inches (0.065 m^2) <u>is not permitted.</u> <u>Fire-resistance rated</u> glazing <u>in excess of 100 sq inches (0.065 m^2)</u> shall be permitted in fire door assemblies when tested as components of the door assemblies, and not as glass lights, and shall have a maximum transmitted temperature rise of 450° F (250° C) in accordance with 715.4.4.

> ~~**Exception:** The maximum transmitted temperature end rise is not required in buildings equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.3.1.2.~~

Reason: This code change will make the size limits fire protection glazing in 60-and 90-minute doors in exit enclosures and passageways consistent with size limits for 60-and 90-minute doors elsewhere in the code. The presence of sprinklers in the building does not eliminate the life safety and fire spread hazard posed by unrestricted transmission of radiant heat flux through large sizes of fire protection rated glazing panels in 60-and-90-minute doors, especially when those doors are protecting exit enclosures and exit passageways deemed essential for occupant life safety.

Fire test data show that at 45-minutes, fire protection rated products such as ceramics and wired glass transmit in excess of 20 kW/m^2. At 20 minutes of fire exposure, these materials transmit in excess of 10 kW/m^2, and at 10 minutes of fire exposure, transmit 5 kW/m^2. See http://www.safti.com/video/resist/resistive.html See Chart Cumulative Radiant Heat Energy Data Chart below, prepared by the test sponsor, Vetrotech SaintGobain. The Society of Fire Protection Engineers Fire Protection Engineering Handbook identifies a fairly obvious tolerance limit for exposure to radiant heat of 2.5 kW/m^2 due to unbearable pain. (See SFPE Handbook of Fire Protection Engineering, 2nd edition, page 2-114)



Included as further support of this code change are two test reports from the Coast Guard testing of (1) Ceramic (FireLite) in steel bulkheads and (2) wired glass in steel bulkheads. Temperature rise and radiant heat flux measurements were recorded. The tests were intended to measure radiant heat flux and surface temperature performance at 60 minutes. The tests can be summarized as follows:

Wired Glass Test

The test of the wired glass panels resulted in glazing failure prior to 60-minutes, so radiant heat and temperature rise were only recorded up to the time of the wired glass failure.

Test 1

Heat flux at end of test (41:24 minutes) - 71 kW/m sq.
Surface temperature - wired glass temperature - 730 degrees C; steel frame - 540 degrees C

Test 2

Heat flux at end of test (37:46 minutes) - 48 kW/m sq.
Surface temperature - wired glass temperature - 730 degrees C; steel frame - 550 degrees C

Test 3

Heat flux at end of test (48:30 minutes) - 57 kW/m sq.
Surface temperature - wired glass temperature - 760 degrees C; steel frame - 585 degrees C

Conclusion on page 8 - As the window panes began to reach their melting point and flow out of the test frame, the recorded heat flux levels showed obvious increases. In all three tests, the recoded heat flux increased approximately 5-7 kW/m sq. until the wire glass fell out of the test frame and the test was terminated.

Ceramic (FireLite) Test

Test 1

Heat flux at end of test (60:00 minutes) - 75 kW/m sq.
Surface temperature - ceramic glass temperature - 800 degrees C; steel frame - 600 degrees C

Test 2

Heat flux at end of test (60:00 minutes) - 69 kW/m sq.
Surface temperature -ceramic glass temperature - 800 degrees C; steel frame - 600 degrees C

Test 3

Heat flux at end of test (60:00 minutes) - 73 kW/m sq.
Surface temperature -ceramic glass temperature - 800 degrees C; steel frame - 600 degrees C

According to these test reports, the surface temperature is significantly higher on the glazing than it is on the steel frame. Also, the report notes that the radiant heat measurements taken that included the "cooler steel frame" were several percentages lower than the view that included just the glazing. (see Ceramic test report, page 6.)

As further support, the following is a published listing of the ceramic product that was tested in the weblink video provided above, which shows a maximum tested area of 3627 sq. inches.

Product Designation: Keralite FR-F, Keralite FR-R, Keralite FR-L, Keralite
Thickness: 3/16 in. or 5/16 in. (5 or 8 mm)
Glazing Compound: closed cell PVC tape for 3/4 hr and 1 hr ratings. Kerafix ceramic tape for 1-1/2 hr ratings.
Furnace Pressure: Neutral and Positive

Rating	**Application**	**Max Exposed Area of Glass (Sq In.)**	**Max Width of Exposed Glass (In.)**	**Max Height of Exposed Glass (In.)**	**Min Depth of Groove (In.)**	**Groove Width (In.)**	**Building Code Marking**
1 hr.	Door	3627	46-1/2	78	5/8	5/16, 7/16	D-H-NT-60
1 hr.	Window, Transom, Sidelight	3627	46-1/2	78	5/8	5/16, 7/16	D-H-NT-60, OH-60

The use of this much glazing in a fire door protecting an exit enclosure or passageway is a threat to life safety, and should not be permitted.

Finally, the current provision, which appears to allow fire protection rated glazing to exceed 100 sq. inches when the building is sprinklered, was never intended by the proponent of the code change to the 2000 IBC that allowed fire resistance rated glazing that limited temperature rise to 450 F degrees to exceed 100 sq. inches. In the Draft 2000 IBC, there was one exception in the section specifying the requirements for temperature rise doors in exit enclosures and passageways, which applied to allow a non-temperature rise door when the building is sprinklered. The proposal submitted in 1998 that amended that section to allow fire resistance rated glazing to exceed 100 sq. inches when tested to limit temperature rise to 450- degrees F did not propose a second exception that would allow fire protection glazing to exceed 100 sq. inches when the building was sprinklered. However, when the monograph was published, a duplicate exception was printed, though never intended or proposed by the proponent of that code change.

The proponent of the 1998 code change intended this section to limit fire protection rated glazing to 100 sq. inches, consistent with the size limits provided by the legacy codes, and currently applicable in Section Section 715.4.7.1—regardless of whether the building is sprinklered. The same reasons for limiting fire protection glazing in 90-minute fire doors certainly apply in 60-minute exit enclosure and passageway fire doors.

As stated in NFPA 80 (2007), Annex I:

Traditional glazing materials have been prohibited from being used in fire windows in exit stair enclosures because of the concern for radiant heat transfer. Recently, the model building codes also incorporated requirements for limiting the temperature rise on the unexposed face of fire doors opening into exit stair enclosures in order to address the problem of heat transfer (both conducted and reradiated) that could expose evacuating occupants passing doors at each landing. Therefore, caution should be exercised when considering glazing materials with fire protection ratings of 60-minutes or more in such applications, since they can transmit excessive radiant heat into the exit stair enclosure. However, glazing materials with fire resistance ratings are suitable for such situations, since they have been tested to limit radiant heat transfer.

In sum, there is good reason to clarify that fire protection rated glazing is limited to 100 sq. inches in 1-hour exit enclosures and passageways, without an exception when automatic sprinklers are installed in accordance with Chapter 9 provisions. These exit enclosures and passageways are integral to life safety, and there is no justification for not providing for passive fire protection, protecting occupants from dangerous radiant heat levels from fully glazed exit enclosure doors, especially since the cost of fire resistance rated glazing is comparable to the cost of laminated safety-rated ceramics.

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: Code change proposals FS100 and FS107 propose similar revisions to Section 715.4.4.1. The committee needs to make its intent clear with respect to these provisions.

ICCFILENAME: OKeeffe-FS1-715.4.4.1

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The committee agreed that the presence of sprinklers in the building should not eliminate the life safety and fire spread hazard posed by unrestricted transmission of radiant heat flux through large sizes of fire protection rated glazing panels especially when those doors are protecting exit enclosures or passageways.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Bob Eugene, representing Underwriters Laboratories, Inc., requests Disapproval.

Commenter's Reason: The Committee action of Approval as Submitted manages to create confusion regarding doors in exit enclosures and exit passageways. Based on 715.4.4, in a NFPA 13 or 13R protected building, the opaque door panel is *not limited* to 450ºF temperature rise above ambient, but with the change to 715.4.4.1, the glazing within that same door panel would be *limited* to 450ºF temperature rise. This creates an inconsistency between 715.4.4 and 715.4.4.1 without technical justification.

It would also necessitate revising the marking scheme to add a designation for a fire-resistance-rated glazing that doesn't meet the ASTM E119 temperature requirements when in door applications, but does meet 450ºF temperature rise.

The revised text adds confusion and will foster further misunderstanding on product use and application not only within the Code and Architectural Community but also with manufacturers and suppliers of doors and frames.

Final Action: AS AM AMPC____ D

FS101-09/10-PART II
1703.5.4 (New)

NOTE: PART I DID NOT RECEIVE A PUBLIC COMMENT AND IS ON THE CONSENT AGENDA. PART I IS REPRODUCED FOR INFORMATIONAL PURPOSES ONLY FOLLOWING ALL OF PART II.

Proposed Change as Submitted

Proponent: William F. O'Keeffe, representing SAFTIFirst

PART II- IBC STRUCTURAL

Add new text as follows:

1703.5.4 Method of labeling. Information required to be permanently identified on the product shall be acid etched, sand blasted, ceramic fired, laser etched, embossed or of a type that, once applied, cannot be removed without being destroyed.

Reason: This code change provides for a method of permanently identifying information required by the code on the label. The language for permanent identification is taken from Section 2403.1, which applies to the permanent identification of information on glazing required by Chapter 24. This clarifies that the same method of permanent identification applies to other labeling required in the code, and specifically, Chapter 7.

This change also makes an editorial correction to Section 715.4.7.3 by correcting the reference to 715.4.7.3.1, instead of the incorrect reference to 715.5.9.1.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: OKeeffe-FS5-703.5

Public Hearing Results

PART II- IBC STRUCTURAL

Committee Action: **Approved as Submitted**

Committee Reason: To be consistent with the committee's action on FS101-09/10 Part I.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Thomas S. Zaremba, Roetzel & Andress, representing Glazing Industry Code Committee (GICC), Committee of the Glass Association of North America (GANA), requests Disapproval.

Commenter's Reason: FS101 Part II should be disapproved. In support of Part II of FS101, the Proponent says that: "[t]he language for permanent identification is taken from Section 2403.1, which applies to the permanent identification of information on glazing required by Chapter 24." What the Proponent did not tell the Committee is that the language found in this proposal is taken from the second paragraph of Section 2403.1 and that paragraph only applies to tempered glass. Further, the Proponent failed to tell the Committee that, even where these same marking techniques (namely acid etching, sand blasting etc.) are found in connection with the designation of safety glazing in Section 2406.3, exceptions from compliance with these marking techniques exist for all types of glazings "other than tempered glass." The reason that these methods of labeling are mandated only for tempered glass is because tempered glass must be manufactured to size and cannot be cut in the field. It is, therefore, easy to apply acid etchings, laser etchings or sand blasted labels to each specially manufactured light of tempered glass. However, it is, simply, impracticable to require these methods of labeling for all other types of glazings that can be cut in the field.

The mandatory inclusion of these labeling techniques for all products is, simply, overbroad and impracticable and Final Action Agenda voters are urged to vote against the standing motion to approve FS101 Part II "As Submitted" in order to vote in favor of a motion to disapprove FS101 Part II.

Final Action: AS AM AMPC____ D

NOTE: PART I REPRODUCED FOR INFORMATIONAL PURPOSES ONLY – SEE ABOVE

FS101-09/10, PART I- IBC FIRE SAFETY

Revise as follows:

703.5 Fire-resistance-rated glazing. Fire-resistance-rated glazing, when tested in accordance with ASTM E 119 or UL 263 and complying with the requirements of Section 707, shall be permitted. Fire-resistance-rated glazing shall bear a label or other identification showing the name of the manufacturer, the test standard and the identifier "W-XXX," where the "XXX" is the fire-resistance rating in minutes. Such label or identification shall be issued by an agency and shall be permanently ~~affixed to~~ identified on the glazing.

715. 4.7.3 Labeling. Fire-protection-rated glazing shall bear a label or other identification showing the name of the manufacturer, the test standard and information required in Section ~~715.5.9.1~~ 715.4.7.3.1 that shall be issued by an approved agency and shall be permanently ~~affixed to~~ identified on the glazing.

715. 5.9 Labeling. Fire-protection-rated glazing shall bear a label or other identification showing the name of the manufacturer, the test standard and information required in Section 715.5.9.1 that shall be issued by an approved agency and shall be permanently ~~affixed to~~ identified on the glazing.

Reason: This code change provides for a method of permanently identifying information required by the code on the label. The language for permanent identification is taken from Section 2403.1, which applies to the permanent identification of information on glazing required by Chapter 24. This clarifies that the same method of permanent identification applies to other labeling required in the code, and specifically, Chapter 7.

This change also makes an editorial correction to Section 715.4.7.3 by correcting the reference to 715.4.7.3.1, instead of the incorrect reference to 715.5.9.1.

Cost Impact: The code change proposal will not increase the cost of construction.

PART I- IBC FIRE SAFETY
Committee Action: **Approved as Submitted**

Committee Reason: The committee agreed that the proposed glazing marking is appropriate and consistent with Section 2403.1.

Assembly Action: **None**

FS102-09/10
715.5

Proposed Change as Submitted

Proponent: William F. O'Keeffe, representing SAFTIFirst

715.5 Fire-protection-rated glazing. Glazing in fire window assemblies shall be fire-protection rated in accordance with this section and Table 715.5. Glazing in fire door assemblies shall comply with Section 715.4.7. Fire-protection-rated glazing in fire window assemblies shall be tested in accordance with and shall meet the acceptance criteria of NFPA 257 or UL 9. Fire-protection-rated glazing shall also comply with NFPA 80. Openings in nonfire-resistance-rated exterior wall assemblies that require protection in accordance with Section 705.3, 705.8, 705.8.5 or 705.8.6 shall have a fire protection rating of not less than 3/4 hour.

Exceptions:

1. Wired glass in accordance with Section 715.5.4
2. Fire-protection-rated glazing in 0.5-hour fire-resistance-rated partitions is permitted to have an 0.33-hour fire-protection rating.

715.5.8 Interior fire window assemblies. Fire-protection-rated glazing used in fire window assemblies located in fire partitions and fire barriers shall be limited to use in assemblies with a maximum fire-resistance rating of 1 hour in accordance with this section.

715.5.8.1 Where 3/4–hour fire protection window assemblies permitted. Fire-protection-rated glazing requiring 45-minute opening protection in accordance with Table 715.5 shall be limited to fire partitions designed in accordance with Section 709 and fire barriers utilized in the applications set forth in Sections 707.3.6 and 707.3.8 where the fire-resistance rating does not exceed 1 hour.

715.5.8.2 Area limitations. The total area of fire-protection rated window~~s~~ assemblies shall not exceed 25 percent of the area of a common wall with any room.

Reason: This code change is a clarification that fire protection-rated window assemblies are subject to area limits. Since there are some window assemblies that are fire resistance rated to ASTM E119, this code change aids the user in clarifying that fire protection rated window assemblies are subject to these limits.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: OKeeffe-FS10-715.5-2

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The term "assemblies" appropriately includes the frame, which makes the requirements more conservative. Further, this is consistent with the committee's actions on FS107-09/10.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Thomas S. Zaremba, Roetzel & Andress, representing Glazing Industry Code Committee (GICC), a Committee of the Glass Association of North America (GANA), requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

715.5.8.2 Area limitations. The total area of <u>the glazing in</u> fire-protection rated window assemblies shall not exceed 25% of the area of a common wall with any room.

(portions of proposal not shown, remain unchanged)

Commenter's Reason: In recommending approval of this proposal, it is believed that the Committee intended to make references to fire windows uniform throughout Chapter 7 by referring to them as "fire window assemblies" rather than merely as "windows" or "fire windows" since the testing and rating of fire windows includes their assemblies. However, adopting this proposal as submitted will alter how the 25% area limitation established in 715.5.8.2 is calculated. As written, the proposal would add the framing and other opaque assembly materials to the calculation of the 25% limitation. Since no evidence was submitted justifying a need to change the method of calculating the 25% limitation, the modification proposed by this Public Comment would 1- retain the proposed changes needed to make references to "fire window assemblies" uniform, but retain the current method of calculating the 25% area limitation. In that regard, it would include only the total area of the glazing, not the opaque materials used in the fire window assembly.

Final Action Agenda voters are urged to vote against the standing motion to approve FS102 as submitted in order to vote in favor of a motion to adopt the proposal "As Modified" by this Public Comment.

Final Action: AS AM AMPC____ D

FS107-09/10

702, 703.5, 715.2, 715.3, 715.3.1, Table 715.3 (New), 715.4, 715.4.1, 715.4.2, 715.4.3, 715.4.3.1, 715.4.3.2, 715.5.4, 715.4.4, 715.4.4.1, 715.4.5, 715.4.6, 715.4.6.1, 715.4.6.1.1, 715.4.7, 715.4.7.1, 715.5.8.1.1, 715.5.8.1.2, 715.5.8.1.2.1, 715.5.8.1.2.2, 715.4.7.2, 715.4.7.3, 715.5, 715.4.7.3.1, 715.4.7.4, 715.5.8, 715.5.8.1, 715.5.8.2, 715.6.8.3, Table 715.5, 715.5.9, 715.5.9.1, TABLE 715.4,

Proposed Change as Submitted

Proponent: Paul K. Heilstedt, PE, FAIA, Chair, representing ICC Code Technology Committee (CTC); William F. O'Keeffe, representing SAFTIFirst

1. Add new text:

SECTION 702 DEFINITIONS

<u>**Fire-rated glazing.** Glazing with either a fire protection rating or a fire resistance rating.</u>

2. Revise as follows:

SECTION 703 FIRE RESISTANCE RATINGS AND FIRE TESTS

703.5 Fire-resistance-rated glazing. Fire-resistance-rated glazing, when tested in accordance with ASTM E 119 or UL 263 and complying with the requirements of Section 707, shall be permitted. Fire-resistance-rated glazing shall bear a label ~~or other identification showing the name of the manufacturer, the test standard and the identifier "W-XXX," where the "XXX" is the fire-resistance rating in minutes. Such label or identification shall be~~ marked in accordance with Table 715.3 issued by an approved agency and shall be permanently affixed to the glazing.

SECTION 715 OPENING PROTECTIVES

715.1 General. (*No change to current text)*

715.2 Fire-resistance-rated glazing. Fire-resistance-rated glazing tested as part of a fire-resistance-rated wall assembly in accordance with ASTM E 119 or UL 263 and labeled in accordance with Section 703.5, shall be permitted in fire doors and fire window assemblies where tested and installed in accordance with their listings and shall not otherwise be required to comply with this section.

3. Add new text as follows:

715.3 Marking Fire-Rated Glazing Assemblies Fire-rated glazing assemblies shall be marked in accordance with Tables 715.3, 715.5, and 715.6.

715.3.1 Fire-rated glazing that exceeds the code requirements. Fire-rated glazing assemblies marked as complying with hose stream requirements (H) shall be permitted in applications that do not require compliance with hose stream requirements. Fire-rated glazing assemblies marked as complying with temperature rise requirements (T) shall be permitted in applications that do not require compliance with temperature rise requirements. Fire-rated glazing assemblies marked with ratings (XXX) that exceed the ratings required by this code shall be permitted.

Table 715.3
Marking Fire-Rated Glazing Assemblies

Fire Test Standard	Marking	Definition of Marking
ASTM E119 or UL 263	W	Meets wall assembly criteria.
NFPA 257 or UL 9	OH	Meets fire window assembly criteria including the hose stream test.
NFPA 252 or UL 10B or UL 10C	D H T	Meets fire door assembly criteria. Meets fire door assembly "Hose Stream" test. Meets to 450º F temperature rise criteria for 30 minutes
	XXX	The time in minutes of the fire resistance or fire protection rating of the glazing assembly

~~715.3~~ 715.4 Alternate methods for determining fire-protection. *(No change to current text)*

~~715.4~~ 715.5 Fire door and shutter assemblies. *(No change to current text)*

Exceptions:

(Exceptions to remain unchanged)

~~715.4.1~~ 715.5.1 Side hinged or pivoted swinging doors. *(No change to current text)*

~~715.4.2~~ 715.5.2 Other types of assemblies. *(No change to current text)*

~~715.4.3~~ 715.5.3 Door assemblies in corridors and smoke barriers. Fire door assemblies required to have a minimum fire protection rating of 20 minutes where located in corridor walls or smoke barrier walls having a fire-resistance rating in accordance with Table ~~715.4~~ 715.5 shall be tested in accordance with NFPA 252, UL 10B or UL 10C without the hose stream test.

Exceptions:

(Exceptions to remain unchanged)

~~715.4.3.1~~ 715.5.3.1 Smoke and draft control. *(No change to current text)*

~~715.4.3.2~~ 715.5.3.2 Glazing in door assemblies. In a 20-minute fire door assembly, the glazing material in the door itself shall have a minimum fire-protection rating of 20-minutes and shall be exempt from the hose stream test. Glazing material in any other part of the door assembly, including transom lites and sidelites, shall be tested in accordance with NFPA 257 or UL 9, including hose stream test, in accordance with Section 715.5.

715.5.4 Door assemblies in other fire partitions. Fire door assemblies required to have a minimum fire-protection rating of 20-minutes where located in other fire partitions having a fire resistance rating of 0.5-hour in accordance with Table 715.4 shall be tested in accordance with NFPA 252, UL 10B or UL 10C with the hose stream test.

(Renumber subsequent sections)

~~715.4.4~~ 715.5.5 Doors in exit enclosures and exit passageways. Fire door assemblies in exit enclosures and exit passageways shall have a maximum transmitted temperature ~~end point~~ rise of not more than 450F degrees (250C degrees) above ambient at the end of 30 minutes of standard fire test exposure.

Exception: The maximum transmitted temperature rise is not required ~~limited~~ in buildings equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.3.1.2.

~~715.4.4.1~~ 715.5.5.1 Glazing in doors. Fire protection rated glazing shall be limited to 100-sq. inches (0.065 m^2). ~~Fire protection-rated glazing in excess of 100 sq.inches (0.065 m^2) shall be permitted in fire door assemblies when~~ unless the glazing has been tested as components of the door assemblies and not as glass lights, and ~~shall have~~ has a maximum transmitted temperature rise of 450F degrees (250C degrees) in accordance with Section ~~715.4.4~~ 715.5.5.

Exception: The maximum temperature rise is not ~~required~~ limited in buildings equipped with an automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.3.1.2.

~~715.4.5~~ 715.5.6 Fire door frames with transom lights and sidelights. Door frames with transom lights, sidelights, or both shall be permitted where a ¾-hour fire protection rating or less is required in accordance with Table 715.4. ~~Where a fire protection rating exceeding ¾ hour is required in accordance with Table 715.4,~~ Fire door frames with transom lights, sidelights, or both, ~~shall be permitted where~~ installed with fire-resistance rated glazing tested as an assembly in accordance with ASTM E119 or UL 263 shall be permitted where a fire-protection rating exceeding ¾-hour is required in accordance with Table 715.4.

~~715.4.6~~ 715.5.7 Labeled protective assemblies. *(No change to current text)*

~~715.4.6.1~~ 715.5.7.1 Fire door labeling requirements. Fire doors shall be labeled showing the name of the manufacturer or other identification readily traceable back to the manufacturer, the name or trademark of the third-party inspection agency, the fire protection rating and, where required for fire doors in exit enclosures and exit passageways by Section ~~715.4.4~~ 715.5.5, the maximum transmitted temperature point. Smoke and draft control doors complying with UL 1784 and shall be labeled as such and shall also comply with Section ~~715.4.6.3~~ 715.5.7.3. Labels shall be approved and permanently affixed. The label shall be applied at the factory or location where fabrication and assembly are performed.

~~715.4.6.1.1~~ 715.5.7.1.1 Light kits, louvers and components. Listed light kits and louvers and their required preparations shall be considered as part of the labeled door where such installations are done under the listing program of the third-party agency. Where tested for such use, fire doors and door assemblies shall be permitted to consist of components, including glazing, vision light kits and hardware that are labeled, listed or classified by different third party agencies.

~~715.4.6.2~~ 715.5.7.2 Oversized doors. *(No change to current text)*

~~715.4.6.3~~ 715.5.7.3 Smoke and draft control door labeling requirements. *(No change to current text)*

~~715.4.7~~ 715.5.8 Glazing material. *(No change to current text)*

~~715.4.7.1~~ 715.5.8.1 Size limitations. Fire-protection-rated glazing ~~used in fire doors~~ shall comply with the size limitations of NFPA 80, and as provided in sections 715.5.8.1.1 and 715.8.1.2.

~~Exceptions:~~

715.5.8.1.1 Fire-resistance-rated glazing in door assemblies in fire walls and fire barriers rated greater than 1-hour. Fire-resistance-rated glazing tested to ASTM E119 or UL 263 and NFPA 252, UL10B or UL 10C shall be permitted in fire door assemblies located in fire walls and in fire barriers in accordance with Table 715.4 to the maximum size tested and in accordance with their listings.

715.5.8.1.2 Fire-protection-rated glazing in door assemblies in fire walls and fire barriers rated greater than 1-hour. Fire-protection-rated glazing shall be prohibited in fire walls and fire barriers except as provided in 715.5.8.1.2.1 and 715.5.8.1.2.2

715.5.8.1.2.1 Horizontal exits. ~~1. Fire protection rated glaing in fire doors located in fire walls shall be prohibited except where serving a fire door in a horizontal exit, a self closing swinging door shall be permitted to have a vision panel of not more than 100 square inches without a dimension exceeding 10 inches.~~ Fire-protection-rated glazing shall be permitted as vision panels in self-closing swinging fire door assemblies serving as horizontal exits in fire walls where limited to 100 square inches with no dimension exceeding 10 inches.

715.5.8.1.2.2 Fire barriers. ~~2.~~ Fire-protection-rated glazing ~~shall not be installed in fire doors~~ shall be permitted in fire doors having a 1-1/2-hour fire protection rating intended for installation in fire barriers, where limited to 100 square inches. ~~unless the glazing is not more than 100 square inches in area.~~

~~715.4.7.2~~ 715.5.8.2 Exit and elevator protectives. *(No change to current text)*

~~715.4.7.3~~ 715.5.8.3 Labeling. *(No change to current text)*

~~715.4.7.3.1~~ 715.5.8.3.1 Identification. *(No change to current text)*

~~715.4.7.4~~ 715.5.8.4 Safety glazing. *(No change to current text)*

(Renumber subsequent sections)

~~715.5.8~~ 715.6.8 Interior fire window assemblies. Fire-protection-rated glazing used in fire window assemblies located in fire partitions and fire barriers shall be limited to use in assemblies with a maximum fire-resistance rating of 1-hour in accordance with this section.

~~715.5.8.1~~ 715.6.8.1 Where ¾-hour fire-protection window assemblies permitted. Fire-protection-rated glazing requiring 45 minute opening protection in accordance with Table ~~715.5~~ 715.6 shall be limited to fire partitions designed in accordance with Section 709 and fire barriers utilized in the applications set forth in Sections 707.3.6 and 707.3.8 where the fire resistance rating does not exceed 1 hour. Fire-resistance-rated glazing assemblies tested in accordance with ASTM E119 or UL 263 shall not be subject to the limitations of this section.

~~715.5.8.2~~ 715.6.8.2 Area limitations. The total area of windows shall not exceed 25 percent of the area of a common wall with any room.

715.6.8.3. Where 1/3- hour fire-protection window assemblies permitted. Fire-protection-rated glazing shall be permitted in window assemblies tested to NFPA 257 or UL 9 in smoke barriers and fire partitions requiring 1/3-hour opening protection in accordance with Table 715.6

TABLE ~~715.5~~ 715.6
FIRE WINDOW ASSEMBLY FIRE-PROTECTION RATINGS

TYPE OF WALL ASSEMBLY	REQUIRED WALL ASSEMBLY RATING (hours)	MINIMUM FIRE WINDOW ASSEMBLY RATING (hours)	FIRE RATED GLAZING MARKING
Interior walls			
Fire walls	All	NP[a]	W-xxx[b]
Fire barriers	>1	NP[a]	W-xxx[b]
	1	NP[a]	W-xxx[b]
Incidental use areas (707.3.6), Mixed occupancy separations(707.3.8)	1	¾	OH-45 or W-60
Fire partitions	1	¾	OH-45 or W-60
	0.5	1/3	OH-20 or W-30
Smoke barriers	1	¾	OH-45 or W-60
Exterior walls	>1	1-1/2	OH-90 or W-XXX[B]
	1	¾	OH-45 or W-60
	0.5	1/3	OH-20 or W-30
Party wall	All	NP	Not Applicable

NP – Not Permitted

a. Not permitted except fire resistance rated glazing assemblies tested to ASTM E119 or UL 263, as specified in Section 715.2

b. xxx = The fire rating duration period in minutes, which shall be equal to the fire resistance rating required for the wall assembly.

~~715.5.9~~ 715.6.9 Labeling. Fire-protection-rated glazing shall bear a label or other identification showing the name of the manufacturer, the test standard and information required ~~Section 715.5.9.1~~ Table 715.6 that shall be issued by an approved agency and shall be permanently affixed to the glazing.

~~**715.5.9.1 Identification.** For fire protection-rated glazing, the label shall bear the following two-part identifiers: "OH – XXX." "OH" shall indicate that the glazing has been tested to and meets both the fire protection and the hose-stream requirements of NFPA 257 or UL 9. "XXX" shall indicate the fire-protection rating period, in minutes, that was tested.~~

a. Two doors, each with a fire protection rating of 1-1/2 hours, installed on opposite sides of the same opening in a fire wall, shall be deemed equivalent in fire protection rating to one 3-hour fire door.
b. For testing requirements, see Section 715.5.3 ~~715.4.3~~.
c. Fire resistance rated glazing tested to ASTM E119 per section 715.2 shall be permitted, in the maximum size tested.
d. Except where the building is equipped throughout with an automatic sprinkler and the fire-rated glazing meets the criteria established in Section 715.5.5.1.
e. Under the column heading "Fire rated glazing marking door vision panel", W refers to the fire-resistance rating of the glazing, not the frame.

Reason:
(Heilstedt) The ICC Board established the ICC Code Technology Committee (CTC) as the venue to discuss contemporary code issues in a committee setting which provides the necessary time and flexibility to allow for full participation and input by any interested party. The code issues are assigned to the CTC by the ICC Board as "areas of study". Information on the CTC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CTC effort can be downloaded from the following website: http://www.iccsafe.org/cs/cc/ctc/index.html. Since its inception in April/2005, the CTC has held seventeen meetings - all open to the public.

This proposed change is a result of the CTC's investigation of the area of study entitled "Labeling of Fire Rated Glazing". The scope of the activity is noted as:

Identify root causes of problems selecting, specifying, installing, and inspecting fire protective and fire resistive glazing and other assembly components including the frames. Propose identification requirements and other related code changes.

The marking provisions of the IBC applicable to fire rated glazing ("Marking Provisions") were first adopted as a part of Chapter 7 of the IBC in 2004. In the last development cycle, the Fire Safety Committee recommended that the ICC Board consider submitting the marking of fire rated glazing to the Code Technology Committee (CTC) as an area of study since repeat proposals to change the Marking Provisions were being submitted on a regular basis.

The ICC Board referred the Marking Provisions to the CTC as an area of study and a Study Group (SG), Chaired Carl Wren, was formed. The SG consisted of both fire and building code officials; architects; engineers; fire rated window and door manufacturers; primary fire rated glazing manufacturers; and a fire protection engineer. It was recognized by the SG that the existing marking system, as those marks were designated in product listings, was leading to fire protection products in applications not allowed by the IBC. After numerous meetings and a full hearing before the CTC, the SG and the CTC unanimously approved proposing these changes to the IBC's Marking Provisions.

The primary objective of the CTC in proposing these changes is to make the Marking Provisions of Chapter 7 easier to understand and enforce and to minimize the possibility that the system could result in confusion between fire protection rated products in applications where fire-resistance rated products meeting ASTM E 119 are permitted. The proposal includes the following changes:

1- Adds a new Table 715.3, to define and relate the various test standards for fire rated glazing to the designations used to mark fire rated glazing. A new definition of the term "fire rated glazing" would also be included.

2- While the designations "W," "OH," "D," "DT," "DH" and "XXX" used to mark fire rated glazing will remain as they were originally adopted in 2004, the marking of fire rated glazing in fire door assemblies (D) are simplified by deleting the NH designation (not hose stream tested) and the NT designation (not temperature rise tested). It is clarified that those designations correspond to test standards, not end uses. Tables 715.4 and 715.5 show the markings required for acceptance in specified applications.

3- All text provision used to define and relate test standards to marking designations are deleted in favor of including all of the required marking provisions in Tables 715.3, 715.4 and 715.5. This is intended to provide building and fire code officials with easy access to all of the information needed when inspecting fire window and fire door installations, including required marking designations.

4- In connection with removing many of the text provisions referring to the marking of fire rated glazing and the inclusion of all pertinent marking requirements in tables 715.4 and 715.5, a number of columns are added to those Tables. These new columns specify the required designations that the building and fire code officials will need to look for when inspecting fire rated glazing in the various categories of fire resistance rated walls, fire door assemblies and fire window assemblies identified in Tables 715.4 and 715.5.

5- The size limitation provisions starting at 715.4.6.1 are re-written to eliminate the use of "exceptions" and thus clarify them - no substantive changes to these provisions are intended.

6- It was determined that Table 715.4 inadvertently omitted reference to 1 1/2 hour doors in shaft, exit enclosures and exit passageway walls and this proposal adds that reference to the Table.

7- The Marking Provisions have been written to clarify that fire protection rated glazing tested to NFPA 257 and used in transoms and sidelites in certain fire barriers and corridor walls will also have to be tested to NFPA 252 since they are a part of a door assembly. Accordingly, these glazings are marked D-H-OH-XXX.

(O'Keefe) The marking provisions of the IBC applicable to fire rated glazing ("Marking Provisions") were first adopted as a part of Chapter 7 of the IBC in 2004. In the last development cycle, the Fire Safety Committee recommended that the ICC Board consider submitting the marking of fire rated glazing to the Code Technology Committee (CTC) as an area of study since repeat proposals to change the Marking Provisions were being submitted on a regular basis, because of confusion and misuse of products being marked by individual manufacturers under the current system.

The ICC Board referred the Marking Provisions to the CTC as an area of study and a Study Group (SG), Chaired by Carl Wren, was formed. The SG consisted of both fire and building code officials; architects; engineers; fire rated window and door manufacturers; primary fire rated glazing manufacturers; and a fire protection engineer.

It was recognized by the SG that the existing marking system, as those marks were designated in product listings, was leading to the misuse of fire protection products in applications not allowed by the IBC. It was also recognized that "T" marking were being applied by some manufacturers to designate use of fire protection products in temperature rise doors that in fact did not limit temperature rise and should not be so marked. Attached as support are documents submitted to the CTC Labeling Study Group that show the confusion in listings showing end-use marks that are not permitted by the IBC. After numerous meetings and a full hearing before the CTC, the SG and the CTC unanimously approved proposing these changes to the IBC's Marking Provisions.

The primary objective of the CTC in proposing these changes is to make the Marking Provisions of Chapter 7 easier to understand and enforce and to minimize the possibility that the system could result in confusion between fire protection rated products in applications where fire-resistance rated products meeting ASTM E 119 are required. The proposal includes the following changes:

1- Adds a new Table 715.3, to define and relate the various test standards for fire rated glazing to the designations used to mark fire rated glazing. A new definition of the term "fire rated glazing" would also be included.

2- While the designations "W," "OH," "D," "DT," "DH" and "XXX" used to mark fire rated glazing will remain as they were originally adopted in 2004, the marking of fire rated glazing in fire door assemblies (D) are simplified by deleting the NH designation (not hose stream tested) and the NT designation (not temperature rise tested). It is clarified that those designations correspond to compliance with test standards only, not that they are permitted for end uses. Tables 715.4 and 715.5 show the markings required for acceptance in specified applications.

3- All text provision used to define and relate test standards to marking designations are deleted in favor of including all of the required marking provisions in Tables 715.3, 715.4 and 715.5. This is intended to provide building and fire code officials with easy access to all of the information needed when inspecting fire window and fire door installations, including required marking designations.

4- In connection with removing many of the text provisions referring to the marking of fire rated glazing and the inclusion of all pertinent marking requirements in tables 715.4 and 715.5, a number of columns are added to those Tables. These new columns specify the required designations that the building and fire code officials will need to look for when inspecting fire rated glazing in the various categories of fire resistance rated walls, fire door assemblies and fire window assemblies identified in Tables 715.4 and 715.5.

5- The size limitation provisions starting at 715.4.6.1 are re-written to eliminate the use of "exceptions" and thus clarify them - no substantive changes to these provisions are intended.

6- It was determined that Table 715.4 inadvertently omitted reference to 1 1/2 hour doors in shaft, exit enclosures and exit passageway walls and this proposal adds that reference to the Table.

7- The Marking Provisions have been written to clarify that fire protection rated glazing tested to NFPA 257 and used in transoms and sidelites in certain fire barriers and corridor walls will also have to be tested to NFPA 252 since they are a part of a door assembly. Accordingly, these glazings are marked D-H-OH-XXX. It has also been clarified where fire rated glazing products must be tested to and marked as complying with ASTM E119 in sidelight and transom assemblies in openings requiring greater than ¾-hour protection, and for glazing sizes exceeding 100 sq. inches in doors rated 1-hour and greater.

8. Section 715.4.6.1 was revised to clarify labeling of door assembly components, and to recognize that door assemblies are permitted to have components labeled by different test agencies.

Bibliography: Examples of UL Listing Markings submitted to CTC Labeling Study Group.

Cost Impact: This code change will not increase the cost of construction.

ICCFILENAME: HEILSTEDT-FS3-702

Public Hearing Results

Committee Action: Approved as Submitted

Committee Reason: The committee agreed with the reorganization of the glazing provisions and the clarity of the fire rated glazing marking provisions. The revised provisions will give the code official all they need to determine if glazing is being used in the right locations.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Bob Eugene, representing Underwriters Laboratories, Inc., requests Disapproval.

Commenter's Reason: We applaud the CTC for attempting to clarify glazing requirements in Section 715. A copy of how the finished Section 715 would look with the changes was not provided in the monograph or to the code development committee. When we literally cut and pasted the proposal together, a number of correlation errors and misnumbered sections were found. These errors and inconsistencies cannot be easily corrected with a public comment, so we reluctantly feel this proposal should be disapproved. Some, but not all, of the problems we found include the following:

1. Section 715.2 states that fire-resistance rated glazing shall not otherwise be required to comply with this section (Section 715), but the proposal then introduces new requirements for fire-resistance rated glazing in section 715.5.8.1.1, 715.6.8.1, Table 715.3 and Table 715.5. This is a conflict.
2. The glazing marking requirements in table 715.3 are confusing and do not correlate well with glazing marking requirements in section 715.5.8.3.1 (formerly section 715.4.7.3) and in Table 715.6 (formerly 715.5). Manufacturers have already changed their markings to meet the requirements established in the 2006 code. This will require manufacturers to change the markings again. A mixture of the new and old markings in the field will create confusion during inspections.
3. Table 715.3 includes a column with the "Definition of Marking", which seems more like code commentary language and not mandatory code language.
4. Section 101.3 clearly states that the code includes the minimum requirements to be met. It is unnecessary, and bad precedence, to include section 715.3.1 titled "Fire rated glazing that exceeds code requirements". For example, there is no need to indicate that 90-minute rated glazing can be used in a 45-minute application. If it is done here then do we need to repeat this concept throughout the code? This is better suited for code commentary, if there is considered a need to communicate that the minimum code requirements can be exceeded.
5. We found what appeared to be incorrect section references in the following new sections: 715.5.3.2, Table 715.4, 715.4, and 715.5.8.
6. Section 715.5.8.1 is titled "Size limitations" and indicates, "Fire-protection rated glazing shall comply with 715.5.8.1.1 and 715.5.8.1.2. However, the new Section 715.5.8.1.1 covers "fire-resistant" glazing, not "fire-protection" glazing. This is outside the scope of this section.
7. The proposal included a numbering system that included five decimal points (e.g. section 715.5.8.1.2.1) which is confusing and may not comply with ICC guidelines. It would be much clearer to organize the sections in a fashion that avoids this level of complexity. This would have been more evident if a final version of how the revised code would look was provided.
8. Section 715.4.6.1.1 suggests components of the door assembly may be labeled, listed or classified by different third party agencies *where tested for such use*. How is an AHJ to know if these components were tested for such use? It would be more appropriate to state when *listed and labeled for such use* by different third party agencies.
9. This marking scheme appears to set a precedent that may allow glazing that does not meet hose or temperature criteria to be installed in applications where it is required.

Again, we applaud the CTC for their work on this, but more work and additional review is needed before this proposal is ready for adoption in the code.

Final Action: AS AM AMPC____ D

FS113–09/10
716.5.3 (IMC 607.5.5)

Proposed Change as Submitted

Proponent: Dave Frable, US General Services Administration, representing the US General Services Administration

Revise as follows:

716.5.3 (IMC 607.5.5) Shaft enclosures. Shaft enclosures that are permitted to be penetrated by ducts and air transfer openings shall be protected with *approved* fire and smoke *dampers* installed in accordance with their listing.

Exceptions:

1. *Fire dampers* are not required at penetrations of shafts where:
   1.1. Steel exhaust subducts are extended at least 22 inches (559 mm) vertically in exhaust shafts, provided there is a continuous airflow upward to the outside; or
   1.2. Penetrations are tested in accordance with ASTM E 119 or UL 263 as part of the fire-resistance-rated assembly; or
   1.3. Ducts are used as part of an *approved* smoke control system designed and installed in accordance with Section 909 and where the *fire damper* will interfere with the operation of the smoke control system; or

1.4. The penetrations are in parking garage exhaust or supply shafts that are separated from other building shafts by not less than 2-hour fire-resistance-rated construction.

2. In Group B and R occupancies equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1, *smoke dampers* are not required at penetrations of shafts where:

   2.1. Kitchen, clothes dryer, bathroom and toilet room exhaust openings are installed with steel exhaust subducts, having a minimum wall thickness of 0.187-inch (0.4712 mm) (No. 26 gage);

   2.2. The subducts extend at least 22 inches (559 mm) vertically; and

   2.3. An exhaust fan is installed at the upper terminus of the shaft that is powered continuously in accordance with the provisions of Section 909.11, so as to maintain a continuous upward airflow to the outside.

3. *Smoke dampers* are not required at penetrations of shafts in Group B occupancies equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1 where the air in ducts continues to move and the air handling system is configured to prevent recirculation of return or exhaust air upon fire conditions.

4.~~3.~~ *Smoke dampers* are not required at penetration of exhaust or supply shafts in parking garages that are separated from other building shafts by not less than 2-hour fire-resistance-rated construction.

5.~~4.~~ *Smoke dampers* are not required at penetrations of shafts where ducts are used as part of an *approved* mechanical smoke control system designed in accordance with Section 909 and where the *smoke damper* will interfere with the operation of the smoke control system.

6.~~5.~~ *Fire dampers* and *combination fire/smoke dampers* are not required in kitchen and clothes dryer exhaust systems when installed in accordance with the *International Mechanical Code*.

Reason: The intent of this code change is to acknowledge that Group B occupancies protected by an operational fire sprinkler system where the air in ducts continues to move and the air handling system is configured to prevent recirculation of return or exhaust air upon fire conditions provides an acceptable level of safety for building occupants and therefore does not warrant the need for the installation of smoke dampers at all penetrations of shaft duct/air transfer opening penetrations. This code change proposes to remove the current requirement for smoke dampers in shaft wall penetrations, but leave fire dampers in place. This is because smoke travel through ducted ventilation shafts has not been a contributing factor to fire deaths in sprinklered Group B occupancies in recent history. Note: all high-rise office fires where smoke spread has been cited as a problem have either occurred in unsprinklered buildings, partially sprinklered buildings or buildings subject to terrorist attacks. Fire sprinklers control the burning rate (and thus limit smoke production) and maintain near ambient temperature which limits the buoyancy forces that drive smoke to the shafts where stack affect may cause smoke spread to other floors. It is also widely accepted that operating fire sprinklers will prevent room flashover and full floor fires, and will limit the size of room fires. The reliability of sprinklers should not be called into question as an NFPA report issued in 2005 indicated that automatic fire sprinklers successfully operating in reported structural fires was an exemplary 93%. This same report indicated that two-thirds of the automatic fire sprinkler system failures were because the automatic fire sprinkler systems were shut off, an unlikely scenario where jurisdictions adopt the IBC since the IBC requires the supervision of the automatic fire sprinkler system. Hence, the successful operation of an automatic fire sprinkler system designed and installed in compliance with the IBC requirements could be reasonably estimated at 98% (or better, since NFPA indicated that a number of fire incidents extinguished by sprinklers may not even be reported).

In addition to fire sprinklers, these buildings have a number of additional safeguards in place. For example, the IMC and NFPA 90A both require duct smoke detectors to shut off of air handling equipment to minimize the potential of smoke spread through ventilation ducts. Also, the 2009 edition of the IBC now requires a number of additional safety enhancements such as: two way communication at elevator landings; an increase of 50% in egress capacity for exit stairs in all buildings; increased cohesive/adhesive bond strength for sprayed fire resistive materials; exit stair path markings in all high rise buildings; fire service access elevators for buildings greater than 120 feet; and an additional stair and redundant sprinkler risers for buildings greater than 420 feet, etc.

Given the aforementioned protection coupled with the excellent track record for sprinklered B occupancies, and keeping in mind that the purpose of the IBC is to provide minimum requirements to safeguard occupants of buildings from fire and other hazards attributed to the built environment based on sound technical documentation, we strongly believe that it is unreasonable to require smoke dampers in shaft duct/air transfer opening penetrations as an additional means for slowing or stopping the spread of smoke throughout a building.

Note: Though not relevant to this code change, NFPA 90A does not require smoke dampers in shaft walls regardless of whether the building is sprinklered. Also note that some jurisdictions (e.g., Commonwealth of Virginia) are granting similar modifications to the requirement for smoke dampers in exhaust ducts because it is impractical to comply with the IBC and there is no demonstrated need.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: Frable-FS1-716.5.3

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee felt that the sprinkler threshold was confusing as written with respect to the area to be sprinklered throughout; the Group B area or the entire building. Further, perhaps this proposal would be better located under current exception #2. Lastly, the language "air……moves" and "prevent recalculation" is confusing as it seems to contradict.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Dave Frable, US General Services Administration, representing the US General Services Administration, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

716.5.3 (IMC 607.5.5) Shaft enclosures. Shaft enclosures that are permitted to be penetrated by ducts and air transfer openings shall be protected with *approved* fire and smoke *dampers* installed in accordance with their listing.

Exceptions:

1. *Fire dampers* are not required at penetrations of shafts where:
   1.1. Steel exhaust subducts are extended at least 22 inches (559 mm) vertically in exhaust shafts, provided there is a continuous airflow upward to the outside; or
   1.2. Penetrations are tested in accordance with ASTM E 119 or UL 263 as part of the fire-resistancerated assembly; or
   1.3. Ducts are used as part of an *approved* smoke control system designed and installed in accordance with Section 909 and where the *fire damper* will interfere with the operation of the smoke control system; or
   1.4. The penetrations are in parking garage exhaust or supply shafts that are separated from other building shafts by not less than 2-hour fire-resistance-rated construction.
2. In Group B and R occupancies equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1, *smoke dampers* are not required at penetrations of shafts where:
   2.1. Kitchen, clothes dryer, bathroom and toilet room exhaust openings are installed with steel exhaust subducts, having a minimum wall thickness of 0.187-inch (0.4712 mm) (No. 26 gage);
   2.2. The subducts extend at least 22 inches (559 mm) vertically; and
   2.3. An exhaust fan is installed at the upper terminus of the shaft that is powered continuously in accordance with the provisions of Section 909.11, so as to maintain a continuous upward airflow to the outside.
3. *Smoke dampers* are not required at penetrations of shafts in Group B occupancies that are equipped throughout the entire building with an *automatic sprinkler system* in accordance with Section 903.3.1.1 ~~where the air in ducts continues to move and the air handling system is configured to prevent recirculation of return or exhaust air upon fire conditions.~~ and equipped with an exhaust fan at the upper terminus of the shaft to maintain a upward airflow to the outside that meets one of the following
   3.1. The exhaust fan is powered continuously in accordance with the provisions of Section 909.11.
   3.2. The exhaust fan is powered upon operation of any fire alarm system initiating device and once operated, the exhaust fan is powered continuously in accordance with the provisions of Section 909.11.
4. *Smoke dampers* are not required at penetration of exhaust or supply shafts in parking garages that are separated from other building shafts by not less than 2-hour fire-resistance-rated construction.
5. *Smoke dampers* are not required at penetrations of shafts where ducts are used as part of an *approved* mechanical smoke control system designed in accordance with Section 909 and where the *smoke damper* will interfere with the operation of the smoke control system.
6. *Fire dampers* and *combination fire/smoke dampers* are not required in kitchen and clothes dryer exhaust systems when installed in accordance with the *International Mechanical Code*.

Commenter's Reason: The intent of this code change is to acknowledge that Group B occupancies protected by an operational fire sprinkler system throughout the buildings where also equipped with an exhaust fan in the shaft equipped with two sources of power that is capable of maintaining an upward airflow (either at all times or upon activation of the fire alarm system) provides an acceptable level of safety for building occupants and therefore does not warrant the need for the installation of smoke dampers at all penetrations of shaft duct/air transfer opening penetrations. This code change proposes to remove the current requirement for smoke dampers in shaft wall penetrations, but leave fire dampers in place. This is because smoke travel through ducted ventilation shafts has not been a contributing factor to fire deaths in sprinklered Group B occupancies in recent history. Note: all high-rise office fires where smoke spread has been cited as a problem have either occurred in unsprinklered buildings, partially sprinklered buildings or buildings subject to terrorist attacks. Fire sprinklers control the burning rate (and thus limit smoke production) and maintain near ambient temperature which limits the buoyancy forces that drive smoke to the shafts where stack affect may cause smoke spread to other floors

It is also widely accepted that operating fire sprinklers will prevent room flashover and full floor fires, and will limit the size of room fires. The reliability of sprinklers for office buildings should not be called into question as an NFPA report issued in 2009 indicated that automatic wet-pipe fire sprinklers successfully operating in reported structural fires was an exemplary 96%. This same report indicated that two thirds of the automatic fire sprinkler system failures were because the automatic fire sprinkler systems were shut off, an unlikely scenario where jurisdictions adopt the IBC since the IBC requires the supervision of the automatic fire sprinkler system. Hence, the successful operation of an automatic fire sprinkler system designed and installed in compliance with the IBC requirements could be reasonably estimated at 98% (or better, since NFPA indicated that a number of fire incidents extinguished by sprinklers may not even be reported). The report also indicated that in office buildings with wet-pipe sprinklers that operated were 99% effective.

In addition to fire sprinklers, these buildings have a number of additional safeguards in place. For example, the IMC and NFPA 90A both require duct smoke detectors to shut off of air handling equipment to minimize the potential of smoke spread through ventilation ducts. Also, the 2009 edition of the IBC now requires a number of additional safety enhancements such as: two way communication at elevator landings; an increase of 50% in egress capacity for exit stairs in all buildings; increased cohesive/adhesive bond strength for sprayed fire resistive materials; exit stair path markings in all high rise buildings; fire service access elevators for buildings greater than 120 feet; and an additional stair and redundant sprinkler risers for buildings greater than 420 feet, etc.

This code change addresses the technical issues raised by the Fire Safety Committee. Regarding where best located in the code, this change is being proposed as a new exception 3, instead of being tacked on to existing exception 2, because it is only being offered to B occupancies and it does require a 22 inch subduct that is required by exception 2 given the latter is not common practice for return air handling systems in Group B occupancies.

Given the aforementioned protection coupled with the excellent track record for sprinklered B occupancies, and keeping in mind that the purpose of the IBC is to provide minimum requirements to safeguard occupants of buildings from fire and other hazards attributed to the built environment based on sound technical documentation, we strongly believe that it is unreasonable to require smoke dampers in shaft duct/air transfer opening penetrations as an additional means for slowing or stopping the spread of smoke throughout a building.

Note: Though not relevant to this code change, NFPA 90A does not require smoke dampers in shaft walls regardless of whether the building is sprinklered. Also note that some jurisdictions (e.g., Commonwealth of Virginia) are granting similar modifications to the requirement for smoke dampers in exhaust ducts because it is impractical to comply with the IBC and there is no demonstrated need.

Final Action: AS AM AMPC____ D

FS118-09/10-PART I
717.2.1

Proposed Change as Submitted

Proponent: Rick Thornberry, PE, The Code Consortium, Inc., representing Cellulose Insulation Manufacturers Association (CIMA)

PART I – IBC FIRE SAFETY

Revise as follows:

717.2.1 Fireblocking materials. Fireblocking shall consist of the following materials:

1. Two-inch (51 mm) nominal lumber.
2. Two thicknesses of 1-inch (25 mm) nominal lumber with broken lap joints.
3. One thickness of 0.719-inch (18.3 mm) wood structural panels with joints backed by 0.719-inch (18.3 mm) wood structural panels.
4. One thickness of 0.75-inch (19.1 mm) particleboard with joints backed by 0.75-inch (19 mm) particleboard.
5. One-half-inch (12.7 mm) gypsum board.
6. One-fourth-inch (6.4 mm) cement-based millboard.
7. Batts or blankets of mineral wool, mineral fiber or other approved materials installed in such a manner as to be securely retained in place.
8. Spray-applied cellulose insulation installed as tested for the specific application

Reason: This code change simply adds a new Item 8 to the list of fireblocking materials to recognize spray-applied cellulose insulation as a suitable fireblocking material. It qualifies the use of spray-applied cellulose insulation by indicating that it must be installed as tested for the specific application. The Cellulose Insulation Manufacturers Association (CIMA) has conducted a variety of fireblocking fire tests based on the ASTM E119 time-temperature fire curve exposure to demonstrate that spray-applied cellulose insulation will serve as an adequate fireblocking material.

It should be noted that spray-applied cellulose insulation is different than loose-fill cellulose insulation in that it is sprayed in place using a nozzle under pressure with a small quantity of water added to the insulation to activate the adhesive that, when dried, holds the cellulose insulation in place. Thus, it can be exposed in vertical applications, as well as horizontal applications. Furthermore, it will remain in place after it has dried without any need to restrain or otherwise contain or enclose it.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: Thornberry-FS4-717.2.1; RB-1-R302.11.1

Public Hearing Results

PART I- IBC FIRE SAFETY
Committee Action: **Approved as Modified**

Modify the proposal as follows:

717.2.1 Fireblocking materials. Fireblocking shall consist of the following materials:

1. Two-inch (51 mm) nominal lumber.
2. Two thicknesses of 1-inch (25 mm) nominal lumber with broken lap joints.
3. One thickness of 0.719-inch (18.3 mm) wood structural panels with joints backed by 0.719-inch (18.3 mm) wood structural panels.
4. One thickness of 0.75-inch (19.1 mm) particleboard with joints backed by 0.75-inch (19 mm) particleboard.
5. One-half-inch (12.7 mm) gypsum board.
6. One-fourth-inch (6.4 mm) cement-based millboard.
7. Batts or blankets of mineral wool, mineral fiber or other approved materials installed in such a manner as to be securely retained in place.
8. ~~Spray-applied~~ cellulose insulation installed as tested for the specific application

Committee Reason: The committee agreed that cellulose insulation used as fireblocking has been substantiated as another valid option and which allows for current construction practices. The modification allows for more types of cellulose insulation to be used as fireblocking material.

Assembly Action: None

Individual Consideration Agenda

These items are on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Ali M. Fattah, PE, City of San Diego, Development Services Department, representing San Diego Area Chapter of ICC, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

Part I – IBC-Fire Safety

717.2.1 Fireblocking materials. Fireblocking shall consist of the following materials:

1. Two-inch (51 mm) nominal lumber.
2. Two thicknesses of 1-inch (25 mm) nominal lumber with broken lap joints.
3. One thickness of 0.719-inch (18.3 mm) wood structural panels with joints backed by 0.719-inch (18.3 mm) wood structural panels.
4. One thickness of 0.75-inch (19.1 mm) particleboard with joints backed by 0.75-inch (19 mm) particleboard.
5. One-half-inch (12.7 mm) gypsum board.
6. One-fourth-inch (6.4 mm) cement-based millboard.
7. Batts or blankets of mineral wool, mineral fiber or other approved materials installed in such a manner as to be securely retained in place.
8. Cellulose insulation installed as ~~tested~~ listed for the specific application.

Commenter's Reason: Requiring the Code Official to review test reports will place an undue burden. The product listing will place conditions of application such as density, material composition, etc.

Public Comment 2:

Tony Crimi, A.C. Consulting Solutions Inc, representing North American Insulation Manufacturers Association (NAIMA), requests Disapproval.

Commenter's Reason: In the IBC, Fireblocking is installed to resist the free passage of flame to other areas of the building through concealed spaces. The ASTM E119 Standard does not contain any specific test configurations for evaluating fireblocking. While the testing submitted by CIMA may be based on exposure to an ASTM E119 time-temperature curve, the details of how the concealed space is protected, and how the fireblocking materials are installed, is not described. More importantly, the proposed code change language itself does not describe the need to conduct any testing in accordance with an ASTM E119 time-temperature curve, nor does it indicate how the fireblocking is to be installed in the assembly, or what, if any, pass/fail criterion are used to decide if the material has performed successfully. Presumably an ASTM E84 test could also be used to conduct an evaluation of "…. installed as tested for the specific application", even though it is a completely different fire exposure, and not related to an ASTM E119 test. At a minimum, a specific test standard, or fire exposure condition, needs to be defined within this new requirement.

Consumer Product Safety Commission ("CPSC") regulates cellulose insulation as a recognized fire threat. The regulation is codified as part of the Code of Federal Regulations (16 C.F.R. § 1404). Indeed, the CPSC states the following in its codified regulations:

> Based on available fire incident information, engineering analysis of the probable fire scenarios, and laboratory tests, the Consumer Product Safety Commission has determined that fire may occur where cellulose insulation is improperly installed too close to the sides or over the top of recessed electrical light fixtures, or installed too close to the exhaust flues from heat producing devices or apparatus such as furnaces, water heaters, and space heaters. These fires may result in serious injuries or deaths. Presently available information indicates that fires may occur where cellulose insulation is improperly installed even though the cellulose insulation complies with the Commission's amended interim standard for cellulose insulation. (16 C.F.R. § 1404.2)

To warn consumers and installers of this danger, the CPSC requires that manufacturers of cellulose insulation label all containers of cellulose with the following statement, using capital letters, CAUTION POTENTIAL FIRE HAZARD. (16 C.F.R. § 1404.4(a)) The CPSC also imposes additional warning language on the manufacturers of cellulose insulation.

Furthermore, the modification to permit loose-fill cellulose insulation to be used as a fireblocking material is not justifiable. Even the proponent noted in their reason statement that spray-applied cellulose insulation is different than loose-fill cellulose insulation in that it is sprayed in place using a nozzle under pressure with a small quantity of water added to the insulation to activate the adhesive that, when dried, holds the cellulose insulation in place. Thus, it can be exposed in vertical applications, as well as horizontal applications. Furthermore, it will remain in place after it has dried without any need to restrain or otherwise contain or enclose it. There is no such assurance with loose-fill cellulose insulation.

Final Action: AS AM AMPC____ D

FS118-09/10-PART II
IRC R302.11.1

Proposed Change as Submitted

Proponent: Rick Thornberry, PE, The Code Consortium, Inc., representing Cellulose Insulation Manufacturers Association (CIMA)

PART II – IRC BUILDING/ENERGY

Revise as follows:

R302.11.1 Fireblocking materials. Except as provided in Section R302.11, Item 4, fireblocking shall consist of the following materials:

1. Two-inch (51 mm) nominal lumber.
2. Two thicknesses of 1-inch (25 mm) nominal lumber with broken lap joints.
3. One thickness of 23/32-inch (18.3 mm) wood structural panels with joints backed by 23/32-inch (18.3 mm) wood structural panels.
4. One thickness of ¾-inch (19.1 mm) particleboard with joints backed by ¾-inch (19 mm) particleboard.
5. One-half-inch (12.7 mm) gypsum board.
6. One-quarter-inch (6.4 mm) cement-based millboard.
7. Batts or blankets of mineral wool or glass fiber or other approved materials installed in such a manner as to be securely retained in place.
8. Spray-applied cellulose insulation installed as tested for the specific application.

Reason: This code change simply adds a new Item 8 to the list of fireblocking materials to recognize spray-applied cellulose insulation as a suitable fireblocking material. It qualifies the use of spray-applied cellulose insulation by indicating that it must be installed as tested for the specific application. The Cellulose Insulation Manufacturers Association (CIMA) has conducted a variety of fireblocking fire tests based on the ASTM E119 time-temperature fire curve exposure to demonstrate that spray-applied cellulose insulation will serve as an adequate fireblocking material.

It should be noted that spray-applied cellulose insulation is different than loose-fill cellulose insulation in that it is sprayed in place using a nozzle under pressure with a small quantity of water added to the insulation to activate the adhesive that, when dried, holds the cellulose insulation in place. Thus, it can be exposed in vertical applications, as well as horizontal applications. Furthermore, it will remain in place after it has dried without any need to restrain or otherwise contain or enclose it.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: Thornberry-FS4-717.2.1; RB-1-R302.11.1

Public Hearing Results

PART II - IRC
Committee Action: **Approved as Modified**

Modify proposal as follows:

R302.11.1 Fireblocking materials. Except as provided in Section R302.11, Item 4, fireblocking shall consist of the following materials:

1. Two-inch (51 mm) nominal lumber.
2. Two thicknesses of 1-inch (25 mm) nominal lumber with broken lap joints.
3. One thickness of 23/32-inch (18.3 mm) wood structural panels with joints backed by 23/32-inch (18.3 mm) wood structural panels.
4. One thickness of ¾-inch (19.1 mm) particleboard with joints backed by ¾-inch (19 mm) particleboard.
5. One-half-inch (12.7 mm) gypsum board.
6. One-quarter-inch (6.4 mm) cement-based millboard.
7. Batts or blankets of mineral wool or glass fiber or other approved materials installed in such a manner as to be securely retained in place.
8. ~~Spray-applied~~ Cellulose insulation installed as tested for the specific application.

Committee Reason: This change will increase the list of products that can be used for fire blocking and will permit more options. The modification removes the limitation to spray-applied cellulose.

Assembly Action: **None**

Individual Consideration Agenda

These items are on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Ali M. Fattah, PE, City of San Diego, Development Services Department, representing San Diego Area Chapter of ICC, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

Part II – IRC Building/Energy

R302.11.1 Fireblocking materials. Except as provided in Section R302.11, Item 4, fireblocking shall consist of the following materials:

1. Two-inch (51 mm) nominal lumber.
2. Two thicknesses of 1-inch (25 mm) nominal lumber with broken lap joints.
3. One thickness of 23/32-inch (18.3 mm) wood structural panels with joints backed by 23/32-inch (18.3mm) wood structural panels.
4. One thickness of ¾-inch (19.1 mm) particleboard with joints backed by ¾-inch (19 mm) particleboard.
5. One-half-inch (12.7 mm) gypsum board.
6. One-quarter-inch (6.4 mm) cement-based millboard.
7. Batts or blankets of mineral wool or glass fiber or other approved materials installed in such a manner as to be securely retained in place.
8. Cellulose insulation installed as ~~tested~~ <u>listed</u> for the specific application.

Commenter's Reason: Requiring the Code Official to review test reports will place an undue burden. The product listing will place conditions of application such as density, material composition, etc.

Public Comment 2:

Tony Crimi, A.C. Consulting Solutions Inc, representing North American Insulation Manufacturers Association (NAIMA), requests Disapproval.

Commenter's Reason: In the IBC, Fireblocking is installed to resist the free passage of flame to other areas of the building through concealed spaces. The ASTM E119 Standard does not contain any specific test configurations for evaluating fireblocking. While the testing submitted by CIMA may be based on exposure to an ASTM E119 time-temperature curve, the details of how the concealed space is protected, and how the fireblocking materials are installed, is not described. More importantly, the proposed code change language itself does not describe the need to conduct any testing in accordance with an ASTM E119 time-temperature curve, nor does it indicate how the fireblocking is to be installed in the assembly, or what, if any, pass/fail criterion are used to decide if the material has performed successfully. Presumably an ASTM E84 test could also be used to conduct an evaluation of "…. installed as tested for the specific application", even though it is a completely different fire exposure, and not related to an ASTM E119 test. At a minimum, a specific test standard, or fire exposure condition, needs to be defined within this new requirement.

Consumer Product Safety Commission ("CPSC") regulates cellulose insulation as a recognized fire threat. The regulation is codified as part of the Code of Federal Regulations (16 C.F.R. § 1404). Indeed, the CPSC states the following in its codified regulations:

> Based on available fire incident information, engineering analysis of the probable fire scenarios, and laboratory tests, the Consumer Product Safety Commission has determined that fire may occur where cellulose insulation is improperly installed too close to the sides or over the top of recessed electrical light fixtures, or installed too close to the exhaust flues from heat producing devices or apparatus such as furnaces, water heaters, and space heaters. These fires may result in serious injuries or deaths. Presently available information indicates that fires may occur where cellulose insulation is improperly installed even though the cellulose insulation complies with the Commission's amended interim standard for cellulose insulation. (16 C.F.R. § 1404.2)

To warn consumers and installers of this danger, the CPSC requires that manufacturers of cellulose insulation label all containers of cellulose with the following statement, using capital letters, CAUTION POTENTIAL FIRE HAZARD. (16 C.F.R. § 1404.4(a)) The CPSC also imposes additional warning language on the manufacturers of cellulose insulation.

Furthermore, the modification to permit loose-fill cellulose insulation to be used as a fireblocking material is not justifiable. Even the proponent noted in their reason statement that spray-applied cellulose insulation is different than loose-fill cellulose insulation in that it is sprayed in place using a nozzle under pressure with a small quantity of water added to the insulation to activate the adhesive that, when dried, holds the cellulose insulation in place. Thus, it can be exposed in vertical applications, as well as horizontal applications. Furthermore, it will remain in place after it has dried without any need to restrain or otherwise contain or enclose it. There is no such assurance with loose-fill cellulose insulation.

Final Action: AS AM AMPC____ D

FS122-09/10
719.1

Proposed Change as Submitted

Proponent: Tony Crimi, A.C. Consulting Solutions Inc., representing North American Insulation Manufacturers Association

Revise as follows:

719.1 General. Insulating materials, including facings such as vapor retarders and *vapor-permeable membranes*, similar coverings and all layers of single and multilayer reflective foil insulations, shall comply with the requirements of this section. Where a flame spread index or a smoke-developed index is specified in this section, such index shall be determined in accordance with ASTM E 84 or UL 723. Any material that is subject to an increase in flame spread index or smoke-developed index beyond the limits herein established through the effects of age, moisture or other atmospheric conditions shall not be permitted.

Exceptions:

2. Foam plastic insulation shall comply with Chapter 26 and have a smoke developed index of not more than 450.

(Exceptions not shown, remain unchanged)

Reason: The exception for foamed plastics in Chapter 26 does not adequately cover smoke developed performance of foamed plastics. Current requirements for glass fiber, mineral fiber, cellulose and reflective plastic core insulation all require both flame spread and smoke development requirements either based on ASTM E84 or UL 723 or 803.1.2. Alternative methods are acceptable for use, however, their performance level needs to address the same hazards as the base requirement, plus any additional hazards that might arise as a result of a specific material.

Justification: For all other thermal and sound insulating materials within the IBC, **including non-combustible insulation materials**, the minimum performance level for materials permitted to be used includes at least some requirements for both flame spread (fire growth) and smoke production. These requirements are primarily based on either ASTM E84 testing or alternative methods such as NFPA 286, CAN/ULC-S102.2, or even UL 1715 with the inclusion of the criterion from 803.1.2. However, in the case of foamed plastics, of the four alternative test methods permitted by 2603.9, only NFPA 286 contains any limits on smoke developed for any foamed plastics by virtue of the inclusion of a reference to section 803.1.
Room corner tests such as FM 4880, UL 1040, NFPA 286 or UL 1715 do evaluate fire growth and flashover. However, with the exception of the criteria for NFPA 286 in 803.1.2, the pass/fail criteria proposed for the room corner tests in the proposed acceptance criteria do not include quantitative evaluation of smoke density. Criteria for fire and smoke performance of building materials are based as much on issues arising from smoke production from burning materials, and smoke migration within the occupied spaces. It is not reasonable to provide an exception to the basic ASTM E84 flame spread and smoked developed requirements which apply to all other types of insulations, even noncombustible insulations, for foamed plastics based on room corner tests unless the limits on smoke production are applied to all of the room corner tests.
There are numerous reported instances of the hazards associated with smoke production from building materials. One is the tragic fire at the Greenwood Health Center in Hartford, CT on Feb 26 2003. The New York Times quoted Chief Charles A. Teale of the Hartford Fire Department as stating that "Most of the 10 residents killed, ranging in ages from 27 to 76, died of smoke inhalation". The same article further goes on to quote officials as saying: "The nursing home itself suffered little damage, though, and the fire was put out in about 15 minutes. Most of the residents were then led back inside, and by midday, 84 of the 148 residents remained at the center".

It is reasonable to allow alternative methods of testing materials to determine their acceptability for use, however, their performance criteria needs to address the same hazards as the base requirement, plus any additional hazards that might arise as a result of a specific material.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: CRIMI-FS8-719.1

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee agreed that Chapter 26, Section 2603 already requires this and therefore this proposal is redundant.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Tony Crimi, A.C. Consulting Solutions Inc., representing North American Insulation Manufacturers Association (NAIMA), requests Approval as Submitted.

Commenter's Reason: The purpose of this public comment is to ensure that the IBC requirements for smoke development ratings for foamed plastic materials are clearly stated and easily enforceable. On its own, the requirements under Special Approvals in 2603.9 do not adequately cover smoke developed performance of foamed plastics. In the published report of the Baltimore Code Action Hearings, the Committee agreed that Chapter 26, Section 2603 already requires this and therefore felt that this proposal was redundant. We agree entirely that it is, or at least should be, required. The proposed change here is merely a clarification designed to simplify the code for users, and prevent inadvertent misinterpretation.

The principal concern is that the language of Section 2603.3 begins with the words "Unless otherwise indicated in this section,…." Since 2603.9 is in the same section as 2603.3, and another of the exceptions (#4) in 719.1 directs the code user to 2603.9 for foamed plastic insulations greater than 4 inches in thickness, there have been instances were compliance with the ASTM E84 and UL 723 smoke development ratings have been overlooked.

Final Action: AS AM AMPC____ D

FS123-09/10
719.7

Proposed Change as Submitted

Proponent: Marcelo M. Hirschler, GBH International, representing American Fire Safety Council

Revise as follows:

719.7 Insulation and covering on pipe and tubing. Insulation and covering on pipe and tubing shall have a flame spread index of not more than 25 and a smoke-developed index of not more than 450. This shall include insulation coverings on exposed water supply and drainpipes under accessible lavatories and sinks.

> **Exception:** Insulation and covering on pipe and tubing installed in plenums shall comply with the *International Mechanical Code.*

Reason: There have been some statements that insulation coverings required on exposed water supply and drainpipes for ADA compliance are not really insulation products and, therefore, need to comply with the requirements for insulation in the IBC. This code proposal is simply clarification.

The ADA requires that exposed hot water and drainpipes under lavatories and sinks be insulated (sections 4.19.4 and 4.24.6). The ICC/ANSI A117.1/2003 Standard (Accessible and Usable Buildings and Facilities 606.6 Exposed Pipes and Surfaces) states that: "*Water supply and drainpipes under lavatories and sinks shall be insulated or otherwise configured to protect against contact. There shall be no sharp or abrasive surfaces under lavatories and sinks.*" This indicates that we are dealing with an exposed insulation product or material.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: HIRSCHLER-FS2-719.7.doc

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee's disapproval was based on the following reasons: This level of protection is not required by the code; this material and application poses no threat to life-safety and regulating it achieves nothing; this proposal would require a Class A finish on a material that is used in a space where other interior finishes are required to only be Class C; the code already requires this material to meet Section 719.7, so this is redundant text or should be handled as an exception if it were not required; and lastly, the ability to enforce this after the building occupancy is a concern.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Marcelo M. Hirschler (GBH International) representing American Fire Safety Council, Approval as Modified by this Public Comment.

Modify the proposal as follows:

719.7 Insulation and covering on pipe and tubing. Insulation and covering on pipe and tubing shall have a flame spread index of not more than 25 and a smoke-developed index of not more than 450. This shall include insulation coverings on exposed water supply and drainpipes under ~~accessible~~ lavatories and sinks.

Exception: Insulation and covering on pipe and tubing installed in plenums shall comply with the *International Mechanical Code.*

Commenter's Reason: The technical committee was split on the reasons for disapproving this proposal. With the change to go beyond just accessible lavatories and sinks this addresses one concern expressed. Some of the committee members clearly felt that the added sentence was unnecessary as they stated "the code already requires this material to meet Section 719.7, so this is redundant text or should be handled as an exception if it were not required". However, an explicit statement is important because other committee members felt that this requirement was not needed.

This is not a proprietary product. There are at present at least 4 manufacturers who make these materials and make them so as to meet the requirements of ASTM E 84 of a flame spread index not to exceed 25 and a smoke developed index not to exceed 450. They are: IPS Corporation (500 Distribution Parkway, Collierville, TN, 38017, also known as TrueBro) and their Soft Guard Pus line of products (web site: http://www.ipscorp.com/truebro/softguard), Johns Manville (717 17th St, Denver, CO, 80202) and their Zeston 2000 Series PVC Insulated Fitting Covers and Jacketing (web site: http://www.jm.com/insulation/performance_materials/products/ci55_zeston_2000_pvc.pdf), Plumberex Specialty Products (PO Box 1864, Palm Springs, CA, 92263) and their various lines of products (web site: http://www.plumberex.com/products.htm), and Proto Corporation (10500 47th Street North, Clearwater, FL, 33762) and their line of Proto Fitting Covers, made of Regular PVC and LoSmoke PVC (web site: http://www.protocorporation.com/specifications_pdfs/proto_submittal_sheet.pdf). Other manufacturers use plenum grade insulation materials (ASTM E 84 25/50) for this application (such as tapes).

It is interesting that the US Access Board, who is required to protect the disabled and enforce ADA, has come on record as stating that they feel this requirement is needed for the protection of the disabled and that this requirement is consistent with the requirements of ICC/ANSI A117.1-2003 because the coverings are insulation. The following e-mail from Marsh Mazz of the US Access Board shows that.

From: Mazz, Marsha [mailto:mazz@Access-Board.gov]
Sent: Tuesday, September 29, 2009 6:55 AM
To: Howard Ahern (Plumberex)

Subject: RE: Pipe and Drain Coverings

Our General Counsel, Mr. James Raggio, requested that I reply to your inquiry regarding an interpretation of the intent of the Access Board's accessibility guidelines pertaining to exposed pipes and surfaces beneath accessible lavatories and sinks. You asked if the requirement that the pipes be "insulated or otherwise configured to protect against contact" is intended to provide thermal protection as well as protection from sharp surfaces, or only to prevent contact with sharp surfaces.

The Access Board's most recent accessibility guideline is the 2004 Americans with Disabilities Act (ADA) and Architectural Barriers Act (ABA) Accessibility Guidelines. Section 606.5 of these guidelines requires the following: *606.5 Exposed Pipes and Surfaces. Water supply and drain pipes under lavatories and sinks shall be insulated or otherwise configured to protect against contact. There shall be no sharp or abrasive surfaces under lavatories and sinks.*

Criteria in the 2004 ADA and ABA Accessibility Guidelines is based on previous Access Board accessibility guidelines. The lavatory and sink requirement first appeared in 1989, in Section 1190.31(k) of the Access Board's *Minimum Guidelines and Requirements for Accessible Design (MGRAD)*. At that time, the Access Board's accessibility guidelines referenced the ANSI A117.1-1986 Edition. The ANSI A117.1 included the following requirement: *4.19.4 Exposed Pipes and Surfaces. Hot water and drain pipes under lavatories or sinks shall be insulated or otherwise protected if they abut the clearance areas indicated in Fig. 31. There shall be no sharp or abrasive surfaces under lavatories or sinks.*

In 1991, the Access Board issued the Americans with Disabilities Act Accessibility Guidelines (ADAAG) based on its earlier accessibility guidelines. ADAAG retained the earlier requirement in Sections 4.19 Lavatories and 4.24 Sinks. The requirement specifies that: *Hot water and drain pipes under lavatories [and sinks] shall be insulated or otherwise configured to protect against contact. There shall be no sharp or abrasive surfaces under lavatories*. Despite minor changes in wording, the requirements for lavatories and sinks has remained unchanged in the Access Board's accessibility guidelines since 1989.

After publication of ADAAG in 1991, the Access Board published the *ADAAG Manual - a guide to the Americans with Disabilities Act Accessibility Guidelines*. The substance of the Manual is available on-line at http://www.access-board.gov/adaag/about/guide.htm. In the Manual, the Access Board stated the following regarding the exposed pipes and sharp surfaces beneath lavatories:

Exposed Pipes and Surfaces [4.19.4]

To prevent burns, hot water pipes and drain pipes under lavatories must be insulated or otherwise configured to protect against contact. Exposed sharp or abrasive edges are prohibited. Foam or fiber insulation with protective over-wrap on drain, hot water supply, and sharp edges or commercially available rigid pipe covers will satisfy this requirement. The P-trap may also be installed parallel to the wall so that it is located outside the knee/toe space. If an under-lavatory enclosure is used, the specified knee and toe clearances must be maintained.

This guidance clarifies that the Board's requirement is intended to protect against burns due to contact with hot pipes and drains as well as to reduce the potential for injury due to contact with sharp or abrasive elements. Please note that while the Access Board's current accessibility guidelines include provisions for limiting water temperature to 120°F maximum in bathtubs and showers, the guidelines include no such provisions at lavatories and sinks. The reference to "hot water" was removed in 2004 guidelines because it was thought that there was equal potential for wheelchair users to experience adverse reactions or discomfort resulting from contact with cold water supply lines as with those that are hot.

As background to your inquiry, you provided differing interpretations of a parallel requirement in the ICC/ANSI A117.1-2003 Edition from staff at the International Code Council (attached) and a number of state building officials regarding this matter. The Access Board is authorized to provide technical assistance and guidance on its accessibility guidelines and standards. However, we cannot interpret state or local building codes. Please bear in mind that the Access Board does not establish requirements for fire resistant construction, interior finishes or other building materials intended to reduce the risk of flame spread or smoke development. Generally, these requirements are established in state, local and model building and fire codes which usually reference the ASTM E 84 *Standard Test Method for Surface Burning Characteristics of Building Materials*. The Access Board does not provide guidance regarding these building and fire code requirements.

If you have further questions, please don't hesitate to contact me at the telephone number below or by e-mail.

Regards,

Marsha K. Mazz

Public Comment 2:

Howard Ahern representing Plumberex Specialty Products Inc, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

719.7 Insulation and covering on pipe and tubing. Insulation and covering on pipe and tubing shall have a flame spread index of not more than 25 and a smoke-developed index of not more than 450. This shall include insulation coverings ~~on exposed water supply and drainpipes under accessible lavatories and sinks.~~ required by ANSI A117.1 Section 606.6.

Exception: Insulation and covering on pipe and tubing installed in plenums shall comply with the *International Mechanical Code.*

Commenter's Reason: This language is needed to clarify that any insulation covering material on pipe & tubing shall comply with IBC 719.7 including insulation covering materials used to comply with ANSI A117.1. There has been confusion as to whether insulation material requirements for ANSI A117.1 is categorized as a thermal application. The U.S. Access Board issued a letter stating the requirement is "To prevent burns exposed hot water & drain pipes must be insulated." In addition to preventing burns and thermal shock from hot water pipes, the cold water supply must also be insulated to prevent thermal shock as well as protect from sharp surfaces.

The National Mechanical Insulation Committee (NMIC) and the National Insulation Association (NIA) and the mechanical insulation industry has generally adopted the following category definitions:

Category	*Definition*
Cryogenic Applications	*-50 F & Below*
***Thermal Applications**:*	
Refrigeration, chill water and below ambient applications	***-49 F to +75** F*
Medium to high temperature applications	*+**76 F to 1,200 F***
Refractory Applications	*+ 1,200 F & Above*

Insulation that is required by the ADA, ADAAG, ANSI A117.1 and the ABA for exposed drain and water pipes to prevent "thermal Shock" have a service temperature which are classified as a Thermal Application and therefore requires Thermal Insulation and coverings on the pipe.

This is not an arbitrary requirement, IBC 719.7 only exception is for plenum use and there is no exception for the thermal insulation coverings material on pipe used to comply with ANSI A117.1. When Thermal Insulation materials are used as an Interior Finish it is regulated by IBC Chapter 8 Interior Finish Section 803.8: (Thermal & Sound Insulation) Section 803.8 shall comply with IBC Section 719.

ASTM has recognized the risks of combustion posed by PVC jacketing. In the published standard **ASTM C 930-05,** which addresses potential health and safety concerns associated with thermal insulation materials and accessories,

ASTM C 930 identifies "thermal burns, impaired vision from smoke, and toxic effects," as possible negative effects from "combustion" of "PVC jacketing." The proposed amendments to Section 719.7 would address these risks, in so far as they are posed by the PVC jacketing used in under sink pipe insulation, by clarifying that the limits on surface burning characteristics of insulation already imposed by Section 719.7 apply to under sink pipe insulation, as well." This standard referenced the

Consumer Product Safety Commission, NFPA, ANSI, ASTM, EPA, North American Insulation Manufactures Assn. and the National Science Foundation etc.

The following is a response (underlined) to the FS committee's comments:

1. "The Code already requires this material to meet Section 719.7, so this is redundant text". *The added language is very much needed to clarify a thermal insulation ANSI A117.1 requirement and to regulate highly combustible materials that produce large volumes of smoke.*
2. "This material and application poses no threat to life-safety"- *Material that is highly combustible and produces large volumes of smoke is a Life Safety threat especially for people with disabilities. In addition ASTM standard C90 clearly identifies potential threats to life safety from thermal insulation combustion as well as the U.S. Fire Administration report on School fires which reports over 6,000 structural school fires in U.S. schools annually, most of these structural fires are started in the bathrooms.*

3. “This level of protection is not required by the code.” - *719.7 only exception is for plenum use and there is no exception for this insulation and covering material on pipe under lavatories and sinks. IBC Chapter 8 Interior Finish Section 806.3 Thermal Insulation also refers back to Section 719 for its material.*
4. “Would require a Class A finish on a material that is used in a space where other interior finishes are required to only be Class C.”- This is thermal insulation material and not Interior Finish “Trim” material , IBC Chapter 8 clearly defines Thermal Insulation and Trim and the different flame spread and smoke maximum allowed indexes of the ASTM E84 test for each.

The main overwhelming concern for the materials in this safety proposal is combustion and smoke. Insulation covering to protect people with disabilities heightens the requirement that the material be properly tested and conforms to required limits already adopted by the IBC. The added language is not redundant and is needed to bring clarification to this particular ANSI A117.1 requirement that is not exempted by 719.7.

Final Action: AS AM AMPC____ D

FS127-09/10
Table 720.1(3)

Proposed Change as Submitted

Proponent: Sam Francis representing American Forest & Paper Association

Add new text as follows:

TABLE 720.1(3)
MINIMUM PROTECTION FOR FLOOR AND ROOF SYSTEMS[a,q]

FLOOR OR ROOF CONSTRUCTION	ITEM NUMBER	CEILING CONSTRUCTION	THICKNESS OF FLOOR OR ROOF SLAB (inches)				MINIMUM THICKNESS OF CEILING (inches)			
			4 hr	3 hr	2 hr	1 hr	4 hr	3 hr	2 hr	1 hr
30. Wood I-joist (minimum I-joist depth 9-1/2" with a minimum flange depth of 1-1/2" and a minimum flange cross-sectional area of 2.25 square inches; minimum web thickness of 3/8") @24" o.c. Fiberglass insulation placed between I-joists supported by the resilient channels.	30-1.1	Minimum 0.019" thick resilient channel 16" o.c. (Channels doubled at wallboard end joints), placed perpendicular to the joists and attached to each joist by 1-1/4" Type S drywall screws. Two Layers of ½" Type X gypsum wallboard applied with the long dimension perpendicular to the I-joists with end joints staggered. The base layer is fastened with 1-1/4" Type S drywall screws spaced 12" o.c. and the face layer is fastened with 1-5/8" Type S drywall screws spaced 12" o.c. Face layer end joints shall not occur on the same I-joist as base layer end joints and edge joints shall be offset 24" from base layer joints. Face layer to also be attached to base layer with 1-1/2" Type G drywall screws spaced 8" o.c. placed 6" from face layer end joints. Face layer wallboard joints to be taped and covered with joint compound.	—	—	—	Varies	—	—	—	5/8

Reason: Many code officials have come to rely upon Table 720 as the preferred source of information regarding fire resistance rated assemblies. Because of its importance, we believe that the table should offer the most common generic assemblies. Floor systems utilizing I-joists have increased from less than 10 percent in 1990 to more than 50 percent. With the increased prevalence of I-joist floor/ceiling assemblies, including this assembly in the table will make the IBC more complete and it will be more useful to code officials. It is also expected that the document will be "user friendly", particularly for designers. In an effort to fulfill this expectation, we propose this common assembly for incorporation into Table 720.1(3). It is supported by ASTM E-119 test results as shown on the attached page. The following information and test results are provided with the understanding that their inclusion does not place them within the copyright release requirements of the signature statement.

Cost Impact: This code change proposal will reduce the cost of construction by an unknown amount.

ICCFILENAME: FRANCIS-FS4-TABLE 720.1(3)

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: Disapproval was based on lack of supporting data (test report) to verify this assembly. Approved design can contain many details and specifications and the committee could not verify these without a test report that included a description.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Sam Francis, American Wood Council/AF&PA, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

TABLE 720.1(3)
MINIMUM PROTECTION FOR FLOOR AND ROOF SYSTEMSa,q

FLOOR OR ROOF CONSTRUCTION	ITEM NUMBER	CEILING CONSTRUCTION	THICKNESS OF FLOOR OR ROOF SLAB (inches)				MINIMUM THICKNESS OF CEILING (inches)			
			4 hr	3 hr	2 hr	1 hr	4 hr	3 hr	2 hr	1 hr
30. Wood I-joist (minimum I-joist depth 9-1/2" with a minimum flange depth of 1-1/2" and a minimum flange cross-sectional area of 2.25 square inches; minimum web thickness of 3/8") @24" o.c. Fiberglass insulation placed between I-joists supported by the resilient channels.	30-1.1	Minimum 0.019" thick resilient channel 16" o.c. (Channels doubled at wallboard end joints), placed perpendicular to the joists and attached to each joist by 1-1/4" Type S drywall screws. Two Layers of ½" Type X gypsum wallboard applied with the long dimension perpendicular to the <u>resilient channel</u> ~~I-joists~~ with end joints staggered. The base layer is fastened with 1-1/4" Type S drywall screws spaced 12" o.c. and the face layer is fastened with 1-5/8" Type S drywall screws spaced 12" o.c. Face layer end joints shall not occur on the same <u>resilient channel</u> ~~I-joist~~ as base layer end joints and edge joints shall be offset 24" from base layer joints. Face layer to also be attached to base layer with 1-1/2" Type G drywall screws spaced 8" o.c. placed ~~6~~ " <u>1-1/2"</u> from face layer end joints. Face layer wallboard joints to be taped and covered with joint compound.	—	—	—	Varies	—	—	—	5/8

Commenter's Reason: This proposal was submitted to be inserted into Table 720.1(3) as a new item in the table. This design is identical to the assembly shown at AWC's website and was tested using the ASTM E119 test procedure. The REASON STATEMENT in the submittal made reference to the test results. Due to the nature of the electronic submittal and electronic publication of the monograph, the actual test report and data was not transmitted to the committee. Committee members correctly refused to vote in the affirmative on an assembly for which the supporting test data was not provided. In an effort to overcome the problems in distributing the report and data, we are making it available at our website. This satisfies the committee's concern and represents compelling documentation for acceptance of this proposal AS MODIFIED. While making the modifications for FS128, it became apparent that we had made a typing error in entering the information about the construction of the assembly. Namely, the gypsum board long dimension should be perpendicular to the resilient channel, not the joists. So this Public Comment is to ACCEPT the proposal as modified with that correction. The corrected version matches the tested assembly. The information regarding the tested assembly may be found at

<u>http://www.awc.org/fire/testreport.html</u> username: guest password: awc

The test report you see when you choose FS127 is labeled on the website as WIJ1.7. This information was the basis for the original submission of this assembly by AWC to have the assembly listed in Table 720.

More assemblies which have been tested and demonstrated to afford a fire resistance rating mean more flexibility for designers and results in lower construction costs.

Final Action: AS AM AMPC____ D

FS128-09/10
Table 720.1(3)

Proposed Change as Submitted

Proponent: Sam Francis representing American Forest & Paper Association

Revise as follows:

TABLE 720.1(3)
MINIMUM PROTECTION FOR FLOOR AND ROOF SYSTEMS[a,q]

FLOOR OR ROOF CONSTRUCTION	ITEM NUMBER	CEILING CONSTRUCTION	THICKNESS OF FLOOR OR ROOF SLAB (inches)				MINIMUM THICKNESS OF CEILING (inches)			
			4 hr	3 hr	2 hr	1 hr	4 hr	3 hr	2 hr	1 hr
23. Wood I-joist (minimum joist depth 9-1/4" with a minimum flange depth of 1 $^{5}/_{16}$" and a minimum flange cross-sectional area of ~~2.3~~ 2.25 square inches) at 24" o.c. spacing with ~~1" by 4 inch (nominal)~~ a minimum 1x4 (3/4" x 3.5" actual) ~~wood furring strip spacer~~ ledger strip applied parallel to and covering the bottom of the bottom flange of each member, tacked in place. 2" mineral wool insulation, 3.5 pcf (nominal) installed adjacent to the bottom flange of the I-joist and supported by the ~~1"x4" furring strip spacer~~ 1x4 ledger strip.	23-1.1	½" deep single leg resilient channel 16" on center (channels doubled at wallboard end joints), placed perpendicular to the furring strip and joist and attached to each joist by 1-7/8" Type S drywall screws, 5/8" Type C gypsum wallboard applied perpendicular to the channel with end joints staggered at least 4' and fastened with 1-1/8 Type S drywall screws spaced 7" on center. Wallboard joints to be taped and covered with joint compound.	—	—	—	Varies	—	—	—	5/8
27. Wood I-joist (minimum I-joist depth 9-1/2" with a minimum flange depth of 1 $^{5}/_{16}$ " and a minimum flange cross-sectional area of 1.95 square inches; minimum web thickness of 3/8") @24" o.c.	27-1.1	Minimum 0.019" thick resilient channel 16" o.c. (Channels doubled at wallboard end joints), placed perpendicular to the joists and attached to each joist by ~~1-5/8~~ 1-1/4" Type S drywall screws. Two Layers of ½" Type X gypsum wallboard applied with the long dimension perpendicular to the I-joists with end joints staggered. The base layer is fastened with 1-1/4" Type S drywall screws spaced 12" o.c. and the face layer is fastened with 1-5/8" Type S drywall screws spaced 12" o.c. Face layer end joints shall not occur on the same I-joist as base layer end joints and edge joints shall be offset 24" from base layer joints. Face layer to also be attached to base layer with 1-1/2" Type G drywall screws spaced 8" o.c. placed 6" from face layer end joints. Face layer wallboard joints to be taped and covered with joint compound.	—	—	—	Varies	—	—	—	1

Reason: Editorial corrections to entries in the table.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: FRANCIS-FS3-TABLE 720.1(3)

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee felt that the requirements were being decreased without justification and therefore the proposal was more than editorial.

Assembly Action: **None**

<u>Individual Consideration Agenda</u>

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Sam Francis, American Wood Council/AF&PA, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

TABLE 720.1(3)
MINIMUM PROTECTION FOR FLOOR AND ROOF SYSTEMSa,q

FLOOR OR ROOF CONSTRUCTION	ITEM NUMBER	CEILING CONSTRUCTION	THICKNESS OF FLOOR OR ROOF SLAB (inches)				MINIMUM THICKNESS OF CEILING (inches)			
			4 hr	3 hr	2 hr	1 hr	4 hr	3 hr	2 hr	1 hr
23. Wood I-joist (minimum joist depth 9-1/4" with a minimum flange depth of 1 5/16" and a minimum flange cross-sectional area of 2.25 square inches) ~~at~~ <u>@</u>24" o.c. spacing with a minimum 1x4 (3/4" x 3.5" actual) <u>wood</u> ledger strip applied parallel to and covering the bottom of the bottom flange of each member, tacked in place. 2" mineral wool insulation, 3.5 pcf (nominal) installed adjacent to the bottom flange of the I-joist and supported by the 1x4 ledger strip.	23-1.1	½" deep single leg resilient channel 16" on center (channels doubled at wallboard end joints), placed perpendicular to the ~~furring~~ <u>ledger </u>strip and joist and attached to each joist by 1-7/8" Type S drywall screws~~,~~<u>.</u> 5/8" Type C gypsum wallboard applied perpendicular to the channel with end joints staggered at least 4' and fastened with 1-1/8 Type S drywall screws spaced 7" on center. Wallboard joints to be taped and covered with joint compound.	—	—	—	Varies	—	—	—	5/8
27. Wood I-joist (minimum I-joist depth 9-1/2" with a minimum flange depth of 1 5/16 " and a minimum flange cross-sectional area of 1.95 square inches; minimum web thickness of 3/8") @<u> </u>24" o.c.	27-1.1	Minimum 0.019" thick resilient channel 16" o.c. (Channels doubled at wallboard end joints), placed perpendicular to the joists and attached to each joist by 1-1/4" Type S drywall screws. Two Layers of ½" Type X gypsum wallboard applied with the long dimension perpendicular to the <u>resilient channel</u> ~~I-joists~~ with end joints staggered. The base layer is fastened with 1-1/4" Type S drywall screws spaced 12" o.c. and the face layer is fastened with 1-5/8" Type S drywall screws spaced 12" o.c. Face layer end joints shall not occur on the same <u>resilient channel</u> ~~I-joist~~ as base layer end joints and edge joints shall be offset 24" from base layer joints. Face layer to also be attached to base layer with 1-1/2" Type G drywall screws spaced 8" o.c. placed ~~6"~~ <u>1-1/2"</u> from face layer end joints. Face layer wallboard joints to be taped and covered with joint compound.	—	—	—	Varies	—	—	—	1

Commenter's Reason: AWC is seeking to have the committee action overturned in favor of the Modification contained in this Comment. The proposal was submitted to be an editorial "clean-up" of the item in the Table 720.1(3). This design is identical to the assembly shown at AWC's website and was tested using the ASTM E119 test procedure. Another submission this cycle made some of the same editorial comments as was shown in our original submittal. When the item was published in the Electronic Monograph for the hearings in Baltimore, it had the editorial corrections made to our submittal. Those changes made this submittal appear to be substantively changing the item in the table. It does NOT SUBSTANTIVELY CHANGE the item. Instead, it corrects all the errors of the item as it is published in the table. The text, as modified herein makes this item match the assembly intended to be described by this item in Table 720.1(3).

In our original submission, the REASON STATEMENT made reference to the test results. Due to the nature of the electronic submittal and electronic publication of the monograph, the actual test report and data was not transmitted to the committee. Committee members appropriately refused to vote in the affirmative on an assembly for which the supporting test data was not provided. Unlike FS127, this assembly is already in the table and the previous committees have seen the test data so we did not provide it with this submittal. However, in an effort to satisfy all concerns, we are making the test report and data from the original submittal available at our website. This satisfies the committee's concern and represents compelling documentation for acceptance of this proposal AS SUBMITTED. The information may be found at http://www.awc.org/fire/testreport.html

username: guest password: awc

The test reports you see when you choose FS128 are labeled on the website as WIJ1.3 for table item number 23-1.1 and WIJ1.6 for table item number 27-1.1. This information was the basis for the original submission of this assembly by AWC. Due to the electronic format of the ICC monograph, AWC failed to ensure this information was readily available to the committee in a timely manner. It was distributed to the public at the hearing in Baltimore. Because of its work load, the committee did not have time to consider these data.

More assemblies which have been tested and demonstrated to afford a fire resistance rating means flexibility for designers and results in lower construction costs.

Final Action: AS AM AMPC____ D

FS133-09/10, Part I
708.14, 801.4

Proposed Change as Submitted

Proponent: Joe Holland or Dave Bueche, Hoover Treated Wood Products, representing Hoover Treated Wood Products

PART I – IBC FIRE SAFETY

Add new text as follows:

801.3 Fire retardant paints and coating. Fire retardant paints and coating applied to wood products shall be permitted in accordance with this chapter for interior finish when there is a change of occupancy. Paints and coatings shall comply with NFPA 703 and be maintained in accordance with the International Fire Code.

(Renumber subsequent sections)

Reason: To correlate the IBC with the IFC and IEBC. This proposal incorporates the provisions currently contained in the IFC and IEBC. Both of these documents are concerned with structures after being occupancy. The IBC does govern existing buildings when there is a change of occupancy, Chapter 34. There is concern with this class of product being used in inappropriate applications in new construction.

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: Standard NFPA 703 is currently referenced in the I-codes.

ICCFILENAME: HOLLAND-BUESHE-FS1-801.1.1.3; S2-2303.3

Public Hearing Results

PART I- IBC FIRE SAFETY
Committee Action: Disapproved

Committee Reason: the committee felt that this proposal could prohibit the use of a product for new construction that may meet the code for such a use. Further, requirements for change of occupancy belongs in Chapter 34 or the International Existing Building Code for existing buildings.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Joseph Holland and Dave Bueche representing Hoover Treated Wood Products Inc, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

801.3 Fire retardant paints and coating. Fire retardant paints and coating applied to wood products shall be permitted in accordance with this chapter for interior finish when there is a change of occupancy. Paints and coatings shall comply with NFPA 703 <u>and Section 1703</u> and be maintained in accordance with the International Fire Code.

Commenter's Reason: Committee felt this was a provision for Chapter 34. We disagree. The building code discusses change of occupancy and what is required. Chapter 8 contains the general provisions. Chapter 34 contains the specific provisions. The proposed section is a general provision as it applies to wood products painted to reduce the flame spread.

Final Action: AS AM AMPC____ D

FS133-09/10, Part II
2303.3

Proposed Change as Submitted

Proponent: Joe Holland or Dave Bueche, Hoover Treated Wood Products, representing Hoover Treated Wood Products

PART II – IBC STRUCTURAL

Add new text as follows:

<u>**2303.3 Fire retardant paints and coating.** Fire retardant paints and coating applied to wood products shall be permitted in accordance with Chapter 8. Paints and coatings shall comply with NFPA 703 and be maintained in accordance with the International Fire Code.</u>

(Renumber subsequent sections)

Reason: To correlate the IBC with the IFC and IEBC. This proposal incorporates the provisions currently contained in the IFC and IEBC. Both of these documents are concerned with structures after being occupancy. The IBC does govern existing buildings when there is a change of occupancy, Chapter 34. There is concern with this class of product being used in inappropriate applications in new construction.

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: Standard NFPA 703 is currently referenced in the I-codes.

ICCFILENAME: HOLLAND-BUESHE-FS1-801.1.1.3; S2-2303.3

Public Hearing Results

PART II- IBC STRUCTURAL
Committee Action: **Disapproved**

Committee Reason: Based on the committee's action on FS133-09/10 Part I.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Joseph Holland and Dave Bueche representing Hoover Treated Wood Products Inc, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

2303.3 Fire retardant paints and coating. Fire retardant paints and coating applied to wood products shall be permitted in accordance with Section 801.3 ~~Chapter 8. Paints and coatings shall comply with NFPA 703 and be maintained in accordance with the International Fire Code.~~

Commenter's Reason: Section 801.3 refers one to NFPA 703 and the IFC, they are not needed to be repeated. Part II clarifies that painted products are not FRTW and are allowed only for interior finish where they can be maintained.

Final Action: AS AM AMPC____ D

FS139-09/10
809 (New)

Proposed Change as Submitted

Proponent: Joe McELvaney, representing self

Add new Section as follows:

Section 809
Children's Playground Structures

809.1 Children's playground structures. Structures intended as children's playgrounds that exceed 10 feet (3048 mm) in height and 150 square feet (14 m2) in area shall comply with Sections 809.1.1 through 809.1.4.

809.1.1 Materials. Children's playground structures shall be constructed of noncombustible materials or of combustible materials that comply with the following:

1. Fire-retardant-treated wood complying with Section 2302.
2. Light-transmitting plastics complying with Section 2606.
3. Foam plastics (including the pipe foam used in soft-contained play equipment structures) having a maximum heat-release rate not greater than 100 kilowatts when tested in accordance with UL 1975.
4. Aluminum composite material (ACM) meeting the requirements of Class A interior finish in accordance with Chapter 8 when tested as an assembly in the maximum thickness intended for use.
5. Textiles and films complying with the flame propagation performance criteria contained in NFPA 701.
6. Plastic materials used to construct rigid components of soft-contained play equipment structures (such as tubes, windows, panels, junction boxes, pipes, slides and decks) exhibiting a peak rate of heat release not exceeding 400 kW/m^2 when tested in accordance with ASTM E 1354 at an incident heat flux of 50 kW/m^2 in the horizontal orientation at a thickness of 6 mm.
7. Ball pool balls, used in soft-contained play equipment structures, having a maximum heat-release rate not greater than 100 kilowatts when tested in accordance with UL 1975. The minimum specimen test size shall be 36 inches by 36 inches (914mmby 914 mm) by an average of 21 inches (533 mm) deep, and the balls shall be held in a box constructed of galvanized steel poultry netting wire mesh.
8. Foam plastics shall be covered by a fabric, coating or film meeting the flame propagation performance criteria of NFPA 701.
9. The floor covering placed under the children's playground structure shall exhibit a Class I interior floor finish classification, as described in Section 804, when tested in accordance with NFPA 253.

809.1.2 Fire protection. Children's playground structures located within the compartment shall be provided with the same level of approved fire suppression and detection devices required for similar structures in the same compartment.

809.1.3 Separation. Children's playground structures shall have a minimum horizontal separation from other structures of 20 feet (6090 mm).

809.1.4 Area limits. Children's playground structures shall not exceed 300 square feet (28 m^2) in area, unless a special investigation has demonstrated adequate fire safety.

Reason: The current 2009 IBC has a section 402.12 for children's playground structures. This section currently only applies to Malls. However children's playground equipment can be found in all types of buildings and not just in malls. This new section will allow the code official to enforce these rules in any building that chooses to have children's playground equipment.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: MCELVANEY-FS1-809 NEW.doc

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee felt that Chapter 4 requirements should perhaps be removed if these requirements were to move to Chapter 8, however the committee was not convinced that Chapter 8 was appropriate as it deals only with interior finishes. Chapter 4 might be more appropriate as it deals with amusement structures. Lastly, the terms structure and compartment need to be defined in this context.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Marcelo M. Hirschler (GBH International), representing American Fire Safety Council; Robert J. Davidson (Davidson Code Concepts, LLC) representing self, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

~~**402.12 Children's playground structures.** Structures intended as children's playgrounds that exceed 10 feet (3048 mm) in height and 150 square feet (14 m^2) in area shall comply with Sections 402.12.1 through 402.12.4.~~

~~**402.12.1 Materials.** Children's playground structures shall be constructed of noncombustible materials or of combustible materials that comply with the following:~~

1. ~~Fire-retardant-treated wood.~~
2. ~~Light-transmitting plastics complying with Section 2606.~~
3. ~~Foam plastics (including the pipe foam used in soft-contained play equipment structures) having a maximum heat-release rate not greater than 100 kW when tested in accordance with UL 1975.~~
4. ~~Aluminum composite material (ACM) meeting the requirements of Class A interior finish in accordance with Chapter 8 when tested as an assembly in the maximum thickness intended for use.~~
5. ~~Textiles and films complying with the flame propagation performance criteria contained in NFPA 701.~~
6. ~~Plastic materials used to construct rigid components of soft-contained play equipment structures (such as tubes, windows, panels, junction boxes, pipes, slides and decks) exhibiting a peak rate of heat release not exceeding 400 kW/m^2 when tested in accordance with ASTM E 1354 at an incident heat flux of 50 kW/m^2 in the horizontal orientation at a thickness of 6 mm.~~
7. ~~Ball pool balls, used in soft-contained play equipment structures, having a maximum heat release rate not greater than 100 kW when tested in accordance with UL 1975. The minimum specimen test size shall be 36 inches by 36 inches (914 mm by 914 mm) by an average of 21 inches (533 mm) deep, and the balls shall be held in a box constructed of galvanized steel poultry netting wire mesh.~~
8. ~~Foam plastics shall be covered by a fabric, coating or film meeting the flame propagation performance criteria of NFPA 701.~~
9. ~~The floor covering placed under the children's playground structure shall exhibit a Class I interior floor finish classification, as described in Section 804, when tested in accordance with NFPA 253.~~

~~**402.12.2 Fire protection.** Children's playground structures located within the mall shall be provided with the same level of *approved* fire suppression and detection devices required for kiosks and similar structures.~~

~~**402.12.3 Separation.** Children's playground structures shall have a minimum horizontal separation from other structures within the mall of 20 feet (6090 mm).~~

~~**402.12.4 Area limits.** Children's playground structures shall not exceed 300 square feet (28 m^2) in area, unless a special investigation has demonstrated adequate fire safety.~~

402.12 Children's play structures. Children's play structures shall comply with Section 424. The minimum horizontal separation between children's play structures, kiosks and similar structures within the mall shall be 20 feet (6096 mm).

Section ~~809~~ 424
Children's Play ~~Playground~~ Structures

~~809.1~~ 424.1 Children's play ~~playground~~ structures. ~~Structures intended as children's playgrounds~~ Children's play structures installed inside all occupancies covered by this code that exceed 10 feet (3048 mm) in height and 150 square feet (14 m2) in area shall comply with Sections 424.2 through 424.5 ~~809.1.1 through 809.1.4~~.

~~809.1.1~~ 424.2 Materials. Children's play ~~playground~~ structures shall be constructed of noncombustible materials or of combustible materials that comply with the following:

1. Fire-retardant-treated wood complying with Section 2302.
2. Light-transmitting plastics complying with Section 2606.
3. Foam plastics (including the pipe foam used in soft-contained play equipment structures) having a maximum heat-release rate not greater than 100 kilowatts when tested in accordance with UL 1975 or when tested in accordance with NFPA 289, using the 20 kW ignition source.
4. Aluminum composite material (ACM) meeting the requirements of Class A interior finish in accordance with Chapter 8 when tested as an assembly in the maximum thickness intended for use.
5. Textiles and films complying with the flame propagation performance criteria contained in NFPA 701.
6. Plastic materials used to construct rigid components of soft-contained play equipment structures (such as tubes, windows, panels, junction boxes, pipes, slides and decks) exhibiting a peak rate of heat release not exceeding 400 kW/m^2 when tested in accordance with ASTM E 1354 at an incident heat flux of 50 kW/m^2 in the horizontal orientation at a thickness of 6 mm.
7. Ball pool balls, used in soft-contained play equipment structures, having a maximum heat-release rate not greater than 100 kilowatts when tested in accordance with UL 1975 or when tested in accordance with NFPA 289, using the 20 kW ignition source. The minimum specimen test size shall be 36 inches by 36 inches (914 mm by 914 mm) by an average of 21 inches (533 mm) deep, and the balls shall be held in a box constructed of galvanized steel poultry netting wire mesh.
8. Foam plastics shall be covered by a fabric, coating or film meeting the flame propagation performance criteria of NFPA 701.
9. The floor covering placed under the children's play ~~playground~~ structure shall exhibit a Class I interior floor finish classification, as described in Section 804, when tested in accordance with NFPA 253.

~~809.1.2~~ 424.3 Fire protection. Children's play ~~playground~~ structures ~~located within the compartment~~ shall be provided with the same level of approved fire suppression and detection devices required for other ~~similar~~ structures in the same occupancy ~~compartment~~.

~~809.1.3~~ 424.4 Separation. Children's play structures shall have a minimum horizontal separation from building walls, partitions and from elements of the means of egress of 5 feet (1524 mm). Children's play ~~playground~~ structures shall have a minimum horizontal separation from other children's play structures of 20 feet (6090 mm).

~~809.1.2~~ 424.5 Area limits. Children's playground structures shall not exceed 300 square feet (28 m^2) in area, unless a special investigation, acceptable to the code official, has demonstrated adequate fire safety.

Commenter's Reason: The technical committee was concerned that the proposal was placed in the wrong location because Chapter 8 addresses interior finish only, and suggested that it would be better placed in Chapter 4 as a separate section. That is why a new section is being proposed for this language. The intent of this proposal is that it should apply to all such large children's playground structures (to be called play structures), as long as they are placed indoors. As stated by the original submitter, children's play equipment can be found in all types of buildings and not just in malls.

The revised language also makes a few other changes that handle the issue raised by the technical committee of the words "similar structures" and "compartment". In the revised language the words "similar" and "compartment" are eliminated from the new section and it simply discusses "children's play structures".

Since new Section 424 covers children's play structures in all buildings, there is no need to retain the same requirements in their entirety in Section 402.12. Section 402.12 was revised to retain only the 20-foot separation requirements between children's play structures, kiosks and similar structures, which are only applicable in malls.

In areas other than covered malls, the code does not currently include separation distances between kiosks and children's' play structure. However, it was felt appropriate to include both a 20-foot separation between children's play structures (if there is more than one) and a minimum five-foot separation from walls, partitions and elements of the means of egress to ensure that adequate space is provided around the structure for proper sprinkler operation and unimpeded egress.

The new language also makes the change approved by the IFC committee in F58 parts I and II, where it allows the use of NFPA 289 as an alternate for UL 1975. NFPA 289 is more versatile than UL 1975 and is also likely to offer lower variability. The 20 kW gas burner ignition source in NFPA 289 was specifically designed with the intent of being a substitute for UL 1975.

Analysis: NFPA 289 was introduced in Code Change Proposal F58 09/10 Parts I and II and was found to be in compliance with ICC's policy on referenced standards.

Final Action: AS AM AMPC____ D

FS142-09/10
1403.5 (New)

Proposed Change as Submitted

Proponent: Jesse J. Beitel, Hughes Associates, Inc., representing The Extruded Polystyrene Foam Association

Add new text as follows:

1403.5 Vertical and Lateral Flame Propagation. Exterior walls greater than 20 feet (6 096 mm) in height above grade plane that contain combustible exterior wall coverings shall be tested in accordance with and comply with the acceptance criteria of NFPA 285.

Exceptions:

1. Exterior walls of Type V construction
2. Exterior walls that contain as the only combustible material, one or more of the following components:
    1. Thermal- and sound-insulating materials that meet the requirements of Section 1406.2.2.
    2. Architectural trim and embellishments.
    3. Combustible exterior wall veneers installed to heights not exceeding 40 ft. above grade plane.

(Renumber subsequent numbers)

Reason: This new section is proposed to address the potential vertical and lateral flame spread that can occur either on or within exterior wall assemblies that contain combustible materials.

Newer construction practices such as the addition of combustible weather resistant barriers allow significant amounts of combustible materials/products (other than foam plastics) to be installed on or in exterior walls. This code change proposal adds the requirement for NFPA 285 testing for exterior walls that contain these types of combustible materials. This requirement is already in place for any exterior walls that contain foam plastic insulation or use MCM exterior veneers.

Testing has shown that when a combustible weather resistive barrier was added to an exterior wall system that had successfully met the criteria for NFPA 285, that the addition of the barrier caused failure to occur in the NFPA 285 test.

Small-scale testing has shown that these types of materials can provide significant amounts of combustible fuel loading to a wall assembly and they are not currently regulated by the Code.

With the advent of newer exterior wall technologies such as “rainscreen” systems, the openings in the exterior veneer will allow flames and or heat to readily impact and ignite the barrier material. Due to the built-in standoffs of these systems, the barrier materials could then exhibit significant vertical or lateral flame propagation.

The Code proposal requires the NFPA 285 testing for exterior walls on Types I, II, III, or IV construction since these types of construction allow either none or limited combustibles in the exterior walls. The 20 ft. height limit provides a safety margin on the height of wall that can use these materials without testing. Also, while the code allows combustible exterior wall covering up to 40 ft., this proposal has as a limit 20 ft. since these materials can provide a hidden or concealed fire situation.

Cost Impact: The code change proposal will increase the cost of construction.

Analysis: Standard NFPA 285 is currently referenced in the I-codes.

ICCFILENAME: BEITEL-FS1-1403.5.doc

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee was concerned that there was no area limitations imposed on architectural trim or exterior wall veneers.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jesse J. Beitel, Hughes Associates Inc, representing Extruded Polystyrene Foam Association, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

1403.5 Vertical and Lateral Flame Propagation. Exterior walls on buildings of Type I, II, III or IV construction that are greater than ~~20~~ 40 feet (12 192 mm) in height above grade plane and ~~that~~ contain a combustible water-resistive barrier ~~exterior wall coverings~~ shall be tested in accordance with and comply with the acceptance criteria of NFPA 285.

~~**Exceptions:**~~

1. ~~Exterior walls of Type V construction~~
2. ~~Exterior walls that contain as the only combustible material, one or more of the following components:~~
   1. ~~Thermal- and sound-insulating materials that meet the requirements of Section 1406.2.2.~~
   2. ~~Architectural trim and embellishments.~~
3. ~~Combustible exterior wall veneers installed to heights not exceeding 40 ft. above grade plane.~~

(Renumber subsequent sections.)

Reason: This new section is proposed to address the potential vertical and lateral flame spread that can occur either on or within exterior wall assemblies that contain combustible materials.

Newer construction practices such as the addition of combustible water-resistant barriers allow significant amounts of combustible materials/products (other than foam plastics) to be installed on or in exterior walls. This code change proposal adds the requirement for NFPA 285 testing for exterior walls that contain these types of combustible materials. This requirement is already in place for any exterior walls that contain foam plastic insulation or use MCM exterior veneers.

Testing has shown that when a combustible water-resistive barrier was added to an exterior wall system that had successfully met the criteria for NFPA 285, that the addition of the barrier caused failure to occur in the NFPA 285 test.

Small-scale testing has shown that these types of materials can provide significant amounts of combustible fuel loading to a wall assembly and they are not currently regulated by the Code.

With the advent of newer exterior wall technologies such as “rainscreen” systems, the openings in the exterior veneer will allow flames and or heat to readily impact and ignite the barrier material. Due to the built-in standoffs of these systems, the barrier materials could then exhibit significant vertical or lateral flame propagation.

The Code proposal requires the NFPA 285 testing for exterior walls on Types I, II, III, or IV construction since these types of construction allow either none or limited combustibles in the exterior walls. The 40 ft. height limit follows the code allowance for combustible exterior wall covering up to 40 ft.

This Comment has revised the original proposal by being more specific with respect to addressing the materials of concern. Floor discussion and potential modifications all addressed exceptions and not the issue that gave rise to this code change. The comment now addresses the concerns raised by the Committee and others.

Final Action: AS AM AMPC____ D

FS143-09/10
1404.12 (New)

Proposed Change as Submitted

Proponent: Marcelo M. Hirschler, GBH International, representing American Fire Safety Council

1. Add a new definition as follows:

SECTION 1402
DEFINITIONS

Polypropylene siding - a shaped material, made principally from polypropylene homopolymer, or copolymer, which in some cases may contain fillers and/or reinforcements, that is used to clad exterior walls of buildings.

2. Add new section as follows

1404.12 Polypropylene siding. Polypropylene siding shall be certified and labeled as conforming to the requirements of 1404.12.1, 1404.12.2 or 1404.12.3 by an approved quality control agency. Polypropylene siding shall be installed in accordance with the manufacturer's installation instructions.
1404.12.1 Flame Spread Index. The polypropylene siding material shall comply with the requirements of ASTM D 7254. The certification shall be accompanied by a test report stating that all portions of the test specimen ahead of the flame front remained in position during the test in accordance with ASTM E 84 or UL 723.

1404.12.2 Heat Release. The polypropylene siding material shall comply with the requirements of ASTM D 7254 and a 4 foot by 8 foot (1.22 x 2.44 m) section of the polypropylene siding material shall exhibit a peak rate of heat release not exceeding 100 kW when tested in accordance with NFPA 289 using the 20 kW ignition source at the thickness intended for use.

1404.12.3 Fire Separation Distance. The polypropylene siding shall comply with all the requirements of ASTM D 7254 and the fire separation distance between a building with polypropylene siding and the adjacent building shall be no less than 10 feet (3.05 m).

1405.18 Polypropylene siding. Polypropylene siding conforming to the requirements of this section and complying with 1404.12 shall be permitted on exterior walls of buildings of Type V construction located in areas where the basic wind speed specified in Chapter 16 does not exceed 100 miles per hour (45 m/s) and the building height is less than or equal to 40 feet (12 192 mm) in Exposure C. Where construction is located in areas where the basic wind speed exceeds 100 miles per hour (45 m/s), or building heights are in excess of 40 feet (12 192 mm), tests or calculations indicating compliance with Chapter 16 shall be submitted. Polypropylene siding shall be secured to the building so as to provide weather protection for the exterior walls of the building.

1405.18.1 Application. The siding shall be applied over sheathing or materials listed in Section 2304.6. Siding shall be applied to conform with the water-resistive barrier requirements in Section 1403. Siding and accessories shall be installed in accordance with approved manufacturer's instructions. Unless otherwise specified in the approved manufacturer's instructions, nails used to fasten the siding and accessories shall have a minimum 0.313-inch (7.9 mm) head diameter and 0.125-inch (3.18 mm) shank diameter. The nails shall be corrosion resistant and shall be long enough to penetrate the studs or nailing strip at least 0.75 inch (19 mm). Where the siding is installed horizontally, the fastener spacing shall not exceed 16 inches (406 mm) horizontally and 12 inches (305 mm) vertically. Where the siding is installed vertically, the fastener spacing shall not exceed 12 inches (305 mm) horizontally and 12 inches (305 mm) vertically.

3. Add new standards to Chapter 35 as follows:

ASTM D 7254-07 Standard specification for polypropylene (PP) siding,
NFPA 289-09 Standard Method of Fire Test for Individual Fuel Packages

Reason: Polypropylene siding is being used in construction now although the IBC does not permit it. Therefore, it is important to regulate the use of polypropylene siding in a way that it can be used safely. The new sections are similar to the existing sections on vinyl siding, except for the fire testing. Vinyl siding is known to have adequate fire performance since the siding needs to be made of rigid (unplasticized) PVC in accordance with ASTM D 3679. Polypropylene is known not to have adequate fire performance unless properly fire retarded.

A new standard specification has been issued for polypropylene siding, ASTM D 7254. The specification addresses many of the key requirements for the material. Unfortunately the fire test requirement in ASTM D 7254 is not explicit enough. ASTM D 7254 does not require that, when fire testing is conducted in the ASTM E 84 (Steiner tunnel), the test specimen must remain in place during the test and flaming drips and falling test specimens are not allowed to happen. This requirement is critical for materials that are used exposed so that the flame spread index assesses actual surface flame spread on the material surface. The standards committee responsible for the ASTM E 84 fire test (ASTM E05) decided that this issue should be addressed in the code rather than in the standard itself. Polypropylene that has not been appropriately fire retarded will release abundant amount of heat, much more than other combustible sidings permitted by the code, such as wood siding or vinyl (PVC) siding, and spread fire through flaming drips. Such flaming drips will contribute to ignite mulch and debris found near the building and spread the fire. Table 1 shows such results.

Recent fire tests were also conducted in the Steiner tunnel, ASTM E 84, on a rigid PVC material 0.06 in. thick; it exhibited a flame spread index of 10. Under the same test conditions, a fire retarded polypropylene material 0.15 in. thick exhibited a flame spread index of 50. These are both very adequate values, in view of the fact that both the polypropylene material and the PVC material remained in place during the ASTM E 84 test and did not generate flaming drips.

Table 1: Results of Steiner Tunnel Tests (ASTM E 84)

Material	Flame Spread Index	Maximum Flame Front Advance (ft)	Time to Max. Flame Front Advance (min:s)	Flaming on Floor (Duration) (min:s)
PVC	10	4.6	7:48	None
FR Polypropylene	50	19.5	6:24	4:18

This shows that it is possible to use fire retarded polypropylene materials that give very adequate flame spread values and also very adequate heat release values, without flaming drips. Consequently, polypropylene siding should only be used when it is shown to exhibit the appropriate fire performance.

When polypropylene siding material (which does not have the appropriate fire performance) is tested in ASTM E 84 (Steiner tunnel) the test specimen will often fall ahead of the arrival of the flame giving incorrect results.

Table 2 shows new results of cone calorimeter heat release tests with polypropylene and PVC:

Table 2: Results of Cone Calorimeter (ASTM E 1354) Tests

Material	Peak Heat Release Rate	Total Heat Released	Time to Ignition	Effective Heat of Combustion	Fire Performance Index
	kW/m^2	MJ/m^2	s	MJ/kg	$s\ m^2/kW$
PVC	186.8	16.7	36	9.2	0.19
Non FR Polypropylene	768.3	47.2	23	40.3	0.03

Table 3 shows some earlier results with polypropylene, PVC and wood materials in the cone calorimeter:

Table 3 - Cone Calorimeter Data on Plastics and Douglas Fir

Material	Pk HRR (kW/m^2)	THR (MJ/m^2)	TTI (s)	EHC (MJ/kg)	FPI ($s\ m^2/kW$)
		Flux 20 kW/m^2			
PVC Rigid, Custom Inj. Mold.	40	3.0	5159	1.4	1343
PVC Rigid, Extrusion	102	2.9	3591	7.3	31.4
PP Non FR	1170	231.3	218	72.0	0.19
PP FR	236		382	23.6	1.62
PE Non FR	913	161.9	403	41.1	0.44
XLPE FR	88	87.6	750	22.4	8.08
Douglas Fir	237	46.5	254	13.1	1.10
		Flux 40 kW/m^2			
PVC Rigid, Custom Inj. Mold.	175	24.3	73	5.1	0.42
PVC Rigid, Extrusion	183	90.8	85	13.3	0.46
PP Non FR	1509	206.9	86	42.1	0.06
PP FR	243		80	23.9	0.33
PE Non FR	1408	221.0	159	46.6	0.06
XLPE FR	192	126.2	105	24.2	0.55
Douglas Fir	221	64.1	34	17.6	0.15
		Flux 70 kW/m^2			
PVC Rigid, Custom Inj. Mold.	191	93.0	45	12.7	0.24
PVC Rigid, Extrusion	190	96.5	48	10.8	0.25
PP Non FR	2421	231.1	41	43.1	0.02
PE Non FR	2735	227.5	47	42.6	0.02
XLPE FR	268	129.2	35	24.7	0.13
Douglas Fir	196	50.0	12	13.5	0.06

Table 3 shows that, when tested in the cone calorimeter, ASTM E 1354, under the same conditions, it was found that non fire retarded polypropylene exhibits a peak heat release rate of 1509 kW/m^2, while a non fire retarded PVC material exhibits a peak heat release rate of 183 kW/m^2, and a Douglas fir material exhibits a peak heat release rate of 221 kW/m^2. Such a very high heat release rate is unacceptable for a siding material. Testing in the cone calorimeter, including the testing above, is normally conducted in the horizontal orientation with radiant heat exposing the test specimen from above, thus capturing any flaming drips and assessing their effects.

Table 4 shows that wood materials, when not fire retarded, will usually exhibit flame spread index values that are less than 200 and will correspond to Class B or Class C categories. At the same time rigid PVC (vinyl) materials will generally exhibit flame spread index values less than 25. Neither wood nor PVC materials will cause flaming drips or molten material burning on the ground.

Table 4. Steiner tunnel (ASTM E 84) Data for Wood and Vinyl Materials

Material/Product	Flame Spread Index Low	Flame Spread Index High	Material/Product	Flame Spread Index Low	Flame Spread Index High
Cellulose fiberboard ceiling tile	70	80	Ponderosa pine B	105	170

Cottonwood	115		Poplar	170	185
Cypress	145	150	Red Gum	140	155
Douglas fir	70	100	Red oak flakeboard	70	190
Douglas fir overlay	110	140	Red Oak Flooring	100	100
Douglas fir/cedar plywood	190	230	Red Pine	140	
Eastern White Pine	85		Redwood	65	70
Hemlock/cedar plywood	190		Southern yellow pine	130	195
Lauan hardwood	150	170	Vinyl faced plywood	110	130
Lodgepole Pine	95		Vinyl profile	15	20
Maple flooring	105		Vinyl Siding	10	15
Northern white pine A	190	215	Vinyl vapor barrier	10	15
Northern white pine B	120	180	Walnut	130	140
Pacific silver fir	70		West Coast Hemlock	60	70
Pacific Yellow Cedar	80		Western Red Cedar	70	
Particleboard	135	180	Western spruce	100	
Plywood paneling over gypsum	130	150	Western white pine	75	
Ponderosa pine A	170	230	Yellow birch	105	110

Figure 1 shows char from a PVC siding fire (no foam backing): the material softened, charred and burned but is still substantially intact. Figure 2 shows a vertical PP sheet melting and resulting in flaming drips on the floor.

The reason that heat release rate and floor flaming are important issues is because it has been shown that the heat radiated by siding is a major contributor to the ignition of neighboring houses, as is the spread of fire along the ground, particularly when there are loose combustibles present.

That is the reason that the third option allows polypropylene siding to be used, but with a larger separation distance, when the results of the ASTM E 84/UL 723 (Steiner tunnel) test are based on a test specimen that is not self supporting and falls to the floor of the tunnel during the test. The standard ASTM E 84 states: "1.4 Testing of materials that melt, drip, or delaminate to such a degree that the continuity of the flame front is destroyed, results in low flame spread indices that do not relate directly to indices obtained by testing materials that remain in place." Therefore valid test results require the test specimen to stay in place ahead of the exposing flame.

Polypropylene siding should not be used in buildings other than Type V construction.

Figure 1 – remains of vinyl siding fire

Figure 2 Polypropylene siding melting and flaming on the floor.
(No figure 2 attached)

NFPA 289 was developed to test individual fuel packages and is similar in concept to UL 1975, already widely used in the code.

Cost Impact The code does not at present allow the use of polypropylene siding. In order to safely use polypropylene siding construction costs would have to increase either by using materials that would meet test requirements for adequate fire safety or by increasing fire separation distances.

Analysis: Code change proposal FS143 and FS144 address new requirements for polypropylene siding. The committee needs to make its intent clear with respect to these provisions. A review of the standard(s) proposed for inclusion in the code, ASTM D 7254-07 and NFPA 289-09, for compliance with ICC criteria for referenced standards given in Section 3.6 of Council Policy #CP 28 will be posted on the ICC website on or before September 24, 2009.

ICCFILENAME: HIRSCHLER-FS6-1404.12.doc

Public Hearing Results

Note: The following analysis was not in the Code Change monograph but was published on the ICC website at http://www.iccsafe.org/cs/codes/Documents/2009-10cycle/ProposedChanges/Standards-Analysis.pdf :

Analysis: Review of the proposed new standards indicated that, in the opinion of ICC staff, the standard did comply with ICC standards criteria.

Committee Action: Disapproved

Committee Reason: The committee was concerned that NFPA 289 was not appropriate for polypropylene materials. Further, no fire data to substantiate the fire hazard was provided.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Marcelo M. Hirschler (GBH International), representing American Fire Safety Council, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

Polypropylene siding - a shaped material, made principally from polypropylene homopolymer, or copolymer, which in some cases may contain fillers and/or reinforcements, that is used to clad exterior walls of buildings.

1404.12 Polypropylene Siding. Polypropylene siding shall be certified and labeled as conforming to the requirements of ASTM D 7254 and those of 1404.12.1 or those of 1404.12.2 ~~or 1404.12.3~~ by an approved quality control agency. Polypropylene siding shall be installed in accordance with the requirements of 1405.18 and in accordance with the manufacturer's installation instructions. Polypropylene siding shall be secured to the building so as to provide weather protection for the exterior walls of the building.

1404.12.1 Flame Spread Index. ~~The polypropylene material shall comply with the requirements of ASTM D7254.~~ The certification of the flame spread index shall be accompanied by a test report stating that all portions of the test specimen ahead of the flame front remained in position during the test in accordance with ASTM E 84 or UL 723.

~~**1404.12.2 Heat Release**. The polypropylene siding material shall comply with the requirements of ASTM D 7254 and a 4 foot by 8 foot (1.22 x 2.44 m) section of the polypropylene siding material shall exhibit a peak rate of heat release not exceeding 100 kW when tested in accordance with NFPA 289 using the 20 kW ignition source at the thickness intended for use.~~

1404.12.~~3~~2 Fire Separation Distance. ~~The polypropylene siding shall comply with all the requirements of ASTM D7254 and~~ The fire separation distance between a building with polypropylene siding and the adjacent building shall be no less than 10 feet (3.05 m).

1405.18 Polypropylene siding. Polypropylene siding conforming to the requirements of this section and complying with 1404.12 shall be limited to exterior walls of Type VB construction located in areas where the wind speed specified in Chapter 16 does not exceed 100 miles per hours (45 m/s) and the building height is less than or equal to 40 feet (12,192 mm) in Exposure C. Where construction is located in areas where the basic wind speed exceeds 100 miles per hour (45 m/s), or building heights are in excess of 40 feet (12,192 mm), tests or calculations indicating compliance with Chapter 16 shall be submitted. Polypropylene siding shall be installed in accordance with the manufacturer's installation instructions. Polypropylene siding shall be secured to the building so as to provide weather protection for the exterior walls of the building.

~~**1405.18.1 Application.** The siding shall be applied over sheathing or materials listed in Section 2304.6. Siding shall be applied to conform with the water-resistive barrier requirements in Section 1403. Siding and accessories shall be installed in accordance with approved manufacturer's instructions. Unless otherwise specified in the approved manufacturer's instructions, nails used to fasten the siding and accessories shall have a minimum 0.313-inch (7.9 mm) head diameter and 0.125-inch (3.18 mm) shank diameter. The nails shall be corrosion resistant and shall be long enough to penetrate the studs or nailing strip at least 0.75 inch (19 mm). Where the siding is installed horizontally, the fastener spacing shall not exceed 16 inches (406 mm) horizontally and 12 inches (305 mm) vertically. Where the siding is installed vertically, the fastener spacing shall not exceed 12 inches (305 mm) horizontally and 12 inches (305 mm) vertically.~~

CHAPTER 35

ASTM D 7254 *Standard specification for polypropylene (PP) siding*
~~***NFPA 289*** *Standard Method of Fire Test for Individual Fuel Packages (2009)*~~

Commenter's Reason: The committee had a valid concern regarding the use of NFPA 289 for testing this material and this option has been eliminated. Polypropylene siding material does not normally contain flame retardants or any other additives that will prevent it from forming a pool fire as soon as it is exposed to a flame. Therefore, when polypropylene siding is exposed to the flame in the ASTM E 84 Steiner tunnel test it immediately starts melting and burning occurs in the floor of the tunnel, with no material left in the tunnel ceiling where the test sample should be. This material gets a low flame spread index (ASTM D 7254 requires a flame spread index under 200, just like for wood siding) but it is not a valid result because the material is no longer in the test position when the flame comes by.

This is a problem because polypropylene that is not properly flame retarded will generate about 4 times as much heat as vinyl (PVC) or as wood or even properly fire retarded polypropylene (see peak heat release rate in the table below) and it ignites much more rapidly. Therefore if polypropylene siding is made with typical polypropylene that has not been treated, the siding is a very dangerous product and polypropylene siding should not be allowed to be used based only on the requirements of ASTM D 7254. This means that proposal FS144 should not be approved.

Table: Results of Cone Calorimeter (ASTM E 1354) Tests (4 inch x 4 inch test sample)			
Material	**Peak Heat Release Rate**	**Time to Ignition**	**Effective Heat of Combustion**
	kW/m^2	s	MJ/kg
PVC (vinyl)	190	36	9
Wood	220	34	15
Non FR Polypropylene	770	23	40
FR Polypropylene	200	60	25

It is possible to make properly flame retarded polypropylene and use it for siding because flame retarded polypropylene can easily be compounded so that it does not melt/drip and pass the requirements of a flame spread index of 200 in the ASTM E 84 test. In fact, the original proposal includes an ASTM E 84 test with an FR polypropylene material that gave a flame spread index of 50. Such a material should be permitted for use but not the unsafe material normally offered for sale.

The missing Figure from the proposal (that could also be found with proposal RB148) is found below. It shows what happens when normal non flame retarded polypropylene (the material that is used in siding) burns: it forms a pool fire. The photograph is not polypropylene siding but its component material.

Analysis: Public comments to FS143 and FS144 address new requirements for polypropylene siding. The membership needs to make their preference clear with respect to these provisions.

Final Action: AS AM AMPC____ D

FS144-09/10, Part I
1402 (New), 1404.8 (New), 1405.13 (New), Chapter 35

Proposed Change as Submitted

Proponent: Matthew Dobson, representing Vinyl Siding Institute

PART I – IBC FIRE SAFETY

1. Add new text as follows:

1402 DEFINITIONS

Polypropylene Siding. A shaped material made principally from polypropylene that is used to clad exterior walls covering.

2. Add new text as follows:

1404.8 Polypropylene Siding. Polypropylene siding shall conform to the requirements of ASTM D7254.

(Renumber subsequent sections)

3. Add new text as follows:

1405.13 Polypropylene Siding. Polypropylene siding conforming to the requirements of this section and complying with ASTM D7254 shall be permitted on exterior walls of buildings located in areas where the wind speed specified in Chapter 16 does not exceed 100 miles per hours (45m/s) and the building height is less than or equal to 40 feet (12 192 mm) in Exposure C. Where construction is located in areas where the basic wind speed exceed 100 mile per hour (45 m/s), or building heights are in excess of 40 feet (12 192 mm), tests or calculations indicating compliance with Chapter 16 shall be submitted. Polypropylene siding shall be secured to the building so as to provide weather protection for the exterior walls of the building.

1405.13.1 Application. The siding shall be applied over sheathing or materials listed in Section 2304.6. Siding shall be applied to conform with the weather-resistive barrier requirements in Section 1403. Siding and accessories shall be installed in accordance with approved manufacturer's instructions.

(Renumber subsequent sections)

4. Add new text to Chapter 35 standards as follows:

ASTM D7254 – 07 Standard Specification for Polypropylene (PP) Siding…1402, 1404.8, 1405.13

Reason: The purpose of this change is to assist code officials with the recognition of polypropylene (PP) siding. This product has reached a level of maturity including the establishment of an acceptance criterion through ES and an ASTM product standard. By providing this recognition in the code, building officials will be able to quickly reference the product and installation provisions.

Currently there is confusion in the market place between vinyl siding and PP siding. In many instances the PP siding is thought to be vinyl siding, this new language will help the code official to understand the requirements of the product established by ES and ASTM and what to enforce relative to its installation.

D7254 – 07 Standard Specification for Polypropylene (PP) Siding

The ASTM standard provides all necessary manufacturing tests and specifications to ensure the product meets the intent of the code from safety and welfare to wind performance. Included with this proposal are copies of the acceptance criteria and the ASTM standard D7254.

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: Code change proposal FS143 and FS144 address new requirements for polypropylene siding. The committee needs to make its intent clear with respect to these provisions. A review of the standard(s) proposed for inclusion in the code, ASTM D7254-07, for compliance with ICC criteria for referenced standards given in Section 3.6 of Council Policy #CP 28 will be posted on the ICC website on or before September 24, 2009.

ICCFILENAME: DOBSON-FS1-1404.8; RB2-202 PART II

Public Hearing Results

Note: The following analysis was not in the Code Change monograph but was published on the ICC website at http://www.iccsafe.org/cs/codes/Documents/2009-10cycle/ProposedChanges/Standards-Analysis.pdf :

Analysis: Review of the proposed new standard indicated that, in the opinion of ICC staff, the standard did comply with ICC standards criteria.

PART I- IBC FIRE SAFETY
Committee Action: Approved as modified

Modify the proposal as follows:

Polypropylene Siding. A shaped material, made principally from polypropylene homopolymer, or copolymer, which in some cases may contain fillers and/or reinforcements, that is used to clad exterior walls of buildings ~~covering~~.

1405.13 Polypropylene Siding. Polypropylene siding conforming to the requirements of this section and complying with ASTM D7254 shall be limited to ~~permitted on~~ exterior walls of Type VB construction ~~buildings~~ located in areas where the wind speed specified in Chapter 16 does not exceed 100 miles per hours (45m/s) and the building height is less than or equal to 40 feet (12 192 mm) in Exposure C. Where construction is located in areas where the basic wind speed exceed 100 mile per hour (45 m/s), or building heights are in excess of 40 feet (12 192 mm), tests or calculations indicating compliance with Chapter 16 shall be submitted. Polypropylene siding shall be secured to the building so as to provide weather protection for the exterior walls of the building.

(Portions of the proposal not shown remain unchanged)

Committee Reason: The committee agreed that ASTM D7254 was the appropriate material standard and appropriate installation requirements were provided. The modification created further consistency with the referenced standard and the current ICC ES Acceptance Criteria.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Matthew Dobson, Vinyl Siding Institute (VSI), requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

1405.13 Polypropylene Siding. Polypropylene siding conforming to the requirements of this section and complying with ASTM D7254 shall be limited to exterior walls of Type V~~B~~ construction, unless it has been tested in accordance with NFPA 268 and complies with section 1406.2 located in areas where the wind speed specified in Chapter 16 does not exceed 100 miles per hours (45m/s) and the building height is less than or equal to 40 feet (12 192 mm) in Exposure C. Where construction is located in areas where the basic wind speed exceed 100 mile per hour (45 m/s), or building heights are in excess of 40 feet (12 192 mm), tests or calculations indicating compliance with Chapter 16 shall be submitted. Polypropylene siding shall be secured to the building so as to provide weather protection for the exterior walls of the building.

(Portion of proposal not shown, remains unchanged.)

Commenter's Reason: The modifications to this proposal, which were accepted by the IBC FS committee, reflected what is currently in the acceptance criteria for polypropylene siding, AC366. In reviewing this issue further and after discussions with ICC-ES staff it was confirmed that the reference to Type VB in AC366 is an error and will be corrected, hopefully by these hearings. It was supposed to reference to Type V and was processed as an editorial fix to Type VB. Additionally we have added the referenced sections of the IBC that have to do with testing protocol necessary should the product be used with other types of construction. This change in language is also from AC366. This modification makes the code consistent with the products current acceptance criteria.

Analysis: Public comments to FS143 and FS144 address new requirements for polypropylene siding. The membership needs to make their preference clear with respect to these provisions.

Public Comment 2:

Sam Francis, American Wood Council/AF&PA, request Disapproval.

Polypropylene is a new combustible product designed for the exterior of buildings. Its fire performance in this intended application is unknown. Additionally, ASTM D7254 purports to provide fire regulation by requiring polypropylene siding to perform to a flame spread rating Class C per ASTM E84 the "Standard Test Method for Surface Burning Characteristics of Building Materials." However, the Scope E84 is limited to materials that do not melt and drip when heated. Polypropylene melts and drips when heated and thus not suitable for classifying in accordance with E84. A more appropriate test for evaluating exterior fire performance is ASTM E2707 "Standard Test Method for Determining Fire Penetration of Exterior Wall

Assemblies Using a Direct Flame Impingement Exposure." The proponents have not provided any E2707 technical data for polypropylene and other comparable siding for comparison.

Public Comment 3:

Marcelo M. Hirschler (GBH International), representing American Fire Safety Council, requests Disapproval.

When polypropylene siding is normally sold it is made with material that neither contains flame retardants nor contains any other additives that will prevent it from forming a pool fire as soon as it is exposed to a flame. Therefore, when polypropylene siding is exposed to the flame in the ASTM E 84 Steiner tunnel test it immediately starts melting and burning occurs in the floor of the tunnel, with no material left in the tunnel ceiling where the test sample should be. This material gets a low flame spread index (ASTM D 7254 requires a flame spread index under 200, just like for wood siding) but it is not a valid result because the material is no longer in the test position when the flame comes by. Therefore if polypropylene siding is made with typical polypropylene that has not been treated, the siding is a very dangerous product and polypropylene siding should not be allowed to be used based only on the requirements of ASTM D 7254.

It is also notable that the IRC-BE committee agreed that polypropylene siding should not be added to the IRC code but the IBC-FS committee supported its addition to the IBC code, where it would be allowed into more severe applications. This is not safe.

Polypropylene siding should only be approved if it meets some type of added fire safety requirements beyond those the industry incorporated into ASTM D 7254, for example as required by the public comments I submitted for RB148 (for the IRC) and by FS143 (for the IBC). If that level of safety cannot be required, the use of polypropylene siding should not be approved by the code.

The figure that follows shows what happens when normal non flame retarded polypropylene (the material that is used in siding) burns: it forms a pool fire. The photograph is not polypropylene siding but its component material.

Final Action: AS AM AMPC____ D

FS144-09/10, Part II
IRC R202, 703.13, 703.13.1, Chapter 44

Proposed Change as Submitted

Proponent: Matthew Dobson, representing Vinyl Siding Institute

1. Add new text as follows:

R202 DEFINITIONS

Polypropylene Siding. A shaped material made principally from polypropylene that is used to clad exterior walls covering.

2. Add new text as follows:

TABLE R703.4
WEATHER–RESISTANT SIDING ATTACHMENT AND MINIMUM THICKNESS

SIDING MATERIAL	NOMINAL THICKNESS[a] (inches)	JOINT TREATMENT	Water Resistive Barrier Required	Wood or wood structural panel sheathing	Fiberboard sheathing into stud	Gypsum sheathing into stud	Foam plastic sheathing into stud	Direct to studs	Number or spacing of fasteners
(NEW) Polypropylene Siding[x]	Varies	Lap	Yes	0.120 nail (shank) with a .313 head[y,z]	Not allowed[aa,bb]	Not allowed[aa,bb]	Not allowed[aa,bb]	Not allowed	As specified by the manufacturer instructions or test report

(Portions of table and footnotes not shown remain unchanged)

aa. Where the sheathing is applied directly over wood structural panels or other approved backing capable of independently resisting the design wind pressure, the polypropylene siding shall be installed in accordance with the manufacturer's installation instructions.

bb. Where the polypropylene siding manufacturer's product specifications provide an approved design wind pressure rating for installation over fiberboard, gypsum or foam plastic sheathing, use of this design wind pressure rating shall be permitted and the siding shall be installed in accordance with the manufacture's installation instructions.

3. Add new text as follows:

R703.13 Polypropylene Siding. Polypropylene siding shall comply with requirements of ASTM D 7254.

R703.13.1 Installation. Polypropylene siding shall be installed in accordance with the manufacturer's installation instructions.

4. Add new text to Chapter 44 standards as follows:

ASTM D7254 – 07 Standard Specification for Polypropylene (PP) Siding…Table R703.4, R703.13

Reason: The purpose of this change is to assist code officials with the recognition of polypropylene (PP) siding. This product has reached a level of maturity including the establishment of an acceptance criterion through ES and an ASTM product standard. By providing this recognition in the code, building officials will be able to quickly reference the product and installation provisions.

Currently there is confusion in the market place between vinyl siding and PP siding. In many instances the PP siding is thought to be vinyl siding, this new language will help the code official to understand the requirements of the product established by ES and ASTM and what to enforce relative to its installation.

D7254 – 07 Standard Specification for Polypropylene (PP) Siding

The ASTM standard provides all necessary manufacturing tests and specifications to ensure the product meets the intent of the code from safety and welfare to wind performance. Included with this proposal are copies of the acceptance criteria and the ASTM standard D7254.

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: Code change proposal FS143 and FS144 address new requirements for polypropylene siding. The committee needs to make its intent clear with respect to these provisions. A review of the standard(s) proposed for inclusion in the code, ASTM D7254-07, for compliance with ICC criteria for referenced standards given in Section 3.6 of Council Policy #CP 28 will be posted on the ICC website on or before September 24, 2009.

ICCFILENAME: DOBSON-FS1-1404.8; RB2-202 PART II

Public Hearing Results

Note: The following analysis was not in the Code Change monograph but was published on the ICC website at http://www.iccsafe.org/cs/codes/Documents/2009-10cycle/ProposedChanges/Standards-Analysis.pdf :

Analysis: Review of the proposed new standard indicated that, in the opinion of ICC staff, the standard did comply with ICC standards criteria.

PART II - IRC
Committee Action: Disapproved

Committee Reason: Based on the committee's previous action on RB148-09/10. Also, this material is not permitted in the IBC.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Matthew Dobson, Vinyl Siding Institute Inc (VSI), requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

Polypropylene Siding. A shaped material, made principally from polypropylene homopolymer, or copolymer, which in some cases may contain fillers and/or reinforcements, that is used to clad exterior walls of buildings ~~covering~~.

Table R703.4
WEATHER–RESISTANT SIDING ATTACHMENT AND MINIMUM THICKNESS

SIDING MATERIAL	NOMINAL THICKNESS[a] (inches)	JOINT TREATMENT	Water Resistive Barrier Required	Wood or wood structural panel sheathing	Fiberboard sheathing into stud	Gypsum sheathing into stud	Foam plastic sheathing into stud	Direct to studs	Number or spacing of fasteners
(NEW) Polypropylene Siding[x]	Varies	Lap	Yes	Min. Nom. 0.120 nail (shank) with a .313 head[y,z]	Not allowed[aa,bb]	Not allowed[aa,bb]	Not allowed[aa,bb]	Not allowed	As specified by the manufacturer instructions or test report

aa. Where the sheathing is applied directly over wood structural panels or other approved backing capable of independently resisting the design wind pressure, the polypropylene siding shall be installed in accordance with the manufacturer's installation instructions.

bb. 703.13 Polypropylene Siding. Polypropylene siding shall comply with requirements of ASTM D 7254.

703.13.1 Installation. Polypropylene siding shall be installed in accordance with the manufacturer's installation instructions.

CHAPTER 44

ASTM D7254 – 07 Standard Specification for Polypropylene (PP) Siding…Table R703.4, R703.13

Commenter's Reason: The companion version of this proposal was accepted by the IBC Fire Safety Committee (see FS144 Part I). One of the reasons the IRC Building/Energy Committee did not accept the proposal is because the provision is not currently in the IBC. The IBC Fire Safety committee has accepted this proposal for the IBC so it is logical to have the similar provision placed in the IRC.

This change will help code officials understand how to identify the difference between vinyl siding and polypropylene siding by using the established ASTM standard as criteria for acceptance in the IRC and IBC. Currently polypropylene siding is recognized through the established acceptance criteria which includes the ASTM standard and will continue to be in the future.

By recognizing polypropylene siding in both the IRC and IBC building officials will be able to easily determine when polypropylene siding is allowed and when it is not allowed. For example in higher density settings when lot-line requirements and fire rated assemblies are applied in section R302 of the IRC, polypropylene siding would not be allowed where vinyl siding is allowed.

This change will make buildings safer and give building and fire officials a clearer understanding of how the products are different and should be regulated differently.

Public Comment 2:

Marcelo M. Hirschler (GBH International), representing American Fire Safety Council, requests Disapproval.

When polypropylene siding is normally sold it is made with material that neither contains flame retardants nor contains any other additives that will prevent it from forming a pool fire as soon as it is exposed to a flame. Therefore, when polypropylene siding is exposed to the flame in the ASTM E 84 Steiner tunnel test it immediately starts melting and burning occurs in the floor of the tunnel, with no material left in the tunnel ceiling where the test sample should be. This material gets a low flame spread index (ASTM D 7254 requires a flame spread index under 200, just like for wood siding) but it is not a valid result because the material is no longer in the test position when the flame comes by. Therefore if polypropylene siding is made with typical polypropylene that has not been treated, the siding is a very dangerous product and polypropylene siding should not be allowed to be used based only on the requirements of ASTM D 7254.

It is also notable that the IRC-BE committee agreed that polypropylene siding should not be added to the IRC code but the IBC-FS committee supported its addition to the IBC code, where it would be allowed into more severe applications. This is not safe.

Polypropylene siding should only be approved if it meets some type of added fire safety requirements beyond those the industry incorporated into ASTM D 7254, for example as required by the public comments I submitted for RB148 (for the IRC) and by FS143 (for the IBC). If that level of safety cannot be required, the use of polypropylene siding should not be approved by the code.

The figure that follows shows what happens when normal non flame retarded polypropylene (the material that is used in siding) burns: it forms a pool fire. The photograph is not polypropylene siding but its component material.

Final Action: AS AM AMPC____ D

FS145-09/10
1402 (New), 1404.13 (New), Table 1405.2, 1405.10.2 (New)

Proposed Change as Submitted

Proponent: Olene Bigelow, representing International Masonry Institute

1. Add new text as follows:

1402 DEFINITIONS

COMPOSITE NATURAL STONE. A veneer consisting of natural stone laminated to, or combined with, other like units to form a larger unit, or to dissimilar materials to form a cladding to be anchored or adhered to an approved substrate.

2. Add new text as follows:

1404.13 Porcelain Tile. Porcelain tile shall conform to the requirements of ANSI 137.1.3 for ceramic tile having an absorption of 0.5% or less according to ANSI 137.4.1 – Class Table and ANSI 137.1.6.1 Allowable Properties by Tile Type – Table 10.

3. Revise as follows:

TABLE 1405.2
MINIMUM THICKNESS OF WEATHER COVERINGS

Covering Type	Minimum Thickness (Inches)
Porcelain Tile	0.25
Composite Natural Stone	0.50

(Portions of table not shown remain unchanged)

4. Add new text as follows:

1405.10.2 Exterior adhered masonry veneers - porcelain tile and composite natural stone. Adhered units shall not exceed 5/8" thickness and a maximum of 24" in any face dimension nor more than 3 square feet in total face area and shall not weigh more than 9 pounds per square foot. Porcelain tile and composite natural stone shall be adhered to an approved backing system.

Reason: There is currently no definition for composite natural stone in the IBC. This proposal would add that definition. Currently, there is no definition for porcelain tile in the IBC. As one of myriad types of ceramic tile, its unique characteristics and extremely low absorption rate requires it be dealt with differently from other materials, especially when applied as an exterior adhered veneer. These materials are relatively new in exterior applications and fall outside the scope of TMS 402/ACI 530/ASCE 6. With no specific code requirements found in IBC, installations of these materials are being found inadequate and some significant failures have occurred. See attached photographs. When these units and/or their adhesion system fail, for whatever ultimate reason, public safety is put at risk.

Here, only a few units have fallen, so far. No mechanical attachment.

Another project: Upon stripping the façade, it appears an attempt was made to “anchor” the units, but it was clearly unsuccessful

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: Standards ANSI A137 are currently referenced in the I-codes.

Public Hearing Results

Committee Action: Disapproved

Committee Reason: The committee was concerned about the disposition of the referenced standard, ANSI 137. Further, the committee felt the proposal should be limited to porcelain tiles only and suggests the proponent bring the change back for final action with the approved standard and the suggested revisions.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Olene Bigelow, representing International Masonry Institute, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

1402 DEFINITIONS

~~**COMPOSITE NATURAL STONE.** A veneer consisting of natural stone laminated to, or combined with, other like units to form a larger unit, or to dissimilar materials to form a cladding to be anchored or adhered to an approved substrate.~~

~~**1404.13 Porcelain Tile.**~~ **PORCELAIN TILE.** Porcelain tile shall conform to the requirements of ANSI 137.1.3 for ceramic tile having an absorption of 0.5% or less according to ANSI 137.4.1 – Class Table and ANSI 137.1.6.1 Allowable Properties by Tile Type – Table 10.

TABLE 1405.2
MINIMUM THICKNESS OF WEATHER COVERINGS

Covering Type	Minimum Thickness (Inches)
Porcelain Tile	0.25
~~Composite Natural Stone~~	~~0.50~~

(Portions of table not shown remain unchanged)

1405.10.2 Exterior adhered masonry veneers - porcelain tile ~~and composite natural stone~~. Adhered units shall not exceed 5/8" thickness and a maximum of 24" in any face dimension nor more than 3 square feet in total face area and shall not weigh more than 9 pounds per square foot. Porcelain tile ~~and composite natural stone~~ shall be adhered to an approved backing system.

Commenter's Reason: Currently, there is no definition for porcelain tile in the IBC. As one of myriad types of ceramic tile, its unique characteristics and extremely low absorption rate requires it be dealt with differently from other materials, especially when applied as an exterior adhered veneer. These materials are relatively new in exterior applications and fall outside the scope of TMS 402/ACI 530/ASCE 6. With no specific code requirements found in IBC, installations of these materials are being found inadequate and some significant failures have occurred. Since no code provisions exist to cover these exterior applications, installers are sometimes using the same setting materials that are used for interior applications, which is inappropriate in most cases. When these units and/or their adhesion system fail, for whatever ultimate reason, public safety is put at risk.

In response to the committee's request, the proposal as submitted for final action is limited to porcelain tile only. Further, as requested by the committee, two printed and two digital copies of the referenced standard in question, ANSI 137.1 – 2008 edition have been forwarded to ICC staff.

Final Action: AS AM AMPC____ D

FS149-09/10
1405.7

Proposed Change as Submitted

Proponent: Gary J. Ehrlich, PE, representing National Association of Home Builders

Revise as follows:

1405.7 Stone veneer. Stone veneer units not exceeding 10 inches (254 mm) in thickness shall be anchored directly to masonry, concrete or to stud construction by one of the following methods:

1. *(No change to current text)*
2. With <u>wood</u> stud backing, a 2-inch by 2-inch (51 by 51 mm) 0.0625-inch (1.59 mm) corrosion-resistant wire mesh with two layers of water-resistive barrier in accordance with Section 1404.2 shall be applied directly to wood studs spaced a maximum of 16 inches (406 mm) o.c. On studs, the mesh shall be attached with 2-inch-long (51 mm) corrosion-resistant steel wire furring nails at 4 inches (102 mm) o.c. providing a minimum 1.125-inch (29 mm) penetration into each stud and with 8d common nails at 8 inches (203 mm) o.c. into top and bottom plates or with equivalent wire ties. There shall be not less than a 0.1055-inch (2.68 mm) corrosion-resistant wire, or approved equal, looped through the mesh for every 2 square feet (0.2 m2) of stone veneer. This tie shall be a loop having legs not less than 15 inches (381 mm) in length, so bent that it will lie in the

stone veneer mortar joint. The last 2 inches (51 mm) of each wire leg shall have a right-angle bend. One-inch (25 mm) minimum thickness of cement grout shall be placed between the backing and the stone veneer.

3. With cold-formed steel stud backing, a 2-inch by 2-inch (51 by 51 mm) 0.0625-inch (1.59 mm) corrosion-resistant wire mesh with two layers of water-resistive barrier in accordance with Section 1404.2 shall be applied directly to steel studs spaced a maximum of 16 inches (406 mm) o.c. The mesh shall be attached with 2-inch-long (51 mm) corrosion-resistant #8 self-drilling, tapping screws at 4 inches (102 mm) o.c. providing a minimum 0.5-inch (12.7 mm) penetration into each stud, and at 8 inches (203 mm) o.c. into top and bottom tracks or with equivalent wire ties. There shall be not less than a 0.1055-inch (2.68 mm) corrosion-resistant wire, or approved equal, looped through the mesh for every 2 square feet (0.2 m2) of stone veneer. This tie shall be a loop having legs not less than 15 inches (381 mm) in length, so bent that it will lie in the stone veneer mortar joint. The last 2 inches (51 mm) of each wire leg shall have a right-angle bend. One-inch (25 mm) minimum thickness of cement grout shall be placed between the backing and the stone veneer. The cold-formed steel framing members shall have a minimum uncoated thickness of 0,043 inches (1.09 mm).

Reason: The purpose of this proposal is to provide guidance for stone veneer anchored to cold-formed steel stud backing. The current language only addresses wood studs, leaving attachment to cold-formed steel stud backing as an alternate means and methods. The language mirrors the wood stud language, with appropriate revisions based on ICC-ES stone veneer reports and BIA Technical Note 28B on Brick Veneer/Steel Stud Walls.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: Ehrlich-FS1-1405 7

Public Hearing Results

Committee Action: **Approved as Modified**

Modify the proposal as follows:

1405.7 Stone veneer. Stone veneer units not exceeding 10 inches (254 mm) in thickness shall be anchored directly to masonry, concrete or to stud construction by one of the following methods:

1. *(No change to current text)*
2. With wood stud backing, a 2-inch by 2-inch (51 by 51 mm) 0.0625-inch (1.59 mm) corrosion-resistant wire mesh with two layers of water-resistive barrier in accordance with Section 1404.2 shall be applied directly to wood studs spaced a maximum of 16 inches (406 mm) o.c. On studs, the mesh shall be attached with 2-inch-long (51 mm) corrosion-resistant steel wire furring nails at 4 inches (102 mm) o.c. providing a minimum 1.125-inch (29 mm) penetration into each stud and with 8d common nails at 8 inches (203 mm) o.c. into top and bottom plates or with equivalent wire ties. There shall be not less than a 0.1055-inch (2.68 mm) corrosion-resistant wire, or approved equal, looped through the mesh for every 2 square feet (0.2 m2) of stone veneer. This tie shall be a loop having legs not less than 15 inches (381 mm) in length, so bent that it will lie in the stone veneer mortar joint. The last 2 inches (51 mm) of each wire leg shall have a right-angle bend. One-inch (25 mm) minimum thickness of cement grout shall be placed between the backing and the stone veneer.
3. With cold-formed steel stud backing, a 2-inch by 2-inch (51 by 51 mm) 0.0625-inch (1.59 mm) ~~corrosion-resistant~~ zinc-coated or non-metallic coated wire mesh with two layers of water-resistive barrier in accordance with Section 1404.2 shall be applied directly to steel studs spaced a maximum of 16 inches (406 mm) o.c. The mesh shall be attached with ~~2-inch-long (51 mm)~~ corrosion-resistant #8 self-drilling, tapping screws at 4 inches (102 mm) o.c. ~~providing a minimum 0.5-inch (12.7 mm) penetration into each stud~~, and at 8 inches (203 mm) o.c. into top and bottom tracks or with equivalent wire ties. All screws shall extend through the steel connection a minimum of three exposed threads. There shall be not less than a 0.1055-inch (2.68 mm) ~~corrosion-resistant~~ zinc-coated or non-metallic coated wire, or approved equal, looped through the mesh for every 2 square feet (0.2 m2) of stone veneer. This tie shall be a loop having legs not less than 15 inches (381 mm) in length, so bent that it will lie in the stone veneer mortar joint. The last 2 inches (51 mm) of each wire leg shall have a right-angle bend. One-inch (25 mm) minimum thickness of cement grout shall be placed between the backing and the stone veneer. The cold-formed steel framing members shall have a minimum ~~uncoated~~ bare steel thickness of 0.0428~~3~~ inches (1.087~~9~~ mm).

Committee Reason: This proposal provides a reasonable extension of stone veneer to steel studs in Section 1405.7, item 3. It also clarifies that current item 2 is specifically applicable for anchoring to wood studs. The modification substitutes wording in item 3 that is more in line with common steel industry terminology. The addition of appropriate steel stud requirements exposes problems with the current wood stud requirement (item 2) that should be addressed by a public comment.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Gary J. Ehrlich, PE, representing National Association of Home Builders (NAHB), requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

1405.6 Stone veneer. Stone veneer units not exceeding 10 inches (254 mm) in thickness shall be anchored directly to masonry, concrete or to stud construction by one of the following methods:

1. *(No change to current text)*
2. With wood stud backing, a 2-inch by 2-inch (51 by 51 mm) 0.0625-inch (1.59 mm) zinc-coated or non-metallic coated ~~corrosion-resistant~~ wire mesh with two layers of water-resistive barrier in accordance with Section 1404.2 shall be applied directly to wood studs spaced a maximum of 16 inches (406 mm) o.c. On studs, the mesh shall be attached with 2-inch-long (51 mm) corrosion-resistant steel wire furring nails at 4 inches (102 mm) o.c. providing a minimum 1.125-inch (29 mm) penetration into each stud and with 8d common nails at 8 inches (203 mm) o.c. into top and bottom plates or with equivalent wire ties. There shall be not less than a 0.1055-inch (2.68 mm) zinc-coated or non-metallic coated ~~corrosion-resistant~~ wire, or approved equal, ~~looped through the mesh~~ attached to the stud with 8d annular threaded nails 0.113 inches in diameter (2.807 mm) minimum for every 2 square feet (0.2 m2) of stone veneer. This tie shall be a loop having legs not less than 15 inches (381 mm) in length, so bent that it will lie in the stone veneer mortar joint. The last 2 inches (51 mm) of each wire leg shall have a right-angle bend. One-inch (25 mm) minimum thickness of cement grout shall be placed between the backing and the stone veneer.
3. With cold-formed steel stud backing, a 2-inch by 2-inch (51 by 51 mm) 0.0625-inch (1.59 mm) zinc-coated or non-metallic coated wire mesh with two layers of water-resistive barrier in accordance with Section 1404.2 shall be applied directly to steel studs spaced a maximum of 16 inches (406 mm) o.c. The mesh shall be attached with corrosion-resistant #8 self-drilling, tapping screws at 4 inches (102 mm) o.c., and at 8 inches (203 mm) o.c. into top and bottom tracks or with equivalent wire ties. All screws shall extend through the steel connection a minimum of three exposed threads. There shall be not less than a 0.1055-inch (2.68 mm) zinc-coated or non-metallic coated wire, or approved equal, ~~looped through the mesh~~ attached to the stud with corrosion-resistant #8 self-drilling, tapping screws for every 2 square feet (0.2 m2) of stone veneer. This tie shall be a loop having legs not less than 15 inches (381 mm) in length, so bent that it will lie in the stone veneer mortar joint. The last 2 inches (51 mm) of each wire leg shall have a right-angle bend. One-inch (25 mm) minimum thickness of cement grout shall be placed between the backing and the stone veneer. The cold-formed steel framing members shall have a minimum bare steel thickness of 0.0428 inches (1.087 mm).

Commenter's Reason: The purpose of this public comment is to correlate the stone veneer attachment provisions for wood and cold-formed steel studs and provide further technical improvements. The language for corrosion-resistant mesh and wire under the wood stud section is amended to match the change to zinc- or non-metallic coated mesh and wire made by a Steel Framing Alliance floor modification. Also, at the request of the seismic engineering community, the requirements for the stone tie are changed to require the tie be attached directly to the studs. This is a significantly more stable connection than attaching the tie just to the mesh.

Public Comment 2:

Steven Winkel, FAIA, PE; J. Daniel Dolan, PhD, PE, representing the Federal Emergency Management Agency/Building Seismic Safety Council Code Resource Support Committee (FEMA/BSSC CRSC), requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

1405.7 Stone veneer. Stone veneer units not exceeding 10 inches (254 mm) in thickness shall be anchored directly to masonry, concrete or to stud construction by one of the following methods:

1. *(No change to current text)*
2. With wood stud backing, a 2-inch by 2-inch (51 by 51 mm) 0.0625-inch (1.59 mm) corrosion-resistant wire mesh with two layers of water-resistive barrier in accordance with Section 1404.2 shall be applied directly to wood studs spaced a maximum of 16 inches (406 mm) o.c. On studs, the mesh shall be attached with 2-inch long (51 mm) corrosion-resistant steel wire furring nails at 4 inches (102 mm) o.c. providing a minimum 1.125-inch (29 mm) penetration into each stud and with 8d ~~common~~ annular threaded nails at 8 inches (203 mm) o.c. into top and bottom plates or with equivalent wire ties. There shall be not less than a 0.1055-inch (2.68 mm) corrosion-resistant wire, or approved equal, ~~looped through the mesh~~ attached to the stud with a minimum of a 8d (0.131 in. diameter) annular threaded nail for every 2 square feet (0.2 m^2) of stone veneer. This tie shall be a loop having legs not less than 15 inches (381 mm) in length, so bent that it will lie in the stone veneer mortar joint. The last 2 inches (51 mm) of each wire leg shall have a right-angle bend. One-inch (25 mm) minimum thickness of cement grout shall be placed between the backing and the stone veneer.
3. With cold-formed steel stud backing, a 2-inch by 2-inch (51 by 51 mm) 0.0625-inch (1.59 mm) zinc-coated or non-metallic coated wire mesh with two layers of water-resistive barrier in accordance with Section 1404.2 shall be applied directly to steel studs spaced a maximum of 16 inches (406 mm) o.c. The mesh shall be attached with corrosion-resistant #8 self-drilling, tapping screws at 4 inches (102 mm) o.c., and at 8 inches (203 mm) o.c. into top and bottom tracks or with equivalent wire ties. All screws shall extend through the steel connection a minimum of three exposed threads. There shall be not less than a 0.1055-inch (2.68 mm) corrosion-resistant wire, or approved equal, ~~looped through the mesh~~ attached to the stud with a minimum of a #8 self-drilling, tapping screw extending through the steel framing a minimum of three exposed threads for every 2 square feet (0.2 m2) of stone veneer. This tie shall be a loop having legs not less than 15 inches (381 mm) in length, so bent that it will lie in the stone veneer mortar joint. The last 2 inches (51 mm) of each wire leg

shall have a right-angle bend. One-inch (25 mm) minimum thickness of cement grout shall be placed between the backing and the stone veneer. The cold-formed steel framing members shall have a minimum base steel thickness of 0.0428 inches (1.087 mm).

Commenter's Reason Statement: The modification is proposed for two reasons:

1. In order for the ties between the structural framing and the stone masonry veneer to function properly, they need to be attached to the wall framing (studs). As the two requirements are currently written, the ties (wires) can simply be looped through a steel mesh that is attached to the studs. The wire mesh has too much flexibility to effectively hold the stone in place and, therefore, this modification is submitted to require that the wires or ties be directly attached to the studs.
2. Recent shake table testing at the University of California at San Diego showed that smooth shank nails did not perform satisfactorily when used in withdrawal to hold masonry veneer on a wood light-frame wall system. The nails withdrew from the framing at accelerations below the design load. The requirement that annular threaded (ring-shank) nails be used will correct this problem because of their increased withdrawal strength and lower sensitivity to moisture changes.

Final Action: AS AM AMPC____ D

FS150-09/10, Part I
1405.10.2 (New), 1405.10.2.1 (New), 1405.10.2.2 (New), 1405.10.2.3 (New)

Proposed Change as Submitted

Proponent: John Woestman, The Kellen Company, Representing the Masonry Veneer Manufacturers Association (MVMA)

PART I – IBC FIRE SAFETY

Add new text as follows:

1405.10 Adhered masonry veneer. Adhered masonry veneer shall comply with the applicable requirements in Section 1405.10.1 and Sections 6.1 and 6.3 of TMS 402/ACI 530/ASCE 5.

1405.10.1 Interior adhered masonry veneers. Interior adhered masonry veneers shall have a maximum weight of 20 psf (0.958 kg/m2) and shall be installed in accordance with Section 1405.10. Where the interior adhered masonry veneer is supported by wood construction, the supporting members shall be designed to limit deflection to 1/600 of the span of the supporting members.

1405.10.2 Exterior adhered masonry veneer. Exterior adhered masonry veneer shall be in accordance with section 1405.10

1405.10.2.1 Water-resistive barriers. Water-resistive barriers shall be installed as required in Section 1404.2 and, where applied over wood-based sheathing, shall include a water-resistive vapor-permeable barrier with a performance at least equivalent to two layers of Grade D paper.

> **Exception:** Where the water-resistive barrier that is applied over wood-based sheathing has a water resistance equal to or greater than that of 60-minute Grade D paper and is separated from the adhered masonry veneer by an intervening, substantially nonwater-absorbing layer or drainage space.

1405.10.2.2 Flashing at foundation. A corrosion-resistant screed or flashing of a minimum 0.019-inch (0.48 mm) or 26 gage galvanized or plastic with a minimum vertical attachment flange of 3 ½ inches (89 mm) shall be installed a minimum of 1 inch (25 mm) below the foundation plate line on exterior stud walls in accordance with Section 1405.4 to direct moisture to the exterior. The water-resistive barrier shall lap over the exterior of the attachment flange of the screed or flashing.

1405.10.2.3 Installation. Adhered masonry veneer shall be installed in accordance with the manufacturer's instructions..

Reason:
PART I-The added section for exterior adhered masonry veneer compliments the existing section for interior adhered masonry veneer.

The proposed language for water-resistive barriers is modeled after similar requirements for stucco (section 2510.6).

The proposed language for flashing at the foundation is similar to the weep screed requirements for stucco and compliments the performance requirements of section 1405.4 Flashing (*Flashing shall be installed in such a manner so as to prevent moisture from entering the wall or to redirect it to the exterior . . . . .*) while at the same time allowing for alternates to the stucco-specific weep screed.

Adhered masonry veneer manufacturers require their products to be installed per their instructions and the building code should support this requirement with enforceable language.

Cost Impact: The code change proposal will not increase the cost of construction

ICCFILENAME: WOESTMAN -FS3-1410.2 PART I AND WOESTMAN-RB2-703.12.1 PART II

Public Hearing Results

PART I- IBC FIRE SAFETY
Committee Action: Disapproved

Committee Reason: The committee felt that the proposal was confusing because of the circular code references. Reference back to 1405.10 does not get the code user forward to the subsection of 1405.10.2.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

John Woestman, Kellen Company, representing Masonry Veneer Manufacturers Association (MVMA), requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

1405.10 Adhered masonry veneer. Adhered masonry veneer shall comply with the applicable requirements in Section 1405.10~~.1~~ and Sections 6.1 and 6.3 of TMS 402/ACI 530/ASCE 5.

1405.10.~~2~~1 Exterior adhered masonry veneer. Exterior adhered masonry veneer shall be installed in accordance with section 1405.10 and in accordance with the manufacturer's instructions.

1405.10.~~2~~1.1 Water-resistive barriers. Water-resistive barriers shall be installed as required in Section ~~1404.2~~ 2510.6. ~~and, where applied over wood-based sheathing, shall include a water-resistive vapor-permeable barrier with a performance at least equivalent to two layers of Grade D paper.~~

> ~~**Exception:** Where the water-resistive barrier that is applied over wood-based sheathing has a water resistance equal to or greater than that of 60-minute Grade D paper and is separated from the adhered masonry veneer by an intervening, substantially nonwater-absorbing layer or drainage space.~~

1405.10.~~2~~1.2 Flashing at foundation. A corrosion-resistant screed or flashing of a minimum 0.019-inch (0.48 mm) or 26 gauge galvanized or plastic with a minimum vertical attachment flange of 3 1/2 inches (89 mm) shall be installed to extend a minimum of 1 inch (25 mm) below the foundation plate line on exterior stud walls in accordance with Section 1405.4 ~~to direct moisture to the exterior~~. The water-resistive barrier shall lap over the exterior of the attachment flange of the screed or flashing.

1405.10.~~1~~2 Interior adhered masonry veneers. Interior adhered masonry veneers shall have a maximum weight of 20 psf (0.958 kg/m2) and shall be installed in accordance with Section 1405.10. Where the interior adhered masonry veneer is supported by wood construction, the supporting members shall be designed to limit deflection to 1/600 of the span of the supporting members.

Commenter's Reason: This public comment addresses comments at the committee hearings last fall. The section numbering has been revised. Requirements for exterior adhered masonry veneer are placed ahead of existing requirements for interior adhered masonry veneer because code requirements for exterior adhered masonry veneer are expected to be needed more often.

Adhered masonry veneer manufacturers require their products to be installed per their instructions (which complement building code requirements) and the building code should support the requirement to be installed consistent with the manufacturer's instructions with enforceable language.

Requirements for water-resistive barriers are revised to refer to Section 2510.6 (stucco) instead of copying that text to this section of the code. Wall preparation for stucco and for exterior adhered masonry veneer is very similar (flashing, WRB, lath, scratch coat . . .) and referring to Section 2510.6 helps with consistency in the code for WRB requirements.

The proposed language for flashing at the foundation is similar to the flashing at foundation / weep screed requirements for stucco and compliments the performance requirements of Section 1405.4 Flashing (*Flashing shall be installed in such a manner so as to prevent moisture from entering the wall or to redirect it to the exterior . . . . . .*) while at the same time allowing for alternates to the stucco-specific weep screed.

Final Action: AS AM AMPC____ D

FS150-09/10, Part II
IRC R703.12.1 (New)

Proposed Change as Submitted

Proponent: John Woestman, The Kellen Company, Representing the Masonry Veneer Manufacturers Association (MVMA)

PART II – IRC BUILDING/ENERGY

Add new text as follows:

R703.12 Adhered masonry veneer installation. Adhered masonry veneer shall be installed in accordance with the manufacturer's instructions.

<u>**R703.12.1 Flashing at foundation.** A corrosion-resistant screed or flashing of a minimum 0.019-inch (0.48 mm) or 26 gage galvanized or plastic with a minimum vertical attachment flange of 3 ½ inches (89 mm) shall be installed a minimum of 1 inch (25 mm) below the foundation plate line on exterior stud walls in accordance with Section R703.8 to direct moisture to the exterior. The water-resistive barrier, as required by Table R703.4 Footnote w, shall lap over the exterior of the attachment flange of the screed or flashing.</u>

Reason:
PART II- The proposed language for flashing at the foundation is similar to the weep screed requirements for stucco and compliments the flashing performance requirements of section R703.8 Flashing (*Approved* corrosion-resistant flashing shall be applied shingle-fashion in a manner to prevent entry of water into the wall cavity or penetration of water to the building structural framing components . . . .) while at the same time allowing for effective alternates to the stucco-specific weep screed.

Cost Impact: The code change proposal will not increase the cost of construction

ICCFILENAME: WOESTMAN -FS3-1410.2 PART I AND WOESTMAN-RB2-703.12.1 PART II

Public Hearing Results

PART II - IRC
Committee Action: **Approved as Submitted**

Committee Reason: This change provides a prescriptive method for flashing or weep screeds for adhered masonry veneer. The committee suggests the proponent improve the language to clarify where the flashing should start, above or below the plate.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

John Woestman, Kellen Company, representing Masonry Veneer Manufacturers Association (MVMA), requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R703.12 Adhered masonry veneer installation. Adhered masonry veneer shall be installed in accordance with the manufacturer's instructions.

R703.12.1 Flashing at foundation. A corrosion-resistant screed or flashing of a minimum 0.019-inch (0.48 mm) or 26 gage galvanized or plastic with a minimum vertical attachment flange of 3 1/2 inches (89 mm) shall be installed <u>to extend</u> a minimum of 1 inch (25 mm) below the foundation plate line on exterior stud walls in accordance with Section R703.8 ~~to direct moisture to the exterior~~. The water-resistive barrier, as required by Table R703.4 Footnote w, shall lap over the exterior of the attachment flange of the screed or flashing.

Commenter's Reason: This public comment addresses the committee suggestion to clarify where the flashing should be placed.
In addition, this public comment addresses concerns shared with MVMA members regarding the proposed language. Installing flashing in accordance with Section R703.8 requires flashing to "extend to the surface of the exterior wall finish" and requires flashing to "prevent entry of water into the wall cavity or penetration of water to the building structural framing components." The text proposed to be deleted is redundant.

Final Action: AS AM AMPC____ D

FS151-09/10, Part I
1405.10.2 (New), 1405.2.1 (New)

Proposed Change as Submitted

Proponent: John Woestman, The Kellen Company, Representing the Masonry Veneer Manufacturers Association (MVMA)

PART I – IBC FIRE SAFETY

Add new text as follows:

1405.10 Adhered masonry veneer. Adhered masonry veneer shall comply with the applicable requirements in Section 1405.10.1 and Sections 6.1 and 6.3 of TMS 402/ACI 530/ASCE 5.

1405.10.1 Interior adhered masonry veneers. Interior adhered masonry veneers shall have a maximum weight of 20 psf (0.958 kg/m2) and shall be installed in accordance with Section 1405.10. Where the interior adhered masonry veneer is supported by wood construction, the supporting members shall be designed to limit deflection to 1/600 of the span of the supporting members.

<u>**1405.10.2 Exterior adhered masonry veneer**. Exterior adhered masonry veneer shall be in accordance with section 1405.10</u>

<u>**1405.10.2.1 Clearances.** Adhered masonry veneer shall be installed a minimum of 4 inches (102 mm) above the earth or 2 inches (51 mm) above paved areas or ½ inch (12 mm) above exterior walking surfaces supported by the same foundation which supports the exterior wall.</u>

Reason:
PART I: The added section for exterior adhered masonry veneer compliments the existing section for interior adhered masonry veneer.
The clearance requirements are consistent with stucco applications and go one step further by specifying a minimum of ½" clearance to exterior walking surfaces which are supported by the same foundation that supports the wall to which the exterior veneer is adhered. The proposed requirement that both the wall and the walking surface be supported by the same foundation, along with existing IBC flashing performance requirements of section 1405.4 for exterior wall intersections with porches, decks, balconies, and similar architectural features, limits this ½" clearance to building elements stable to each other and required to be flashed to manage water. This ½" clearance requirement allows for architectural and aesthetic improvements in the installation of adhered masonry veneer.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: WOESTMAN -FS4-1410.2 PART I AND WOESTMAN-RB3-R703.12.1 PART II

Public Hearing Results

PART I- IBC FIRE SAFETY
Committee Action: Disapproved

Committee Reason: The committee felt that the proposal was confusing because of the circular code references. Reference back to 1405.10 does not get the code user forward to the subsection of 1405.10.2.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

John Woestman, Kellen Company, representing Masonry Veneer Manufacturers Association (MVMA), requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

1405.10 Adhered masonry veneer. Adhered masonry veneer shall comply with the applicable requirements in Section 1405.10~~.1~~ and Sections 6.1 and 6.3 of TMS 402/ACI 530/ASCE 5.

1405.10.~~2~~1 Exterior adhered masonry veneer. Exterior adhered masonry veneer shall be installed in accordance with section 1405.10 and in accordance with the manufacturer's instructions.

1405.10.~~2~~1.1 Clearances. On exterior stud walls, adhered masonry veneer shall be installed a minimum of 4 inches (102 mm) above the earth, or a minimum of 2 inches (51 mm) above paved areas, or a minimum of 1/2 inch (12 mm) above exterior walking surfaces which are supported by the same foundation ~~which~~ that supports the exterior wall.

1405.10.~~1~~2 Interior adhered masonry veneers. Interior adhered masonry veneers shall have a maximum weight of 20 psf (0.958 kg/m2) and shall be installed in accordance with Section 1405.10 and the manufacturer's instructions. Where the interior adhered masonry veneer is supported by wood construction, the supporting members shall be designed to limit deflection to 1/600 of the span of the supporting members.

Commenter's Reason: This public comment follows the format proposed in FS150 Part I which addresses the committee comments of a circular code reference.

Also, the "clearances" text is revised to clarify the requirements are for exterior stud walls. The clearance requirements are consistent with stucco applications and go one step further by specifying a minimum of ½" clearance to exterior walking surfaces which are supported by the same foundation that supports the wall to which the exterior veneer is adhered. The proposed requirement that both the wall and the walking surface be supported by the same foundation, along with existing IBC flashing performance requirements of section 1405.4 for exterior wall intersections with porches, decks, balconies, and similar architectural features, limits this ½" clearance to building elements stable to each other and required to be flashed to manage water. This ½" clearance requirement allows for architectural and aesthetic improvements in the installation of adhered masonry veneer.

Final Action: AS AM AMPC____ D

Public Hearing Results

PART II- IRC B/E
Committee Action: **Disapproved**

Committee Reason: The committee feels this is a good start but the list needs to be reworked so that the application is clear. The list should appear as numbered items as is done in other sections of the code. The proponent should rework this and bring it back.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

John Woestman, Kellen Company, representing Masonry Veneer Manufacturers Association (MVMA), requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R703.12 Adhered masonry veneer installation. Adhered masonry veneer shall be installed in accordance with the manufacturer's instructions.

R703.12.1 Clearances. <u>On exterior stud walls,</u> ~~A~~<u>a</u>dhered masonry veneer shall be installed

<u>1.</u> ~~a m~~<u>M</u>inimum of 4 inches (102 mm) above the earth, or
<u>2.</u> <u>Minimum of</u> 2 inches (51 mm) above paved areas, or
<u>3.</u> <u>Minimum of</u> 1/2 inch (12 mm) above exterior walking surfaces <u>which are</u> supported by the same foundation ~~which~~ <u>that</u> supports the exterior wall.

Commenter's Reason: This public comment addresses the committee recommendation to list the proposed requirements as numbered items.

This proposal also clarifies the proposed requirements are applicable to stud walls.

The clearance requirements proposed are consistent with stucco applications and go one step further by specifying a minimum of ½" clearance to exterior walking surfaces which are supported by the same foundation that supports the wall to which the exterior veneer is adhered. The proposed requirement that both the wall and the walking surface be supported by the same foundation, along with existing IRC flashing performance requirements of section R703.8 for exterior wall intersections with porches, decks, or stairs, limits this ½" clearance to building elements stable to each other and required to be flashed to manage water. This ½" clearance requirement allows for architectural and aesthetic improvements in the installation of adhered masonry veneer.

Final Action: AS AM AMPC____ D

FS155-09/10, Part I
1406.2.1

Proposed Change as Submitted

Proponent: Michael Love, representing Metropolitan Washington DC Fire Marshal's Committee

PART I – IBC Fire Safety

Revise as follows:

1406.2.1 Ignition resistance. Combustible exterior wall coverings shall be tested in accordance with NFPA 268.

Exceptions:

1. Wood or wood-based products.
2. Other combustible materials covered with an exterior covering other than vinyl sidings listed in Table 1405.2.
3. Aluminum having a minimum thickness of 0.019 inch (0.48mm).
4. Exterior wall coverings on exterior walls of Type V construction.

1406.2.1.1 Fire separation 5 feet or less. Where installed on exterior walls having a fire separation distance of 5 feet (1524 mm) or less to buildings, structures or decks, combustible exterior wall coverings shall not exhibit sustained flaming as defined in NFPA 268.

Exceptions:

1. Decks constructed of fire retardant treated wood
2. Exterior balconies and decks protected by automatic sprinklers as provided for in Section 903.3.1.2.1

1406.2.1.2 Fire separation greater than 5 feet. For fire separation distances greater than 5 feet (1524 mm) to buildings, structures or decks, an assembly shall be permitted that has been exposed to a reduced level of incident radiant heat flux in accordance with the NFPA 268 test method without exhibiting sustained flaming. The minimum fire separation distance required for the assembly shall be determined from Table1406.2.1.2 based on the maximum tolerable level of incident radiant heat flux that does not cause sustained flaming of the assembly.

Exceptions:

1. Decks constructed of fire retardant treated wood
2. Exterior balconies and decks protected by automatic sprinklers as provided for in Section 903.3.1.2.1

Reason:
Part I- A technical change is needed to Section 1406 relating to the lack of fire resistance of the exterior surface of exterior combustible walls when directly exposed to combustible decks. It is likely that code development did not consider the need to require fire resistance for the exterior wall from these structures but there is a growing concern for the number of fires that start on and under combustible decks which when ignited burn fiercely.

This code change proposal is not intended to address all fires that could present an exposure to combustible exterior walls. It focuses on the higher risk and increased likelihood for a fire involving a combustible deck that is directly attached or within five feet of the combustible exterior wall. Since decks would have a limited exposure to a building any additional expenditure for more fire resistant materials is reduced. Ultimately a sheathing of gypsum even in thin layers increases the resistance.

1406.2.1.1 and 1406.2.1.1 both add the same language to include proximity to buildings, structures or decks and allows an exception for decks constructed of fire retardant wood.

This code change proposal is not intended to address all fires that could present an exposure to combustible exterior walls. It focuses on the higher risk and increased likelihood for a fire involving a combustible deck that is directly attached to or within five feet of the combustible exterior wall. Since decks would have a limited exposure to a building any additional expenditure for more fire resistant materials is reduced. Ultimately a sheathing of gypsum even in thin layers increases the resistance.

These fires are rarely extinguished before it has spread into the void of the exterior combustible wall or up the exterior surface of the walls and into the attic. While the most frequent facing surface of the exterior wall is vinyl siding this is listed in specs as non-combustible. There is experience that indicates no effective resistance to fire though as the siding readily melts away to allow fire access to the substrate sheathing which most often is a combustible material such as Oriented Strand Board (OSB), low density fiber board and Rigid Foam Insulation. These common materials are combustible but OSB resists direct flame longer then rigid foam insulation. Tests conducted by the National Institute for Standards and Technology showed that when a plume of heated gases and flame impinges on a combustible exterior wall it will ignite the combustible exterior wall that is within five feet. This scenario may actually be less dramatic then a well advanced fire involving an attached deck which could preheat the combustible wall and directly expose it to a vertical flame. This exposure and create a more intense flame spread vertically on the wall. Some materials used as a substrate to the exterior siding will resist fire more then others; some materials readily spread fire vertically directly to the roof along the exterior surface; into a non-fire resistant soffit then into the attic, or destroys the integrity of the substrate material and the enters the wall void.

Decks have become more like exterior rooms with furniture, outdoor kitchens and primarily the presence of people. Barbecue grills, lighting and the inappropriate disposal of smoking materials are all hazards that have been the causes of fires that first ignite decks then spread easily to and into the structure of a home or similar building. Once ignited decks burn violently with direct flame and radiant heat exposure to combustible exterior walls. The fact that the fuel in a deck is open on all sides which enhances oxidization for complete combustion and ample direct flame as well as preheating from radiant heat make them a perfect primary fire source to feed fires that most often spread to and involve the roof and attic of homes. The direct flaming attack on these walls cause nearly immediate destruction of combustible and easily degraded sidings to allow immediate access and exposure to the interior structure. Due to the unique flow of the heat and gases from the deck fires into the structure these fires most often result in near total loss of structure. In the Washington D.C Metro area these fires have resulted in many fires one incident which killed a firefighter and another fire incident that severely burned multiple firefighters.

Cost Impact: Part I & II- Product information indicates that a product such as a gypsum-based exterior sheathing is comparable to other sheathing and is more resistant to fire.

ICCFILENAME: LOVE-FS1-1406.2.1.1-RB-1-R302.1.2

Public Hearing Results

PART I- IBC FIRE SAFETY
Committee Action: **Disapproved**

Committee Reason: The committee felt the proposal was not coordinated with the definition of fire separation distance, was too broad in its application and was already cover in the projection requirements of the code.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Marcelo M. Hirschler (GBH International), representing American Fire Safety Council; Robert J. Davidson (Davidson Code Concepts, LLC) representing self, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

1406.2.1 Ignition resistance. Combustible exterior wall coverings shall be tested in accordance with NFPA 268.

Exceptions:

1. Wood or wood-based products.
2. Other combustible materials covered with an exterior covering other than vinyl sidings listed in Table 1405.2.
3. Aluminum having a minimum thickness of 0.019 inch (0.48mm).
4. Exterior wall coverings on exterior walls of Type V construction.

1406.2.1.1 Fire separation 5 feet or less. Where installed on exterior walls having a fire separation distance of 5 feet (1524 mm) or less to buildings, structures or decks, combustible exterior wall coverings shall not exhibit sustained flaming as defined in NFPA 268.

<u>**Exceptions:**</u>

~~1. Decks constructed of fire retardant treated wood~~

<u>1. Decks constructed of noncombustible materials or of materials that, when tested in accordance with the test procedures set forth in ASTM E 84, or UL 723, for a test period of 30 minutes, comply with the following;</u>

<u>1.1. The material shall exhibit a flame spread index not exceeding 25 and shall show no evidence of progressive combustion following the extended 30 minute test;</u>

<u>1.2. The material shall exhibit a flame front that does not progress more than 10 1/2 feet (3200 mm) beyond the centerline of the burner at any time during the extended 30 minute test; and</u>

<u>1.3. The deck boards shall bear a label indicating the required performance levels.</u>

2. Exterior balconies and decks protected by automatic sprinklers as provided for in Section 903.3.1.2.1

1406.2.1.2 Fire separation greater than 5 feet. For fire separation distances greater than 5 feet (1524 mm) to buildings, structures or decks, an assembly shall be permitted that has been exposed to a reduced level of incident radiant heat flux in accordance with the NFPA 268 test method without exhibiting sustained flaming. The minimum fire separation distance required for the assembly shall be determined from Table1406.2.1.2 based on the maximum tolerable level of incident radiant heat flux that does not cause sustained flaming of the assembly.

~~**Exceptions:**~~

~~1. Decks constructed of fire retardant treated wood~~

~~2. Exterior balconies and decks protected by automatic sprinklers as provided for in Section 903.3.1.2.1~~

Commenter's Reason: The comment restricts the requirement for improved fire performance decks (or sprinklered decks) to buildings with fire separations of up to 5 feet and does not address those where the fire separation is greater. Moreover, the requirement for the decks is more generic than in the original proposal and allows both noncombustible materials and materials that meet a fire test (which fire-retardant-treated wood also meets) so that the materials to be used are not exclusive. Finally, the enforceability is enhanced by the requirement to add a label to the deck boards with the required performance levels.

Final Action: AS AM AMPC____ D

FS155-09/10, Part II
IRC R302.1.2 (New)

Proposed Change as Submitted

Proponent: Michael Love, representing Metropolitan Washington DC Fire Marshal's Committee

PART II – IRC Building/Energy

Add new text as follows:

R302.1 Exterior walls. Construction, projections, openings and penetrations of *exterior walls* of *dwellings* and accessory buildings shall comply with Table R302.1.

Exceptions:

1. Walls, projections, openings or penetrations in walls perpendicular to the line used to determine the *fire separation distance*.
2. Walls of *dwellings* and *accessory structures* located on the same *lot*.
3. Detached tool sheds and storage sheds, playhouses and similar structures exempted from permits are not required to provide wall protection based on location on the *lot*. Projections beyond the *exterior wall* shall not extend over the *lot line*.
4. Detached garages accessory to a *dwelling* located within 2 feet (610 mm) of a *lot line* are permitted to have roof eave projections not exceeding 4 inches (102 mm).
5. Foundation vents installed in compliance with this code are permitted.

R302.1.2. **Combustible Exterior Walls and Combustible Decks .** Combustible exterior wall coverings and sheathing that are ignitable below 12.5 KW/m^2 and exhibit sustained flaming shall not be used where installed on exterior walls having a fire separation distance of 5 feet (1524 mm) to combustible decks or balconies.

Exception: Decks constructed of fire retardant treated wood

Reason:
Part II- Add a new section to IRC Chapter 3 as R302.1.2 to increase fire resistance of combustible exterior walls when directly exposed to combustible decks. It is likely that the code development process did not consider the need to require fire resistance for the exterior wall from decks but there is a growing concern for the number of fires that start on and under combustible decks which when ignited burn fiercely. IRC considers exposure buildings in regard to fire spread but does not include the hazard of combustible deck fires. While IRC has some limited passive fire resistance of residential construction through use of fire blocking and compartmentation it does not recognize the hazard of a deck involved in fire to the structure of the main building through the exterior facing of the wall.

This code change proposal is not intended to address all fires that could present an exposure to combustible exterior walls. It focuses on the higher risk and increased likelihood for a fire involving a combustible deck that is directly attached to or within five feet of the combustible exterior wall. Since decks would have a limited exposure to a building any additional expenditure for more fire resistant materials is reduced. Ultimately a sheathing of gypsum even in thin layers increases the resistance.

These fires are rarely extinguished before it has spread into the void of the exterior combustible wall or up the exterior surface of the walls and into the attic. While the most frequent facing surface of the exterior wall is vinyl siding this is listed in specs as non-combustible. There is experience that indicates no effective resistance to fire though as the siding readily melts away to allow fire access to the substrate sheathing which most often is a combustible material such as Oriented Strand Board (OSB), low density fiber board and Rigid Foam Insulation. These common materials are combustible but OSB resists direct flame longer then rigid foam insulation. Tests conducted by the National Institute for Standards and Technology showed that when a plume of heated gases and flame impinges on a combustible exterior wall it will ignite the combustible exterior wall that is within five feet. This scenario may actually be less dramatic then a well advanced fire involving an attached deck which could preheat the combustible wall and directly expose it to a vertical flame. This exposure and create a more intense flame spread vertically on the wall. Some materials used as a substrate to the exterior siding will resist fire more then others; some materials readily spread fire vertically directly to the roof along the exterior surface; into a non-fire resistant soffit then into the attic, or destroys the integrity of the substrate material and the enters the wall void.

Decks have become more like exterior rooms with furniture, outdoor kitchens and primarily the presence of people. Barbecue grills, lighting and the inappropriate disposal of smoking materials are all hazards that have been the causes of fires that first ignite decks then spread easily to and into the structure of a home or similar building. Once ignited decks burn violently with direct flame and radiant heat exposure to combustible exterior walls. The fact that the fuel in a deck is open on all sides which enhances oxidization for complete combustion and ample direct flame as well as preheating from radiant heat make them a perfect primary fire source to feed fires that most often spread to and involve the roof and attic of homes. The direct flaming attack on these walls cause nearly immediate destruction of combustible and easily degraded sidings to allow immediate access and exposure to the interior structure. Due to the unique flow of the heat and gases from the deck fires into the structure these fires most often result in near total loss of structure. In the Washington D.C Metro area these fires have resulted in many fires one incident which killed a firefighter and another fire incident that severely burned multiple firefighters.

Cost Impact: Part I & II- Product information indicates that a product such as a gypsum-based exterior sheathing is comparable to other sheathing and is more resistant to fire.

ICCFILENAME: LOVE-FS1-1406.2.1.1-RB-1-R302.1.2

Public Hearing Results

PART II- IRC B/E
Committee Action: Disapproved

Committee Reason: This is intended for a specific type of housing but the language addresses more than intended. This change would create permit issues with respect to replacement. This will make compliance difficult. Also, the content of the deck could ignite even though the exception is used.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Marcelo M. Hirschler (GBH International), representing American Fire Safety Council; Robert J. Davidson (Davidson Code Concepts, LLC) representing self, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R302.1 Exterior walls. Construction, projections, openings and penetrations of *exterior walls* of *dwellings* and accessory buildings shall comply with Table R302.1.

Exceptions:

1. Walls, projections, openings or penetrations in walls perpendicular to the line used to determine the *fire separation distance*.
2. Walls of *dwellings* and *accessory structures* located on the same *lot*.
3. Detached tool sheds and storage sheds, playhouses and similar structures exempted from permits are not required to provide wall protection based on location on the *lot*. Projections beyond the *exterior wall* shall not extend over the *lot line*.
4. Detached garages accessory to a *dwelling* located within 2 feet (610 mm) of a *lot line* are permitted to have roof eave projections not exceeding 4 inches (102 mm).
5. Foundation vents installed in compliance with this code are permitted.

~~**R302.1.2. Combustible Exterior Walls and Combustible Decks.** Combustible exterior wall coverings and sheathing that are ignitable below 12.5 KW/m^2 and exhibit sustained flaming shall not be used where installed on exterior walls having a fire separation distance of 5 feet (1524 mm) to combustible decks or balconies.~~

~~**Exception:** Decks constructed of fire retardant treated wood.~~

<u>**R302.1.2 Combustible Exterior Walls and Combustible Decks.** In areas where the authority having jurisdiction determines that there is elevated danger of fires starting on or under decks and where decks or balconies are separated from exterior walls by a fire separation distance of 5 feet (1524 mm) or less, the exterior walls and decks shall comply with one R302.1.2.1 or R302.1.2.2.</u>

<u>**R302.1.2.1 Exterior Walls.** The exterior walls shall have exterior wall coverings and sheathing constructed of materials that, when exposed to an incident heat flux of 12.5 kW/m^2, do not ignite or spread flame.</u>

<u>**R302.1.2.2 Deck Construction.** The decks shall be constructed of noncombustible materials or of materials that, when tested in accordance with the test procedures set forth in ASTM E 84, or UL 723, for a test period of 30 minutes, comply with the R302.1.2.2.1 through R302.1.2.2.3.</u>

<u>**R302.1.2.2.1 Flame spread.** Material shall exhibit a flame spread index not exceeding 25 and shall show no evidence of progressive combustion following the extended 30 minute test.</u>

<u>**R302.1.2.2.2 Flame front**. Material shall exhibit a flame front that does not progress more than 10 1/2 feet (3200 mm) beyond the centerline of the burner at any time during the extended 30 minute test.</u>

<u>**R302.1.2.2.3 Label.** The deck boards shall bear a label indicating the required performance levels.</u>

Commenter's Reason: The technical committee was concerned that the proposal addressed too many different types of occupancies and this was addressed by limiting the application to construction in areas where the ahj determines that there is an elevated danger of fires starting under decks. Moreover, additional concerns involved compliance and clarification of fire performance; the enforceability is enhanced by the requirement to add a label to the deck boards with the required performance levels. This was also clarified by amending the language. Finally, the concern about the use of a single material, fire retardant treated wood was also addressed by discussing fire performance of the deck. The heat flux of 12.5 kW/m^2 was chosen because it is the heat flux used in NFPA 268, and that ensures that the ignitability and flame spread is minimized and that some degree of fire protection is applied. NFPA 268 is required in Chapter 14 of the IBC but is not referenced in the IRC and it is not included in the comment.

Final Action: AS AM AMPC____ D

1404.12, 1405.2, 1405.18 (New), 1405.18.1 (New), Table 1405.18.1 (New), 1405.18.2 (New), 1405.18.2.1 (New), Table 1405.18.2.1 (New), 1405.18.2.2 (New), Table 1405.18.2.2 (New), 1405.14.1, 1405.14.2 (New), 1405.14.2.1 (New), 1405.14.2.2 (New), 1405.14.2.3 (New), 2304.6;

Proposed Change as Submitted

Proponent: Jay H. Crandell, PE, d/b/a ARES Consulting, representing the Foam Sheathing Coalition

PART I – IBC STRUCTURAL

1. Add new text as follows:

1404.12 Foam plastic sheathing. Foam plastic sheathing shall comply with requirements for foam plastic insulation in Section 2603. When used as a water-resistive barrier, the foam plastic sheathing material and installation shall be approved in accordance with Section 1404.2.

2. Revise as follows:

1405.2 Weather protection. *Exterior walls* shall provide weather protection for the building. The materials of the minimum nominal thickness specified in Table 1405.2 shall be acceptable as *approved* weather coverings. Foam plastic sheathing used in exterior wall covering assemblies with approved exterior weather coverings shall comply with Section 1405.18.

3. Add new text as follows:

1405.18 Foam plastic sheathing. Foam plastic sheathing used in exterior wall covering assemblies shall comply with this section, Section 2603, Chapter 13, and the foam sheathing manufacturer's approved installation instructions.

1405.18.1 Minimum thickness. The thickness of foam plastic sheathing shall comply with Table 1405.18.1.

> **Exception:** Where foam plastic sheathing is applied directly over or behind wall sheathing or other solid substrate capable of separately resisting the required wind pressure, the limitations of Table 1405.18.1 shall not apply.

For SI: 1 inch = 25.4 mm, 1 mile per hour = 1.609 km/h
NP = not permitted

1. Tabulated maximum wind speed values are based on a mean roof height of 30-feet (9.1 m). Multiply maximum wind speed by 0.95 for a mean roof height of 45 feet (13.7 m) or 0.9 for a mean roof height of 60 feet (18.3 m). For greater mean roof heights, an approved design shall be required.
2. Foam plastic sheathing panels shall be permitted to be oriented parallel or perpendicular to framing members.
3. Foam plastic sheathing shall meet or exceed the following material standards: Expanded Polystyrene (EPS) – ASTM C578 (Type II, min.1.35 lb/ft^3 density), Polyisocyanurate – ASTM C1289 (Type 1, min.), and extruded polystyrene (XPS) – ASTM C578 (Type X, min. 1.30 lb/ft^3 density). Where a “faced” product is indicated, a facer shall be provided on both faces of the foam plastic sheathing. Where facing is not indicated in the table, faced and unfaced foam plastic sheathing shall be permitted. For all foam plastic sheathing products, approved manufacturer data shall be permitted in lieu of the table requirements.
4. Multiply tabulated maximum wind speed by 0.85 for wind exposure C or by 0.78 for wind exposure D.
5. Interior finish shall be minimum 1/2-inch (12.7 mm) thick gypsum wall board or an approved product with equivalent or greater out-of-plane bending strength and stiffness.

1405.18.2 Siding attachment over foam sheathing. Siding shall be attached over foam sheathing in accordance with Section 1405.18.2.1, Section 1405.18.2.2, or an approved design. In no case shall the siding material be used in a manner that exceeds its application limits.

Exception: Where the siding manufacturer has provided approved installation instructions for application over foam sheathing, those requirements shall apply.

1405.18.2.1 Direct siding attachment. Approved weather coverings installed directly over foam sheathing without separation by an air space shall comply with Table 1405.18.2.1 in regard to nail diameter, penetration, and nail spacing for the applicable foam sheathing thickness and wind speed condition. The siding fastener and siding installation shall otherwise comply with Chapter 14.

Exceptions:

1. For adhered masonry veneer, refer to Section 1405.10
2. For vinyl siding, refer to Section 1405.14.
3. For exterior insulation and finish systems, refer to Section 1408.

TABLE 1405.18.2.1
FASTENING REQUIREMENTS FOR DIRECT SIDING ATTACHMENT OVER FOAM PLASTIC SHEATHING[1,2]

Minimum Nail Diameter[3] (inches)	Nail Spacing along Stud[4] (inches)	Maximum Foam Sheathing Thickness[5] (inches)	16”oc WALL FRAMING Maximum Wind Speed (mph)			24”oc WALL FRAMING Maximum Wind Speed (mph)		
			Exposure B	Exposure C	Exposure D	Exposure B	Exposure C	Exposure D

	12	1.5	110	90	85	90	DR	DR
0.135	6	3	140	120	110	130	110	100
	8	3	140	120	110	110	90	85
	12	2	110	90	85	90	DR	DR

For SI: 1 inch = 25.4 mm; 1 mph = 1.609 km/h
DR = design required

1. Maximum wind speed values are based on a minimum 1-1/4 inch (31.8 mm) penetration of a smooth shank nail fastener into wood framing of Spruce-Pine-Fir or any wood species with a specific gravity of 0.42 or greater in accordance with AFPA/NDS.

2. Tabulated maximum wind speed values are based on a mean roof height of 30-feet (9.1 m). Multiply maximum wind speed by 0.95 for a mean roof height of 45 feet (13.7 m) or 0.9 for a mean roof height of 60 feet (18.3 m). For greater mean roof heights, an approved design shall be required.
3. Nail fasteners shall comply with ASTM F1667, except nail length shall be permitted to exceed ASTM F1667 standard lengths to provide a minimum 1-1/4 inch (31.8 mm) penetration into wood framing. Specified nails in accordance with Chapter 1405 or the siding manufacturer's approved installation instructions shall meet all other requirements in ASTM F1667 or be otherwise approved for the intended application.
4. 'Nail spacing along stud' refers to spacing of siding fasteners in the vertical direction. A minimum of one fastener shall be applied at each intersection of an individual siding member with a wall stud.
5. Maximum foam sheathing thickness values are based on a maximum 24-inch (0.6 m) stud spacing, a maximum siding dead load of 11 psf (0.53 kPa), and S_{DS} per Section 1613.5.4 not exceeding 0.83g. Siding dead load shall not exceed 8 psf (0.39 kPa) for and S_{DS} of 1.17g, 6 psf (0.29 kPa) for S_{DS} of 1.5g, or 3.0 psf (0.14 kPa) for S_{DS} of 3.0 g.

1405.18.2.2 Offset siding attachment. When an airspace separates the siding from direct contact with the foam plastic sheathing, the approved weather coverings shall be attached in accordance with Chapter 14 to minimum 1x3 wood furring strips placed over the foam sheathing. Furring shall be attached through the foam sheathing to wall framing in accordance with Table 1405.18.2.2. When placed horizontally, wood furring strips shall be preservative treated wood in accordance with Section 2303.1.8 or naturally durable wood and fasteners shall be corrosion resistant in accordance with Section 2304.9.5.

Exception: Furring strips shall not be required over foam plastic sheathing behind anchored stone and masonry veneer installed in accordance with Section 1405.6. Veneer ties shall be installed on the surface of the foam plastic sheathing with fasteners of sufficient length to pass through the thickness of foam plastic sheathing and penetrate framing to provide required pull-out resistance determined in accordance with Chapter 16.

TABLE 1405.18.2.2
FASTENING REQUIREMENTS FOR WOOD FURRING OVER FOAM PLASTIC SHEATHING[1,2,3]

Fastener Type	Minimum Penetration into Wall Framing (inches)	Fastener Spacing in Furring[4] (inches)	Maximum Thickness of Foam Sheathing[5] (inches)	16"oc FURRING Maximum Wind Speed (mph) Exposure B	Exposure C	Exposure D	24"oc FURRING Maximum Wind Speed (mph) Exposure B	Exposure C	Exposure D

For SI: 1" = 25.4 mm; 1 mph = 1.609 km/h
DR = design required
1. Furring strips shall be spaced a maximum of 24"oc in a vertical or horizontal orientation. Table values are based on minimum ¾-inch (19.1 mm) thick furring strip and wood studs of Spruce-Pine-Fir or any softwood species with a specific gravity of 0.42 or greater per AFPA/NDS.
2. Tabulated maximum wind speed values are based on a mean roof height of 30-feet (9.1 m). Multiply maximum wind speed by 0.95 for a mean roof height of 45 feet (13.7 m) or 0.9 for a mean roof height of 60 feet (18.3 m). For greater mean roof heights, an approved design shall be required.
3. Where minimum required siding fastener penetration exceeds ¾ inch (19.1 mm), a minimum 2x furring strip shall be used unless approved deformed shank siding nails or siding screws are used to provide equivalent withdrawal strength.
4. In a vertical orientation, furring strips shall be located over wall studs and attached with the required fastener spacing. In a horizontal orientation, furring strips shall be fastened at each stud intersection with a number of fasteners equivalent to the required fastener spacing. In no case shall fasteners be spaced more than 24 inches (0.6 m) apart.
5. Maximum foam sheathing thickness values are based on a maximum 24-inch (0.6 m) stud spacing, a maximum siding dead load of 11 psf (0.53 kPa), and S_{DS} per Section 1613.5.4 not exceeding 0.83g. Siding dead load shall not exceed 8 psf (0.39 kPa) for and S_{DS} of 1.17g, 6 psf (0.29 kPa) for S_{DS} of 1.5g, or 3.0 psf (0.14 kPa) for S_{DS} of 3.0 g.
6. Lag screws shall be installed with a standard cut washer and shall be pre-drilled in accordance with AF&PA NDS-05. Approved self-drilling screws of equal or greater shear and withdrawal strength shall be permitted without pre-drilling.

4. Revise as follows:

1405.14.1 Application. The siding shall be applied over sheathing or materials listed in Section 2304.6 or foam plastic sheathing in accordance with Sections 1405.14.2 and 1405.18. Siding shall be applied to conform with the water-resistive barrier requirements in Section 1403. Siding and accessories shall be installed in accordance with approved manufacturer's instructions. Unless otherwise specified in the approved manufacturer's instructions, nails used to fasten the siding and accessories shall have a minimum 0.313-inch (7.9 mm) head diameter and 1/8-inch (3.18 mm) shank diameter. The nails shall be corrosion resistant and shall be long enough to penetrate the studs or nailing strip at least 3/4 inch (19 mm). Where the siding is installed horizontally, the fastener spacing shall not exceed 16 inches (406 mm) horizontally and 12 inches (305 mm) vertically. Where the siding is installed vertically, the fastener spacing shall not exceed 12 inches (305 mm) horizontally and 12 inches (305 mm) vertically.

5. Add new text as follows:

1405.14.2 Foam Plastic Sheathing. Vinyl siding used with foam plastic sheathing shall be installed in accordance with 1405.14.2.1, 1405.14.2.2., and 1405.14.2.3.

Exception: Where the foam plastic sheathing is applied directly over wood structural panels, fiberboard, gypsum sheathing, or other approved backing capable of independently resisting the design wind pressure, the vinyl siding shall be installed in accordance with 1405.14.1.

1405.14.2.1 Basic Wind Speed Not Exceeding 90 mph and Exposure Category B. Where the basic wind speed does not exceed 90 mph, the Exposure Category is B and gypsum wall board or equivalent is installed on the side of the wall opposite the foam plastic sheathing, the minimum siding fastener penetration into wood framing shall be 1-1/4 inches (32 mm) using minimum 0.120-inch diameter nail (shank) with a minimum 0.313-inch diameter head, and fastened 16 inches on center. The foam plastic sheathing shall comply with Section 1405.18.1 and shall not exceed a maximum thickness of 1.5 inches (38 mm) for a 0.120-inch diameter nail or 2.0 inches (51 mm) for a 0.135-inch diameter nail. Vinyl siding shall be permitted to be installed on furring strips in accordance with Section 1405.18.2.2 and the siding manufacturer's installation instructions when foam plastic sheathing thickness complies with Section 1405.18.1.

1405.14.2.2 Basic Wind Speed Exceeding 90mph or Exposure Categories C and D. Where the basic wind speed exceeds 90 mph or the Exposure Category is C or D, or all conditions of 1405.14.2.1 are not met, the adjusted design pressure rating for the assembly shall meet or exceed the wind loads required by Chapter 16. The design wind pressure rating of the vinyl siding for installation over solid sheathing as provided in the vinyl siding manufacturer's product specifications shall be adjusted for the following wall assembly conditions:

1. For wall assemblies with foam plastic sheathing on the exterior side and minimum ½-inch (12.7 mm) thick gypsum wall board or equivalent on the interior side of the wall, the vinyl siding's design wind pressure rating shall be multiplied by 0.39.
2. For wall assemblies with foam plastic sheathing on the exterior side and no gypsum wall board or equivalent on the interior side of wall, the vinyl siding's design wind pressure rating shall be multiplied by 0.27.

   Exception: The above adjustments shall not apply when vinyl siding is attached to wood furring strips installed over the foam plastic sheathing in accordance with Section 1405.18.2.2 and such installation is in accordance with the vinyl siding manufacturer's installation instructions.

1405.14.2.3 Manufacturer Specification. Where the vinyl siding manufacturer's product specifications provide an approved design wind pressure rating for installation over foam plastic sheathing, use of this design wind pressure rating shall be permitted and the siding shall be installed in accordance with the manufacturer's installation instructions.

6. Revise as follows:

2304.6 Wall sheathing. Except as provided for in Section 1405 for weatherboarding or where stucco construction that complies with Section 2510 is installed, enclosed buildings shall be sheathed with one of the materials of the nominal thickness specified in Table 2304.6, foam sheathing in accordance with Section 1405.18, or any other approved material of equivalent strength and durability.

Reason:

Part I-As with a related IRC proposal, this proposal is a comprehensive clarification and upgrading of requirements for foam plastic sheathing and siding installation over foam plastic sheathing. It primarily addresses adequate foam sheathing thickness and siding attachment over foam sheathing to resist a range of design wind load conditions, beyond which design is required or installation in accordance with manufacturer instructions specific to application of siding over foam sheathing. It also provides siding connections through foam sheathing that provide adequate support to resist the dead load of siding installed over foam sheathing and limits the siding weight, particularly in higher seismic conditions (beyond which design is required or approved installation guidelines). As a whole, these provisions are necessary to ensure appropriate use of foam sheathing and siding materials together on exterior wall assemblies in a way that best compliments existing exterior wall covering provisions in Chapter 14. A detailed explanation of the test data and analysis justifying the proposed requirements can be found at www.foamsheathing.org.

In support of proposed new Section 1405.18.1, the wind pressure resistance of foam sheathing used in this proposal is based on certified full-scale (4'x8' panel) testing conducted at the NAHB Research Center, Inc. Samples included specimens from various manufacturers representing the industry at large. The design wind speed data (without rounding or capping values) is shown in the table below for informational purposes. The values in the proposed table have been rounded to the nearest 5 mph increment and capped at 130 mph (Exposure B) which corresponds to a maximum wind speed of 110 mph in exposure C or 100 mph Exposure D. This proposal is needed to avoid potential exclusion of foam sheathing products due to the incompleteness of current code requirements which can negatively affect other concerns such as energy conservation code requirements and green building interests. Most importantly, these requirements will ensure that foam sheathing is used appropriately to prevent building envelope damage, particularly in higher wind conditions and with thinner material used on more widely spaced studs (e.g., 24"oc center on gable roof ends which typically have no interior finish). These requirements also agree reasonably well with the generally successful use of foam sheathing on typical wall assemblies (e.g., 16"oc framing or 24"oc framing with interior finish) on many buildings in lower wind regions of the U.S.

TABLE R703.3.1- Part A (Actual design values based on test data – not rounded or capped as in the proposal)
MAXIMUM WIND SPEED (mph – 3 SECOND GUST) PERMITTED
FOR FOAM PLASTIC SHEATHING
WITH DIRECTLY ATTACHED SIDING PER SECTION R703.3.2.1

Foam Sheathing Material[3]	Foam Sheathing Nominal Thickness (in)	Maximum Wind Speed (mph) – Exposure B[4]			
		Walls with Interior Finish[5]		Walls without Interior Finish	
		16"oc framing	24"oc framing	16"oc framing	24"oc framing
EPS	¾" (unfaced) 1" (unfaced) 1-1/2" (unfaced)	110 147 222	73 98 148	92 123 186	61 82 124
Polyiso-cyanurate	½" (faced) ¾" (faced) 1" (faced) 1-1/2" (faced)	136 177 193 207	91 118 129 138	114 148 162 173	76 99 108 116
XPS	½" (faced) ¾" (unfaced) 1" (unfaced) 1-1/2" (unfaced)	125 109 145 208	84 73 97 139	105 91 121 174	70 61 81 116

Design value based on the minimum tested uniform pressure capacity for each sheathing type and thickness category divided by a safety factor of 1.5 and ASCE 7-05 positive pressure design loads for wall corner zone and a 10 sq ft wind effective area (negative pressure is resisted by the foam sheathing and siding assembly). Because the 1.5 safety factor is applied to a minimum test value (not the average), these requirements are more stringent than safety margins required for other building envelop components such as doors and windows which are also important to envelope integrity. This "minimum test value" basis also serves to better control safety margins with regard to variability in material properties or performance.

TABLE R703.3.1 – Part B (Actual design values based on test data – not rounded or capped as in the proposal)
MAXIMUM WIND SPEED (mph – 3 SECOND GUST) PERMITTED
FOR FOAM PLASTIC SHEATHING
WITH FURRED SIDING PER SECTION R703.3.2.2[1]

Foam Plastic Sheathing Material[2]	Foam Sheathing Nominal Thickness (in)[2]	Maximum Wind Speed (mph) – Exposure B[3,4]			
		Walls with Interior Finish[5]		Walls without Interior Finish	
		16"oc framing	24"oc framing	16"oc framing	24"oc framing
EPS	¾" 1" ≥1-1/2"	95 127 192	63 85 128	80 106 161	53 71 107
Polyiso-cyanurate	½" (faced) ¾" (faced) 1" (faced) ≥1-1/2" (faced)	118 153 167 179	78 102 112 120	98 128 140 150	66 85 93 100
XPS	½" (faced) ¾" 1" ≥1-1/2"	108 94 126 180	72 63 84 120	91 79 105 151	61 53 70 101

Design value based on the minimum tested uniform pressure capacity for each sheathing type and thickness category divided by a safety factor of 1.5 and ASCE 7-05 negative pressure design loads for wall corner zone and a 10 sq ft wind effective area. Because the siding is spaced away from foam sheathing in this wall covering assembly condition, it does not contribute to foam sheathing resistance. Thus, the foam sheathing must independently resist the negative wind pressure load. The furring strips provide adequate bearing at connection to secure the foam sheathing as well as the siding material.

In support of proposed new Section 1405.18.2, the generalized connection requirements for siding over foam sheathing are based on an analysis using the AF&PA NDS-2005 connection design provisions in consideration of withdrawal to resist wind pressure and shear strength to resist siding dead load. To account for the "gap" in the connection caused by the presence of foam sheathing, the provisions of AF&PA TR12 were used to downgrade connection strength based on the thickness of foam sheathing (i.e., width of gap in the connection). The design shear strength was based on calculated ultimate capacity divided by a safety factor of 2 while conservatively ignoring any benefit of the foam material filling the gap in the siding or furring connection to wall framing. Wind loads were based on application of the full ASCE 7-05 components and cladding wind pressure applied to the exterior wall covering while conservatively ignoring any distribution of wind pressure to other wall layers. In addition, the wind pressures were based on the most stringent wall corner zone condition and an effective wind area of 10 sq ft.

Addition of new Section 1405.14.2 provides special requirements and limitations for use of foam plastic sheathing with vinyl siding. The proposed changes are consistent approved changes now included in the 2009 IRC. These changes are needed to ensure appropriate use of vinyl siding wind pressure ratings when foam sheathing is used, thus preventing inadequate performance.

Limited changes to other parts of the code are made in coordination with the above improvements.

Part II- As with a related IBC proposal, this proposal is a comprehensive clarification and upgrading of requirements for foam sheathing and siding installation over foam sheathing. It primarily addresses adequate foam sheathing thickness and siding attachment over foam sheathing to resist design wind loads within the scope of the IRC (e.g., up to 110 mph, Exposure D). It also provides siding connections through foam sheathing that provide adequate support to resist the dead load of siding installed over foam sheathing. As a whole, these provisions are necessary to ensure appropriate use of foam sheathing and siding materials together on exterior wall assemblies in a way that best compliments existing exterior wall covering provisions in Section R703 of the code. A detailed explanation of the test data and analysis justifying the proposed requirements can be found at www.foamsheathing.org.

In support of proposed new Section R703.3.1, the wind pressure resistance of foam sheathing used in this proposal is based on certified full-scale (4'x8' panel) testing conducted at the NAHB Research Center, Inc. Samples included specimens from various manufacturers representing the industry at large. The design wind speed data (without rounding or capping values) is shown in the table below for informational purposes. The values in the proposed table have been rounded to the nearest 5 mph increment and capped at 130 mph (Exposure B) as this corresponds to a maximum wind speed of 110 mph in exposure C, which is essentially the scope limit of the IRC. This proposal is needed to avoid potential exclusion of foam sheathing products due to the incompleteness of current code requirements which can negatively affect other concerns such as energy conservation code requirements and green building interests. Most importantly, these requirements will ensure that foam sheathing is used appropriately to prevent building envelope damage, particularly in higher wind conditions and with thinner material used on more widely spaced studs (e.g., 24"oc center on gable roof ends which typically have no interior finish). These requirements also agree reasonably well with the generally successful use of foam sheathing on typical wall assemblies (e.g., 16"oc framing or 24"oc framing with interior finish) on many homes in lower wind regions of the U.S.

TABLE R703.3.1- Part A (Actual design values based on test data – not rounded or capped as in the proposal)

Polyiso-cyanurate	½" (faced) ¾" (faced) 1" (faced) ≥1-1/2" (faced)	118 153 167 179	78 102 112 120	98 128 140 150	66 85 93 100
XPS	½" (faced) ¾" 1" ≥1-1/2"	108 94 126 180	72 63 84 120	91 79 105 151	61 53 70 101

Design value based on the minimum tested uniform pressure capacity for each sheathing type and thickness category divided by a safety factor of 1.5 and ASCE 7-05 negative pressure design loads for wall corner zone and a 10 sqft wind effective area. Because the siding is spaced away from foam sheathing in this wall covering assembly condition, it does not contribute to foam sheathing resistance. Thus, the foam sheathing must independently resist the negative wind pressure load. The furring strips provide adequate bearing at connection to secure the foam sheathing as well as the siding material.

In support of proposed new Section R703.3.2, the generalized connection requirements for siding over foam sheathing are based on an analysis using the AF&PA NDS-2005 connection design provisions in consideration of withdrawal to resist wind pressure and shear strength to resist siding dead load. To account for the "gap" in the connection caused by the presence of foam sheathing, the provisions of AF&PA TR12 were used to downgrade connection strength based on the thickness of foam sheathing (i.e., width of gap in the connection). The design shear strength was based on calculated ultimate capacity divided by a safety factor of 2 while conservatively ignoring any benefit of the foam material filling the gap in the siding or furring connection to wall framing. Wind loads were based on application of the full ASCE 7-05 components and cladding wind pressure applied to the exterior wall covering while conservatively ignoring any distribution of wind pressure to other wall layers. In addition, the wind pressures were based on the most stringent wall corner zone condition and an effective wind area of 10 sqft.

Changes to other parts of Section R703, including changes to Table R703.4 and various siding attachment requirements, are made in coordination with the above improvements.

Cost Impact: The code change proposal will increase the cost of construction.

Analysis: ASTM standards within this proposed are currently referenced in the I-codes.

Public Hearing Results

PART I- IBC FIRE SAFETY
Committee Action: Disapproved

Committee Reason: The proponent requested disapproval at this time so that the proposal requirements for foam plastic sheathing can be better coordinated with the energy code. This includes the treatment of positive and negative wind pressures, performance of the lateral force system as well as fastener requirements.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jay H. Crandell, PE, ARES Consulting, representing Foam Sheathing Coalition; Mark Nowak, representing Steel Framing Alliance, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

1404.12 Foam plastic sheathing. Foam plastic sheathing shall comply with requirements for foam plastic insulation in Section 2603. When used as a water-resistive barrier, the foam plastic sheathing material and installation shall be approved in accordance with Section 1404.2. When used in exterior wall covering assemblies in accordance with Table 1405.18.1 of Section 1405.18.1, foam sheathing shall be identified by the trademarks of an *approved* testing and inspection agency in accordance with Section 1703 and 2603.2 indicating compliance with the wind pressure resistance requirements of Table 1405.18.1 where not already addressed in the applicable material standards.

1405.18 Foam plastic sheathing. Foam plastic sheathing used in exterior wall covering assemblies shall comply with this section, Section 2603, Chapter 13, and the foam sheathing manufacturer's approved installation instructions. Wall assemblies with foam plastic sheathing that are intended to serve as part of the lateral force resisting system of a structure shall be braced with approved materials designed to resist the in-plane shear force determined in accordance with Chapter 16. Wall assemblies with foam plastic sheathing attached to gravity load supporting members that require buckling restraint shall have such restraint provided by other approved materials. The use of foam plastic sheathing in accordance with this section shall not be permitted where the basic wind speed exceeds 110 mph.

~~**1405.18.1 Minimum thickness.** The thickness of foam plastic sheathing shall comply with Table 1405.18.1.~~

Exceptions:

1. Where foam plastic sheathing is covered with ~~applied directly over or behind~~ wall sheathing or other solid material ~~substrate~~ capable of separately resisting the required wind pressure, the limitations of Section 1405.18.1 and the basic wind speed limit of 110 mph ~~Table 1405.18.1~~ shall not apply.
2. Where foam plastic sheathing is covered with cladding and applied directly over wall sheathing or other solid material, all capable of separately resisting the full design wind pressure, the limitations of Section 1405.18.1 and the basic wind speed limit of 110 mph shall not apply.

1405.18.1 Minimum thickness. The thickness of foam plastic sheathing shall comply with Table 1405.18.1. The components and cladding design wind pressure determined in accordance with Section 1609 shall not exceed the allowable wind pressure value in accordance with Table 1405.18.1.

~~NP = not permitted~~

1. ~~Tabulated maximum wind speed values are based on a mean roof height of 30 feet (9.1 m). Multiply maximum wind speed by 0.95 for a mean roof height of 45 feet (13.7 m) or 0.9 for a mean roof height of 60 feet (18.3 m). For greater mean roof heights, an approved design shall be required.~~
2. ~~Foam plastic sheathing panels shall be permitted to be oriented parallel or perpendicular to framing members.~~
3. ~~Foam plastic sheathing shall meet or exceed the following material standards: Expanded Polystyrene (EPS) – ASTM C578 (Type II, min.1.35 lb/ft^3 density), Polyisocyanurate – ASTM C1289 (Type 1, min.), and extruded polystyrene (XPS) – ASTM C578 (Type X, min. 1.30 lb/ft^3 density). Where a “faced” product is indicated, a facer shall be provided on both faces of the foam plastic sheathing. Where facing is not indicated in the table, faced and unfaced foam plastic sheathing shall be permitted. For all foam plastic sheathing products, approved manufacturer data shall be permitted in lieu of the table requirements.~~
4. ~~Multiply tabulated maximum wind speed by 0.85 for wind exposure C or by 0.78 for wind exposure D.~~
5. ~~Interior finish shall be minimum 1/2-inch (12.7 mm) thick gypsum wall board or an approved product with equivalent or greater out-of-plane bending strength and stiffness.~~

For SI: 1 inch = 25.4 mm, 1 pound per square foot (psf) = 0.0479 kPa.
NP = not permitted (allowable design wind pressure less than 10 psf)

1. Foam plastic sheathing panels shall be permitted to be oriented parallel or perpendicular to framing members.
2. Foam plastic sheathing shall meet or exceed the following material standards: Expanded Polystyrene (EPS) – ASTM C578 (Type II, min.1.35 lb/ft^3 density), Polyisocyanurate – ASTM C1289 (Type 1, min.), and extruded polystyrene (XPS) – ASTM C578 (Type X, min. 1.30 lb/ft^3 density). Where a “faced” product is indicated, a facer shall be provided on both faces of the foam plastic sheathing. Where facing is not indicated in the table, faced and unfaced foam plastic sheathing shall be permitted. For all foam plastic sheathing products, approved manufacturer data shall be permitted in lieu of the table requirements.
3. Interior finish shall be minimum 1/2-inch (12.7 mm) thick gypsum wall board or an approved product with equivalent or greater out-of-plane bending strength and stiffness.

1405.18.2 Siding attachment over foam sheathing. Siding shall be attached over foam sheathing in accordance with Section 1405.18.2.1, Section 1405.18.2.2, or an approved design. In no case shall the siding material be used in a manner that exceeds its application limits. When required by the basic wind speed and wind exposure applicability of Section 1706, wall cladding installation over foam sheathing shall be subject to special inspection in accordance with Section 1706.4.

Exception: Where the siding manufacturer has provided approved installation instructions for application over foam sheathing, those requirements shall apply.

1405.18.2.1 Direct siding attachment. Approved weather coverings installed directly over foam sheathing without separation by an air space shall comply with Table 1405.18.2.1 in regard to minimum fastening requirements ~~nail diameter, penetration, and nail spacing~~ and maximum foam sheathing thickness limitations to support siding dead load ~~for the applicable foam sheathing thickness and wind speed condition~~. The siding fastener and siding installation shall otherwise comply with Chapter 14, shall be capable of resisting all other applicable design loads determined in accordance with Chapter 16, and in no case shall result in a less stringent fastening requirement than required by Chapter 14 or the manufacturer’s installation instructions for the specific siding material used.

Exception~~s~~:

~~1.~~ ~~For adhered masonry veneer, refer to Section 1405.10.~~
~~2.~~ ~~For vinyl siding, refer to Section 1405.14.~~
~~3.~~ For exterior insulation and finish systems, refer to Section 1408.

~~DR = design required~~

1. ~~Maximum wind speed values are based on a minimum 1-1/4 inch (31.8 mm) penetration of a smooth shank nail fastener into wood framing of Spruce-Pine-Fir or any wood species with a specific gravity of 0.42 or greater in accordance with AFPA/NDS.~~
2. ~~Tabulated maximum wind speed values are based on a mean roof height of 30-feet (9.1 m). Multiply maximum wind speed by 0.95 for a mean roof height of 45 feet (13.7 m) or 0.9 for a mean roof height of 60 feet (18.3 m). For greater mean roof heights, an approved design shall be required.~~
3. ~~Nail fasteners shall comply with ASTM F1667, except nail length shall be permitted to exceed ASTM F1667 standard lengths to provide a minimum 1-1/4 inch (31.8 mm) penetration into wood framing. Specified nails in accordance with Chapter 1405 or the siding manufacturer's approved installation instructions shall meet all other requirements in ASTM F1667 or be otherwise approved for the intended application.~~
4. ~~'Nail spacing along stud' refers to spacing of siding fasteners in the vertical direction. A minimum of one fastener shall be applied at each intersection of an individual siding member with a wall stud.~~
5. ~~Maximum foam sheathing thickness values are based on a maximum 24-inch (0.6 m) stud spacing, a maximum siding dead load of 11 psf (0.53 kPa), and S_{DS} per Section 1613.5.4 not exceeding 0.83g. Siding dead load shall not exceed 8 psf (0.39 kPa) for and S_{DS} of 1.17g, 6 psf (0.29 kPa) for S_{DS} of 1.5g, or 3.0 psf (0.14 kPa) for S_{DS} of 3.0 g.~~

For SI: 1 inch = 25.4 mm; 1 pound per square foot (psf) = 0.0479 kPa
DR = design required

1. Tabulated requirements are based on wood framing of Spruce-Pine-Fir or any wood species with a specific gravity of 0.42 or greater in accordance with AFPA/NDS and minimum 33 ksi steel for 33 mil and 43 mil steel and 50 ksi steel for 54 mil steel or thicker.
2. Nail fasteners shall comply with ASTM F1667, except nail length shall be permitted to exceed ASTM F1667 standard lengths. Self-drilling tapping screw fasteners for connection of siding to steel framing shall comply with the requirements of AISI S200. Specified fasteners in accordance with Chapter 1405 or the siding manufacturer's approved installation instructions shall meet all other requirements in ASTM F1667, AISI S200 or be otherwise approved for the intended application.

1405.18.2.2 Offset siding attachment. When an airspace separates the siding from direct contact with the foam plastic sheathing, the approved weather coverings shall be attached in accordance with Chapter 14 to minimum 1x3 wood or minimum 33 mil steel hat channel furring ~~strips~~ placed over the foam sheathing. Furring shall be attached through the foam sheathing to wall framing in accordance with Table 1405.18.2.2 in regard to minimum fastening requirements and maximum foam sheathing thickness limitations to support siding dead load. Furring and connections shall be separately designed to resist all other applicable loads determined in accordance with Chapter 16. When placed horizontally, wood furring ~~strips~~ shall be preservative treated wood in accordance with Section 2303.1.8 or naturally durable wood and fasteners shall be corrosion resistant in accordance with Section 2304.9.5. Steel hat channel furring shall have a minimum G60 galvanized coating.

> **Exception:** Furring ~~strips~~ shall not be required over foam plastic sheathing behind anchored stone and masonry veneer installed in accordance with Section 1405.6. Veneer ties shall be installed on the surface of the foam plastic sheathing with fasteners of sufficient length to pass through the thickness of foam plastic sheathing and penetrate framing to provide required pull-out resistance determined in accordance with Chapter 16.

~~DR = design required~~

1. ~~Furring strips shall be spaced a maximum of 24"oc in a vertical or horizontal orientation. Table values are based on minimum ¾-inch (19.1 mm) thick furring strip and wood studs of Spruce-Pine-Fir or any softwood species with a specific gravity of 0.42 or greater per AFPA/NDS.~~
2. ~~Tabulated maximum wind speed values are based on a mean roof height of 30-feet (9.1 m). Multiply maximum wind speed by 0.95 for a mean roof height of 45 feet (13.7 m) or 0.9 for a mean roof height of 60 feet (18.3 m). For greater mean roof heights, an approved design shall be required.~~
3. ~~Where minimum required siding fastener penetration exceeds ¾ inch (19.1 mm), a minimum 2x furring strip shall be used unless approved deformed shank siding nails or siding screws are used to provide equivalent withdrawal strength.~~
4. ~~In a vertical orientation, furring strips shall be located over wall studs and attached with the required fastener spacing. In a horizontal orientation, furring strips shall be fastened at each stud intersection with a number of fasteners equivalent to the required fastener spacing. In no case shall fasteners be spaced more than 24 inches (0.6 m) apart.~~
5. ~~Maximum foam sheathing thickness values are based on a maximum 24-inch (0.6 m) stud spacing, a maximum siding dead load of 11 psf (0.53 kPa), and S_{DS} per Section 1613.5.4 not exceeding 0.83g. Siding dead load shall not exceed 8 psf (0.39 kPa) for and S_{DS} of 1.17g, 6 psf (0.29 kPa) for S_{DS} of 1.5g, or 3.0 psf (0.14 kPa) for S_{DS} of 3.0 g.~~
6. ~~Lag screws shall be installed with a standard cut washer and shall be pre-drilled in accordance with AF&PA NDS-05. Approved self-drilling screws of equal or greater shear and withdrawal strength shall be permitted without pre-drilling.~~

TABLE 1405.18.2.2
FURRING MINIMUM FASTENING REQUIREMENTS FOR APPLICATION
OVER FOAM PLASTIC SHEATHING TO SUPPORT SIDING DEAD LOAD[1,2]

				16	4	3	0.5	4	2	DR
				24	4	2	DR	4	0.5	DR

For SI: 1" = 25.4 mm; 1 pound per square foot (psf) = 0.0479 kPa.
DR = design required

1. Table values are based on: (1) minimum ¾-inch (19.1 mm) thick wood furring and wood studs of Spruce-Pine-Fir or any softwood species with a specific gravity of 0.42 or greater per AFPA/NDS, (2) minimum 33 mil steel hat channel furring of 33 ksi steel, and (3) steel framing of indicated nominal steel thickness and minimum 33 ksi steel for 33mil and 43 mil steel and 50 ksi steel for 54 mil steel or thicker.
2. Nail fasteners shall comply with ASTM F1667, except nail length shall be permitted to exceed ASTM F1667 standard lengths. Self-drilling tapping screw fasteners for connection of siding to steel framing shall comply with the requirements of AISI S200. Specified fasteners in accordance with Chapter 1405 or the siding manufacturer's approved installation instructions shall meet all other requirements in ASTM F1667 or AISI S200 or be otherwise approved for the intended application.
3. Where the required siding fastener penetration into wood material exceeds ¾ inch (19.1 mm) and is not more than 1-1/2 inches (38.1 mm), a minimum 2x wood furring shall be used unless approved deformed shank siding nails or siding screws are used to provide equivalent withdrawal strength allowing connection to 1x wood furring.
4. Furring shall be spaced a maximum of 24"oc in a vertical or horizontal orientation. In a vertical orientation, furring shall be located over wall studs and attached with the required fastener spacing. In a horizontal orientation, furring strips shall be fastened at each stud intersection with a number of fasteners equivalent to the required fastener spacing. In no case shall fasteners be spaced more than 24 inches (0.6 m) apart.
5. Lag screws shall be installed with a standard cut washer. Lag screws and wood screws shall be pre-drilled in accordance with AF&PA/NDS. Approved self-drilling screws of equal or greater shear and withdrawal strength shall be permitted without pre-drilling.

1405.14.2 Foam Plastic Sheathing. Vinyl siding used with foam plastic sheathing shall be installed in accordance with 1405.14.2.1, 1405.14.2.2 and 1405.14.2.3.

Exception: Where the foam plastic sheathing is applied directly over wood structural panels, fiberboard, gypsum sheathing, or other approved backing capable of independently resisting the design wind pressure, the vinyl siding shall be installed in accordance with 1405.14.1.

1405.14.2.1 Basic Wind Speed Not Exceeding 90 mph and Exposure Category B. Where the building mean roof height does not exceed 30 feet (9.1 m), the basic wind speed does not exceed 90 mph, the Exposure Category is B and gypsum wall board or equivalent is installed on the side of the wall opposite the foam plastic sheathing, the minimum siding fastener penetration into wood framing shall be 1-1/4 inches (32 mm) using minimum 0.120-inch diameter nail (shank) with a minimum 0.313-inch diameter head, and fastened 16 inches on center. The foam plastic sheathing shall comply with Section 1405.18.1 and shall not exceed a maximum thickness of 1.5 inches (38 mm) for a 0.120-inch diameter nail or 2.0 inches (51 mm) for a 0.135-inch diameter nail. Vinyl siding shall be permitted to be installed on furring strips in accordance with Section 1405.18.2.2 and the siding manufacturer's installation instructions when foam plastic sheathing thickness complies with Section 1405.18.1.

1405.14.2.2 Basic Wind Speed Exceeding 90mph or Exposure Categories C and D. Where the basic wind speed exceeds 90 mph or the Exposure Category is C or D, or all conditions of 1405.14.2.1 are not met, the adjusted design pressure rating for the assembly shall meet or exceed the wind loads required by Chapter 16. The design wind pressure rating of the vinyl siding for installation over solid sheathing as provided in the vinyl siding manufacturer's product specifications shall be adjusted for the following wall assembly conditions:

1. For wall assemblies with foam plastic sheathing on the exterior side and minimum ½-inch (12.7 mm) thick gypsum wall board or equivalent on the interior side of the wall, the vinyl siding's design wind pressure rating shall be multiplied by 0.39.
2. For wall assemblies with foam plastic sheathing on the exterior side and no gypsum wall board or equivalent on the interior side of wall, the vinyl siding's design wind pressure rating shall be multiplied by 0.27.

~~**Exception:** The above adjustments shall not apply when vinyl siding is attached to wood furring strips installed over the foam plastic sheathing in accordance with Section 1405.18.2.2 and such installation is in accordance with the vinyl siding manufacturer's installation instructions.~~

1405.14.2.3 Manufacturer Specification. Where the vinyl siding manufacturer's product specifications provide an approved design wind pressure rating for installation over foam plastic sheathing, use of this design wind pressure rating shall be permitted and the siding shall be installed in accordance with the manufacturer's installation instructions.

(Portions of proposal not shown, remain unchanged).

Commenter's Reason: This public comment responds to constructive criticism and supportive recommendations received at the first hearing. Every effort has been made to follow-up with the various interests and to respond with improvements to the original proposal. These improvements are also coordinated with a complimentary PC on FS156-09/10 Part 2 (IRC) as also requested by the IRC CDC which approved the original proposal with a request for further refinements at Final Action. These refinements are coordinated and comprehensively made in this one PC for reasons addressed separately as follows:

Inclusion of Steel Framing

Tables 1405.18.2.1 and 1405.18.2.2 now include siding connections for use with light-frame cold-formed steel in addition to light-frame wood as requested at the first hearing. These are needed to provide siding connection solutions applicable to light-frame cold-formed steel construction to ensure coordination with IECC energy code requirements for this type of construction (as mentioned in the IBC-S committee's reason for disapproval). The Steel Framing Alliance (SFA), American Iron and Steel Institute (AISI), and the Foam Sheathing Coalition (FSC) have worked together toward this end.

The original proposal included connection solutions for attachment of siding over foam sheathing only for wood framing. But, the scope of the original proposal was not otherwise limited to wood framing (i.e., requirements in Table 1405.18.1 of the original proposal are applicable to both wood and steel framing). The IRC committee approved the original FS156-09/10 proposal, but also expressed concern to "work with industry and bring the needed improvement back to the Final Action."

Steel framing was not addressed in the original proposal only because test data was not available at that time to justify appropriate solutions. Subsequently, the steel industry together with New York State Research and Energy Development Authority (NYSERDA) has conducted a testing program to provide justification to the solutions proposed in this PC. A report on this testing will be made available at the Final Action hearing and, as soon as available, by request to the proponent (Mark Nowak, SFA, mnowak@steelframing.org). These tests provide the necessary performance data for appropriately designing siding connections to steel framing that span through a thickness of foam sheathing.

These proposed provisions for light-frame cold-formed steel construction are not only coordinated with ICC energy code requirements, but they are necessary to ensure that foam insulation requirements as required by the ICC energy code are implemented in a structurally sound manner. Support of this PC is urged.

Inclusion of Additional Siding Weight Categories:

The original proposal was based on a minimum 11 psf siding dead load (for siding attachment requirements over foam sheathing). While various siding manufacturers supported the original proposal (or remained neutral), several expressed the desire to be included, such as the Masonry Veneer Manufacturers Association. Thus, a 25 psf siding weight category and connection requirements have been included in this PC. This also required inclusion of a 3 psf siding weight category such that the lighter weight sidings would not be unduly penalized by basing the table only on heavier siding types.

Simplification, Clarification and Editorial Improvements:

Content from table footnotes moved into tables for visual clarity and ease of access.
Removed confusing wind speed requirements from siding attachment table otherwise intending to address connection requirements for support of siding dead load and limit foam thickness. The text is clarified to more explicitly require that the siding attachment be separately designed to resist other loading conditions, including wind.
Adjusted fastener sizes to be compatible with pneumatic fasteners at request of ISANTA
Various editorial improvements to language, table headings, etc.

Additional technical justification for siding connections over foam sheathing

The FSC has also done additional testing of siding over foam sheathing connection assemblies for attachments to wood framing. These tests add further confirmation of the adequacy of the proposed siding attachment requirements for wood framing and support of siding weight. It also confirms that siding deflections will be limited to less than 0.015" as commonly used as a design basis for wood connections. A report documenting this testing will also be made available at the final action hearing and will be posted at www.foamsheathing.org as soon as available.

Strengthened QC requirements for foam sheathing wind pressure resistance properties

One of the concerns raised at the first code development hearing on FS156 was related to having assurance that foam sheathing products meet the wind pressure performance requirements upon which the proposal (namely Table 1405.18.1) is based. This public comment addresses that concern by clarifying implementation a code-recognized "approved agency" approach that already exists and is commonly used for foam sheathing and other products.

First, 2009 IBC Section 2603.2 gives foam plastic insulation requirements for use of an approved agency and labeling to ensure end use complies with code requirements as follows:

> **2603.2 Labeling and identification.** Packages and containers of foam plastic insulation and foam plastic insulation components delivered to the job site shall bear the *label* of an *approved agency* showing the manufacturer's name, product listing, product identification and information sufficient to determine that the end use will comply with the code requirements.

Second, 2009 IBC Section 2603.5.4 provides an example of product performance criteria (test method and minimum performance indices) which the "approved agency" must consider in meeting the requirements of Section 2603.2:

> **2603.5.4 Flame spread and smoke-developed indexes.** Foam plastic insulation, exterior coatings and facings shall be tested separately in the thickness intended for use, but not to exceed 4 inches (102 mm), and shall each have a flame spread index of 25 or less and a smoke-developed index of 450 or less as determined in accordance with ASTM E 84 or UL 723.

Third, the Approved Agency is defined in Sections 202 and 1702.1 of the 2009 IBC as follows:

> **APPROVED AGENCY.** An established and recognized agency regularly engaged in conducting tests or furnishing inspection services, when such agency has been *approved*.

And, the responsibilities of the Approved Agency include:

> **1703.1 Approved agency.** An *approved agency* shall provide all information as necessary for the *building official* to determine that the agency meets the applicable requirements.
>
> **1703.1.1 Independence.** An *approved agency* shall be objective, competent and independent from the contractor responsible for the work being inspected. The agency shall also disclose possible conflicts of interest so that objectivity can be confirmed.

1703.5 Labeling. Where materials or assemblies are required by this code to be *labeled*, such materials and assemblies shall be *labeled* by an *approved agency* in accordance with Section 1703. Products and materials required to be labeled shall be labeled in accordance with the procedures set forth in Sections 1703.5.1 through 1703.5.3.

This approach is also used for other materials such as:

2303.1.4 Wood structural panels. Wood structural panels, when used structurally (including those used for siding, roof and wall sheathing, subflooring, diaphragms and built-up members), shall conform to the requirements for their type in DOC PS 1 or PS 2. Each panel or member shall be identified for grade and glue type by the trademarks of an *approved* testing and grading agency. Wood structural panel components shall be designed and fabricated in accordance with the applicable standards listed in Section 2306.1 and identified by the trademarks of an *approved* testing and inspection agency indicating conformance with the applicable standard. In addition, wood structural panels when permanently exposed in outdoor applications shall be of exterior type, except that wood structural panel roof sheathing exposed to the outdoors on the underside is permitted to be interior type bonded with exterior glue, Exposure 1.

Additionally, a Fabricated Item is defined as follows:

FABRICATED ITEM. Structural, load-bearing or lateral load-resisting assemblies consisting of materials assembled prior to installation in a building or structure, or subjected to operations such as heat treatment, thermal cutting, cold working or reforming after manufacture and prior to installation in a building or structure. Materials produced in accordance with standard specifications referenced by this code, such as rolled structural steel shapes, steel-reinforcing bars, masonry units, and wood structural panels or in accordance with a standard, listed in Chapter 35, which provides requirements for quality control done under the supervision of a third-party quality control agency shall not be considered "fabricated items."

The above described "approved agency" process has shown itself effective and this public comment merely clarifies the application of this process to assure the structural properties (wind pressure resistance) of foam sheathing align with the basis of the proposed end-use requirements and limitations. The minimum performance requirements are based on a representative sample of currently manufactured products of each type as reported by the NAHB Research Center, Inc. (report available at www.foamsheathing.org). Support for this PC is urged.

Strengthened Scope Limitations on Foam Sheathing Applications

At the request of the insurance industry, a 110 mph wind speed limit has also been implemented in this proposal for foam sheathing. In addition, wind pressure requirements have been strengthened to require use of negative pressure values in all cases, even when siding is placed over foam sheathing and the siding is separately capable of resisting the full negative design wind pressure.

These provisions are needed for the above reasons, provide improvements for appropriate use of foam sheathing, and provide needed solutions for coordination with the energy code requirements. Again, your approval as modified is urged.

Final Action: AS AM AMPC____ D

Proposed Change as Submitted

Proponent: Jay H. Crandell, PE, d/b/a ARES Consulting, representing the Foam Sheathing Coalition

PART II – IRC BUILDING/ENERGY

1. Add new text as follows:

R703.3 Foam plastic sheathing. Foam plastic sheathing used in exterior wall covering assemblies shall comply with this section, Section R316, Chapter 11 and the manufacturer's installation instructions.

R703.3.1 Minimum thickness. The thickness of foam plastic sheathing shall comply with Table R703.3.1.

Exception: Where foam plastic sheathing is applied directly over or behind wall sheathing or other solid substrate capable of separately resisting the required wind pressure, the limitations of Table R703.3.1 shall not apply.

TABLE R703.3.1
REQUIREMENTS FOR FOAM PLASTIC SHEATHING
IN EXTERIOR WALL COVERING ASSEMBLIES[1,2]

EPS	¾” 1” ≥1-1/2”	95 125 130	NP 85 130	NP 105 130	NP NP 105

For SI: 1 inch = 25.4 mm, 1 mile per hour = 1.609 km/h
NP = not permitted

1. Tabulated maximum wind speed values are based on a mean roof height of 30-feet (9.1 m). Multiply maximum wind speed by 0.95 for a mean roof height of 45 feet (13.7 m).
2. Foam plastic sheathing panels shall be permitted to be oriented parallel or perpendicular to framing members.
3. Foam plastic sheathing shall meet or exceed the following material standards: Expanded Polystyrene (EPS) – ASTM C578 (Type II, min.1.35 lb/ft^3 density), Polyisocyanurate – ASTM C1289 (Type 1, min.), and extruded polystyrene (XPS) – ASTM C578 (Type X, min. 1.30 lb/ft^3 density). Where a “faced” product is indicated, a facer shall be provided on both faces of the foam plastic sheathing. Where facing is not indicated in the table, faced and unfaced foam plastic sheathing shall be permitted. For all foam plastic sheathing products, approved manufacturer data shall be permitted in lieu of the table requirements.
4. Multiply tabulated maximum wind speed by 0.85 for wind exposure C or by 0.78 for wind exposure D.
5. Interior finish shall be minimum 1/2-inch (12.7 mm) thick gypsum wall board or an approved product with equivalent or greater out-of-plane bending strength and stiffness.

R703.3.2 Siding attachment over foam sheathing. Siding shall be attached over foam sheathing in accordance with Section R703.3.2.1, Section R703.3.2.2, or an approved design. In no case shall the siding material be used in a manner that exceeds its application limits.

Exception: Where the siding manufacturer has provided installation instructions for application over foam sheathing, those requirements shall apply.

R703.3.2.1 Direct siding attachment. Siding installed directly over foam sheathing without separation by an air space shall comply with Table R703.3.2.1 in regard to nail diameter, penetration, and nail spacing for the applicable foam sheathing thickness and wind speed condition. The siding fastener and siding installation shall otherwise comply with Section R703.4 and Table R703.4.

Exceptions:

1. For vinyl siding, refer to Section R703.11.2.
2. For exterior insulation and finish systems, refer to Section R703.9.
3. For adhered veneer, refer to Section R703.12.

TABLE R703.3.2.1
FASTENING REQUIREMENTS FOR DIRECT SIDING
ATTACHMENT OVER FOAM PLASTIC SHEATHING[1,2]

Minimum Nail Diameter[3] (inches)	Nail Spacing along Stud[4] (inches)	Maximum Foam Sheathing Thickness[5] (inches)	16"oc WALL FRAMING Maximum Wind Speed (mph)			24"oc WALL FRAMING Maximum Wind Speed (mph)

	8	3	140	120	110	110	90	85
	12	2	110	90	85	90	DR	DR

For SI: 1 inch = 25.4 mm; 1 mph = 1.609 km/h
DR = design required

1. Maximum wind speed values are based on a minimum 1-1/4 inch (31.8 mm) penetration of a smooth shank nail fastener into wood framing of Spruce-Pine-Fir or any wood species with a specific gravity of 0.42 or greater in accordance with AFPA/NDS.
2. Tabulated maximum wind speed values are based on a mean roof height of 30-feet (9.1 m). Multiply maximum wind speed by 0.95 for a mean roof height of 45 feet (13.7 m).
3. Nail fasteners shall comply with ASTM F1667, except nail length shall be permitted to exceed ASTM F1667 standard lengths to provide a minimum 1-1/4 inch (31.8 mm) penetration into wood framing. Specified nails in accordance with Section R703.4 or the siding manufacturer's installation instructions shall meet all other requirements in ASTM F1667 or be otherwise approved for the intended application.
4. 'Nail spacing along stud' refers to spacing of siding fasteners in the vertical direction. A minimum of one fastener shall be applied at each intersection of an individual siding member with a wall stud.
5. Maximum foam sheathing thickness values are based on a maximum 24-inch (0.6 m) stud spacing and a maximum siding dead load of 11 psf (0.53 kPa) based on 7/8-inch (22 mm) thick Portland cement plaster, For Seismic Design Category D2, the maximum siding dead load shall be 8 psf.

Fastener Type	Minimum Penetration into Wall Framing (inches)	Fastener Spacing in Furring[4] (inches)	Maximum Thickness of Foam Sheathing[5] (inches)	16"oc FURRING Maximum Wind Speed (mph)			24"oc FURRING Maximum Wind Speed (mph)

R703.3.2.2 Offset siding attachment. When an airspace separates the siding from direct contact with the foam plastic sheathing, the siding shall be attached in accordance with Section R703.4 and Table R703.4 to minimum 1x3 wood furring strips placed over the foam sheathing. Furring shall be attached through the foam sheathing to wall framing in accordance with Table R703.3.2.2. When placed horizontally, wood furring strips shall be preservative treated wood or naturally durable wood and fasteners shall be corrosion resistant in accordance with Section R317.

> **Exception:** Furring strips shall not be required over foam plastic sheathing located behind anchored stone and masonry veneer installed in accordance with Section R703.7. Veneer ties shall be installed in accordance with Section R703.7.4.1.

TABLE R703.3.2.2
FASTENING REQUIREMENTS FOR WOOD FURRING
OVER FOAM PLASTIC SHEATHING[1,2,3]

For SI: 1" = 25.4 mm; 1 mph = 1.609 km/h
DR = design required

1. Furring strips shall be spaced a maximum of 24"oc in a vertical or horizontal orientation. Table values are based on minimum ¾-inch (19.1 mm) thick furring strip and wood studs of Spruce-Pine-Fir or any wood species with a specific gravity of 0.42 or greater per AFPA/NDS.
2. Tabulated maximum wind speed values are based on a mean roof height of 30-feet (9.1 m). Multiply maximum wind speed by 0.95 for a mean roof height of 45 feet (13.7 m).

3. Where minimum required siding fastener penetration exceeds ¾ inch (19.1 mm), a minimum 2x furring strip shall be used unless approved deformed shank siding nails or siding screws are used to provide equivalent withdrawal strength.
4. In a vertical orientation, furring strips shall be located over wall studs and attached with the required fastener spacing. In a horizontal orientation, furring strips shall be fastened at each stud intersection with a number of fasteners equivalent to the required fastener spacing. In no case shall fasteners be spaced more than 24 inches (0.6 m) apart.
5. Maximum foam sheathing thickness values are based on a maximum 24-inch (0.6 m) stud spacing and a maximum siding dead load of 11 psf (0.53 kPa) based on 7/8-inch (22 mm) thick Portland cement plaster. For Seismic Design Category D2, the maximum siding dead load shall be 8 psf.
6. Lag screws shall be installed with a standard cut washer and shall be pre-drilled in accordance with AF&PA NDS-05. Approved self-drilling screws of equal or greater shear and withdrawal strength shall be permitted without pre-drilling.

(Renumber subsequent sections)

2. Revise as follows:

R703.4 Attachments. Unless specified otherwise, all wall coverings shall be securely fastened in accordance with Table R703.4 or with other *approved* aluminum, stainless steel, zinc-coated or other *approved* corrosion-resistive fasteners. Additional requirements in accordance with Section R703.3.2 shall apply when siding is installed over foam sheathing. Where the basic wind speed per Figure R301.2(4) is 110 miles per hour (49 m/s) or higher, the attachment of wall coverings shall be designed to resist the component and cladding loads specified in Table R301.2(2), adjusted for height and exposure in accordance with Table R301.2(3).

For SI: 1 inch = 25.4 mm.

a. Based on stud spacing of 16 inches on center where studs are spaced 24 inches, siding shall be applied to sheathing approved for that spacing.
b. Nail is a general description and shall be T-head, modified round head, or round head with smooth or deformed shanks.
c. Staples shall have a minimum crown width of 7/16-inch outside diameter and be manufactured of minimum 16 gage wire.
d. Nails or staples shall be aluminum, galvanized, or rust-preventative coated and shall be driven into the studs where for fiberboard, or gypsum, or foam plastic sheathing backing is used
e. Aluminum nails shall be used to attach aluminum siding.
f. Aluminum (0.019 inch) shall be unbacked only when the maximum panel width is 10 inches and the maximum flat area is 8 inches. The tolerance for aluminum siding shall be +0.002 inch of the nominal dimension.
g. All attachments shall be coated with a corrosion-resistant coating.
h. Shall be of approved type.
i. Three-eighths-inch plywood shall not be applied directly to studs spaced more than 16 inches on center when long dimension is parallel to studs. Plywood 1/2-inch or thinner shall not be applied directly to studs spaced more than 24 inches on center. The stud spacing shall not exceed the panel span rating provided by the manufacturer unless the panels are installed with the face grain perpendicular to the studs or over sheathing approved for that stud spacing.
j. Wood board sidings applied vertically shall be nailed to horizontal nailing strips or blocking set 24 inches on center. Nails shall penetrate 1 1/2 inches into studs, studs and wood sheathing combined or blocking. For application over foam sheathing, refer to Section R703.3.2.2.
k. Hardboard siding shall comply with CPA/ANSI A135.6.
l. Vinyl siding shall comply with ASTM D 3679.
m. Minimum shank diameter of 0.092 inch, minimum head diameter of 0.225 inch, and nail length must accommodate sheathing and penetrate framing 1 1/2 inches. For application over foam sheathing, minimum shank diameter and penetration into framing shall comply with Section R703.3.2.
n. When used to resist shear forces, the spacing must be 4 inches at panel edges and 8 inches on interior supports.
o. Minimum shank diameter of 0.099 inch, minimum head diameter of 0.240 inch, and nail length must accommodate sheathing and penetrate framing 1 1/2 inches. For application over foam sheathing, minimum shank diameter and penetration into framing shall comply with Section R703.3.2.
p. Vertical end joints shall occur at studs and shall be covered with a joint cover or shall be caulked.
q. See Section R703.10.1.
r. Fasteners shall comply with the nominal dimensions in ASTM F 1667. For application over foam sheathing, refer to Section R703.3.2
s. See Section R703.10.2.
t. Face nailing: one 6dcommonnail through the overlapping planks at each stud. Concealed nailing: one 11 gage 11/2 inch long galv. roofing nail through the top edge of each plank at each stud.
u. See Section R703.2 exceptions.
v. Minimum nail length must accommodate sheathing and penetrate framing 11/2 inches. For application over foam sheathing, refer to Section R703.3.2
w. Adhered masonry veneer shall comply with the requirements of Section R703.6.3 and shall comply with the requirements in Sections 6.1 and 6.3 of ACI 530/ASCE 5/TMS-402.
x. Vertical joints, if staggered shall be permitted to be away from studs if applied over wood structural panel sheathing.
y. Minimum fastener length must accommodate sheathing and penetrate framing .75 inches or in accordance with the manufacturer’s installation instructions. For application over foam sheathing, fastener penetration into framing shall comply with Section R703.3.2.

z. Where approved by the manufacturer's instructions or test report siding shall be permitted to be installed with fasteners penetrating not less than .75 inches throughwood orwood structural sheathing with or without penetration into the framing.
aa. Refer to Section R703.3 for additional requirements.
bb. For siding application over foam sheathing, fastener spacing shall comply with the more stringent requirement of this table or Section R703.3.2.

R703.5.1 Application. Wood shakes or shingles shall be applied either single-course or double-course over nominal 1/2-inch (13 mm) wood-based sheathing or to furring strips over nominal 1/2-inch (13 mm) nonwood sheathing.

> **Exception:** Wood shakes or shingles over foam plastic sheathing, shall be applied to wood furring strips in accordance with Section R703.3.2.2.

A ~~permeable~~ water-resistive barrier shall be provided in accordance with Section R703.2 ~~over all sheathing, with horizontal overlaps in the membrane of not less than 2 inches (51mm) and vertical overlaps of not less than 6 inches (152 mm)~~. Where furring strips are used, they shall be 1 inch by 3 inches or 1 inch by 4 inches (25mmby 76 mm or 25mm by 102 mm), and shall be fastened horizontally to the studs with 7d or 8d box nails. For application over foam plastic sheathing, furring strips shall be fastened in accordance with Section R703.3.2.2. and Furring strips shall be spaced a distance on center equal to the actual weather exposure of the shakes or shingles, not to exceed the maximum exposure specified in Table R703.5.2. The spacing between adjacent shingles to allow for expansion shall not exceed 1/4 inch (6 mm), and between adjacent shakes, it shall not exceed 1/2 inch (13 mm). The offset spacing between joints in adjacent courses shall be a minimum of 11/2 inches (38 mm).

R703.6.1 Lath. All lath and lath attachments shall be of corrosion-resistant materials. Expanded metal or woven wire lath shall be attached with 1 1/2-inch-long (38 mm), 11 gage nails having a 7/16-inch (11.1 mm) head, or 7/8-inch-long (22.2 mm), 16 gage staples, spaced at no more than 6 inches (152 mm), or as otherwise *approved*. For application of maximum 7/8-inch-thick Portland cement plaster over foam plastic sheathing, nail length and shank diameter shall comply with Section R703.3.2.

R703.7.4.1 Size and spacing. Veneer ties, if strand wire, shall not be less in thickness than No. 9 U.S. gage [(0.148 in.) (4 mm)] wire and shall have a hook embedded in the mortar joint, or if sheet metal, shall be not less than No. 22 U.S. gage by [(0.0299 in.)(0.76 mm)] 7/8 inch (22 mm) corrugated. Each tie shall be spaced not more than 24 inches (610 mm) on center horizontally and vertically and shall support not more than 2.67 square feet (0.25 m2) of wall area. For application over foam plastic sheathing, corrugated metal ties shall be fastened through the foam plastic sheathing using a 10d common nail with a minimum penetration of 1 1/2 inches (38 mm) into wood framing for a maximum wind condition of 90 miles per hour (40 m/s) in wind exposure B. For a basic wind speed not exceeding 110 miles per hour (49 m/s) in any wind exposure and in Seismic Design Categories C, D_0, D_1, and D_2, a #8 wood screw with a minimum 1 inch (25.4 mm) penetration into wood wall framing shall be used in each tie. Alternatively, an approved fastener with equivalent withdrawal strength shall be permitted.

> **Exception:** In Seismic Design Category D_0, D_1 or D_2 or townhouses in Seismic Design Category C or in wind areas of more than 30 pounds per square foot pressure (1.44 kPa), each tie shall support not more than 2 square feet (0.2 m2) of wall area.

R703.11.2 Foam plastic sheathing. Vinyl siding used with foam plastic sheathing shall be installed in accordance with Section R703.11.2.1, R703.11.2.2, or R703.11.2.3.

> **Exception:** Where the foam plastic sheathing is applied directly over wood structural panels, fiberboard, gypsum sheathing or other *approved* backing capable of independently resisting the design wind pressure, the vinyl siding shall be installed in accordance with Section R703.11.1.

R703.11.2.1 Basic wind speed not exceeding 90 miles per hour and Exposure Category B. Where the basic wind speed does not exceed 90 miles per hour (40 m/s), the Exposure Category is B and gypsum wall board or equivalent is installed on the side of the wall opposite the foam plastic sheathing, the minimum siding fastener penetration into wood framing shall be 11/4 inches (32 mm) using minimum 0.120-inch diameter nail (shank) with a minimum 0.313-inch diameter head, 16 inches on center. The foam plastic sheathing minimum thickness shall comply with Section R703.3.1 and shall not exceed a maximum thickness of 1.5 inches (38mm) for a 0.120-inch diameter nail or 2.0 inches (51 mm) for a 0.135-inch diameter nail. ~~shall be 1/2-inch-thick (12.7 mm) (nominal) extruded polystyrene per ASTM C578, 1/2-inch-thick (12.7 mm) (nominal) polyisocyanurate per ASTM C1289, or 1-inch-thick (25 mm)(nominal) expanded polystyrene per ASTM C578.~~ Vinyl siding shall be permitted to be installed on furring strips in accordance with Section R703.2.2 using the siding manufacturer's installation instructions when foam plastic sheathing thickness complies with Section R703.3.1.

R703.11.2.2 Basic wind speed exceeding 90 miles per hour or Exposure Categories C and D. Where the basic wind speed exceeds 90 miles per hour (40 m/s) or the Exposure Category is C or D, or all conditions of Section R703.11.2.1 are not met, the adjusted design pressure rating for the assembly shall meet or exceed the loads listed in Tables R301.2(2) adjusted for height and exposure using Section R301.2(3). The design wind pressure rating of the vinyl siding for installation over solid sheathing as provided in the vinyl siding manufacturer's product specifications shall be adjusted for the following wall assembly conditions:

1. For wall assemblies with foam plastic sheathing on the exterior side and minimum ½-inch-thick gypsum wall board or equivalent on the interior side of the wall, the vinyl siding's design wind pressure rating shall be multiplied by 0.39.
2. For wall assemblies with foam plastic sheathing on the exterior side and no gypsum wall board or equivalent on the interior side of wall, the vinyl siding's design wind pressure rating shall be multiplied by 0.27.

   Exception: The above adjustments shall not apply when vinyl siding is attached to wood furring strips installed over the foam plastic sheathing in accordance with Section R703.3.2.2 and such installation is in accordance with the vinyl siding manufacturer's installation instructions.

R703.11.2.3 Manufacturer specification. Where the vinyl siding manufacturer's product specifications provide an *approved* design wind pressure rating for installation over foam plastic sheathing, use of this design wind pressure rating shall be permitted and the siding shall be installed in accordance with the manufacturer's installation instructions.

Reason:
Part II- As with a related IBC proposal, this proposal is a comprehensive clarification and upgrading of requirements for foam sheathing and siding installation over foam sheathing. It primarily addresses adequate foam sheathing thickness and siding attachment over foam sheathing to resist design wind loads within the scope of the IRC (e.g., up to 110 mph, Exposure D). It also provides siding connections through foam sheathing that provide adequate support to resist the dead load of siding installed over foam sheathing. As a whole, these provisions are necessary to ensure appropriate use of foam sheathing and siding materials together on exterior wall assemblies in a way that best compliments existing exterior wall covering provisions in Section R703 of the code. A detailed explanation of the test data and analysis justifying the proposed requirements can be found at www.foamsheathing.org.

In support of proposed new Section R703.3.1, the wind pressure resistance of foam sheathing used in this proposal is based on certified full-scale (4'x8' panel) testing conducted at the NAHB Research Center, Inc. Samples included specimens from various manufacturers representing the industry at large. The design wind speed data (without rounding or capping values) is shown in the table below for informational purposes. The values in the proposed table have been rounded to the nearest 5 mph increment and capped at 130 mph (Exposure B) as this corresponds to a maximum wind speed of 110 mph in exposure C, which is essentially the scope limit of the IRC. This proposal is needed to avoid potential exclusion of foam sheathing products due to the incompleteness of current code requirements which can negatively affect other concerns such as energy conservation code requirements and green building interests. Most importantly, these requirements will ensure that foam sheathing is used appropriately to prevent building envelope damage, particularly in higher wind conditions and with thinner material used on more widely spaced studs (e.g., 24"oc center on gable roof ends which typically have no interior finish). These requirements also agree reasonably well with the generally successful use of foam sheathing on typical wall assemblies (e.g., 16"oc framing or 24"oc framing with interior finish) on many homes in lower wind regions of the U.S.

TABLE R703.3.1- Part A (Actual design values based on test data – not rounded or capped as in the proposal)
MAXIMUM WIND SPEED (mph – 3 SECOND GUST) PERMITTED
FOR FOAM PLASTIC SHEATHING
WITH DIRECTLY ATTACHED SIDING PER SECTION R703.3.2.1

Foam Sheathing Material[3]	Foam Sheathing Nominal Thickness (in)	Maximum Wind Speed (mph) – Exposure B[4]			
		Walls with Interior Finish[5]		Walls without Interior Finish	
		16"oc framing	24"oc framing	16"oc framing	24"oc framing
EPS	¾" (unfaced)	110	73	92	61
	1" (unfaced)	147	98	123	82
	1-1/2" (unfaced)	222	148	186	124
Polyiso-cyanurate	½" (faced)	136	91	114	76
	¾" (faced)	177	118	148	99
	1" (faced)	193	129	162	108
	1-1/2" (faced)	207	138	173	116
XPS	½" (faced)	125	84	105	70
	¾" (unfaced)	109	73	91	61
	1" (unfaced)	145	97	121	81
	1-1/2" (unfaced)	208	139	174	116

Design value based on the minimum tested uniform pressure capacity for each sheathing type and thickness category divided by a safety factor of 1.5 and ASCE 7-05 positive pressure design loads for wall corner zone and a 10 sqft wind effective area (negative pressure is resisted by the foam sheathing and siding assembly). Because the 1.5 safety factor is applied to a minimum test value (not the average), these requirements are more stringent than safety margins required for other building envelop components such as doors and windows which are also important to envelope integrity. This "minimum test value" basis also serves to better control safety margins with regard to variability in material properties or performance.

TABLE R703.3.1 – Part B (Actual design values based on test data – not rounded or capped as in the proposal)
MAXIMUM WIND SPEED (mph – 3 SECOND GUST) PERMITTED
FOR FOAM PLASTIC SHEATHING
WITH FURRED SIDING PER SECTION R703.3.2.2[1]

Foam Plastic Sheathing Material[2]	Foam Sheathing Nominal Thickness (in)[2]	Maximum Wind Speed (mph) – Exposure B[3,4]			
		Walls with Interior Finish[5]		Walls without Interior Finish

	≥1-1/2"	192	128	161	107
Polyiso-cyanurate	½" (faced)	118	78	98	66
	¾" (faced)	153	102	128	85
	1" (faced)	167	112	140	93
	≥1-1/2" (faced)	179	120	150	100
XPS	½" (faced)	108	72	91	61
	¾"	94	63	79	53
	1"	126	84	105	70
	≥1-1/2"	180	120	151	101

Design value based on the minimum tested uniform pressure capacity for each sheathing type and thickness category divided by a safety factor of 1.5 and ASCE 7-05 negative pressure design loads for wall corner zone and a 10 sqft wind effective area. Because the siding is spaced away from foam sheathing in this wall covering assembly condition, it does not contribute to foam sheathing resistance. Thus, the foam sheathing must independently resist the negative wind pressure load. The furring strips provide adequate bearing at connection to secure the foam sheathing as well as the siding material.

In support of proposed new Section R703.3.2, the generalized connection requirements for siding over foam sheathing are based on an analysis using the AF&PA NDS-2005 connection design provisions in consideration of withdrawal to resist wind pressure and shear strength to resist siding dead load. To account for the "gap" in the connection caused by the presence of foam sheathing, the provisions of AF&PA TR12 were used to downgrade connection strength based on the thickness of foam sheathing (i.e., width of gap in the connection). The design shear strength was based on calculated ultimate capacity divided by a safety factor of 2 while conservatively ignoring any benefit of the foam material filling the gap in the siding or furring connection to wall framing. Wind loads were based on application of the full ASCE 7-05 components and cladding wind pressure applied to the exterior wall covering while conservatively ignoring any distribution of wind pressure to other wall layers. In addition, the wind pressures were based on the most stringent wall corner zone condition and an effective wind area of 10 sqft.

Changes to other parts of Section R703, including changes to Table R703.4 and various siding attachment requirements, are made in coordination with the above improvements.

Cost Impact: The code change proposal will increase the cost of construction.

Analysis: ASTM standards within this proposed are currently referenced in the I-codes.

ICCFILENAME: CRANDELL-FS1-1404.12

Public Hearing Results

PART II- IRC B/E

Committee Action: **Approved as Submitted**

Committee Reason: This is a needed addition to the code and will provide an efficient method to provide energy savings. The committee is concerned that this needs improvement but this is a good start. The proponent should work with industry and bring the needed improvement back to the Final Action.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Jay H. Crandell, PE, ARES Consulting, representing Foam Sheathing Coalition; Mark Nowak, representing Steel Framing Alliance, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R703.3 Foam plastic sheathing. Foam plastic sheathing used in exterior wall covering assemblies shall comply with this section, Section R316, Chapter 11 and the manufacturer's installation instructions. Light frame wood and cold-formed steel braced wall lines including foam plastic sheathing shall be braced with approved materials in accordance with Chapter 6. Where lateral buckling restraint of light-frame wood and cold-formed steel studs also is required in Chapter 6, foam sheathing shall not be permitted to provide the required lateral buckling restraint. When used in exterior wall covering assemblies in accordance with Table 703.3.1 of Section R703.3.1, foam sheathing shall be identified by the trademarks of an *approved* testing and inspection agency in accordance with Section 316.2 indicating compliance with the wind pressure resistance requirements of Table R703.3.1 where not already addressed in the applicable material standards. The use of foam plastic sheathing in accordance with this section shall not be permitted where the basic wind speed exceeds 110 mph.

~~**R703.3.1 Minimum thickness.** The thickness of foam plastic sheathing shall comply with Table R703.3.1.~~

Exceptions:

1. Where foam plastic sheathing is covered with ~~applied directly over or behind~~ wall sheathing or other solid material ~~substrate~~ capable of separately resisting the required wind pressure, the limitations of Section R703.3.1 and the basic wind speed limit of 110 mph ~~Table 703.3.1~~ shall not apply.
2. Where foam plastic sheathing is covered with cladding and applied directly over wall sheathing or other solid material, all capable of separately resisting the full design wind pressure, the limitations of Section R703.3.1 and the basic wind speed limit of 110 mph shall not apply.

R703.3.1 Minimum thickness. The thickness of foam plastic sheathing shall comply with Table R703.3.1. The components and cladding design wind pressure determined in accordance with Table R301.2(2) shall not exceed the allowable wind pressure value in accordance with Table R703.3.1.

For SI: 1 inch = 25.4 mm, 1 pound per square foot (psf) = 0.0479 kPa.

NP = not permitted (allowable design wind pressure less than 10 psf)

1. Foam plastic sheathing panels shall be permitted to be oriented parallel or perpendicular to framing members.
2. Foam plastic sheathing shall meet or exceed the following material standards: Expanded Polystyrene (EPS) – ASTM C578 (Type II, min.1.35 lb/ft^3 density), Polyisocyanurate – ASTM C1289 (Type 1, min.), and extruded polystyrene (XPS) – ASTM C578 (Type X, min. 1.30 lb/ft^3 density). Where a "faced" product is indicated, a facer shall be provided on both faces of the foam plastic sheathing. Where facing is not indicated in the table, faced and unfaced foam plastic sheathing shall be permitted. For all foam plastic sheathing products, approved manufacturer data shall be permitted in lieu of the table requirements.
3. Interior finish shall be minimum 1/2-inch (12.7 mm) thick gypsum wall board or an approved product with equivalent or greater out-of-plane bending strength and stiffness.

R703.3.2 Siding attachment over foam sheathing. Siding shall be attached over foam sheathing in accordance with Section R703.3.2.1, Section R703.3.2.2, or an approved design. In no case shall the siding material be used in a manner that exceeds its application limits.

Exception: Where the siding manufacturer has provided installation instructions for application over foam sheathing, those requirements shall apply.

R703.3.2.1 Direct siding attachment. Siding installed directly over foam sheathing without separation by an air space shall comply with Table R703.3.2.1 in regard to minimum fastening requirements ~~nail diameter, penetration, and nail spacing~~ and maximum foam sheathing thickness limitations to support siding dead load ~~for the applicable foam sheathing thickness and wind speed condition~~. The siding fastener and siding installation shall otherwise comply with Section 703.4 and Table R703.4 and in no case shall result in a less stringent fastening requirement than required by Section R703.4 or the manufacturer's installation instructions for the specific siding material used.

Exception~~s~~:

~~1.~~ ~~For adhered masonry veneer, refer to Section 1405.10.~~
~~2.~~ ~~For vinyl siding, refer to Section 1405.14.~~
~~3.~~ For exterior insulation and finish systems, refer to Section 1408.

~~**TABLE R703.3.2.1**~~

For SI: 1 inch = 25.4 mm; 1 pound per square foot (psf) = 0.0479 kPa.

DR = design required

1. Tabulated requirements are based on wood framing of Spruce-Pine-Fir or any wood species with a specific gravity of 0.42 or greater in accordance with AFPA/NDS and minimum 33 ksi steel for 33mil and 43 mil steel and 50 ksi steel for 54 mil steel or thicker.
2. Nail fasteners shall comply with ASTM F1667, except nail length shall be permitted to exceed ASTM F1667 standard lengths. Self-drilling tapping screw fasteners for connection of siding to steel framing shall comply with the requirements of AISI S230. Specified fasteners in accordance with Section R703.4 or the siding manufacturer's approved installation instructions shall meet all other requirements in ASTM F1667, AISI S230 or be otherwise approved for the intended application.

R703.3.2.2 Offset siding attachment. When an airspace separates the siding from direct contact with the foam plastic sheathing, the siding shall be attached in accordance with Section R703.4 and Table R703.4 to minimum 1x3 wood or minimum 33 mil steel hat channel furring ~~strips~~ placed over the foam sheathing. Furring shall be attached through the foam sheathing to wall framing in accordance with Table R703.3.2.2 in regard to minimum fastening requirements and maximum foam sheathing thickness limitations to support siding dead load. The components and cladding design wind pressure determined in accordance with Table R301.2(2) shall not exceed the allowable design wind pressure value in accordance with Table R703.3.2.2. For 25 psf siding weight in accordance with Table R703.3.2.2, the Seismic Design Category shall not exceed D_0 for 16"oc furring or C for 24”oc furring. When placed horizontally, wood furring ~~strips~~ shall be preservative treated wood or naturally durable wood and fasteners shall be corrosion resistant in accordance with Section R317. Steel hat channel furring shall have a minimum G60 galvanized coating.

> **Exception:** Furring ~~strips~~ shall not be required over foam plastic sheathing located behind anchored stone and masonry veneer installed in accordance with Section R703.7. Veneer ties shall be installed in accordance with Section R703.7.4.1.

~~For SI: 1” = 25.4 mm; 1 mph = 1.609 km/h~~
~~DR = design required~~

1. ~~Furring strips shall be spaced a maximum of 24”oc in a vertical or horizontal orientation. Table values are based on minimum ¾-inch (19.1 mm) thick furring strip and wood studs of Spruce-Pine-Fir or any wood species with a specific gravity of 0.42 or greater per AFPA/NDS.~~
2. ~~Tabulated maximum wind speed values are based on a mean roof height of 30-feet (9.1 m). Multiply maximum wind speed by 0.95 for a mean roof height of 45 feet (13.7 m).~~
3. ~~Where minimum required siding fastener penetration exceeds ¾ inch (19.1 mm), a minimum 2x furring strip shall be used unless approved deformed shank siding nails or siding screws are used to provide equivalent withdrawal strength.~~
4. ~~In a vertical orientation, furring strips shall be located over wall studs and attached with the required fastener spacing. In a horizontal orientation, furring strips shall be fastened at each stud intersection with a number of fasteners equivalent to the required fastener spacing. In no case shall fasteners be spaced more than 24 inches (0.6 m) apart.~~
5. ~~Maximum foam sheathing thickness values are based on a maximum 24-inch (0.6 m) stud spacing and a maximum siding dead load of 11 psf (0.53 kPa) based on 7/8-inch (22 mm) thick Portland cement plaster. For Seismic Design Category D2, the maximum siding dead load shall be 8 psf.~~
6. ~~Lag screws shall be installed with a standard cut washer and shall be pre-drilled in accordance with AF&PA NDS-05. Approved self-drilling screws of equal or greater shear and withdrawal strength shall be permitted without pre-drilling.~~

		#10 screw (0.333" head)	Steel thickness +3 threads	12	4	3	1.5	4	3	DR	81.9	54.6
				16	4	3	0.5	4	2	DR	61.5	41.0
				24	4	2	DR	4	0.5	DR	35.1	23.4

For SI: 1" = 25.4 mm; 1 pound per square foot (psf) = 0.0479 kPa. DR = design required

1. Table values are based on: (1) minimum ¾-inch (19.1 mm) thick wood furring and wood studs of Spruce-Pine-Fir or any softwood species with a specific gravity of 0.42 or greater per AFPA/NDS, (2) minimum 33 mil steel hat channel furring of 33 ksi steel, and (3) steel framing of indicated nominal steel thickness and minimum 33 ksi steel for 33mil and 43 mil steel and 50 ksi steel for 54 mil steel or thicker. Steel hat channel shall have a minimum 7/8-inch (22.2 mm) depth.
2. Nail fasteners shall comply with ASTM F1667, except nail length shall be permitted to exceed ASTM F1667 standard lengths. Self-drilling tapping screw fasteners for connection of siding to steel framing shall comply with the requirements of AISI S230. Specified fasteners in accordance with Section R703.4 or the siding manufacturer's approved installation instructions shall meet all other requirements in ASTM F1667 or AISI S230 or be otherwise approved for the intended application.
3. Where the required siding fastener penetration into wood material exceeds ¾ inch (19.1 mm) and is not more than 1-1/2 inches (38.1 mm), a minimum 2x wood furring shall be used unless approved deformed shank siding nails or siding screws are used to provide equivalent withdrawal strength allowing connection to 1x wood furring.
4. Furring shall be spaced a maximum of 24"oc in a vertical or horizontal orientation. In a vertical orientation, furring shall be located over wall studs and attached with the required fastener spacing. In a horizontal orientation, furring strips shall be fastened at each stud intersection with a number of fasteners equivalent to the required fastener spacing. In no case shall fasteners be spaced more than 24 inches (0.6 m) apart.
5. Lag screws shall be installed with a standard cut washer. Lag screws and wood screws shall be pre-drilled in accordance with AF&PA/NDS. Approved self-drilling screws of equal or greater shear and withdrawal strength shall be permitted without pre-drilling.

(Portion of proposal not shown, remain unchanged.)

Commenter's Reason: While the original proposal was approved as submitted, IRC CDC recommended further refinements at Final Action. Every effort has been made to follow-up with the various interests and to respond with improvements to the original proposal, even though approved as submitted. The improvements in this PC are also coordinated with a complimentary PC on FS156-09/10 Part1 (IBC). These refinements are coordinated in this one PC for reasons addressed separately as follows:

Inclusion of Steel Framing

Tables R703.2.1 and R703.2.2 now include siding connections for use with light-frame cold-formed steel siding in addition to light-frame wood as requested at the first hearing. These are needed to provide siding connection solutions applicable to light-frame cold-formed steel construction to ensure coordination with IRC Ch11 and IECC energy code requirements for this type of construction. The Steel Framing Alliance (SFA), American Iron and Steel Institute (AISI), and the Foam Sheathing Coalition (FSC) have worked together toward this end.

The original proposal included connection solutions for attachment of siding over foam sheathing only for wood framing. But, the scope of the original proposal was not otherwise limited to wood framing (i.e., requirements in Table 1405.18.1 of the original proposal are applicable to both wood and steel framing). The IRC committee approved the original FS156-09/10 proposal, but also expressed concern to "work with industry and bring the needed improvement back to the Final Action."

Steel framing was not addressed in the original proposal only because test data was not available at that time to justify appropriate solutions. Subsequently, the steel industry together with New York State Research and Energy Development Authority (NYSERDA) has conducted a testing program to provide justification to the solutions proposed in this PC. A report on this testing will be made available at the Final Action hearing and, as soon as available, by request to the proponent (Mark Nowak, SFA, mnowak@steelframing.org). These tests provide the necessary performance data for appropriately designing siding connections to steel framing that span through a thickness of foam sheathing.

These proposed provisions for light-frame cold-formed steel construction are not only coordinated with ICC energy code requirements, but they are necessary to ensure that foam insulation requirements as required by the ICC energy code are implemented in a structurally sound manner. Support of this PC is urged.

Inclusion of Additional Siding Weight Categories:

The original proposal was based on a minimum 11 psf siding dead load (for siding attachment requirements over foam sheathing). While various siding manufacturers supported the original proposal (or remained neutral), several expressed the desire to be included, such as the Masonry Veneer Manufacturers Association. Thus, a 25 psf siding weight category and connection requirements have been included in this PC. This also required inclusion of a 3 psf siding weight category such that the lighter weight sidings would not be unduly penalized by basing the table only on heavier siding types.

Simplification, Clarification and Editorial Improvements:

Content from table footnotes moved into tables for visual clarity and ease of access.
Removed confusing wind speed requirements from siding attachment table otherwise intending to provide minimum connections for support of siding dead load only and limit foam thickness accordingly. The text is clarified to more explicitly require that the siding attachment be separately designed to resist wind loads.
Adjusted fastener sizes to be compatible with pneumatic fasteners at request of ISANTA
Various editorial improvements to language, table headings, etc.

Additional technical justification for siding and furring connections over foam sheathing

The FSC has also funded additional testing of siding over foam sheathing connection assemblies for attachments to wood framing. These tests add further confirmation of the adequacy of the proposed siding attachment requirements for wood framing. It also confirms that siding deflections will be limited to less than 0.015" as commonly used as a design basis for wood connections. A report documenting this testing will also be made available at the final action hearing and will be posted at www.foamsheathing.org as soon as available.

Strengthened QC requirements for foam sheathing wind pressure resistance properties

One of the concerns raised at the first code development hearing on FS156 was related to having assurance that foam sheathing products meet the wind pressure performance requirements upon which the proposal (namely Table R703.3.1) is based. This public comment addresses that concern by clarifying implementation a code-recognized "approved agency" approach that already exists and is commonly used for foam sheathing and other products. The "approved agency" process has shown itself effective and this public comment merely clarifies the application of this process to assure the structural properties (wind pressure resistance) of foam sheathing align with the basis of the proposed end-use requirements and limitations. The minimum performance requirements are based on a representative sample of currently manufactured products of each type as reported by the NAHB Research Center, Inc. (report available at www.foamsheathing.org).

Strengthened Scope Limitations on Foam Sheathing Applications

At the request of the insurance industry, a 110 mph wind speed limit has also been implemented in this proposal for foam sheathing. In addition, wind pressure requirements have been strengthened to require use of negative pressure values in all cases, even when siding is placed over foam sheathing and the siding is separately capable of resisting the full negative design wind pressure.

These provisions are needed for the above reasons, provide improvements for appropriate use of foam sheathing, and provide needed solutions for coordination with the energy code requirements. Again, your approval as modified is urged.

Public Comment 2:

Kimdolyn Boone representing DuPont Building Innovations, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R703.5.1 Application. Wood shakes or shingles shall be applied either single-course or double-course over nominal 1/2-inch (13 mm) wood-based sheathing or to furring strips over nominal 1/2-inch (13 mm) nonwood sheathing.

> **Exception:** Wood shakes or shingles over foam plastic sheathing, shall be applied to wood furring strips in accordance with Section R703.3.2.2.

A permeable water-resistive barrier shall be provided in accordance with Section R703.2. Where furring strips are used, they shall be 1 inch by 3 inches or 1 inch by 4 inches (25mmby 76 mm or 25mm by 102 mm), and shall be fastened horizontally to the studs with 7d or 8d box nails. For application over foam plastic sheathing, furring strips shall be fastened in accordance with Section R703.3.2.2. and Furring strips shall be spaced a distance on center equal to the actual weather exposure of the shakes or shingles, not to exceed the maximum exposure specified in Table R703.5.2. The spacing between adjacent shingles to allow for expansion shall not exceed 1/4 inch (6 mm), and between adjacent shakes, it shall not exceed 1/2 inch (13 mm). The offset spacing between joints in adjacent courses shall be a minimum of 11/2 inches (38 mm).

(Portions of proposal not shown, remain unchanged.)

Commenter's Reason: The purpose of this public comment is to re-insert the word "permeable" which is already in the 2009 code and was removed by the original proposal.

In the technical hearings the committee approved this proposal but also noted that the proposal requires work. This public comment addresses one of the flaws with the original proposal. We look forward to combining this public comment with other public comments from the industry that address other flaws.

It is not appropriate to remove the descriptor "permeable". The removal of the word "permeable" changes the water-resistive barrier requirement because the "permeable" designation is specific to shingle/shake cladding and is not included in Section 703.2.   Reducing the water-resistive barrier permeability may result in the reduction in the wall structure's ability to dry and thus be detrimental to building performance. The proponent provided no information to support the removable of the word "permeable".

This proponent also proposed or supported modifications to remove "permeable" from other agenda items (FS150 part 1 and RB134) at the technical hearings. All of these modifications/proposals were disapproved by the technical committee. As stated in the Report of Hearings, the FS156 proposal listed in the monograph did not strike this word; it was stricken in the errata (which was not published to the ICC website). The permeability requirement was not a topic of discussion in the public hearing on this item.

Public Comment 3:

John Ingargiola, Federal Emergency Management Agency, requests Disapproval.

FEMA is opposed to requirements for foam plastic sheathing in exterior wall coverings as shown in code change proposal FS156. A number of technical concerns were expressed by FEMA at the Baltimore hearings and these concerns and others are summarized herein. In many cases, recommendations are provided to the proponent of FS156 so that FEMA concerns can be addressed and a revised proposal can be supported. The following are among concerns with requirements of FS156:

A) Wall sheathing applications under FS156 extend far beyond results from tests raising questions over safe application of the requirements. For siding applied directly over foam plastic sheathing, several installation details are used in the tests which are not included as construction requirements or limitations for use of foam sheathing. These include the following: (i) foam sheathing attached to all framing at 12" on center with 7/16" head x 0.120" shank diameter galvanized roofing nails, (ii) all foam sheathing edges backed with and nailed to framing, and (iii) no adjoining foam sheathing panel edge joints over a common stud. Also, FS156 broadly permits use of foam sheathing in thicknesses greater than 1-1/2" yet the maximum thickness tested in negative pressure assembly tests was ½". Additional product testing is recommended to ensure that failure mechanisms are properly addressed for each product based on code required construction methods.

B) Table R703.3.2.1 Fastening Requirements for Direct Siding Attachment Over Foam Plastic Sheathing does not identify fastener head size for use to attach siding. Negative pressure tests utilized siding nails with 3/8" diameter head; however, a smaller head size is permitted to be used per other requirements of the code. Therefore, the strength of the overall system based on tests may be in excess of strength for actual applications where smaller head sizes are permitted.

C) The Factor of Safety of 1.5 used to adjust test pressures to allowable pressures is too small relative to that provided by structural sheathing. The factor of safety of 1.5 for vinyl siding wind ratings has previously been identified as an area of concern in a FEMA Mitigation Assessment Team Report (Hurricane Ike) due to observed failures of siding. An increased safety factor for applications where the foam sheathing and siding are assumed to act as a composite structural element to resist wind is needed to ensure the integrity of the building envelop and to protect against a "through wall" wind pressure failure of the building envelope should either the siding of foam sheathing fail. In some cases, interior gypsum wallboard failure may precipitate a "through wall" failure given the system approach used to establish vinyl siding and foam sheathing requirements in the IRC (e.g. interior gypsum wallboard considered to resist a portion of wind pressures). A safety factor of 3 is commonly associated with structural wall sheathing applications based on the average factor of safety for nail withdrawal. If a safety factor of 3 were to be used rather than 1.5, tabulated wind speeds for many of the products would be reduced by approximately 30%.

D) There is no assurance that the structural properties of the foam sheathing used in the tests, which are necessary to ensure resistance to wind pressures, are representative of structural characteristics of foam sheathing permitted under FS156. FS156 broadly permits applications for foam sheathing including those with and without proprietary "facers" that contribute to the strength of the product. It is recommended that a mechanism for "fingerprinting" structural characteristics of foam sheathing products used in wind resistance tests be established and monitored as part of a product standard to ensure wind resistance performance is maintained in wall sheathing applications. These characteristics include bending capacity, bending stiffness, and nail head pull through.

E) The testing and analysis does not represent the effect of fluctuating positive and negative pressures expected in real wind events. The allowable pressure rating of 1-1/2" EPS foam sheathing (e.g. 89 psf or wind speed of 222 mph) appears high relative to wood structural panel products used in wall sheathing applications. For example 19/32" wood structural panel has an allowable pressure capacity of 90 psf in accordance with the *Special Design Provisions for Wind and Seismic* (SDPWS). The similarity in allowable pressure ratings is due in part to differences in safety levels, differences in test methods, and differences in analysis methods between foam sheathing and commonly used structural products for wall sheathing applications.

Public Comment 4:

Edward L. Keith, PE, representing APA – The Engineered Wood Association, requests Disapproval.

Request that the body overturn the committee's recommendation for approval as submitted and disapprove the code change proposal.

The intent of the original code change proposal is to prescriptively permit the use of non-structural foam insulation as a structural wall sheathing for all wall locations that are not required as wall bracing. This proposal would permit the use of non-structural foam sheathing in areas with a design wind speed of 130 mph. This proposal is seriously flawed by ignoring the life-safety consideration mandated by the IRC, not to mention the increased risk for property damage.

Provisions of Section R301.2.1, reproduced below, clearly require the wall sheathing to be designed for the loads normal to the wall surface (important provisions are underlined for clarity).

> ***R301.2.1 Wind limitations.*** *Buildings and portions thereof shall be limited by wind speed, as defined in Table R301.2(1) and construction methods in accordance with this code. Basic wind speeds shall be determined from Figure R301.2(4). Where different construction methods and structural materials are used for various portions of a building, the applicable requirements of this section for each portion shall apply. <u>Where loads for wall coverings</u>, curtain walls, roof coverings, exterior windows, skylights, garage doors and exterior doors <u>are not otherwise specified, the loads listed in Table R301.2(2) adjusted for height and exposure using Table R301.2(3) shall be used to determine design load performance requirements for wall coverings</u>, curtain walls, roof coverings, exterior windows, skylights, garage doors and exterior doors…*

This proposal takes the advantage of a loop hole in the IRC found in Section R301.1: The loop hole permits prescriptive portions to be deemed-to-comply with the intent of the code, as seen below:

> ***R301.1 Applications.*** *…Buildings and structures constructed as prescribed by this code are deemed to comply with the requirements of this section*.

The intent of this provision is to permit methods with a proven <u>history</u> of adequate performance not to be required to meet the engineering requirements of the code. It is disingenuous to use these provisions to permit systems with known performance issues to be exempt from the structural requirements of the code.

Thunderstorms in the Midwest (Evansville, Indiana and Southwest Missouri, areas of nominal 85 mph wind speed) have left countless houses stripped of siding and foam wall sheathing. In most cases the actual wind loads were well below the maximum design wind speed. In some cases only the wall sections containing the wall bracing panels were left to protect the interior of the home (see photos below). Additional photos are available in the Spring and Summer issues of the 2008 Wood Design Focus.

Figure 1. – Foam and vinyl wall covering failure.
(Storm damage – Southern IN, 2005)

Figure 2 – Foam and vinyl wall covering failure while wall bracing panel remains.
(Storm damage, Springfield, MO, 2006)

Please note that the legacy codes, the ICC, as well as their corresponding product evaluation organizations have long required all structural products to meet all of the below 3 requirements:

1. They must be manufactured to proprietary or consensus based structural standards. These standards describe the minimum physical properties, testing criteria, and durability requirements that must be met by the material for its intended end use.
2. An established quality control program must be in place and supported by the manufacturer to insure that the minimum standards are being met by the production facility.
3. An approved third-party quality assurance inspection agency must be under contract to monitor the manufacturer's QC program and issue trademark stamps.

These requirements are designed to protect the public from unsafe construction. While foam insulation boards are manufactured to <u>insulation standards</u>, these products meet none of the structural requirements specified for all other structural products. Unlike wood structural panels or structural fiberboard sheathing, foam insulation is not manufactured to consensus-based structural product manufacturing standards. As such, the structural performance of foam sheathing is undefined and uncontrolled. Furthermore, the quality control and quality assurance programs adopted by the foam sheathing manufacturers are limited to the control of insulation characteristics of the products, but not the structural performance. The use of non-structural sheathing for structural applications is a serious life-safety issue.

Sections R612.5 and R612.6 require the same level of protection for windows and doors as is required for wood structural panels and structural fiberboard products:

__R612.5 Performance.__ Exterior windows and doors shall be designed to resist the design wind loads specified in Table R301.2(2) adjusted for height and exposure per Table R301.2(3).

__R612.6 Testing and labeling.__ Exterior windows and sliding doors shall be tested by an approved independent laboratory, and bear a label identifying manufacturer, performance characteristics and approved inspection agency to indicate compliance with AMA/WDMA/CSA 101/I.S.2/A440…

It is interesting to note that these requirements for windows and doors will be maintained in place while the walls are prescriptively permitted to be protected only by non-structural foam insulation that has none of the historic manufacturing safeguards in place. We used to hope that our windows and doors were as strong as our walls in a storm; this proposal effectively reverses this expectation!

We urge overturning of the committee due to the serious flaw of the proposal in ignoring the important life-safety issue.

Public Comment 5:

Dennis Pitts representing American Wood Council, American Forest & Paper Association, requests Disapproval.

While some limited testing of rigid foam sheathing has been conducted, these products are not structural materials. Structural properties and requirements have not been quantified, quality control requirements to have not been specified, and product labeling to ensure proper selection and structural performance do not exist. To date, these products rely on the contribution of other construction elements to resist racking and out-of-plane loads. At the IBC Structural Committee hearings during discussion of FS156 Part I, a number of issues of concern were identified by various groups and the proponent of Part I asked for it to be denied. These same issues were raised at the IRC Committee hearings during the discussion of Part II, but the proponent chose to ignore them, as did a majority of the IRC Committee members. In review, the following points were made:

1. The various foam sheathing insulation board products on the market are proprietary products manufactured and qualified under various material specifications; Expanded Polystyrene (EPS) – ASTM C578 (Type II), Polyisocyanurate – ASTM C1289 (Type 1), and Extruded Polystyrene (XPS) – ASTM C578 (Type X). These material specifications ensure that the product meets minimum density, thermal, and consistency requirements; however, these material specifications are not product standards and do not reference testing or state structural requirements needed to determine and regulate these products in structural applications.
2. Testing provided by the Foam Sheathing Coalition in support of this change and verified by others suggests that a significant portion of the out-of-plane bending capacity of the foam sheathing board results from the proprietary facers that are applied to the insulation. These facers are neither identified nor required. Since there are no product standards to regulate these products, the manufacturer can use any facer material to qualify the board but use anything else or leave the facer off completely if so chosen. As a result, any claims as to the capacity of any specific product would be limited to a single manufacturer and, potentially, to a single run of the product.
3. Fastener requirements outlined in the proposal are unreasonable. For example, Table 1405.18.2.1 recommends the use of a 0.120" nail, penetrating at least 1.25" into the wood framing, to attach 3" thick foam sheathing. This would require a nail that is at least 4.25" long to be driven through the foam and hit the 1.5" thick framing member… nearly 50% longer than the standard length of this size nail. In addition, without high-strength proprietary nails, a nail of this length would likely bend or buckle before penetrating the wood member… but without detection because it would buckle within the 3" foam.
4. Installation provisions, verified by limited negative load (suction) testing, require that the exterior covering, such as vinyl siding, be used to hold the foam sheathing on to the exterior wall. In this application, the exterior covering becomes the "structural element" of the building envelope. Efforts have been made to show that the exterior covering and foam sheathing act as a system to resist the wind loads; however, the suitability of this design approach is questionable because the survival of the entire wall envelope is dependant on the exterior covering (e.g. vinyl siding). Dynamic loading effects caused by wind turbulence are ignored in the proposed change. Fluctuating positive and negative pressures will play a greater role in the loss of flexible coverings than negative pressures alone as utilized in testing.

Based on these concerns, we strongly recommend that the ICC membership reconsider the IRC Committee's recommendation and follow the IBC Structural Committee's recommendation and deny this change. Until such time as a product standard for these products is developed that addresses structural requirements, product changes, proprietary facers, structural quality control, and product labeling, these products should continue to be reviewed and evaluated by one of the Evaluation Services as an alternative material and used as an alternative means of meeting the requirements of the code.

Final Action: AS AM AMPC____ D

FS166-09/10
2603.4.1.5, 2603.6

<u>Proposed Change as Submitted</u>

Proponent: Tony Crimi, AC Consulting Solutions Inc., representing North American Insulation Manufacturers Association

Revise as follows:

2603.4.1.5 Roofing. Foam plastic insulation under a roof assembly or roof covering <u>having a smoke-developed index of not more than 450, and</u> ~~that is~~ installed in accordance with the code and the manufacturer's instructions shall be separated from the interior of the building by wood structural panel sheathing not less than 0.47 inch (11.9 mm) in thickness bonded with exterior glue, with edges supported by blocking, tongue-and-groove joints or other approved type of edge support, or an equivalent material. A thermal barrier is not required for foam plastic insulation that is a part of a Class A,B or C roof-covering assembly, provided the assembly with the foam plastic insulation satisfactorily passes FM 4450 or UL 1256.

2603.6 Roofing. Foam plastic insulation meeting the requirements of Sections 2603.2, 2603.3 and 2603.4 <u>and having a smoke-developed index of not more than 450,</u> shall be permitted as part of a roof-covering assembly, provided the assembly with the foam plastic insulation is a Class A, B or C roofing assembly where tested in accordance with ASTM E 108 or UL 790.

Reason: Fires in roofing materials can occur during installation or maintenance of roofing, during the normal course of operations, or during maintenance and installation of building equipment. While ASTM E108 and UL 790 are a means of evaluating fire spread, they do not measure smoke production.

Although roofing materials are installed on the exterior of a building, the smoke from burning roof insulations can be a hazard to both firefighters and the environment. Combustible smoke and off-gassing from combustible insulating materials pose a serious risk to building occupants and firefighters. Excessive quantities of smoke emanating from burning roofing materials also prevent effective firefighting operations, potentially delay response times or the effectiveness of fire fighting operations. There are also documented cases of fires starting in roofing materials causing sprinklers inside the building to activate and cause additional property damage.

Even when a fire is contained within the building, sufficient heat can be generated through a metal roof deck to cause smoldering combustion and smoke release. While a smoke developed index of 450 is consistent with some interior applications, it still represents a limit which most foam plastic insulations can conform with.

Several foam plastic insulation products have direct-to-steel-deck approvals from both FM and UL. FM approval for Class 1 roof systems based on passing FM 4450 and UL 1256. Both of these tests are specifically referenced in the IBC. The International Building Code (IBC) already waives the requirements for a thermal barrier for foam plastic roof insulation used in roof deck construction that complies with FM 4450 or UL 1256. Some minimum smoke developed rating should be maintained.

Cost Impact: This proposal should not increase the cost of construction.

ICCFILENAME: CRIMI FS9 AND FS10

<u>Public Hearing Results</u>

Committee Action: **Disapproved**

Committee Reason: The committee felt that Section 2603.3 already has this requirement and therefore this proposal is redundant.

Assembly Action: **None**

<u>Individual Consideration Agenda</u>

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Tony Crimi, AC Consulting Solutions Inc, representing North American Insulation Manufacturers' Association (NAIMA), requests Approval as Submitted.

Commenter's Reason: Fires in roofing materials can occur during installation or maintenance of roofing, during the normal course of operations, or during maintenance and installation of building equipment. While ASTM E108 and UL 790 are a means of evaluating fire spread, they do not measure smoke production. In this case, contrary to the published committee reason, smoke development ratings for roofing insulations and coverings are clearly exempted in 2603.3 Exception #3, and in 2603.6.

Although roofing materials are installed on the exterior of a building, the smoke from burning roof insulations can be a hazard to both firefighters and the environment. Air intakes are often installed through the roofing. In the event of a fire on the roof, smoke will be drawn back into the building through these intakes. Similarly, occupants of adjacent buildings and neighborhoods can also be affected by smoke emanating from combustible roof insulations. Emissions from fires in roofing materials have a serious impact on the environment. Not only are the combustion gases toxic at the site of the fire, but during a fire, very large quantities of particulates are also released into the environment. The particles consist among others of soot, tar, unburned materials, and inorganic debris.

In addition to the reasons include with the original Proposal, it should also be acknowledged that rooftop Occupancies are becoming increasingly popular. The existing provisions for rooftop structures in Chapter 15 are largely prescriptive and do not envision facilities such as restaurant seating, gardens, or performances on rooftops.

Final Action: AS AM AMPC____ D

FS167-09/10
2603.4.1.5, 2603.4.1.5.1, 2603.4.1.5.2

Proposed Change as Submitted

Proponent: Mike Ennis, Single Ply Roofing Industry (SPRI), representing the Single Ply Roofing Industry (SPRI)

Revise as follows:

2603.4.1.5 Roofing. Foam plastic insulation under a roof assembly or roof covering shall comply with Sections 2603.4.1.5.1 and 2603.4.1.5.2 as applicable.

2603.4.1.5.1 Wood roof decks. A thermal barrier is not required for foam plastic insulation that is part of a Class A, B or C roof-covering assembly, provided the assembly ~~under a roof assembly or roof covering that~~ is installed in accordance with the code and the manufacturer's instructions and is ~~shall be~~ separated from the interior of the building by wood structural panel sheathing not less than 0.47 inch (11.9 mm) in thickness bonded with exterior glue, with edges supported by blocking, tongue-and-groove joints or other approved type of edge support, or an equivalent material.

2603.4.1.5.2 Any roof deck. A thermal barrier is not required for foam plastic insulation that is part of a Class A, B or C roof-covering assembly, provided the assembly with the foam plastic insulation satisfactorily passes FM 4450 or UL 1256.

Reason: The proposed wording is offered to clarify when the two exceptions for a thermal barrier in Section 2603.4.1.5 are applicable. The first sentence in the current version 2603.4.1.5 is only applicable when a wood roof deck is used. The second sentence is applicable for any type of roof deck. The proposed wording provides clarification without changing the intent.

Cost Impact: The code change proposal will not increase the cost of construction

ICCFILENAME: ENNIS-FS2-2603.4.1.5

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee felt that the current language was clearer than the proposal.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Mike Ennis, representing Single Ply Roofing Industry (SPRI), requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

2603.4.1.5 Roofing. A thermal barrier is not required for foam plastic insulation under a roof assembly or roof covering if either of the following conditions are met: ~~shall comply with Sections 2603.4.1.5.1 and 2603.4.1.5.2 as applicable.~~

~~**2603.4.1.5.1 Wood roof decks.**~~ 1. A thermal barrier is not required for foam plastic insulation that is part of a Class A, B or C roof-covering assembly, provided the assembly is installed in accordance with the code and the manufacturer's instructions and is separated from the interior of the building by wood structural panel sheathing not less than 0.47 inch (11.9 mm) in thickness bonded with exterior glue, with edges supported by blocking, tongue-and-groove joints or other approved type of edge support, or an equivalent material.

~~**2603.4.1.5.2 Any roof deck.**~~ 2. A thermal barrier is not required for foam plastic insulation that is part of a Class A, B or C roof-covering assembly, provided the assembly with the foam plastic insulation satisfactorily passes FM 4450 or UL 1256.

Commenter's Reason: The original code change proposal was submitted to provide clarification to the thermal barrier exception language for roofing contained in Section 2603.4.1.5 Roofing. This section provides two separate conditions for which the thermal barrier is not required. The first is a construction option. Roof decks constructed with minimum 0.47" thick structural wood panel sheathing, with edges supported by blocking, tongue and groove joints or other approved types of edge support do not require a thermal barrier. The second option offered in this Section is a testing option. If the roof assembly has passed UL1256 or FM4450, then a thermal barrier is not required. In the current Section 2603.4.1.5 these options are contained in the same paragraph and it is not clear that they are two separate options. During the code change hearings the Committee felt the proposed wording was more confusing than the current wording. This modification is offered to provide additional clarification.

Final Action: AS AM AMPC____ D

FS180-09/10

2606.5, 2609.1.1 (New), 2610.1.1 (New)

Proposed Change as Submitted

Proponent: J. Nigel Ellis, representing Ellis Fall Safety Solutions, LLC

1. Revise as follows:

2606.5 Structural requirements. Light-transmitting plastic materials in their assembly shall be of adequate strength and durability to withstand the loads indicated in Chapter 16. Technical data shall be submitted to establish stresses, maximum unsupported spans and such other information for the various thicknesses and forms used as deemed necessary by the *building official*. Every skylight shall be guarded by a standard skylight screen or a fixed standard railing on all exposed sides. Skylight screens shall be of such construction and mounting that they are capable of withstanding a load of at least 200 lbs applied perpendicularly at any one area on the screen. They shall also be of such construction and mounting that under ordinary loads or impacts, they will not deflect downward sufficiently to break the glass below them. The construction shall be of grillwork with openings not more than 4 inches long or of slatwork with openings not more than 2 inches wide with length unrestricted.

2. Add new text as follows:

2609.1 General. Light-transmitting plastic roof panels shall comply with this section and Section 2606. Light-transmitting plastic roof panels shall not be installed in Groups H, I-2 and I-3. In all other groups, light-transmitting plastic roof panels shall comply with any one of the following conditions:

1. The building is equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1.
2. The roof construction is not required to have a fire-resistance rating by Table 601.
3. The roof panels meet the requirements for roof coverings in accordance with Chapter 15.

2609.1.1 Guarding. Light-transmitting roof panels and assemblies shall be guarded as required by Section 2606.5.

3. Add new text as follows:

2610.1 Light-transmitting plastic glazing of skylight assemblies. Skylight assemblies glazed with light-transmitting plastic shall conform to the provisions of this section and Section 2606. Unit skylights glazed with light-transmitting plastic shall also comply with Section 2405.5.

> **Exception:** Skylights in which the light-transmitting plastic conforms to the required roof-covering class in accordance with Section 1505.

2610.1.1 Guarding. Unit skylight assemblies shall be guarded as required by Section 2606.5.

Reason: The proposed wording is verbatim Federal OSHA standard from 1971 and needs to be reflected in the building code because Chapter 16 loading is inadequate for human falls onto skylights and skylight manufacturers are not the only users of the skylights they produce. In other words some building owners may not be employers who maintain the roof skylights and therefore need the protection from the manufacturers in each installation going forward with the inclusion or design integration of a necessary hazard control.

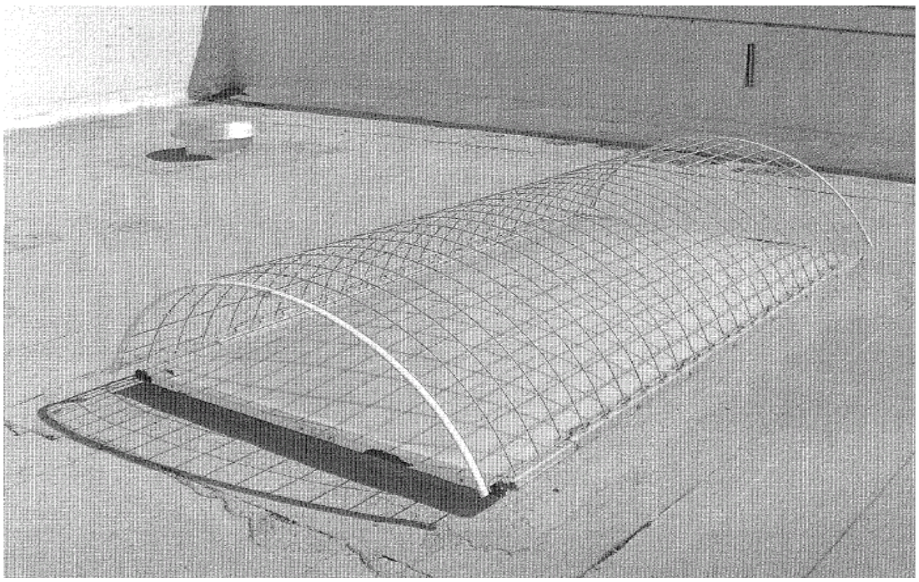
Fatalities from falls through skylights which category for inclusion includes light-transmitting panels and smoke vents are documented by the Bureau of Labor Statistics which in 2006 accounted for 36 deaths in non-government buildings in the USA www.bls.gov. Skylights have their own fatal fall category as opposed to roof or floor openings that also have their own listing. The Federal requirement for General Industry is 29CFR1910.23(a)(4) and (e)(8) which became mandatory in 1971 for employers.

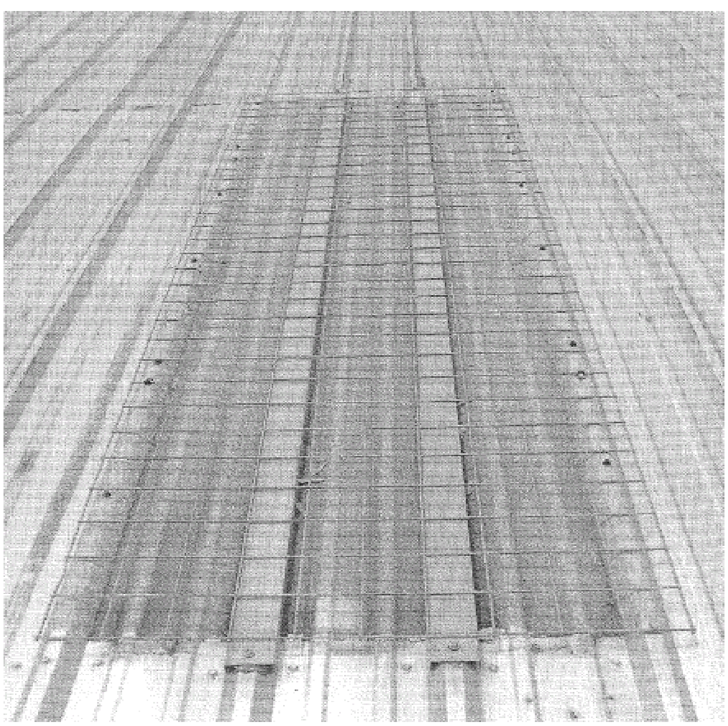
There are also similar requirements in the 1926.500-503 Construction regulations that equate skylights with open holes and require the use of adequate covers. The ANSI A1264.1 and A10.18 are similarly worded but all are aimed ineffectively at employers with exposed employees but not exposed independent contractors who visit dozens of building roofs each month without a feasible protection method e.g. HVAC, Laborers, roofers, Window Cleaners etc.).

However after 38 years not even 1% of skylights have the required screen protection. Ref Plasteco President Key Sandow. Skylight manufacturers do not mark their skylights clearly in the same way that auto glazers do, so that manufacturers may never know their skylight ever failed to support a falling worker. Instead, the blame falls on the injured person for not knowing to stay away from or be careful around skylights. My experience is that workers do not know the degree of danger stepping close to skylights until it is too late nor do their employers.

Plastic skylights may survive impacts from falling or tripping by the trades (of which there may be 25 or more) when new but almost all suffer from uv light degradation over the years. An alternative that also takes care of controlling intruders is under-skylight grills especially for opening smoke vents and similar skylights and corrosive conditions and sometimes both to reduce fall distances to 4 ft or less per OSHA General Industry requirements. Skylights are maintained today by sealing leaks with silicone, fiberglass or equivalent and appear in “good” condition on maintenance company reports to the building owner if they do not presently leak despite the fact that they have cracks after a few years in the sun and are patched regularly. There is no common lifetime for plastic skylights that may now be 50+ years old and users do not currently replace a skylight unless a leak cannot be stemmed.

The request is to include the federal requirement in the IBC Building Code and carry the responsibility to architects, engineers and building owners and managers to protect the work trades that maintain the roof systems in those buildings by including adequate protection in specifications. No building owner expects that a skylight will have a disastrously weak strength that a worker can step onto and through as the years progress eventually almost as easily as pushing a finger through. The OSHA interpretation by John Miles in 1984 does not anticipate the degradation that occurs with almost all synthetic-related skylights nor the dynamic force of a slip, trip and/or fall by a passing worker. Use of personal fall arrest is a last resort but no system is legal without a 5,000 lbs anchorage point which is simply unavailable on a roof unless designed by a structural engineer and regularly recertified (OSHA 1926.500-503 and ANSI Z359-2007 The Fall Protection Code) and building owners do not contract or pay for 5000 lbs anchors in their roofs or confirm roof strengths with any contractors at this time (ref: 1926.501(a)(2) adequate surface strength requirements). Examples of skylight screens follow:





Cost Impact: Approx. $300 including a 4’x8’ skylight screen and installation

ICCFILENAME: ELLIS-FS1-2606.5

Public Hearing Results

This code change was heard by the IBC Structural Code Development Committee.

Committee Action: Disapproved

Committee Reason: As worded, the proposal would require guards or screens at all skylights and that is considered unnecessary. The requirement should also apply to skylights that are not glass, yet the proposed text specifically refers to the glass below the guard. In addition the area of the screen over which the 200 pound force should be applied in not specified. A consensus test standard is being worked on currently that should resolve this.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

J. Niegel Ellis, Ellis Fall Safety Solutions LLC, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

2606.5 Structural requirements. Light-transmitting plastic materials in their assembly shall be of adequate strength and durability to withstand the loads indicated in Chapter 16. Technical data shall be submitted to establish stresses, maximum unsupported spans and such other information for the various thicknesses and forms used as deemed necessary by the *building official*. Every plastic unit skylight shall be guarded by a standard metal skylight screen ~~or a fixed standard railing on all exposed sides~~ or equivalent. Skylights and their screens or equivalent barriers shall be of such construction and mounting that they are each capable of withstanding a load of at least 200 lbs falling 48 inches or of equivalent energy applied perpendicularly at any ~~one~~ area on the skylight or screen that represents a falling body part. ~~They shall also be of such construction and mounting that under ordinary loads or impacts, they will not deflect downward sufficiently to break the glass below them. The construction shall be of grillwork with openings not more than 4 inches long or of slatwork with openings not more than 2 inches wide with length unrestricted.~~

(Portions of proposal not shown remain unchanged.)

Commenter's Reason: The proposed wording is Federal OSHA standard from 1971 amended based on Committee recommendations at the ICC Baltimore meeting and should be reflected in the building code because Chapter

16 loading is inadequate for human falls onto skylights and skylight manufacturers are not the only users of the skylights they produce. In other words some building owners may not be employers who maintain the roof skylights and therefore need the protection from the manufacturers in each installation going forward with the inclusion or design integration of a necessary hazard control.

Fatalities from falls through skylights which category for inclusion includes light-transmitting panels and smoke vents are documented by the Bureau of Labor Statistics which in 2006 accounted for 36 deaths in non-government buildings in the USA www.bls.gov and 22 in 2007. Skylights have their own fatal fall category as opposed to roof or floor openings that also have their own listing. The Federal requirement for General Industry is 29CFR1910.23(a)(4) and (e)(8) which became mandatory in 1971 for employers. However hazard prevention is the goal that we seek.

There are also similar requirements in the 1926.500-503 Construction regulations that equate skylights with open holes and require the use of adequate covers. The ANSI A1264.1 and A10.18 are similarly worded but all are aimed ineffectively at employers with exposed employees but not exposed independent contractors who visit dozens of building roofs each month without a feasible protection method e.g. HVAC, Laborers, roofers, Window Cleaners etc.).

However after 38 years not even 1% of plastic skylights have the required screen protection. Ref: Plasteco President Key Sandow. Skylight manufacturers do not mark their skylights clearly in the same way that auto glazers do, so that manufacturers may never know their skylight ever failed to support a falling worker. Instead, the blame falls on the injured person for not knowing to stay away from or be careful around skylights. My experience is that workers do not know the degree of danger stepping close to skylights until it is too late nor do their employers.

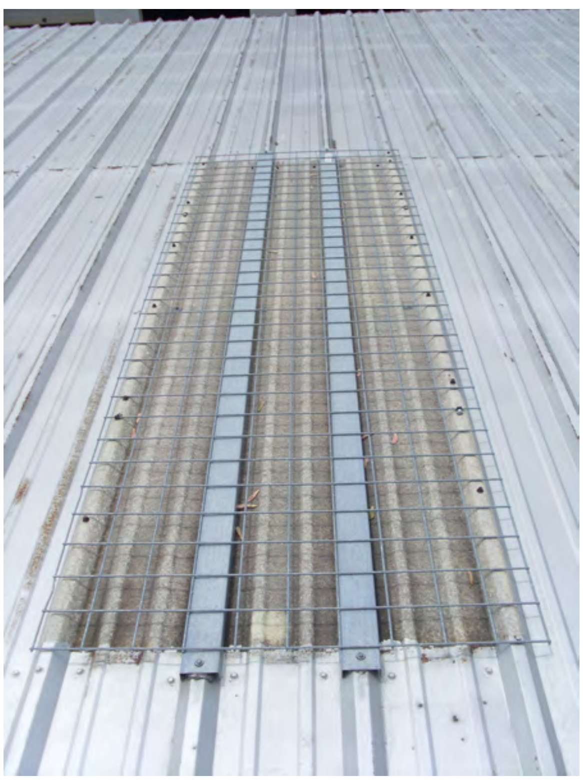
Plastic skylights may survive impacts from falling or tripping by the trades (of which there may be 28 or more) when new but almost all suffer from progressive uv light degradation over a few years where even sitting and leaning against a skylight is often sufficient to cause breakage like an egg shell due to stress crack crazing . An alternative that also takes care of controlling intruders is under-skylight grills especially for opening smoke vents and similar skylights and corrosive conditions and sometimes both to reduce fall distances to 4 ft or less per OSHA General Industry requirements. Skylights are maintained t-day by sealing leaks with silicone, fiberglass or equivalent and appear in "good" condition on maintenance company reports to the building owner if they do not presently leak despite the fact that they have cracks after a few years in the sun and are patched regularly. There is no common lifetime for plastic skylights that may now be 50+ years old and users do not currently replace a skylight unless a leak cannot be stemmed.

The request is to include the amended federal requirement in the IBC Building Code and carry the responsibility to architects, engineers and building owners and managers to protect their work force and the work trades that maintain the roof systems in those buildings by including adequate protection in specifications. No building owner expects that a skylight will have a disastrously weak strength that a worker can step or trip onto and through as the years progress eventually almost as easily as pushing a finger through the light. The OSHA interpretation by John Miles in 1984 does not anticipate the degradation that occurs with almost all synthetic-related skylights nor the dynamic force of a slip, trip and/or fall by a passing worker. Use of personal fall arrest is a last resort but no such system is legal without a 5,000 lbs anchorage point which is simply unavailable on a roof unless designed by a structural engineer and regularly recertified (OSHA 1926.500-503 and ANSI Z359-2007 the Fall Protection Code) and building owners typically do not contract or pay for 5000 lbs anchors in their roofs or confirm roof strengths with any contractors at this time (ref: 1926.501(a)(2) for adequate surface strength requirements).

Note: Glazed skylight already must have screens under the glass under some circumstances; see IBC 2405.3, so the precedent is already set for much more stable and safe skylighting, Plastic skylights will always degrade and hence they and their screen or equivalent protection should be available to building users as soon as possible. The ASTM E06.51.25 standards committee is working to finalize the estimated size of body parts to give further testing guidance. Examples of skylight screens a. and b. follow:

a.

b. I cannot upload a. and b. so I will forward to Dave Bowman separately (same as previous two pictures from 09/10)



Cost Impact: a. Approx. $400 including a 4'x8' domed skylight screen and installation with security screws/bolts (b. alt. 10'x3' approx. light transmitting panel screen)

Final Action: AS AM AMPC____ D

FS181-09/10
2610.2

Proposed Change as Submitted

Proponent: Ennis, representing the Single Ply Roofing Industry (SPRI))

Revise as follows:

2610.2 Mounting. The light-transmitting plastic shall be mounted above the plane of the roof on a curb constructed in accordance with the requirements for the type of construction classification, but at least 4 inches (102 mm) above the plane of the roof. ~~Edges of the light-transmitting plastic skylights or domes shall be protected by metal or other approved noncombustible material, or the~~ The light transmitting plastic dome or skylight shall be shown to be able to resist ignition where exposed at the edge to a flame from a Class B brand as described in ASTM E 108 or UL 790.

Exceptions:

1. Curbs shall not be required for skylights used on roofs having a minimum slope of three units vertical in 12 units horizontal (25-percent slope) in occupancies in Group R-3 and on buildings with a nonclassified roof covering.
2. ~~The metal or noncombustible edge material is not required where nonclassified roof coverings are permitted.~~

Reason: The flames of the Class B brand can extend above the noncombustible edge and contact the dome, allowing for the possibility of catching fire and test failure. ASTM E108 tests have been conducted on products with non-combustible edge material in which the flame extended beyond the noncombustible edge material and contacted the dome. This could result in ignition of the dome depending upon the type of material used for the dome. Testing per ASTM E108 or UL790 with a Class B brand should be the accepted requirement.

Cost Impact: The code change proposal will not increase the cost of construction

ICCFILENAME: ENNIS-F3-2610.2 AND ENNIS-F5-2610.2

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee felt there was a lack of data to indicate that a plastic skylight with metal edge protection is a fire exposure problem.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Mike Ennis representing Single Ply Roofing Industry (SPRI), requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

2610.2 Mounting. The light-transmitting plastic shall be mounted above the plane of the roof on a curb constructed in accordance with the requirements for the type of construction classification, but at least 4 inches (102 mm) above the plane of the roof. The light transmitting plastic dome or skylight shall be shown to be able to resist ignition where exposed at the edge to a flame from a Class B brand as described in ASTM E 108 or UL 790.

Exceptions:

1. Curbs shall not be required for skylights used on roofs having a minimum slope of three units vertical in 12 units horizontal (25-percent slope) in occupancies in Group R-3 and on buildings with a nonclassified roof covering.
2. Class B brand testing is not required where nonclassified roof coverings are permitted.

Commenter's Reason: The original code change proposal was submitted to delete the exception for fire testing of light-transmitting plastic skylights in cases where the edges of the skylight were protected by metal or other approved non-combustible material. This proposal was submitted because test experience has shown that non-combustible edge material will not prevent the flames of the burning brand from igniting the plastic dome.

The proposed revision is being submitted to address the following comments from the code change hearings:

1) The Committee felt there was a lack of data to indicate that a plastic skylight with metal edge protection is a fire exposure problem.
   Manufacturers have conducted Class B brand testing in accordance with ASTM E108 and UL790 and have observed flames extending above the non-combustible edge material and contacting the plastic dome. Video evidence of this occurrence can be viewed at the following web link: http://www.spri.org/publications/policy.htm
2) The Committee felt it was inappropriate to require fire testing of skylights where non-classified roof coverings are permitted.
   In the current code language, there is an exception that allows the use of skylights without non-combustible edge materials where non-classified roof coverings are permitted. In the original proposal this exception was deleted. In the proposed revision an exception to testing skylights is provided where non-classified roof coverings are permitted.

Final Action: AS AM AMPC____ D

FS193-09/10
711.5.2, 711.5.3, 711.5.4 (New), 711.7

Proposed Change as Submitted

Proponent: Mike Ashley, C.B.O., representing: Alliance for Fire & Smoke Containment & Control (AFSCC)

Revise as follows:

711.5.2 Smoke and draft control doors. Where required elsewhere in ~~the~~ this code to comply with this section, doors in smoke partitions shall meet the requirements for a smoke and draft control door assembly tested in accordance with UL 1784. The air leakage rate of the door assembly shall not exceed 3.0 cubic feet per minute per square foot (0.015424 $m^3/(s \bullet m^2)$) of door opening at 0.10 inch (24.9 Pa) of water for both the ambient temperature test and the elevated temperature exposure test. Installation of smoke doors shall be in accordance with NFPA 105.

711.5.3 Self- or automatic-closing doors. Where required elsewhere in ~~the~~ this code to comply with this section, doors in smoke partitions shall be self-closing or automatic-closing by smoke detection in accordance with Section 715.4.8.3.

711.5.4 Latching of doors. Where required elsewhere in this code to comply with this section, doors in smoke partitions shall be provided with latches as required for fire doors in accordance with Section 715.4.8.1.

711.7 Ducts and air transfer openings. The space around a duct penetrating a smoke partition shall be filled with an approved material to limit the free passage of smoke. Air transfer openings in smoke partitions shall be provided with a smoke damper complying with Section 716.3.2.2. Where required elsewhere in this code to comply with this section, ducts penetrating a smoke partition shall be provided with smoke dampers as required for corridors in accordance with Section 716.5.4.1.

> **Exception:** Where the installation of a *smoke damper* will interfere with the operation of a required smoke control system in accordance with Section 909, *approved* alternative protection shall be utilized.

Reason: The purpose of this proposed code change is to clarify the application of these sections we're revising, as well as a new Section 711.5.4 which addresses latching requirements for doors that may be installed in smoke partitions under certain conditions. The intent of Sections 711.5.2 and 711.5.3 is to provide a set of criteria for the smoke and draft control doors that might be required elsewhere in the code for smoke partitions depending upon the specific application, without mandating that all doors in smoke partitions meet these requirements where they may not be necessary for the specific application.

A case in point is Section 708.14.1 which was revised during the last code development cycle to include references to Sections 711.5.2 and 711.5.3 in Exception 5 regarding how the doors in the smoke partition are to be protected where the smoke partition substitutes for the 1-hour fire-resistive enclosure for elevator lobbies in sprinklered buildings. It should also be noted that a direct reference to Section 716.5.1 for the protection of duct penetrations of those smoke partitions was also provided in Exception 5. Since that may occur more often than not where certain applications for smoke partitions are prescribed in the future, we decided to incorporate that provision into Section 711.7 in a similar manner to that in Sections 711.5.2 and 711.5.3. We have also provided a reference to Section 715.4.8.1 in our proposed new Section 711.5.4 Latching of Doors in smoke partitions. This is also similar in style to Sections 711.5.2 and 711.5.3 but specifically relates to a latch being required for doors in smoke partitions when prescribed elsewhere in the code, again, such as is the case for Exception 5 to Section 708.14.1.

We believe this will make the code easier to understand, apply, and enforce so that one does not get into a loop when referred back to one of these sections that states "where required elsewhere in this code" and then try to determine how that is intended to apply. So by adding the phrase "to comply with this section," when another section of the code specifies compliance with any of these sections, it will be clear that it is intended to apply to that situation. We believe that with the new Section 711.5.4 and the proposed revisions to Section 711.7, the majority of the situations where opening protectives may be required by other provisions of the code for specific applications of smoke partitions in the future will be covered.

This will eliminate the need to reference other sections throughout the code to implement these requirements. In this way, someone referencing the provisions in smoke partitions will find the various options that are available for protecting openings in such smoke partitions in one location.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: ASHLEY-FS2-711.5.2

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The committee agreed that this proposal appropriately clarifies the intent and application of the requirements for smoke and draft control doors.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

David S. Collins, FAIA, The Preview Group Inc, representing The American Institute of Architects, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

711.5.2 Smoke and draft control doors. Where ~~required elsewhere in this code to comply with this section~~ smoke partitions are permitted by the exceptions to Section 708.14.1 of this code, doors in such smoke partitions shall meet the requirements for a smoke and draft control door assembly tested in accordance with UL 1784. The air leakage rate of the door assembly shall not exceed 3.0 cubic feet per minute per square foot (0.015424 m3/(s • m2)) of door opening at 0.10 inch (24.9 Pa) of water for both the ambient temperature test and the elevated temperature exposure test. Installation of smoke doors shall be in accordance with NFPA 105.

711.5.3 Self- or automatic-closing doors. Where ~~required elsewhere in this code to comply with this section~~ smoke partitions are permitted by the exception to Section 708.14.1 of this code, doors in such smoke partitions shall be self-closing or automatic-closing ~~by smoke detection in accordance with Section 715.4.8.3~~. by the actuation of smoke detectors installed in accordance with Section 907.3 or by loss of power to the smoke detector or hold-open device. Doors that are automatic-closing by smoke detection shall not have more than a 10-second delay before the door starts to close after the smoke detector is actuated.

711.5.4 Latching of doors. Where ~~required elsewhere in this code to comply with this section~~ smoke partitions are permitted by exception number 5 to Section 708.14.1 of this code, doors in such smoke partitions ~~shall be provided with latches as required for fire doors in accordance with Section 715.4.8.1.~~ shall be provided with an active latch bolt that will secure the door when it is closed.

711.7 Ducts and air transfer openings. Ducts and air transfer openings shall comply with this section.

711.7.1 Annular space. The space around a duct penetrating a smoke partition shall be filled with an approved material to limit the free passage of smoke.

711.7.1 Air transfer openings. Air transfer openings in smoke partitions shall be provided with a smoke damper complying with Section 716.3.2.2.

711.7.2 Ducts. Where ~~required elsewhere in this code to comply with this section,~~ smoke partitions are permitted by the exception 5 to Section 708.14.1 ducts penetrating a smoke partition that is also a corridor wall shall be provided with smoke dampers ~~as required for corridors~~ in accordance with Section 716.5.4.1.

Commenter's Reason: The provision for latching doors is new and, similar to the charging language in this section of the code, many of the smoke partition sections indicate that they apply only "where required elsewhere in this code." This leaves the door open for inappropriate application and confusion by the users of the code. It would be simpler and clearer to indicate specifically when latching of doors or dampers in ductwork are required to conform to these sections.

The only places that the 2009 I-Codes that requires smoke partitions is where it is permitted as an alternate to a smoke barrier for elevator lobbies:

708.14.1 Elevator lobby. An enclosed elevator lobby shall be provided at each floor where an elevator shaft enclosure connects more than three stories. The lobby enclosure shall separate the elevator shaft enclosure doors from each floor by fire partitions. In addition to the requirements in Section 709 for fire partitions , doors protecting openings in the elevator lobby enclosure walls shall also comply with Section 715.4.3 as required for corridor walls and penetrations of the elevator lobby enclosure by ducts and air transfer openings shall be protected as required for corridors in accordance with Section 716.5.4.1. Elevator lobbies shall have at least one means of egress complying with Chapter 10 and other provisions within this code.

Exceptions:

5.Smoke partitions shall be permitted in lieu of fire partitions to separate the elevator lobby at each floor where the building is equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1 or 903.3.1.2. In addition to the requirements in Section 711 for smoke partitions, doors protecting openings in the smoke partitions shall also comply with Sections 711.5.2, 711.5.3, and 715.4.8 and duct penetrations of the smoke partitions shall be protected as required for corridors in accordance with Section 716.5.4.1.

The exception describes the requirements for smoke and draft control doors (711.5.2), self- or automatic-closing doors (711.5.3) and door closing for fire doors (715.4.8) as well conforming with the requirements for ductwork if the partition is also a corridor (716.5.4.1). By making these changes, the application of the code is much clearer and the code user isn't burdened with finding a hidden section somewhere in the code that may require these features. By including the specific requirements for the smoke partition, additional confusion in design and enforcement will be avoided.

Final Action: AS AM AMPC____ D

FS195-09/10, Part I
712.9

Proposed Change as Submitted

Proponent: John L. Williams, CBO representing Washington State Department of Health, Construction Review Services

PART I- IBC FIRE SAFETY

Delete without substitution:

~~**712.9 Smoke barrier.** Where horizontal assemblies are required to resist the movement of smoke by other sections of this code in accordance with the definition for smoke barrier, penetrations and joints in such horizontal assemblies shall be protected as required for smoke barriers in accordance with Sections 713.5 and 714.6. Regardless of the number of stories connected by elevator shaft enclosures, doors located in elevator shaft enclosures that penetrate the horizontal assembly shall be protected by enclosed elevator lobbies complying with Section 708.14.1. Openings through horizontal assemblies shall be protected by shaft enclosures complying with Section 708. Horizontal assemblies shall not be allowed to have unprotected vertical openings.~~

Reason: These two sections are new to the 2009 code. They add cost and complicate the design process with no significant benefit. These sections are targeted toward I-2 occupancies, which are required to divide each floor into smoke compartments. There was no evidence provided by the author of this section that smoke transfer between floors in a sprinklered, compartmented building poses a significant hazard. If there was a significant transmission of smoke from one of the smoke compartments on the floor below, the occupants on the higher floor have another smoke compartment to horizontally evacuate to.

The addition of elevator lobbies and enclosing doors could also hamper the horizontal evacuation process. The added number of doors that a patient must be pushed through to get to the adjacent smoke compartment slows the evacuation time.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: WILLIAMS-FS1-712.9

Public Hearing Results

PART I- IBC FIRE SAFETY
Committee Action: **Disapproved**

Committee Reason: The committee felt these sections should remain as the definition of smoke compartment indicates that smoke compartments are enclosed by smoke barriers on all sides, including the top and bottom. Also, this action is consistent with the committee's action on FS196-09/10.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

John Williams representing Washington State Department of Health, Construction Review Services, requests Approval as Submitted.

Commenter's Reason: These two new sections were added in the previous code cycle with the intent to coordinate and clarify the application of the definition of a "smoke compartment." Since the 2000 version of the IBC, a smoke compartment is defined as a space enclosed by smoke barriers, including the top and bottom. The code has given clear instructions on how to deal with vertical smoke barriers, but has been silent on the construction of horizontal smoke barriers. If coordination was the goal, and equally viable solution would be to modify the smoke compartment definition and remove the reference to "top and bottom."

I believe that the previous code's silence regarding the horizontal component of a smoke compartment were intentional. Floors, elevator shafts, stair doors were not intended to meet the requirements of a smoke barrier. The IBC has always required Group I-2 occupancies to be separated into at least two smoke compartments. If smoke migrates vertically from one smoke compartment to the floor above, it will likely be contained by a smoke compartment on that upper floor.

Smoke compartments exist in three types of facilities: Healthcare facilities (Group I-2), prisons (Group I-3) and ambulatory health care facilities (Group B, new to the 2009 code). The facilities operate on a defend-in-place concept. Staff are available to aid in the relocation of incapacitated or restrained occupants to a safer area. All of these occupancies are incredibly fire safe due to the amount of precautions taken in the IBC. The 2009 NFPA report "Structure Fires in Medical, Mental Health and Substance Abuse Facilities" states that during 2003-2006 there have been an annual average of 3,750 fires in these facilities. This resulted in a yearly average of 1 civilian death and 57 injuries. The 2006 NFPA report "U.S. fires in selected occupancies – Prisons and Jails" reports and a yearly average of 1,360 structure fires from 1999-2002. This resulted in no loss of civilian life and 19 injuries.

The NFPA report on healthcare facilities lists a selection of published incidents. Many of these incidents note that there was vertical migration of smoke to upper floors, but they also state that the staff evacuated patients to a safe area. None of these cases implicate vertical smoke migration as a cause of death. For example:

> Illinois Hospital fire: "Some smoke also migrated to the third floor through a loose fitting on a pneumatic tube delivery system. The hospital staff quickly moved patients out of the affected area." No casualties.
> Ohio hospital fire: "Before the fire department's arrival, hospital staff had already accounted for all other nearby patients and moved them from the affected area without injury. Fire damage was confined to the bedding and the mattress, and smoke damage was limited to the wing of origin." One casualty in the room of fire origin.

More recent hospital fire reports also support this concept:

> 2009 New York hospital fire: 600 patients were relocated from the east wings to the west wings of a 12 story hospital building. No casualties.
> 2010 South Carolina hospital fire: Two wings were evacuated to another part of the hospital. No casualties.

These facility types have been safe without the horizontal smoke barrier requirements. In the 2009 codes, we've added retroactive fire sprinkler requirements to hospitals to make them even safer. Existing fire safety systems within hospitals perform well. These new sections that were presented as coordination changes actually added significant requirements to the code without justification. Please approve the original change as submitted.

Final Action: AS AM AMPC____ D

FS195-09/10, Part II
407.4.3

Proposed Change as Submitted

Proponent: John L. Williams, CBO representing Washington State Department of Health, Construction Review Services

PART II- IBC GENERAL

Delete without substitution:

~~**407.4.3 Horizontal assemblies.** Horizontal assemblies supporting smoke barriers required by this section shall be designed to resist the movement of smoke and shall comply with Section 712.9.~~

Reason: These two sections are new to the 2009 code. They add cost and complicate the design process with no significant benefit. These sections are targeted toward I-2 occupancies, which are required to divide each floor into smoke compartments. There was no evidence provided by the author of this section that smoke transfer between floors in a sprinklered, compartmented building poses a significant hazard. If there was a significant transmission of smoke from one of the smoke compartments on the floor below, the occupants on the higher floor have another smoke compartment to horizontally evacuate to.

The addition of elevator lobbies and enclosing doors could also hamper the horizontal evacuation process. The added number of doors that a patient must be pushed through to get to the adjacent smoke compartment slows the evacuation time.

Cost Impact: The code change proposal will not increase the cost of construction.

Final Action: AS AM AMPC____ D

FS196-09/10
708.14.1

<u>Proposed Change as Submitted</u>

Proponent: John L. Williams, CBO representing Washington State Department of Health, Construction Review Services

Revise as follows:

708.14.1 Elevator lobby. An enclosed elevator lobby shall be provided at each floor where an elevator shaft enclosure connects more than three *stories*. The lobby enclosure shall separate the elevator shaft enclosure doors from each floor by *fire partitions*. In addition to the requirements in Section 709 for *fire partitions*, doors protecting openings in the elevator lobby enclosure walls shall also comply with Section 715.4.3 as required for *corridor* walls and penetrations of the elevator lobby enclosure by ducts and air transfer openings shall be protected as required for *corridors* in accordance with Section 716.5.4.1. Elevator lobbies shall have at least one *means of egress* complying with Chapter 10 and other provisions within this code.

Exceptions:

1. Enclosed elevator lobbies are not required at the street floor, provided the entire street floor is equipped with an *automatic sprinkler system* in accordance with Section 903.3.1.1.
2. Elevators not required to be located in a shaft in accordance with Section 708.2 are not required to have enclosed elevator lobbies.
3. Enclosed elevator lobbies are not required where additional doors are provided at the hoistway opening in accordance with Section 3002.6. Such doors shall be tested in accordance with UL 1784 without an artificial bottom seal.
4. Enclosed elevator lobbies are not required where the building is protected by an *automatic sprinkler system* installed in accordance with Section 903.3.1.1 or 903.3.1.2. This exception shall not apply to the following:
   - 4.1. Group I-2 occupancies,
   - 4.2. Group I-3 occupancies, and
   - 4.3. High-rise buildings.
5. Smoke partitions shall be permitted in lieu of *fire partitions* to separate the elevator lobby at each floor where the building is equipped throughout with an *automatic sprinkler system* installed in accordance with Section 903.3.1.1 or 903.3.1.2. In addition to the requirements in Section 711 for smoke partitions, doors protecting openings in the smoke partitions shall also comply with Sections 711.5.2, 711.5.3, and 715.4.8 and duct penetrations of the smoke partitions shall be protected as required for *corridors* in accordance with Section 716.5.4.1.
6. Enclosed elevator lobbies are not required where the elevator hoistway is pressurized in accordance with Section 708.14.2.
7. Enclosed elevator lobbies are not required where the elevator serves only *open parking garages* in accordance with Section 406.3.
8. <u>Enclosed elevator lobbies are not required on floors in I-2 occupancies that are subdivided as required by Section 407.4.</u>

Reason: Elevator lobbies serve no purpose on floors of these types of facilities that “protect in place”. Floors that contain patient sleeping are required to be subdivided into smoke compartments by section 407.4 so that bed ridden patients can be moved from one compartment to another. A small elevator lobby would be no where near the size needed to accommodate bed ridden patients. It is inappropriate to evacuate bed ridden patients from a facility unless there is some catastrophic failure way beyond the intent of the code. This protect in place concept is the reason that these facilities are limited in size based on construction type and required to be sprinklered and fully detected for early detection and response. Additionally, these facilities are required to provided quarterly training and fire alarm drills.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: WILLIAMS-FS2-707.14

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The reference to 407.4 is not appropriate as this section eventually requires enclosed elevator lobbies; further correlation is required. Further, the proposal seems redundant with exception #4. Lastly, removing the lobby enclosure for these buildings would inhibit the ability to defend a fire in place.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

John Williams representing Washington State Department of Health, Construction Review Services, requests Approval as Submitted.

Commenter's Reason: The committee questioned whether the reference to section 407.4 was appropriate, because it would eventually require smoke barriers. References to require elevator lobbies at Group I-2 and any floors containing smoke compartments are all recent additions to the 2009 version of the code. I am also proposing remove the requirement in 407.4 as part of FS 195.

The committee was concerned that the proposal seems redundant with exception #4. Exception #4 deals with sprinklered buildings, not buildings with smoke compartmentation. All existing hospitals will be sprinklered (per the new retroactive sprinkler provisions in the IFC) but not all hospitals have smoke compartments. Smoke compartments provide a function similar to that of an elevator lobby by compartmentalizing the floor and limiting the spread of smoke. They are an adequate trade-off for this occupancy.

The final concern was that the lack of lobbies would inhibit a facilities ability to defend in place. This is simply not supported by the recent fire data, please see my public comment for FS 195. Facilities today are successfully providing a defend in place strategy without elevator lobbies. Please support this change as submitted.

Final Action: AS AM AMPC____ D

INTERNATIONAL WILDLAND-URBAN INTERFACE CODE

WUIC1-09/10
403.4.1

Proposed Change as Submitted

Proponent: Lawrence Brown, CBO, National Association of Home Builders

Revise as follows:

403.4.1 Sign construction. All road identification signs and supports shall be of noncombustible materials. Signs shall be 6 inch (152 mm) minimum in height. ~~have minimum 4-inch-high (102 mm) reflective~~ Letters shall be 4 inch (102 mm) minimum in height with a 1/2 inch (~~12.7~~ 13 mm) minimum stroke. Letters shall be of the reflecting type and be on a contrasting background color. ~~6-inch-high (152 mm) sign~~. Road identification signage shall be mounted ~~at a height of~~ 7 feet (2134 mm) in height measured from the road surface to the bottom of the sign.

Reason: This is an editorial change related to format of text, and to provide clarity as to the intent of the provision. The term "background color" adds clarity as to *contrasting* with the reflective letters. The term "minimum" is added to height for mounting the sign. Without the term "minimum" the height is absolute at 7 feet (cannot be more or less).

Cost Impact: The code change proposal will not increase the cost of construction

ICCFILENAME: BROWN-WUIC1-403.4.1.DOC

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee did not feel that the proposal accomplished its stated objectives, especially with respect to sign mounting height.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Lawrence Brown, CBO, representing National Association of Home Builders (NAHB), requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

403.4.1 Sign construction. All road identification signs and supports shall be of noncombustible materials. Sign faces shall be 6 inch (152 mm) minimum in height. Letters on the signs shall be 4 inch (102 mm) minimum in height with a 1/2 inch (13 mm) minimum stroke. Letters shall be of the reflecting type and be on a contrasting background color. Road identification signage shall be mounted 7 feet (2134 mm) minimum in height measured vertically from the bottom of the sign to the elevation of the near edge of the road surface ~~to the bottom of the sign~~.

Commenter's Reason: The original proposal was mostly an editorial/correlation change dealing with the use of the terms "height", "width", and "depth" throughout all I-Codes. The terms "high", "long" and "deep" are not terms used to describe dimensions and measurements. This correlation is in the process of being made in all I-Codes. The other proposed modifications to the text were to provide clarity as to the intent of the provision. In addition to having over 20 years experience in code enforcement, I also have a background of over 35 years of experience in the sign business. The original proposal added the term "background color" to add clarity as to the need for the sign face background color to be *contrasting* with the reflective letters. The term "minimum" is added to height for the letters mounting the sign. Without the term "minimum" the height is absolute at 7 feet (cannot be more or less). Adding the term "minimum" also correlates this provision with the federal **Manual on Uniform Traffic Control Devices:** MUTCD-2003 (The Federal Highway Administration, Office of Transportation Operations, Room 3408, 400 7th Street, S.W., Washington, DC 20590). This is shown below from a part of the MUTCD requirements:

Section 2A.18 Mounting Height

The minimum height, measured vertically from the bottom of the sign to the top of the curb, or in the absence of curb, measured vertically from the bottom of the sign to the elevation of the near edge of the traveled way, of signs installed at the side of the road in business, commercial, or residential areas where parking or pedestrian movements are likely to occur, or where the view of the sign might be obstructed, shall be 7 feet (see Figure 2A-2).

Final Action: AS AM AMPC____ D

WUIC3-09/10

503.2, Chapter 7

Proposed Change as Submitted

Proponent: John Scott, Roxul, Inc.

1. Revise as follows:

503.2 Ignition-resistant building material. Ignition-resistant building materials shall comply with any one of the following:

1. Extended ASTM E 84 testing. Materials that, when tested in accordance with the test procedures set forth in ASTM E 84 or UL 723, for a test period of 30 minutes, comply with the following:
   - 1.1. Flame spread. Material shall exhibit a flame spread index not exceeding 25 and shall show no evidence of progressive combustion following the extended 30 minute test.
   - 1.2. Flame front. Material shall exhibit a flame front that does not progress more than 10 $^1/_2$ feet (3200 mm) beyond the centerline of the burner at any time during the extended 30 minute test.
   - 1.3. Weathering. Ignition-resistant building materials shall maintain their performance in accordance with this section under conditions of use. Materials shall meet the performance requirements for weathering (including exposure to temperature, moisture and ultraviolet radiation) contained in the following standards, as applicable to the materials and the conditions of use:
     - 1.3.1. MethodA"Test Method for Accelerated Weathering of Fire-Retardant-Treated Wood for Fire Testing" in ASTM D 2898, for fire-retardant-treated wood, wood-plastic composite and plastic lumber materials.
     - 1.3.2. ASTMD7032 for wood-plastic composite materials.
     - 1.3.3. ASTM D 6662 for plastic lumber materials.
   - 1.4. Identification. All materials shall bear identification showing the fire test results.
2. Noncombustible material. Material that complies with the requirements for *noncombustible* materials in Section 202.
3. Fire-retardant-treated wood. Fire-retardant-treated wood identified for exterior use and meeting the requirements of Section 2303.2 of the *International Building Code*.
4. Fire-retardant-treated wood roof coverings. Roof assemblies containing fire-retardant-treated wood shingles and shakes which comply with the requirements of Section 1505.6 of the *International Building Code* and classified as Class A roof assemblies as required in Section 1505.2 of the *International Building Code*.
5. Roof Insulation. Roof insulations that comply with the requirements for Class NC (noncombustible core) in accordance with the requirements of FM 4470.

2. Add new standard to Chapter 7 as follows:

FM Factory Mutual Global Research
Standards Laboratories Department
1301 Atwood Avenue, P.O. Box 7500
Johnston, RI 02919

4470 (2009) Approval Standard for Class 1 Roof Covers .

Reason: To introduce a new type of Ignition-resistant building material into the IWUIC, based upon testing and conformance with the newest edition (2009) of FM 4470 Approval Standard for Single-Ply, Polymer-Modified Bitumen Sheet,Built-Up Roof (BUR) and Liquid Applied Roof Assemblies.

The 2009 edition of FM Approval Standard 4470 has introduced a new category of roofing insulation defined as Class "NC" non-combustible core.

In order for a roof insulation material to be classified as "NC", the roof insulation must meet the following stringent criterion:

1. ASTM D482, Standard Test Method for Ash from Petroleum Products

2. ASTM E2058, Standard Test Methods for Measurement of Synthetic Polymer Material Flammability Using a Fire Propagation Apparatus (FPA)
3. ISO 1716:2002 Reaction to Fire Tests for Building Products - Determination of the Heat of Combustion

The first test acceptance criteria used by FM for these materials is very stringent, and includes a minimum total solids content of 90% per ASTM D 482.

In addition, during the ASTM E2058 test, no visible flaming of the insulation is permitted for the full 15 minute duration, and the test is extended beyond 15 minutes in duration if there is any evidence of the sample still exhibiting mass loss and/or visible vapors being emitted. The test is continued until the mass loss and/or visible vapors have also ceased.

The third test method is ISO Standard 1716 which is used for determination of the Heat of Combustion of building materials. The insulation core must have a maximum heat of combustion of 2.0 kJ/g (860 BTU/lb).

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: FM 4470 (1992) is currently referenced in the IBC.

ICCFILENAME: SCOTT-WUIC1-503.2.DOC

Public Hearing Results

Note: The following analysis was not in the Code Change monograph but was published on the ICC website at http://www.iccsafe.org/cs/codes/Documents/2009-10cycle/ProposedChanges/Standards-Analysis.pdf :

Analysis: Review of the proposed new standard FM 4470 (1986) indicated that it is currently referenced in the IBC.

Committee Action: Disapproved

Committee Reason: The committee did not feel that there is sufficient loss history to justify the proposal and felt that it would be inappropriate to approve a change that would eliminate a wide variety of products that are currently acceptable.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

John Scott, representing Roxul Inc, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

503.2 Ignition-resistant building material. Ignition-resistant building materials shall comply with any one of the following:

1 through 4 *(No change to text)*
5. Noncombustible Roof Insulation. Noncombustible roof insulations shall ~~that~~ comply with the requirements for Class NC (noncombustible core) in accordance with the requirements of FM 4470.

(Portions of proposal not shown, remain unchanged)

Commenter's Reason: This revised proposal introduces a new type of Ignition-resistant building material into the IWUIC, based upon testing and conformance with the newest edition (2009) of FM 4470 Approval Standard for Single-Ply, Polymer-Modified Bitumen Sheet,Built-Up Roof (BUR) and Liquid Applied Roof Assemblies. It does not preclude the use of other roof insulation materials.

The report on the Baltimore hearings indicated that the committee did not feel that there is sufficient loss history to justify the proposal and felt that it would be inappropriate to approve a change that would eliminate a wide variety of products that are currently in use. We believe that this proposal does not does not preclude the use of other roof insulation materials. It merely recognizes that in order for a roof insulation to be considered non-combustible, it needs to comply with the new FM 4470 standard.

There is a long history of losses connected with fires in roofing materials and roof coverings. According to NFPA statistics, an average of 4,200 fires starting with exterior roof coverings, surfaces or finishes made of sawn wood occurred per year during the five year period from 1994 through 1998. These fires caused an average of five civilian deaths, 23 civilian injuries and an estimated $7.0 million in direct property damage per year. During this time period, these fires accounted for 0.7% of the 567,100 total reported structure fires, 0.1% of the 3,744 civilian structure fire deaths, 0.1% of the 21,293 civilian structure fire injuries, and 1.1% of the $7.2 billion in direct property damage. These totals exclude from the analysis fires where the roof covering was recorded as composed of hardboard, plywood, fiberboard or wood pulp, as these products are considered more likely to refer to decking or framing, rather than to shingles and covering. Also excluded are fires where the roof covering was recorded as growing wood, felled but unsawn wood, wood shavings, or unclassified or unknown-type wood. More importantly, this analysis excludes fires that begin with some other fuel but grow and spread primarily through secondary involvement of wooden roof coverings. Such fires cannot be identified in existing national databases.[1]

The IWUIC is designed to go beyond the local Building and Fire Codes to provide minimum regulations intended to mitigate the risk to life and structures from intrusion of fire from wildland fire exposures and fire exposures from adjacent structures, and mitigate structure fires from spreading to wildlands. The extent of this regulation is intended to be tiered commensurate with the relative level of hazard present, which differs from the convention Urban or Rural building environments.

During a wildland/urban interface fire, the roof is the most vulnerable part of a building. One of the biggest dangers lies in the sparks or firebrands such a fire produces, which often blow onto the roof and set it ablaze before the fire itself even approaches the building. Over the years, roof coverings such as wood shingle and wood shake have contributed to some major fire losses. In 1991, for example, a conflagration near Oakland and Berkeley, California, resulted in a major wildland/urban interface fire that killed 25 people, injured 150, and destroyed nearly 2,450 single family dwellings and 437 apartment and condominium units. The fire burned more than 1,600 acres and did an estimated $1.5 billion in damage.[2]

Still another more recent incident occurred on the afternoon of November 1, 2006, at Eastern Guilford High School in Gibsonville, North Carolina. Students had to be evacuated as a fire spread through the building's roof, causing ceilings to collapse into the rooms below. Thick smoke churned ominously into the sky as the fire grew. The fire department in the neighboring community of Whitsett was located just five miles (eight kilometers) away and arrived in minutes, but the speed of the fire and the manner in which it spread made saving the school impossible. All students and staff safely escaped and much of the school's contents were salvageable, but the school, which Alan Purdue, Guilford County Emergency Services chief, says was valued at $41 million, was a total loss. Guilford County Schools administrators say they recovered $17 million in insurance payments [3]

In part, the Objective of the IWUIC is Section 101.3 states: "This code shall supplement the jurisdiction's building and fire codes, if such codes have been adopted, to provide for special regulations to mitigate the fire- and life-safety hazards of the wildland-urban interface areas."

The current requirements for roof insulation in the IWUIC are based on typical IBC and IFC requirements. While the IWUIC has very stringent expectations for Class 1 Ignition Resistant Construction, the definitions in Section 202 of "Noncombustible Roof Coverings" really only applies to the weathering membrane on the exterior surface of the roof (i.e. such as shingles, sheets, and tiles), rather than the potentially high fuel loads coming from the combustible insulation materials beneath them. Consequently, there is a need to further strengthen the requirements for roof insulations in the IWUIC to recognize the fire- and life-safety hazards of the wildland-urban interface areas.

WUIC5-09/10
504.2.1 (New), Chapter 7

<u>Proposed Change as Submitted</u>

Proponent: John Scott, Roxul, Inc.

1. Revise as follows:

<u>**504.2.1 Roof insulation.** Roof insulations that comply with the requirements for Class NC (noncombustible core) in accordance with the requirements of FM 4470.</u>

(Renumber subsequent section)

2. Add new standard to Chapter 7 as follows:

<u>**FM**</u>	<u>Factory Mutual Global Research</u> <u>Standards Laboratories Department</u> <u>1301 Atwood Avenue, P.O. Box 7500</u> <u>Johnston, RI 02919</u>
<u>4470 (2009)</u>	<u>Approval Standard for Class 1 Roof Covers</u> .

Reason: To introduce a new Class of Ignition-resistant building material into the IWUIC, based upon testing and conformance with the newest edition (2009) of FM 4470 Approval Standard for Single-Ply, Polymer-Modified Bitumen Sheet,Built-Up Roof (BUR) and Liquid Applied Roof Assemblies.

The IWUIC has very stringent expectations for Class 1 Ignition Resistant Construction. While the definitions in Section 202 addresses "Noncombustible Roof Coverings", this really only applies to the weathering membrane on the exterior surface of the roof (i.e. such as shingles, sheets, and tiles), rather than the potentially high fuel loads coming from some combustible insulation materials beneath them. Consequently, there is a need to further restrict the use of combustible roof insulations where required.

The 2009 edition of FM Approval Standard 4470 has introduced a new category of roofing insulation defined as Class "NC" non-combustible core.

In order for a roof insulation material to be classified as "NC", the roof insulation must meet the following stringent criterion:

1. ASTM D482, Standard Test Method for Ash from Petroleum Products
2. ASTM E2058, Standard Test Methods for Measurement of Synthetic Polymer Material Flammability Using a Fire Propagation Apparatus (FPA)
3. ISO 1716:2002 Reaction to Fire Tests for Building Products - Determination of the Heat of Combustion

The first test acceptance criteria used by FM for these materials is very stringent, and includes a minimum total solids content of 90% per ASTM D 482.

In addition, during the ASTM E2058 test, no visible flaming of the insulation is permitted for the full 15 minute duration, and the test is extended beyond 15 minutes in duration if there is any evidence of the sample still exhibiting mass loss and/or visible vapors being emitted. The test is continued until the mass loss and/or visible vapors have also ceased.

The third test method is ISO Standard 1716 which is used for determination of the Heat of Combustion of building materials. The insulation core must have a maximum heat of combustion of 2.0 kJ/g (860 BTU/lb).

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: FM 4470 (1992) is currently referenced in the IBC.

ICCFILENAME: SCOTT-WUIC2-504.2.1.DOC

Public Hearing Results

Note: This code change was contained in the errata posted on the ICC website on October 19, 2009. Please go to http://www.iccsafe.org/cs/codes/Pages/09-10ProposedChanges.aspx.

Note: The following analysis was not in the Code Change monograph but was published on the ICC website at http://www.iccsafe.org/cs/codes/Documents/2009-10cycle/ProposedChanges/Standards-Analysis.pdf :

Analysis: Review of the proposed new standard FM 4470 (1986) indicated that it is currently referenced in the IBC.

Committee Action: Disapproved

Committee Reason: The proposal is inconsistent with Section 504.2 which regulates roof assemblies, not the individual components of an assembly. The proposal could also exclude the use of other materials that are currently acceptable. Disapproval is also consistent with the action taken on code change WUIC3-09/10.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

John Scott, representing Roxul Inc, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

504.3 **~~504.2.1~~ Roof insulation.** Roof insulations for Class 1 ignition-resistant construction shall ~~that~~ comply with the requirements for Class NC (noncombustible core) insulation in accordance with ~~the requirements of~~ FM 4470.

(Renumber subsequent sections)

(Portions of the proposal not shown remain unchanged.)

Commenter's Reason: In order to address the Committees concerns, the proposal has been revised to make it consistent with Section 504 of the IWUIC by adding a new article within 504. This revised proposal introduces a new type of Ignition-resistant building material into the IWUIC, based upon testing and conformance with the newest edition (2009) of FM 4470 Approval Standard for Single-Ply, Polymer-Modified Bitumen Sheet,Built-Up Roof (BUR) and Liquid Applied Roof Assemblies.

The IWUIC is designed to go beyond the local Building and Fire Codes to provide minimum regulations intended to mitigate the risk to life and structures from intrusion of fire from wildland fire exposures and fire exposures from adjacent structures, and mitigate structure fires from spreading to wildlands. The extent of this regulation is intended to be tiered commensurate with the relative level of hazard present, which differs from the convention Urban or Rural building environments.

In part, the Objective of the IWUIC is Section 101.3 states: "This code shall supplement the jurisdiction's building and fire codes, if such codes have been adopted, to provide for special regulations to mitigate the fire- and life-safety hazards of the wildland-urban interface areas."

The current requirements for roof insulation do not in the IWUIC are based on typical IBC and IFC requirements. While the IWUIC has very stringent expectations for Class 1 Ignition Resistant Construction, the definitions in Section 202 of "Noncombustible Roof Coverings" really only applies to the weathering membrane on the exterior surface of the roof (i.e. such as shingles, sheets, and tiles), rather than the potentially high fuel loads coming from the combustible insulation materials beneath them. Consequently, there is a need to further strengthen the requirements for roof insulations in the IWUIC to recognize the fire- and life-safety hazards of the wildland-urban interface areas."

Unfortunately, there is an abundance of loss history to justify the need to enhance the current IWUIC requirements for fire connected with roofing materials and roof coverings. According to NFPA statistics, an average of 4,200 fires starting with exterior roof coverings, surfaces or finishes made of sawn wood occurred per year during the five year period from 1994 through 1998. These fires caused an average of five civilian deaths, 23 civilian injuries and an estimated $7.0 million in direct property damage per year. During this time period, these fires accounted for 0.7% of the 567,100 total reported structure fires, 0.1% of the 3,744 civilian structure fire deaths, 0.1% of the 21,293 civilian structure fire injuries, and 1.1% of the $7.2 billion in direct property damage. These totals exclude from the analysis fires where the roof covering was recorded as composed of hardboard, plywood, fiberboard or wood pulp, as these products are considered more likely to refer to decking or framing, rather than to shingles and covering. Also excluded are fires where the roof covering was recorded as growing wood, felled but unsawn wood, wood shavings, or unclassified or unknown-type wood. More importantly, this analysis excludes fires that begin with some other fuel but grow and spread primarily through secondary involvement of wooden roof coverings. Such fires cannot be identified in existing national databases.[1]

Final Action: AS AM AMPC____ D

INTERNATIONAL FIRE CODE

F2-09/10
202 (New)

Proposed Change as Submitted

Proponent: Tom Lariviere, Chairman, Joint Fire Service Review Committee

Add new definition as follows:

SECTION 202
GENERAL DEFINITIONS

<u>**FIRE HAZARD.** Any thing or act which increases or could cause an increase of the hazard or threat of fire to a greater degree than that customarily recognized as normal by persons in the public service regularly engaged in preventing, suppressing or extinguishing fire or any thing or act which could obstruct, delay, hinder or interfere with the operation of the fire department or the safety of occupants in the event of fire.</u>

Reason: The definition of "Fire Hazard" is not currently found in the IFC. The term is used 31 times in the IFC and is found in the following Chapters: 1, 2, 3, 4, 6, 9, 10, 19, 20, 21, 23, 24, 26, 33, 34 and Appendix E. However, the term is not defined in the code. The inclusion of this definition will further clarify the intent of an otherwise ambiguous term.

A similar proposal was discussed in the last code change cycle. Comments were received and have been addressed as follows:

1. "Why not use the standard Webster definition?" – the Webster Dictionary does not define "Fire Hazard"
2. "Is it better to leave as an undefined term." – The definition of "Fire Hazard" is not currently found in the IFC. The term appears in the IFC 31 times. The term is commonly used in the IFC, so it must have some intended value. For a situation to be a fire hazard it must either increase the potential of ignition, or increase the intensity of fire once it does ignite, or obstruct/hinder fire department operations, or obstruct/hinder occupant egress.
3. "What is difference of fire risk and fire hazard?" – Fire risk occurs in all locations and all situations of work, business, and just plain life. The level of fire risk varies in all situations. However when something occurs to raise or affect the normally expected level of fire risk, the potential of ignition increases and this situation then becomes classified as a fire hazard. As specified in the definition, if the situation creates an increase in the potential for fire (fire risk), it is a fire hazard.
4. "This definition would create a conflict with IFC 906.3." – This is incorrect, the words "fire hazard" are used in this section, however, they do not stand alone. The words are used as part of the term "Class A Fire Hazards". To state that the defined term "fire hazard" must be used in defining "Class A Fire Hazard" is incorrect, and is out of context. This is not the same term. The term "Class A Fire Hazard" is a specific and defined term dealing with Class A materials. This makes as little sense as assuming that Chapter 15 Flammable Finishes only applies to flammable liquids. In case you are wondering…Chapter 15 includes flammable liquids, along with combustible liquids and combustible powders, etc.

The definition of "fire hazard", although a somewhat objective definition, is needed to be able to point back to some code reference when the term is used in the code in those 31 locations.

Cost Impact: The code change proposal will increase the cost of construction.

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee felt that the proposal contains vague language, would limit who is deemed capable of recognizing a fire hazard and could result in inconsistent enforcement.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Marcelo M. Hirschler, GBH International, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

SECTION 202
GENERAL DEFINITIONS

FIRE HAZARD. ~~Any thing or act which increases or could cause an increase of the hazard or threat of fire to a greater degree than that customarily recognized as normal by persons in the public service regularly engaged in preventing, suppressing or extinguishing fire or any thing or act which could obstruct, delay, hinder or interfere with the operation of the fire department or the safety of occupants in the event of fire.~~ The potential for harm associated with fire.

Commenter's Reason: The technical committee was concerned about the vague language in the original proposal. It was also concerned that the proposed definition might limit who is deemed to be capable of recognizing a fire hazard and could result in inconsistent enforcement. The revised language in the comment is taken from the ASTM definition for fire hazard and does not discuss who would enforce the concept since that is not necessary in the definition. The issue in the definition should be "what is fire hazard" and nothing else. The definition need not address who recognizes the existence of fire hazard, or who acts on it or whose job it is to notify; all of those actions should be discussed (as they currently are) in the body of the code and not in the section on definitions.

Final Action: AS AM AMPC____ D

F6-09/10
315

Proposed Change as Submitted

Proponent: Tom Lariviere, Chairman, Joint Fire Service Review Committee and Alan Shuman, President, representing the National Association of State Fire Marshals (NASFM)

Revise as follows:

SECTION 315
~~MISCELLANEOUS COMBUSTIBLE MATERIALS~~ GENERAL STORAGE

315.1 General. Storage~~, use and handling of miscellaneous combustible materials~~ shall be in accordance with this section.

315.2 Permit required. A permit for miscellaneous combustible storage shall be ~~obtained in accordance with~~ required as set forth in Section 105.6.

~~315.2~~ 315.3 Storage in buildings. Storage of ~~combustible~~ materials in buildings shall be orderly and stacks shall be stable. Storage of combustible materials shall be separated from heaters or heating devices by distance or shielding so that ignition cannot occur.

(Renumber subsequent sections)

Reason: This proposal will modify this section covering storage in buildings in several different ways.

This proposal is intended to clarify that this section contains requirements which apply to storage in general, not just storage of combustible materials. Specifically, Section 315.2.1 requires that a separation be maintained between the top of storage and ceilings or sprinklers. This requirement applies to all storage, whether combustible or not, and providing a clearance from sprinklers and ceilings is critical whether the materials are combustible or not.

The first sentence of Section 315.1 is revised to delete the reference to "use and handling". As stated in the title of the section, this section applies to "storage". Sections 315.1 and 315.2 deal with storage and there are no requirements for use or handling.

The second sentence of Section 315.1 is separated and creates a new Section 315.2 dealing with permits. This follows standard format throughout the rest of the IFC. The new Section 315.2 is also revised to specify that a permit is required only for storage of combustible materials. Even though this section regulates storage of both combustible and noncombustible materials, only combustible materials are required to obtain a permit when the storage exceeds 2500 cubic feet. The quantity limit is specified in the permit requirements in Section 105.6.29.

Section 315.2 is renumbered to 315.3 and revised to specify that the first sentence applies to ALL storage, and the second sentence applies to combustible storage. This will then state that all storage, whether combustible or not, is regulated and should be orderly. This means that the stored materials, whether combustible or not, are orderly, and that the stacks of stored materials need to be stable. These requirements allow for aisles being maintained, and the reduction of injury or blocking of exit during a seismic event or even when materials are hit with a hose stream during fire operations.

Hazards specific to 'combustible' materials have been more clearly identified. The second sentence in 315.3 is revised to specify that only combustible materials need to be separated from ignition sources. It is not necessary to separate non-combustible materials from ignition sources because there is no hazard.

Cost Impact: The code change proposal will increase the cost of construction**.**

ICCFILENAME: LARIVIERE-F3-315.DOC

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The committee agreed with the proponent's reason statement and felt that the proposal provides needed improvements to clarify the storage requirements.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Lawrence G. Perry, AIA, representing Building Owners and Managers Association (BOMA) International, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

315.1 General. Storage shall be in accordance with this section.

315.2 Permit required. A permit for miscellaneous combustible storage shall be required as set forth in Section 105.6.

315.3 Storage in buildings. Storage of materials in buildings shall be orderly ~~and stacks shall be stable~~. Storage of combustible materials shall be separated from heaters or heating devices by distance or shielding so that ignition cannot occur.

(Renumber subsequent sections)

Commenter's Reason: The modification seeks to delete language that is unclear and unenforceable. What criteria would be used to determine if a stack of stored materials is 'stable'?

Final Action: AS AM AMPC____ D

F7-09/10
316.4 (New)

Proposed Change as Submitted

Proponent: Tom Lariviere, Chairman, Joint Fire Service Review Committee

Add new text as follows:

316.4 Obstructions on roofs. Installing or maintaining wires, cables, ropes, aerial antennas, or other suspended obstructions installed or maintained on the roofs of buildings having a roof slope of less than 30 degrees, shall be located to provide a vertical clearance of not less than 7 feet (2133 mm) between the roof surface and such obstruction.

Exception: Obstructions shall be permitted to be installed less than 7 feet (2133 mm) high provided they are protected in a manner to prevent injury to firefighters working on the roof.

(Renumber subsequent sections)

Reason: This proposal will increase for firefighter safety when performing fire suppression related duties on a rooftop, and will also protect maintenance workers as they are working on a rooftop.

Obstructions below 7 feet from the roof surface may be difficult or impossible to see at night or when obscured by smoke conditions. Many accidents have occurred where an obstruction was not seen and was run into by someone on the roof. In these instances, people have been injured, strangled, entangled, and fallen from rooftops.

This proposal does not prohibit the installation of these items, but it requires that they are identified or protected. For example, protection may be as simple as placing a white 2" diameter plastic pipe around the guy wire used to secure an antenna. Or be constructing an obstruction below the guy wire so that walking under the wire is not possible.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: LARIVIERE-F4-316.4.DOC

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee felt that while the concept is good, it is proposed for the wrong place. It also felt that the proposal would conflict with the *International Building Code* which regulates the initial installations since the proposed provisions would be retroactive. The committee also felt that the phrase "...protected in a manner to prevent injury..." in the exception was vague and should be portrayed as being subject to the approval of the fire code official.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

David S. Collins, FAIA, The Preview Group Inc, representing The American Institute of Architects, requests Approval as Modified by this Public Comment.

Replace the proposal with the following:

<u>**316.4 Obstructions on roofs.** Wires, cables, ropes, antennas, or other suspended obstructions installed on the roof of a building having a roof slope of less than 30 degrees shall not create an obstruction that is less than 7 feet (2133 mm) high above the surface of the roof.</u>

<u>**Exceptions:**</u>

1. <u>Such obstruction shall be permitted where the wire, cable, rope, antennae or suspended obstruction is encased in a white 2" minimum diameter plastic pipe or an approved equivalent.</u>
2. <u>Such obstruction shall be permitted where there is a solid obstruction below such that accidentally walking into the wire, cable, rope, antennae or suspended obstruction is not possible.</u>

Commenter's Reason: During testimony it was noted that the supporting statement in the proposal contained some specific options for how to overcome the prohibition that were not included in the change itself, making the application of the change more difficult to understand. As part of this comment, included in the exceptions are the items that were suggested by the proponent as options.

In addition, the charging language has been simplified and "aerial antennas" have been removed from the list of prohibited obstructions as they are made up of wires and cables. The real issue is not usually the antennae itself, but the guy wires supporting it which may cause the dangerous obstruction. We agree with the concept of providing protection where such obstructions can be dangerous, and believe that the change provides the needed level of protection.

Public Comment 2:

Joe Pierce (Chairman), Dallas Fire Department, representing Joint Fire Service Review Committee, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

316.4 Obstructions on roofs. ~~Installing or maintaining~~ Wires, cables, ropes, aerial antennas, or other suspended obstructions installed ~~or maintained~~ on the roofs of buildings having a roof slope of less than 30 degrees, shall be located to provide a vertical clearance of 7 feet (2133 mm) or more between the roof surface and such obstruction.

Exception: Obstructions may be installed less than 7 feet (2133 mm) high provided they are protected in a manner to prevent injury to firefighters working on the roof.

(Renumber remaining sections…)

Commenter's Reason: The Code Change Proposal was Disapproved at the Code Development Hearing because it was confusing. The revisions in the Public Comment are not intended to regulate "whether" these items are installed on the roof, but if they are installed, they need to be protected.

This proposal does not prohibit the installation of these items, but it requires that they are identified or protected. For example, protection may be as simple as placing a white 2" diameter plastic pipe around the guy wire used to secure an antenna. Or be constructing an obstruction below the guy wire so that walking under the wire is not possible.

Obstructions below 7 feet from the roof surface may be difficult or impossible to see at night or when obscured by smoke conditions. Many accidents have occurred where an obstruction was not seen and was run into by someone on the roof. In these instances, people have been injured, strangled, entangled, and fallen from rooftops.

Final Action: AS AM AMPC____ D

F8-09/10

316.0 (New), 905.3.8 (IBC [F] 905.3.8) (New)

Proposed Change as Submitted

Proponent: Robert J Davidson, Code Consultant/Alan Shuman, President, representing the National Association of State Fire Marshals (NASFM)

Add new text as follows:

SECTION 316.0
ROOF GARDENS AND LANDSCAPED ROOFS

316.1 General. Rooftop gardens and landscaped roofs shall be installed and maintained in accordance with this code and Sections 1505.0 and 1507.16 of the *International Building Code.*

316.2 Rooftop garden or landscaped roof size. Rooftop garden or landscaped roof areas shall not exceed 15,625 ft2 (1,450 m^2) in size for any single area with a maximum dimension of 125 ft (39 m) in length or width. A minimum 3 ft (0.9 m) wide clearance shall be provided between adjacent rooftop garden or landscaped roof areas.

316.3 Rooftop structure and equipment clearance. A minimum 3 ft (0.9 m) wide clearance shall be provided between the rooftop garden or landscaped roof and rooftop structures, including but not limited to mechanical and machine rooms, penthouses, skylights, roof vents, solar panels, antenna supports, and building service equipment.

316.4 Vegetation. Vegetation shall be maintained as described in Sections 316.4.1 and 316.4.2

316.4.1 Irrigation. Supplemental irrigation shall be provided as necessary to maintain levels of hydration necessary to keep green roof plants alive and to keep dry foliage to a minimum.

316.4.2 Dead foliage. Dead foliage and biomass shall be removed immediately.

905.3.8 (IBC [F] 905.3.8) Roof gardens and landscaped roofs. Buildings or structures with roof gardens or landscaped roofs that are equipped with a standpipe shall extend the standpipe to the roof level on which the roof garden or landscaped roof is located.

Reason: As rooftop gardens and landscaped roofs gain in acceptance and popularity reasonable requirements need to be added to the codes to address the fuel load that these additions can add to a building or structure.

New Section 316.0 is proposed to be added to the International Fire Code to manage the size of any one area utilized for these improvements, provide for a reasonable 3 foot clearance to structures and equipment that require access for maintenance and fire response purposes and to control fire exposure. A requirement that means for hydration be provided and that dead foliage and biomass be removed immediately.

A new section is proposed for the construction of buildings that have fire standpipe systems for the standpipe to be extended to the roof if a rooftop garden or landscape is proposed.

Cost Impact: These requirements will increase the cost of construction for those buildings where a roof garden or landscaped roof is proposed to be installed on the roof.

Analysis: Code Change S10-09/10 appears on the hearing order of the IBC-Fire Safety Committee and proposes revisions to IBC Table 1505.1 and Section 1507.16 on this topic. Code change F238-09/10 proposes similar requirements.

ICCFILENAME: DAVIDSON-SHUMAN-F9-316.0.DOC

<u>Public Hearing Results</u>

Committee Action: Approved as Modified

Modify the proposal as follows:

SECTION 316.0
ROOF GARDENS AND LANDSCAPED ROOFS

316.1 General. Rooftop gardens and landscaped roofs shall be installed and maintained in accordance with this code and Sections 1505.0 and 1507.16 of the *International Building Code.*

316.2 Rooftop garden or landscaped roof size. Rooftop garden or landscaped roof areas shall not exceed 15,625 ft^2 (1,450 m^2) in size for any single area with a maximum dimension of 125 ft (39 m) in length or width. A minimum ~~3 ft (0.9 m)~~ <u>6 ft (1.8 m)</u> wide clearance <u>consisting of a Class A-rated roof system complying with ASTM E108 or UL790</u> shall be provided between adjacent rooftop garden or landscaped roof areas.

316.3 Rooftop structure and equipment clearance. <u>For all vegetated roofing systems abutting combustible vertical surfaces, a Class A-rated roof system complying with ASTM E108 or UL790 shall be achieved for a</u> ~~A~~ minimum ~~3 ft (0.9 m)~~ <u>6 ft (1.8 m)</u> wide <u>continuous border placed around rooftop structures and all rooftop equipment</u> ~~clearance shall be provided between the rooftop garden or landscaped roof and rooftop structures~~, including, but not limited to, mechanical and machine rooms, penthouses, skylights, roof vents, solar panels, antenna supports, and building service equipment.

316.4 Vegetation. Vegetation shall be maintained as described in Sections 316.4.1 and 316.4.2

316.4.1 Irrigation. Supplemental irrigation shall be provided as necessary to maintain levels of hydration necessary to keep green roof plants alive and to keep dry foliage to a minimum.

316.4.2 Dead foliage. ~~Dead foliage and~~ <u>Excess</u> biomass, <u>such as overgrown vegetation, leaves and other dead and decaying material,</u> shall be removed <u>at regular intervals not less than two times per year</u> ~~immediately~~.

905.3.8 (IBC [F] 905.3.8) Roof gardens and landscaped roofs. Buildings or structures with roof gardens or landscaped roofs that are equipped with a standpipe shall extend the standpipe to the roof level on which the roof garden or landscaped roof is located.

Committee Reason: The committee felt that the proposal provides needed provisions for the regulation of the specified hazards. The modification provides better correlation with Section 1507.16 of the *International Building Code.*

Analysis: IBC code change S10-09/10 related to this topic was Approved as Modified. Code change F238-09/10 proposing similar requirements to this proposal was Disapproved. See the Report of Hearing for these code changes.

Assembly Action: None

<u>Individual Consideration Agenda</u>

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Dave Frable, U.S. General Services Administration, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

SECTION 316.0
ROOF GARDENS AND LANDSCAPED ROOFS

316.1 General. Rooftop gardens and landscaped roofs shall be installed and maintained in accordance with this code and Sections 1505.0 and 1507.16 of the *International Building Code.*

~~**316.2 Rooftop garden or landscaped roof size.** Rooftop garden or landscaped roof areas shall not exceed 15,625 ft2 (1,450 m2) in size for any single area with a maximum dimension of 125 ft (39 m) in length or width. A minimum 6 ft (1.8 m) wide clearance consisting of a Class A-rated roof system complying with ASTM E108 or UL790 shall be provided between adjacent rooftop garden or landscaped roof areas.~~

~~**316.3 Rooftop structure and equipment clearance**. For all vegetated roofing systems abutting combustible vertical surfaces, a Class A-rated roof system complying with ASTM E108 or UL790 shall be achieved for a minimum 6 ft (1.8 m) wide continuous border placed around rooftop structures and all rooftop equipment, including, but not limited to, mechanical and machine rooms, penthouses, skylights, roof vents, solar panels, antenna supports, and building service equipment.~~

~~**316.4 Vegetation**. Vegetation shall be maintained as described in Sections 316.4.1 and 316.4.2~~

~~**316.4.1 Irrigation**. Supplemental irrigation shall be provided as necessary to maintain levels of hydration necessary to keep green roof plants alive and to keep dry foliage to a minimum.~~

316.2~~4.2~~ Dead foliage. Excess biomass, such as overgrown vegetation, leaves and other dead and decaying material, shall be removed at regular intervals not less than two times per year.

~~**905.3.8 (IBC [F] 905.3.8) Roof gardens and landscaped roofs**. Buildings or structures with roof gardens or landscaped roofs that are equipped with a standpipe shall extend the standpipe to the roof level on which the roof garden or landscaped roof is located.~~

Commenter's Reason: The intent of the proposed modification is to meet the original main intent of the proponent which was to provide reasonable requirements within the IBC to address roof gardens and landscape roofs. However, based on the actions of the Committee, unreasonable requirements for roof gardens and landscape roofs have now been incorporated into the code without any technical justification or fire loss data provided by either the proponent of the original code change proposal or the Committee during their discussions. It is our belief that incorporating unjustified requirements such as these in the code will only lead to many confrontations between Code Officials and City leaders that are promoting green sustainable designs. For example, the new section currently requires:
(1) a minimum 6 foot wide clearance consisting of a Class A rated roof system between adjacent roof gardens and landscape roof areas.
(2) a minimum 6 foot wide clearance consisting of a Class A roof system continuous around the rooftop structure,
(3) a minimum 6 foot wide clearance consisting of a Class A roof system around all roof top equipment and structures

Please note that the 3 requirements above would require a minimum 6 foot wide clearance around the roof top structure as well as all equipment on the roof without taking into consideration roofs having a small footprint. This requirement alone would eliminate many proposed rooftop garden designs on small rooftops in existing buildings. It also requires that existing roof assemblies (e.g., Class B – effective against moderate fire test exposure (see 1505.3) or Class C – effective against light fire test exposure (see 1505.4)) be upgraded to a Class A roof assembly that is effective against a severe fire test exposure. Again, no technical justification has been provided to justify requiring a minimum 6 foot wide clearance or the costs associated with providing Class A roof assemblies for all roof configurations having roof gardens or landscape roofs.

Public Comment 2:

Lawrence G. Perry, AIA, representing Building Owners and Managers Association (BOMA) International, requests Disapproval.

This proposal should be disapproved for the following reasons:
1. Neither 'rooftop gardens' nor 'landscaped roofs' are defined terms. This will lead to inconsistent interpretation and application of any code requirements. While the proposal sets maximum area limitations, it includes no minimum area triggers. Combining the lack of definitions and the lack of any minimum area trigger, a single plant in a pot could trigger compliance with this section.
2. There is no technical substantiation provided for the 6' minimum separation distance between the garden/landscaped areas and almost any roof element. As written, section 316.3 is unclear; it appears to be triggered if a roof has any combustible vertical surfaces, but then applies to all the listed roof elements, not just combustible ones. Additionally, a 6' perimeter around each of the listed roof elements would eliminate a significant portion of potential roof garden areas, with no clear explanation of the hazard being mitigated.
3. There is no justification to extend a standpipe to the roof for any building with a rooftop garden/landscaped roof. As written, this would apply to buildings not even required to have a stair that extends to the roof. In any case, a hose connection inside the building at the top floor level is better protected from both the day-to-day environment and the supposed conflagration hazard posed by rooftop plantings.
4. Requiring 'supplemental irrigation', supposedly to be approved by the fire department, makes no sense. As written, it provides no guidance, and will likely lead to interpretations mandating piped irrigation systems.
5. F9 provides adequate criteria for maintaining plant materials that may be provided on rooftops.

Final Action: AS AM AMPC____ D

F10-09/10
401.6 (New)

Proposed Change as Submitted

Proponent: Michael Jacoby, Seven Valleys, PA, representing self

Add new text as follows:

401.6 Geographical locational Information. A site's geographical location being the site's latitude / longitude coordinates centered on the structure, recorded in decimal for accuracy shall be entered as part of a site's official locational records, in plans and documents.

(Renumber subsequent sections)

Reason: By having accurate geographical locational information which is essential for emergency planning and preparedness to protect those within your communities that have families or loved ones with special needs and by using latitude and longitude coordinates centered on a facility at the time of construction that over time this will eliminate the continuing locational problems being found within mapping databases combined with confusion that you may encounter when Out-Of-Area-Assistance is required for emergencies.

Simply put… State Highway Numbers, Road Names and Postal Delivery Addresses even a community for industrial park may change its name but a site's set of latitude and longitude coordinates will always stay constant.

In other words if you've ever driven to a wrong location when using address numbers and road names etc. especially when every second counts you should immediately understand why this proposed change is so important.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: JACOBY-F1-401.6.DOC

Public Hearing Results

Committee Action: Disapproved

Committee Reason: The committee felt that the proposal is a good concept but that it needs revision to center the location on the facility entrance and not the building itself which would be especially important for mutual aid companies. The proposal should also be specific as to how many decimal places the location description should be carried when recording it in records and what datum the location is taken to.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Michael Jacoby, Seven Valleys, PA, representing self, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

401.6 Geographical Locational Information. A site's geographical location being the site's set of latitude / longitude coordinates centered on a facility's entrance on the structure shall be done by a professional Registered Land Surveyor licensed by the appropriate governing authority using Datum-World Geodetic System (WGS84) recorded in decimal ~~for accuracy~~ degrees in a numeric format ±1 m so that during inspections the fire code official will be able to verify that this lat/long locational information including the name of the surveyor is entered on the construction prints in the cover title block area and shall be entered as part of a site's official records in plans and documents. The responsibility and cost of having the professional Registered Land Surveyor's lat/long information/data recorded on the official site construction plans will be that of the developer/builder.

Commenter Reason: Having accurate geographical locational information which is essential for emergency planning and preparedness is key to protecting life and property of those within your communities, and… after listening to the committee's comments during the last hearing I agree, if we are going to do this right, lets make sure that the set of coordinates, being the location is centered on a facility's entrance and by using this more exact approach it will better benefit our mutual aid companies when Out-Of-Area-Assistance is required so… revisions were made to make it easier for Fire Code Officials at the same time we can now achieve a higher degree of accuracy than was originally proposed.

Since ICC IFC codes will be used worldwide the World Geodetic System **(WGS84)** will be used having the ability of achieving a geocentric globally consistent within ±1 m

Also by using professional resources **(a Professional Registered Land Surveyor Licensed by the appropriate governing authority)** during construction this entrance point's locational information will be **their** responsibility thus assuring that the accuracy of this very important latitude/longitude locational data is now within tolerance.

In doing so, all that a Fire Code Official will have to do is verified that the **Professional Registered Land Surveyor's NAME with the SET OF COORDINATES required** are recorded on the official site construction plans within the cover sheet title block area, during inspections to be later recorded in records so that it can be quickly located during an emergency.

The responsibility including cost of making sure that the Professional Registered Land Surveyor's **NAME** with their **SET OF COORDINATES** lat/long data /information is on the prints will be that of the developer/builder.

To clarify: When **Professional Registered Land Surveyor** services are used **this will eliminate the need** for a Fire Code Official to purchase or carry a handheld GPS device as originally proposed, unless he or she would like to start double-checking locational coordinate data for **data verification purposes** at existing sites which **is not part of this proposal**, when it is discovered that the site's official coordinate data records being used in other database mapping systems is inaccurate, out-of-date or very misleading that could affect local public safety and planning.

Simply put… State Highway Numbers, Road Names and Postal Delivery Addresses even a community or industrial park may change its name but a site's set of latitude and longitude coordinates will always stay constant.

In other words if you've ever driven to a wrong location when using address numbers and road names etc. especially when every second counts you should immediately understand why this is so important.

BIBLIOGRAPHY

Surveyors Datum information in layman's terms

WGS84 http://en.wikipedia.org/wiki/Datum_(geodesy)

WGS84 http://en.wikipedia.org/wiki/WGS84

Cost Impact: The estimated cost should be from $200-$500 maybe less depending on atmospheric conditions at the time of collecting the lat/long data.

Final Action: AS AM AMPC____ D

F12-09/10
404.3.2

Proposed Change as Submitted

Proponent: Gregory J. Cahanin, Cahanin Fire & Code Consulting, representing the Michael Minger Foundation

Revise as follows:

404.3.2 Fire safety plans. Fire safety plans shall include the following:

1. The procedure for reporting a fire or other emergency.
2. The life safety strategy and procedures for notifying, relocating or evacuating occupants, including occupants who need assistance. <u>Emphasis shall be given to identifying individuals with mobility and cognitive disabilities and integrating their special needs into fire safety plans.</u>
3. Site plans indicating the following:
   - 3.1. The occupancy assembly point.
   - 3.2. The locations of fire hydrants.
   - 3.3. The normal routes of fire department vehicle access.
4. Floor plans identifying the locations of the following:
   - 4.1. Exits.
   - 4.2. Primary evacuation routes.
   - 4.3. Secondary evacuation routes.
   - 4.4. Accessible egress routes.
   - 4.5. Areas of refuge.
   - 4.6. Exterior areas for assisted rescue.
   - 4.7. Manual fire alarm boxes.
   - 4.8. Portable fire extinguishers.
   - 4.9. Occupant-use hose stations.
   - 4.10. Fire alarm annunciators and controls.
5. A list of major fire hazards associated with the normal use and occupancy of the premises, including maintenance and housekeeping procedures.
6. Identification and assignment of personnel responsible for maintenance of systems and equipment installed to prevent or control fires.
7. Identification and assignment of personnel responsible for maintenance, housekeeping and controlling fuel hazard sources.

Reason: Provisions for individuals with mobility disabilities are well established in the physical environment requirements of the IBC's Accessibility chapter. Once the building is constructed with the accessibility features the maintenance codes need to have requirements in place that recognize that movement of these individuals in an emergency has to be defined, planned, and communicated. We are also at a point of recognizing that individuals with cognitive disabilities may need additional education or notice of what to do in fire emergencies. This simple addition to the IFC (and the IPMC coordination if approved here) will prompt property owners and operators to consider the sometimes unique needs of the occupants in their buildings in an emergency. This simple requirement begins the dialog between occupants and building operators to help insure that when an emergency occurs everyone will have the opportunity to move safely to the outside. Proper egress planning lessens the burden of emergency personnel in providing rescue services while the suppression effort is ongoing.

The submittal of this proposal and several others with the ICC is part of the work of the Michael H. Minger Foundation, as a result of a Department of Homeland Security Fire Prevention and Safety Grant to study how colleges and universities respond to and provide for students with physical and learning disabilities in a fire event. The study identified model practices being used by campuses regarding fire safety, housing and evacuation policies and procedures. The proposed changes to the IPMC lay the foundation for uniform fire safety planning in the campus environment in a nationally recognized document while also establishing a clear base for egress planning and performance in all types of occupancies.

The Michael H. Minger Foundation was established in 2005. The purpose of the Foundation is to improve fire safety standards and enhance fire safety systems on college and university campuses and to educate parents and students and raise awareness of the reality and risk of campus fires. This non-profit organization was founded to honor the life of Michael H. Minger, an outstanding young man, who lost his life in a college dormitory fire. The Michael Minger Act in Kentucky established a requirement for fire sprinklers in college housing. A governor's task force focusing on campus safety in Kentucky was lead by Gail Minger, the director of the Michael H. Minger Foundation.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: CAHANIN-F2-404.3.2

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee generally felt that the current text adequately addresses occupants who might need assistance and that some occupants who need assistance might be overlooked by the limited application of the proposed text. It was also felt that it is unclear as to who is responsible to identify the specified special needs occupants and could place an undue burden on institutions to do so. Privacy issues in identifying such individuals was also noted as a concern.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Gregory J. Cahanin, Cahanin Fire & Code Consulting, representing Michael Minger Foundation, requests Approved as Modified by this public comment.

Modify the proposal as follows:

404.3.2 Fire safety plans. Fire safety plans shall include the following:

1. The procedure for reporting a fire or other emergency.
2. The life safety strategy and procedures for notifying, relocating or evacuating occupants, including occupants who need assistance. Emphasis shall be given to identifying individuals with mobility, <u>sensory</u>, and cognitive disabilities and integrating their special needs into fire safety plans.

3. through 7. *(No change to current text.)*

Commenter's Reason: Provisions for individuals with mobility disabilities are well established in the physical environment requirements of the IBC's Accessibility chapter. Individuals with sensory disabilities such as hearing and site are provided for in notification devices for fire and signage requirements for egress in Means of Egress. Occupants with cognitive disabilities are not addressed in fire safety plans at this time. Once the building is constructed the maintenance codes need to have requirements in place that recognize that movement of <u>all</u> individuals in an emergency has to be defined, planned, and communicated.

We are also at a point of recognizing that individuals with cognitive disabilities may need additional education or notice of what to do in fire emergencies. This simple addition to the IFC will prompt property owners and operators to consider the sometimes unique needs of the occupants in their buildings in an emergency. While there were committee members who thought that this change would add an unfair requirement upon property owners, they failed to recognize that we are only calling attention to the possible existence of groups with disabilities as a consideration. This simple requirement begins the dialog between occupants and building operators to help insure that when an emergency occurs everyone will have the opportunity to move safely to the outside. Proper egress planning lessens the burden of emergency personnel in providing rescue services while the suppression effort is ongoing.

The committee statement says. "It was also felt that it is unclear as to who is responsible to identify the specified special needs occupants and could place an undue burden on institutions to do so. Privacy issues in identifying such individuals was also noted as a concern." The change says simply to consider the needs of these special groups in developing a plan and add provisions during plan development in <u>anticipation</u> of an expressed need in the building. If the plan has specific educational indicators identified in the plan when it is completed the building owners can immediately provide proper access to individuals based upon the plans provisions already in place. It does not require the specific identification of an individual. There are multiple agencies nationally looking at ways to accommodate individuals and encourage their participation and that is not the role of the Fire Prevention Code. This change will only bring the Fire Prevention Code into the mainstream of considering all of the needs of the general public and does in fact make it more inclusive.

The submittal of this proposal and several others with the ICC is part of the work of the Michael H. Minger Foundation, as a result of a Department of Homeland Security Fire Prevention and Safety Grant to study how colleges and universities respond to and provide for students with physical and learning disabilities in a fire event. The study identified model practices being used by campuses regarding fire safety, housing and evacuation policies and procedures. The proposed changes to the IPMC lay the foundation for uniform fire safety planning in the campus environment in a nationally recognized document while also establishing a clear base for egress planning and performance in all types of occupancies.

The Michael H. Minger Foundation was established in 2005. The purpose of the Foundation is to improve fire safety standards and enhance fire safety systems on college and university campuses and to educate parents and students and raise awareness of the reality and risk of campus fires. This non-profit organization was founded to honor the life of Michael H. Minger, an outstanding young man, who lost his life in a college dormitory fire. The Michael Minger Act in Kentucky established a requirement for fire sprinklers in college housing. A governor's task force focusing on campus safety in Kentucky was lead by Gail Minger, the director of the Michael H. Minger Foundation.

Final Action: AS AM AMPC____ D

F13-09/10
404.6 (New)

Proposed Change as Submitted

Proponent: Gregory J. Cahanin, Cahanin Fire & Code Consulting, representing the Michael Minger Foundation

Add new text as follows:

404.6 Posting of evacuation plan. A posted evacuation plan consisting of a floor plan layout indicating the available evacuation routes with identification of key emergency components, such as areas of rescue assistance, shall be provided near the main entry to the floor or building where access by the general public occurs in Group A-3, B and R-2 occupancies .

Reason: Within ANSI A17.1 for elevators there is now a requirement for 'in case of fire use stairs' placards to be posted at elevator call buttons and this proposal is a better detailed extension of that requirement document in that the posted plan will clearly define where the stairs and areas of rescue assistance are located. A companion proposal for a new 404.5.1 requires posting of egress paths from dorm rooms and this new section is an extension into public area notice.

The information provided on the plan will communicate the available means of egress to the occupants. It is also recognized that there is no specific form of education being provided to the general population related to the provisions being provided for accessibility in buildings. The evacuation plan can begin the educational process by identifying building provisions for egress in a public area.

The submittal of this proposal and several others with the ICC is part of the work of the Michael H. Minger Foundation, as a result of a Department of Homeland Security Fire Prevention and Safety Grant to study how colleges and universities respond to and provide for students with physical and learning disabilities in a fire event. The study identified model practices being used by campuses regarding fire safety, housing and evacuation policies and procedures. The proposed changes to the IPMC lay the foundation for uniform fire safety planning in the campus environment in a nationally recognized document while also establishing a clear base for egress planning and performance in all types of occupancies.

The Michael H. Minger Foundation was established in 2005. The purpose of the Foundation is to improve fire safety standards and enhance fire safety systems on college and university campuses and to educate parents and students and raise awareness of the reality and risk of campus fires. This non-profit organization was founded to honor the life of Michael H. Minger, an outstanding young man, who lost his life in a college dormitory fire. The Michael Minger Act in Kentucky established a requirement for fire sprinklers in college housing. A governor's task force focusing on campus safety in Kentucky was lead by Gail Minger, the director of the Michael H. Minger Foundation.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: CAHANIN-F1-404.6.DOC

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee felt that the proposal should be more specific as to the "key emergency components" mentioned and should be more specific as to where the plans should be posted. The proposed text would also conflict with Section 404.2 which already includes Group R-2 college and university buildings and also provides a much higher threshold for Group A and B occupancies.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Gregory J. Cahanin, Cahanin Fire & Code Consulting, representing Michael Minger Foundation, requests Approved as Modified by this public comment.

Modify the proposal as follows:

~~**404.6 Posting of evacuation plan.**~~ **404.5.1.1 College and university buildings.** A posted evacuation plan consisting of a floor plan layout indicating the available evacuation routes with identification of key emergency components, such as areas of rescue assistance, shall be provided near the main entry to the floor or building where access occurs in Groups A-3~~,~~ and B and in Group R-2 college and university buildings ~~occupancies.~~

Commenter's Reason: Based upon the committee's comments the original proposal has been relocated to become a subpart of fire safety plan distribution consistent with the reference to college and university buildings in 404.2. Section 404.2 only states where a fire safety and evacuation plan is to be prepared and maintained- not who has access to the plan.

The plan distribution requirements in 404.5.1 say tenants and building service personnel receive copies of the fire safety plan. For college and university campus buildings the student may not be either a tenant or campus personnel and needs to be informed and have access to the fire safety plan. A provision for its placement near the main entry to the floor or building provides the owners with a general area of placement for buildings where their lobby area may vary widely in geometry and a more restrictive requirement might be more difficult to enforce. For dormitory sleeping rooms there is a new requirement for the posting of evacuation egress plans on the back of dorm doors and this change complements that change in residence halls.

Within ANSI A17.1 for elevators there is now a requirement for 'in case of fire use stairs' placards to be posted at elevator call buttons and this proposal is a better detailed extension of that requirement document in that the posted plan will clearly define where the stairs and areas of rescue assistance are located.

The information provided on the plan will communicate the available means of egress to the occupants. It is also recognized that there is no specific form of education being provided to the general population related to the provisions being provided for accessibility in buildings. The evacuation plan can begin the educational process by identifying building provisions for egress in a public area. The submittal of this proposal and several others with the ICC is part of the work of the Michael H. Minger Foundation, as a result of a Department of Homeland Security Fire Prevention and Safety Grant to study how colleges and universities respond to and provide for students with physical and learning disabilities in a fire event. The study identified model practices being used by campuses regarding fire safety, housing and evacuation policies and procedures. The proposed changes to the IPMC lay the foundation for uniform fire safety planning in the campus environment in a nationally recognized document while also establishing a clear base for egress planning and performance in all types of occupancies.

The Michael H. Minger Foundation was established in 2005. The purpose of the Foundation is to improve fire safety standards and enhance fire safety systems on college and university campuses and to educate parents and students and raise awareness of the reality and risk of campus fires. This non-profit organization was founded to honor the life of Michael H. Minger, an outstanding young man, who lost his life in a college dormitory fire. The Michael Minger Act in Kentucky established a requirement for fire sprinklers in college housing. A governor's task force focusing on campus safety in Kentucky was lead by Gail Minger, the director of the Michael H. Minger Foundation.

Final Action: AS AM AMPC____ D

F14-09/10

408.4 through 408.4.4 (New), Chapter 47, Appendix K (New)

Proposed Change as Submitted

Proponent: William Winslow, CIH, CFI, CMI, Winslow Partnership, representing self

1. Add new text as follows:

408.4 Group H occupancies and outdoor areas with hazardous materials. Group H occupancies and outdoor areas with hazardous materials shall comply with Sections 408.4.1 through 408.4.4 when such occupancies or facilities are required by 40CFR, Section 68.130 to have a Risk Management Plan (RMP). See Appendix K for further information on chemicals and threshold quantities that require a RMP.

408.4.1 Emergency response plan. An emergency response plan describing procedures for mitigating an unintentional chemical release shall be prepared prior to occupancy. A copy of the plan shall be maintained on-site, and upon request, a copy of the plan shall be provided to the fire code official for approval.

408.4.2 Training. Employees who are designated as emergency responders shall be trained to perform duties assigned in the Emergency Response Plan. Training criteria shall be provided in the Emergency Response Plan.

408.4.3 Equipment. Equipment and supplies specified in the Emergency Response Plan for use in the event of an unintentional chemical release shall be maintained on-site or shall be available for delivery to the site as specified in the plan.

408.4.4 Emergency drill. When required by the fire code official, an annual drill shall be conducted to practice the Emergency Response Plan. The fire code official shall be notified of the date and time of a scheduled drill not less than sixty days prior to the event. When an emergency drill identifies deficiencies in the Emergency Response Plan, the plan shall be updated to correct noted deficiencies.

2. Add new standard to Chapter 47 as follows:

EPA

40 CFR, Part 68 Subparts F and G – 2000	Chemical Accident Prevention Provisions - Regulated Substances for Accidental Release Prevention and Risk Management Plan

3. Add new Appendix K as follows:

(Underlining in the body of the substances tables omitted for clarity)

APPENDIX K
HAZARDOUS MATERIALS AND THRESHOLD QUANTITIES FOR EMERGENCY RESPONSE PLANNING

This appendix is for informational purposes and is not intended for adoption.

SECTION K101
GENERAL

K101.1 Scope. The *International Fire Code*, Section 408.4 establishes requirements for Group H-1, H-2, H-3 and H-4 occupancies and outdoor facilities to have an emergency response plan when threshold quantities for certain chemicals are exceeded. Section 408.4 intends for the emergency response planning requirements, including the list of applicable chemicals and threshold quantities, to:

1. Remain consistent with the U.S. Environmental Protection Agency's (EPA) Risk Management Plan (RMP) filing thresholds specified in Title 40, Section 68.130 of the Code of Federal Regulations, and
2. Remain consistent with the regulations for facilities requiring a RMP, as specified in Section 112(r) of the Clean Air Act.

Table K101(1) and Table K101(2) provide EPA's threshold quantities for regulated chemicals as of January 1, 2009. This information is provided as a reference for application of Section 408.4, but because the list of applicable chemicals and quantities under Federal law may change over time, it is recommended that the source Federal documents be consulted for the most up-to-date information when applying the code.

TABLE K101(1)

[1]A flammable substance when used as a fuel or held for sale as a fuel at a retail facility is excluded from all provisions of 40CFR, Part 68.

Reason: Dalton, Georgia, April 11, 2006 - A final report issued by the U.S. Chemical Safety and Hazard Investigation Board (CSB) concluded inadequate emergency planning by the facility, city, and county contributed to the severity of a runaway chemical reaction and toxic vapor cloud release at MFG Chemical Inc. One problem is that emergency plans required under CCA 112(r) and other federal regulations do not have to be approved by the FCO and do not require periodic drills. This code change will allow the FCO to require emergency planning, training, and drills that meet the needs of the fire department for facilities with hazardous materials that exceed the threshold quantity for risk management planning found in CCA 112(r). It will also ensure that the FCO has the authority to require the plan be written and implemented before a new facility begins operation. The provision for approval by the FCO is in agreement with NFPA 600, which applies to any organized, private, industrial group of employees having fire-fighting response duties, such as emergency brigades, emergency response teams, fire teams, and plant emergency organizations. Section 1.3.2 of NFPA 600 states, " The authority having jurisdiction shall be permitted to examine and approve organization, operations, training". The 60 day notification of an upcoming drill will provide the time necessary for the fire department to include the drill in its training schedule.

Cost Impact: The code change proposal should not increase cost of construction.

Analysis: A review of the standard(s) proposed for inclusion in the code, 40 CFR, Part 68 Subparts F and G – 2000, for compliance with ICC criteria for referenced standards given in Section 3.6 of Council Policy #CP 28 will be posted on the ICC website on or before September 24, 2009.

Public Hearing Results

Note: The following analysis was not in the Code Change monograph but was published on the ICC website at http://www.iccsafe.org/cs/codes/Documents/2009-10cycle/ProposedChanges/Standards-Analysis.pdf :

Analysis: Review of the proposed new standard EPA 40 CFR, Part 68, Subparts F and G - 2000 indicated that, in the opinion of ICC staff, the standard did not comply with ICC standards criteria, Section 3.6.3.2.

Committee Action: Disapproved

Committee Reason: The committee felt that the proposal would put the fire code official in the position of approving a federally-mandated document which the committee felt was inappropriate. It was also noted as unclear as to what, if any, action the fire code official might need to take upon notification required by Section 408.4.4 and who would be responsible for identifying any deficiencies. The classification of some materials listed in the tables were also noted as not being compatible with the material definitions in the IFC.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

William Winslow, Winslow Partnership, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

408.4 Group H occupancies and outdoor areas with hazardous materials. ~~Group H occupancies and outdoor areas with hazardous materials shall comply with Sections 408.4.1 through 408.4.4 when such occupancies or facilities are required by 40CFR, Section 68.130 to have a Risk Management Plan (RMP). See Appendix K for further information on chemicals and threshold quantities that require a RMP.~~ Facilities with one or more Group H occupancies or with an outdoor area containing hazardous materials in amounts that exceed the maximum allowable quantity per outdoor control area shall comply with Sections 408.4.1 through 408.4.4.

Exceptions:

1. Group H occupancies and outdoor areas where storage and use is limited to materials with a NFPA 704 rating of less than 3.
2. Facilities where the total amount of hazardous materials with an NFPA rating of 3 or 4 in outdoor areas and H occupancies does not exceed a combined weight of 50,000 pounds.
3. Group H-5 occupancies and indoor and outdoor HPM storage rooms and areas shall comply with 408.5.

408.4.1 Emergency response plan. An emergency response plan describing procedures for mitigating an unintentional chemical release shall be prepared prior to occupancy or, for existing facilities, within 90 days of written notification by the fire code official. A copy of the plan shall be maintained on-site, and upon request, a copy of the plan shall be provided to the fire code official for approval.

408.4.2 Training. Employees who are designated as emergency responders shall be trained to perform duties assigned in the Emergency Response Plan. Training criteria shall be provided in the Emergency Response Plan.

408.4.3 Equipment. Equipment and supplies specified in the Emergency Response Plan for use in the event of an unintentional chemical release shall be maintained on-site or shall be available for delivery to the site as specified in the plan.

408.4.4 Emergency drill. When required by the fire code official, an annual drill shall be conducted to practice the Emergency Response Plan. The fire code official shall be notified of the date and time of a scheduled drill not less than 14 days prior to the event. When an emergency drill identifies deficiencies in the Emergency Response Plan, the plan shall be updated to correct noted deficiencies.

EPA

~~40 CFR, Part 68 Subparts F and G – 2000~~	~~Chemical Accident Prevention Provisions - Regulated Substances for Accidental Release Prevention and Risk Management Plan~~

~~APPENDIX K~~

~~HAZARDOUS MATERIALS AND THRESHOLD QUANTITIES FOR EMERGENCY RESPONSE PLANNING~~

(Delete entire Appendix K without substitution)

Commenter's Reason: The purpose of this proposal is to add a requirement in the fire code for emergency response planning and training at facilities with large quantities of NFPA hazard class 3 and 4 materials. We can't require compliance with federal regulations, so we need our own tool. Also, the federal regulations may require an emergency plan, but they don't require training to implement the plan. To minimize the burden on small businesses, there are a number of exceptions, including for facilities where the total amount of hazard class 3 and 4 materials is less than 50,000 pounds (5,000 gallons). I don't think there is any disagreement that it is safer for the fire department to respond to a hazmat incident if the facility's staff has an emergency response plan, which it is trained and equipped to implement. Help improve the safety of hazmat emergency responders by overturning the committee's disapproval of this proposal, and vote for Approval as Modified by this Public Comment.

In the reason given for disapproval, the committee was concerned about the incorporation of federal requirements in the original proposal. As a result, all references to federal requirements were removed. Also the semiconductor industry was concerned about HPM facilities. So, in the exceptions there is a clarification that Group H-5 occupancies <u>and indoor and outdoor HPM storage rooms and areas</u> shall comply with 408.5.

Final Action: AS AM AMPC____ D

F16-09/10
503.2.2.1 (New)

Proposed Change as Submitted

Proponent: Carl D. Wren, Fire Department, City of Austin, TX, representing self

Add new text as follows:

<u>**503.2.2.1 Decrease in width.** The fire code official shall have the authority to approve a decrease in the minimum access width. In evaluating reduced access widths, the fire code official shall consider traffic safety issues, maximum building heights, fixed fire suppression systems, the degree of street interconnections, and the adequacy of turning radii. When necessary to demonstrate compliance, the fire code official may require technical assistance provided by traffic safety professionals as well as fire safety professionals in accordance with Section 104.7.2.</u>

Reason: For a number of years the fire service has been exploring strategic partnerships for reducing the overall risk to our communities from a variety of hazards rather than restricting its efforts to simply reducing deaths and injuries from fire related emergencies. This effort is evident in the objectives of the National Fire Academy Course “Strategies for Community Risk Reduction” and its predecessor course “Strategic Analysis of Community Risk Reduction” as well as in the NFPA “Risk Watch” program. With this general idea of overall risk to the community and a specific consideration of the potential for reducing traffic injuries and fatalities in mind, it may often be advantageous to plan for traffic calming during the site plan or subdivision design phases of a project and for the fire code official to be able to choose to accept a design with narrower but significantly interconnected streets over the potential for the jurisdiction to attempt the installation of traffic calming measures as an afterthought, or over the use of cul-de-sacs or other dead-ends with forced turnaround situations.

While the issue of environmental quality is not a goal or objective directly attributed to the fire code, environmental improvements have been a by-product of code development issues such as handling and storing hazardous materials. The EPA has also weighed in on the issue of authority to consider alternate roadway designs and has cited at least two (2) potential benefits of giving fire officials the clear authority to consider and potentially to approve narrower streets in some circumstances. First, representatives of the EPA have noted their position that interconnected narrower streets support more pedestrian friendly cities or neighborhoods and can therefore result in reduced vehicle miles traveled and an attendant reduction in carbon emissions. Second, they have noted that they support this approach as a way to give opportunity to consider and possibly use low-impact development (LID) techniques or green infrastructure for storm water treatment. They believe this will reduce the quantity and improve the quality of storm water runoff.

Finally, this proposal simply clarifies and makes explicit what the proponent considers to be a currently implied authority under IFC sections 104.8, 104.9 and 503.1.2. It affords an opportunity to give developers credit for reduced fire risks due to fire sprinkler protection and acknowledges that there is a potential for major reductions in traffic casualties for well thought out narrow street configurations. Further information on the potential impact of street widths on traffic related injuries can be obtained through a 1997 study by Peter Swift et al that is currently being peer reviewed.

Cost Impact: The code change proposal will not increase the cost of construction.

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: While the committee recognizes the issues surrounding the proposal, it felt that having the width reduction highlighted in a specific section as proposed could be used against the fire code official in reviewing site plan documents for adequate fire apparatus access. It was suggested that it might be more effective to revise current Section 503.2.2 to give the fire code official the authority to modify the width of fire apparatus access roads without specifying whether it is to increase or to decrease the width. It was also noted that the proposal includes a "laundry list" of things to consider when modifying the width, albeit an incomplete one. Such a list should be better located in the commentary and expanded to to include, but not be limited to, consideration of building construction type, wildland-urban interface areas, terrain characteristics and the specific characteristics of fire apparatus. The committee also expressed its preference for code change F17-09/10 to establish needed dialogue regarding fire apparatus road design issues versus traffic safety issues.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Page Dougherty representing self, and Carl D. Wren, Austin, TX Fire Department, representing self, request Approval as Modified by this Public Comment.

Modify the proposal as follows:

503.2.2 Authority. The fire chief ~~code official~~ shall have the authority to modify ~~require an increase in~~ the minimum access widths needed ~~where they are inadequate for fire or rescue operations~~. When necessary to demonstrate compliance, the fire code official is authorized to require technical assistance provided by traffic safety professionals as well as fire safety professionals in accordance with Section 104.7.2.

~~**503.2.2.1 Decrease in width.** The fire code official shall have the authority to approve a decrease in the minimum apparatus access width. In evaluating reduced access widths, the fire code official shall consider traffic safety issues, maximum building heights, fixed fire suppression systems, the degree of street interconnections, and the adequacy of turning radii. When necessary to demonstrate compliance, the fire code official may require technical assistance provided by traffic safety professionals as well as fire safety professionals in accordance with Section 104.7.2.~~

Commenter's Reason (Dougherty): Per the direction of the committee in its reasoning as shown in the Report of the Hearings, this modification of the proposal moves the revision concept into Section 503.2.2 and changes the text to a more general term. The proposed change in this public comment generalizes the authority to allow the fire chief the ability to approve an increase or decrease in fire apparatus access roads and fire lanes. The approval may be determined by the conditions of a proposal, based on fire department access needs in the area and any practical conditions that may affect the area such as topography and any special construction conditions or additional fire protection features to offset access issues. This proposal clarifies the intent of the code as it applies to the fire chief's authority in these cases.

This proposal initially was to allow a decrease in the width for fire apparatus access. However, as was pointed out by one committee member pointed out in his reasoning that sometimes the minimums don't work and a larger turn radius or other feature of the intersection needs to be altered to allow fire apparatus access to an area. It should also be noted that fire departments have allowed decreases in access widths based on topographical and other practical difficulties as allowed in the legacy codes.

I urge the membership to support this Public Comment by voting for the item to be approved as modified by the Public Comment

Commenter's Reason (Wren): As the original submitter, I am trying to follow the direction of the committee in their reason statement as recorded in the Report of the Hearings. This modification of the proposal moves the revision concept into Section 503.2.2 and changes the text to be more general in its application. The proposed change in this public comment gives more latitude to the authority having jurisdiction (AHJ), allowing the fire chief the ability to approve an increase or a decrease in width for fire apparatus access roads and fire lanes when building and/or site conditions and installed protection, or a lack of installed protection, warrant the change. The approval may be determined by the specific conditions of a project or building based on fire department access needs in the area and any practical conditions that may affect the area. Conditions that have been traditionally recognized as having the potential to affect access (specifically access distance in 503.1.1) include topography, nonnegotiable grades, building location on the property, and any special construction conditions as well as additional fire protection features proposed in order to offset access issues. This proposal clarifies the intent of the code as it applies to the fire chief's authority in those cases that specifically deal with access width. My comment mirrors a public comment developed by Mr. Page Dougherty.

I urge the membership to support this Public Comment by voting for the item to be approved as modified by the Public Comment.

Public Comment 2:

John Norquist, representing Congress for the New Urbanism, requests Approval as Submitted.

Commenter's Reason: The language proposed in F16 poses no threat to fire code officials. It provides and makes explicit a measure of flexibility not currently present: Fire marshals can approve widths of less than 20 feet clear when factors including – but not limited to those listed in the proposed language – are considered, but are not required to do so. This is not a laundry list, but examples of factors that should be considered. In itself, this language contains the flexibility necessary for appropriate consideration of local conditions and situations.

The key passage, "The fire code official shall have the authority…" is permissive, not prescriptive. Hypothetically, even if it were phrased "The fire code official *has* the authority…" the language remains permissive; one doesn't have to use that authority if he or she determines circumstances won't allow it. If this flexibility were already in the code, this issue would not have arisen.

If such flexibility is already in the code but incomplete, then the language of F16 fills the gap. Good street designs take into account factors like turning radii, hydrant placement and staging area needs. Modern apparatus has evolved to fit wider streets; it can evolve again. A case in point: the Milwaukee, (Wis.) Fire Department demanded that a custom builder manufacture appropriately sized apparatus, and got them.

Final Action: AS AM AMPC____ D

F17-09/10
504.3.1, 502.1

Proposed Change as Submitted

Proponent: Tom Lariviere, Chairman, Joint Fire Service Review Committee

Add new text as follows:

503.4.1. Traffic calming devices. Traffic calming devices are prohibited unless approved by the *fire code official*.

502.1 Definitions. The following words and terms shall, for the purposes of this chapter and as used elsewhere in this code, have the meanings shown herein.

TRAFFIC CALMING DEVICES. Traffic calming devices are design elements of fire apparatus access roads such as street alignment, installation of barriers, and other physical measures intended to reduce traffic and cut-through volumes, and slow vehicle speeds.

Reason: Many communities are facing increased traffic volumes. Both new and existing streets are experiencing higher vehicular volumes and speeds as drivers attempt to find "short cuts" to ease their commutes. Designers, planning departments and traffic departments are increasingly turning to traffic calming measures to preserve the quality and enjoyment of life for their citizens.

A key interest of all emergency services is to provide timely response to emergencies. Traffic calming devices can unduly delay and result in damage to emergency apparatus. This proposed language will allow fire officials to restrict traffic calming devices to those that will minimize these problems.

Standard emergency medical service response times are based on 4-6 minutes. This time frame is based on the fact that brain damage resulting from cardiac arrest typically occurs within 4-6 minutes. Delaying, or extending, these response times in any fashion places the public at greater risk.

Traffic officials and fire officials both have the responsibility to ensure that public interests are properly considered in their decision-making process. Both sets of officials have detailed regulations to provide for those interests.

This proposal requires approval of traffic calming measures by the fire code official. What it doesn't do is detail how that approval is to be made within various jurisdictions. Each jurisdiction has their own traffic pattern emergency response challenges. The purpose of this proposal is to ensure that the fire department is part of this decision-making process. This proposal requires approval of traffic calming measures in private fire access roads and public roads.

Many traffic calming designs include various road configurations that delay, or even restrict, fire apparatus access. Such items may include "round-abouts", speed humps, narrowing of streets, winding roads rather than straight roads, etc. All of these items slow the response time of any emergency response vehicle whether it be law enforcement, medical services, or fire.

The definition for traffic calming is based on the definition provided by the Institute of Transportation Engineers.

Cost Impact: The code change proposal will not increase the cost of construction**.**

ICCFILENAME: LARIVIERE-F5-504.3.1.DOC

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The committee agreed with the proponent's reason statement and felt that approval of this proposal would be an important first step in establishing needed critical dialogue with urban traffic planning officials so that both fire departments and traffic planners come to understand and respect one another's viewpoints and needs regarding the need for traffic calming devices. The committee recognized the need to provide better speed control for increased safety but emphasized that features which impede or, possibly, prevent emergency vehicle response create a serious public safety hazard. The committee also noted that the prohibitive language of this proposal ("Traffic calming devices are *prohibited*…") does not lend itself to the kind of co-operation between agencies that is essential to this discussion and suggested a public comment be submitted to make the language more approval-oriented.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

John Norquist representing Congress for the New Urbanism, requests Disapproval.

Commenter's Reason: F17 overreaches and will create more friction between the fire service and traffic engineers and municipal planners, not less. Nor will it spark constructive dialog. As written, F17 and its definitions of traffic calming are so broad in scope that by making the fire code official the final judge of street and traffic design, and therefore traffic engineering, it effectively turns fire code officials into *de facto* traffic engineers. Do fire code officials have the background and training to do traffic engineering on top of their current duties? Do they want to be traffic engineers? Will they consider the potential liability stemming from a traffic engineering decision made by someone who is not a qualified traffic engineer?

CNU understands that the intent here is to give fire code officials a seat at the street design table. CNU has been actively engaged in pursuing and creating the very kind of dialog sought by the IFC. But F17 will not create that seat in a positive atmosphere because is the equivalent of jumping up on the table. The decision to approve it should be overturned.

Public Comment 2:

Lawrence G. Perry, AIA, representing Building Owners and Managers Association (BOMA) International, requests Disapproval.

Commenter's Reason: This proposal should be disapproved for the following reasons:

1. "The fire code official shall review and approve all newly proposed traffic calming devices, and shall review and either approve, or require the removal of, every existing traffic calming device in the jurisdiction." This is essentially what the approved language says.
2. Neither the proponents reason statement nor testimony provided any explanation as to how this would be implemented. Rather, the proponents and the committee spoke of how this new code requirement could be used to open a 'dialogue' between the fire service and the traffic planners of a jurisdiction. Code requirements should not ever be written to 'open a dialogue' between agencies of a local jurisdiction. The local fire service would be better served by directly working with their local cohorts from the traffic division, than by creating unrealistic code provisions.
3. The proposed definition of 'Traffic Calming Devices' is so broad as to capture all kinds of elements that would never be appropriate to be regulated outside of the local traffic code. Alignment of streets? The 2012 edition of the IFC will prohibit alignment of streets that calm traffic? That's what the approved language says.
4. If approved as proposed, the 2012 edition of the IFC will likely create thousands of code violations upon adoption in any jurisdiction, and provides no mechanism for how the fire service would assess each proposed and existing 'device', or what criteria would be used to assess each 'device'.

Final Action: AS AM AMPC____ D

F20-09/10, Part I
506.3 (New)

NOTE: PART II DID NOT RECEIVE A PUBLIC COMMENT AND IS ON THE CONSENT AGENDA. PART II IS REPRODUCED ONLY FOR INFORMATIONAL PURPOSES FOLLOWING ALL OF PART I.

Proposed Change as Submitted

Proponent: Robert J Davidson, Code Consultant/Alan Shuman, President, representing the National Association of State Fire Marshals (NASFM)

PART I – IFC

Revise section title and add new text as follows:

SECTION 506
KEY BOXES AND FIRE SERVICE ELEVATOR KEYS

506.3 Standardized fire service elevator keys. All buildings with elevators equipped with Phase I Emergency Recall, Phase II emergency in-car operation, or a Fire Service Access Elevator shall be equipped to operate with a standardized fire service elevator key approved by the fire code official.

Exception: Where there is a practical difficulty to providing a standardized key the owner shall place the building's non-standardized fire service elevator keys in a key box installed in accordance with Section 506.1.

506.3.1 Requirements for standardized fire service elevator keys. Standardized fire service elevator keys shall comply with all of the following:

1. All fire service elevator keys within the jurisdiction shall be uniform and specific for the jurisdiction. Keys shall be cut to a uniform key code.
2. Fire service elevator keys shall be a patent protected design to prevent unauthorized duplication.
3. Fire service elevator keys shall be factory restricted by the manufacturer to prevent the unauthorized distribution of key blanks. No uncut key blanks shall be permitted to leave the factory
4. Fire service elevator keys subject to these rules shall be engraved with the words "DO NOT DUPLICATE".

506.3.2 Access to standardized fire service keys. Access to standardized fire service elevator keys shall be restricted to the following:

1. Elevator owners or their authorized agents;
2. Elevator contractors.
3. Elevator Inspectors of the jurisdiction.
4. Fire code officials of the jurisdiction.
5. The fire department and other emergency response agencies designated by the fire code official.

506.3.3 Duplication or distribution of keys. No person may duplicate a standardized fire service elevator key or issue, give, or sell a duplicated key unless in accordance with this code.

506.3.4 Responsibility to provide keys. The building owner shall provide up to three (3) standardized fire service elevator keys where required by the fire code official, upon installation of a standardized fire service key switch or switches in the building.

Reason: When fire departments and other public agencies respond to emergencies the ability to quickly access the location of the emergency can be the deciding factor of a successful response. Elevators are increasingly being relied upon for emergency operations and their importance has been highlight by recent additions to the International Building Code requiring the installation of fire service access elevators and providing requirements for the installation of occupant evacuation elevators.

One of the difficulties the fire service and other emergency response agencies have when accessing facilities and attempting to use elevators is the increasing number of non-standardized keys which may not be available at the time of response. Even when emergency responders are provided the necessary keys in case of response, the correct key may have to be identified from a large collection of keys for any one building. In larger jurisdictions the sheer number of keys makes the possession of the keys unwieldy for the emergency responders.

The purpose Part1 of this proposal is to provide for a standardized fire service elevator key to reduce the number of keys necessary for accessing elevators in an emergency. As drafted this section will only apply to those buildings that have elevators with Phase I or Phase II emergency service or to those buildings with a fire service access elevator.

The proposal also provides for a level of security for the standardized key. Access to the key that can take control of an elevator is an existing area of vulnerability for buildings and one that was not addressed in the past with simple key designs being utilized. Since this proposal will create a standardized key, it also includes rules for the safeguarding of that key.

Part 2 of this proposal is included to simply place a pointer in the International Building Code should the International Fire Code Committee approve Part 1 of this proposal.

Because the International Codes are written to enable jurisdictions to adopt the codes at the State, Local or Regional levels the proposal follows that format and designated the "fire code official" as the regulating official. However, it is expected, and preferred, that a State level agency designate a standardized key for all jurisdictions to provide for a statewide standardized key.

In preparing this proposal, statewide regulations requiring standardized fire service elevator keys (or Master Elevator Keys) from Florida, Louisiana and New Jersey were reviewed. Since some states and local jurisdictions have already begun to address this issue with the adoption of regulations and other states and jurisdictions are considering this topic it is beneficial to building owners and code officials to have a standard set of requirements contained within the model codes.

Cost Impact: The code change proposal will not increase the cost of new construction.

Analysis: Similar requirements are proposed in code change proposal F40-09/10.

ICCFILENAME: DAVIDSON-SHUMAN-F5-506.3.DOC

Public Hearing Results

PART I- IFC
Committee Action: **Approved as Modified**

Modify the proposal as follows:

506.3 Standardized fire service elevator keys. All buildings with elevators equipped with Phase I Emergency Recall, Phase II emergency in-car operation, or a Fire Service Access Elevator shall be equipped to operate with a standardized fire service elevator key approved by the fire code official.

> **Exception**: ~~Where there is a practical difficulty to providing a standardized key t~~ The owner shall be permitted to place the building's non-standardized fire service elevator keys in a key box installed in accordance with Section 506.1.

(Portions of the proposed code change not shown remain unchanged.)

Committee Reason: The committee agreed with the proponent's reason statement and felt that the proposal would reduce the number of keys that need to be carried in fire apparatus. The modification removes subjective language which could lead to inconsistent enforcement.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Brian Black, BDBlack Codes Inc, representing National Elevator Industry Inc; Sean DeCrane representing International Association of Fire Fighters and Jack J. Murphy representing Fire Safety Directors Association of Greater New York, request Approval as Modified by this Public Comment.

Modify the proposal as follows:

PART I-IFC

SECTION 506
KEY BOXES AND FIRE SERVICE ELEVATOR KEYS

506.3 Standardized fire service elevator keys. All buildings with elevators equipped with Phase I Emergency Recall, Phase II emergency in-car operation, or a Fire Service Access Elevator shall be equipped to operate with a standardized fire service elevator key ~~approved by the fire code official~~ complying with ASME A17.1/CSA B44.

> ~~**Exception**: Where there is a practical difficulty to providing a standardized key the owner shall place the building's non-standardized fire service elevator keys in a key box installed in accordance with Section 506.1.~~

~~**506.3.1 Requirements for standardized fire service elevator keys**. Standardized fire service elevator keys shall comply with all of the following:~~

1. ~~All fire service elevator keys within the jurisdiction shall be uniform and specific for the jurisdiction. Keys shall be cut to a uniform key code.~~
2. ~~Fire service elevator keys shall be a patent protected design to prevent unauthorized duplication.~~
3. ~~Fire service elevator keys shall be factory restricted by the manufacturer to prevent the unauthorized distribution of key blanks. No uncut key blanks shall be permitted to leave the factory~~
4. ~~Fire service elevator keys subject to these rules shall be engraved with the words "DO NOT DUPLICATE".~~

~~**506.3.2 Access to standardized fire service keys**. Access to standardized fire service elevator keys shall be restricted to the following:~~

1. ~~Elevator owners or their authorized agents;~~
2. ~~Elevator contractors.~~
3. ~~Elevator Inspectors of the jurisdiction.~~
4. ~~Fire code officials of the jurisdiction.~~
5. ~~The fire department and other emergency response agencies designated by the fire code official.~~

~~**506.3.3 Duplication or distribution of keys**. No person may duplicate a standardized fire service elevator key or issue, give, or sell a duplicated key unless in accordance with this code.~~

~~**506.3.4 Responsibility to provide keys**. The building owner shall provide up to three (3) standardized fire service elevator keys where required by the fire code official, upon installation of a standardized fire service key switch or switches in the building.~~

Commenter's Reason: The National Elevator Industry Inc. (NEII) is in complete agreement with the proponent's reason statement that firefighters need to quickly access an emergency situation, often use the elevators in a building to do so, and need a standardized fire service elevator key that is secure and that will work throughout a jurisdiction. However, this is already a requirement in the ASME A17.1/CSA B44 *Safety Code for Elevators and Escalators* referenced by the *International Fire Code*:

ASME A17.1a-2008/CSA B44a-08
SECTION 2.27
EMERGENCY OPERATION AND SIGNALING DEVICES

2.27.8 Switch Keys The key switches required by 2.27.2 through 2.27.5 for all elevators in a building shall be operable by the FEO-K1 key. The keys shall be Group 3 Security (see 8.1). A separate key shall be provided for each switch. These keys shall be kept on the premises in a location readily accessible to firefighters and emergency personnel, but not where they are available to the public. This key shall be of a tubular, 7 pin, style 137 construction and shall have a bitting code of 6143521 starting at the tab sequenced clockwise as viewed from the barrel end of the key. The key shall be coded "FEO-K1." The possession of the "FEO-K1" key shall be limited to elevator personnel, emergency personnel, elevator equipment manufacturers, and authorized personnel during checking of Firefighters' Emergency Operation (see 8.1 and 8.6.11.1).
Where provided, a lock box, including its lock and other components, shall conform to the requirements of UL 1037 (see Part 9).

NOTE (2.27.8): Local authorities may specify additional requirements for a uniform keyed lock box and its location to contain the necessary keys.
Group 3 Security is specified in Section 8.1:

8.1.4 Group 3: Emergency Operation Group 3 covers access or operation of equipment by emergency, authorized, and elevator personnel.
In addition to being unnecessary, F20-09/10 has a number of flaws and conflicts with the ASME A17.1/CSA B44 reference standard.

The requirement that keys be "specific for a jurisdiction" [506.3.1(1)] implies a unique key for each jurisdiction such that the key for Dallas elevators would be different than the key for Fort Worth elevators. In fact, all fire service elevator keys in North America are required to be FEO-K1 keys with a specific bitting code;

The requirement for keys with a "patent protected design" [506-3-1(2)] conflicts with the ASME A17 Standards Committee's experience that there are at least two vendors that can provide the FEO-K1 key. Requiring a patent could constitute a restraint of trade. It is also unclear how this could be enforced by a fire code official;

Regarding the requirement that the keys be "factory restricted by the manufacturer" [506.3.1.(3)], it is again unclear how this is enforceable by a code official;

The list of entities that have access to the fire service keys does not include the elevator manufacturer (e.g., Otis, Schlindler, KONER, *etc*).
This code change also creates a conflict in the IBC by specifying that elevators must comply with ASME A17.1/CSA B44 [3001.2] and with this new set of

Final Action: AS AM AMPC____ D

NOTE: PART II REPRODUCED FOR INFORMATIONAL PURPOSES ONLY – SEE ABOVE

PART II – IBC GENERAL

Add new text as follows:

3003.3 Standardized fire service elevator keys. All elevators shall be equipped to operate with a standardized fire service elevator key in accordance with the *International Fire Code*.

Reason: When fire departments and other public agencies respond to emergencies the ability to quickly access the location of the emergency can be the deciding factor of a successful response. Elevators are increasingly being relied upon for emergency operations and their importance has been highlight by recent additions to the International Building Code requiring the installation of fire service access elevators and providing requirements for the installation of occupant evacuation elevators.

One of the difficulties the fire service and other emergency response agencies have when accessing facilities and attempting to use elevators is the increasing number of non-standardized keys which may not be available at the time of response. Even when emergency responders are provided the necessary keys in case of response, the correct key may have to be identified from a large collection of keys for any one building. In larger jurisdictions the sheer number of keys makes the possession of the keys unwieldy for the emergency responders.

The purpose Part1 of this proposal is to provide for a standardized fire service elevator key to reduce the number of keys necessary for accessing elevators in an emergency. As drafted this section will only apply to those buildings that have elevators with Phase I or Phase II emergency service or to those buildings with a fire service access elevator.

The proposal also provides for a level of security for the standardized key. Access to the key that can take control of an elevator is an existing area of vulnerability for buildings and one that was not addressed in the past with simple key designs being utilized. Since this proposal will create a standardized key, it also includes rules for the safeguarding of that key.

Part 2 of this proposal is included to simply place a pointer in the International Building Code should the International Fire Code Committee approve Part 1 of this proposal.

Because the International Codes are written to enable jurisdictions to adopt the codes at the State, Local or Regional levels the proposal follows that format and designated the "fire code official" as the regulating official. However, it is expected, and preferred, that a State level agency designate a standardized key for all jurisdictions to provide for a statewide standardized key.

In preparing this proposal, statewide regulations requiring standardized fire service elevator keys (or Master Elevator Keys) from Florida, Louisiana and New Jersey were reviewed. Since some states and local jurisdictions have already begun to address this issue with the adoption of regulations and other states and jurisdictions are considering this topic it is beneficial to building owners and code officials to have a standard set of requirements contained within the model codes.

Cost Impact: The code change proposal will not increase the cost of new construction.

Analysis: Similar requirements are proposed in code change proposal F40-09/10.

PART II-IBC GENERAL
Committee Action: Approved as Submitted

Committee Reason: The committee agreed with the proponent's reason statement and approved the proposal for consistency with the action taken on Part I.

Assembly Action: None

F21-09/10
507.5.1.1 (New)

Proposed Change as Submitted

Proponent: Daniel E. Nichols, PE, New York State Department of State, Div. of Code Enforcement and Administration

Add new text as follows:

507.5.1.1 Hydrant for standpipe systems. Buildings equipped with a standpipe system installed in accordance with Section 905 shall have a fire hydrant within 100 feet of the fire department connections.

Exception: The distance shall be permitted to be greater than 100 feet when approved by the fire code official.

Reason: NFPA 14 Section 6.4.5.4 requires that a fire hydrant be placed within 100 feet from a fire department connection, unless otherwise approved by the AHJ (6.4.5.4.1). However, this section is generally missed as the site work and site approval is based on the fire apparatus access road and fire department water supply requirements in IFC Chapter 5. By placing this requirement in Section 507, the code user is better directed to this requirement during the site design and not an afterthought as it usually happens during the building permit plan review.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: NICHOLS-F3-507.5.1.1.DOC

Public Hearing Results

Committee Action: Disapproved

Committee Reason: The committee felt that the proposed requirement should apply to all fire department connections, not just those for standpipes.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Daniel E. Nichols PE, New York State Div. of Code Enforcement and Administration, requests Approval as Submitted.

Commenter's Reason: The committee agreed that this should be in this section, but disapproved it because it didn't also cover sprinkler system connections. The original submission is based solely on a requirement in NFPA 14 that gets frequently missed. I did not add sprinkler connections in either the original submission or a public comment since NFPA 13 does not have a distance requirement to a fire hydrant for connections serving sprinkler systems. Adding a requirement for a distance to a fire hydrant from a set of sprinkler connections is best suited for either Section 903 or NFPA 13 since it would be a design requirement of the sprinkler system. Also, I would be against a distance to a sprinkler connection since sprinkler systems are used in rural and suburban areas as a reduction for areas without a municipal water and, in turn, fire hydrants.

This proposal should be approved as submitted to better assist the plan reviewer and designer with appropriate fire hydrant placement and not rely on a fire hydrant spacing requirement buried in a referenced standard.

Final Action: AS AM AMPC____ D

F25-09/10
508.1.5 (IBC [F] 911.1.5)

Proposed Change as Submitted

Proponent: Gary Lewis, Chair, ICC Ad Hoc Committee on Terrorism-Resistant Buildings

Revise as follows:

508.1.5 (IBC [F] 911.1.5) Required features. The fire command center shall comply with NFPA 72 and shall contain the following features.

1. The emergency voice/alarm communication system unit.
2. The fire department communications system.
3. Fire-detection and alarm system annunciator system.
4. Annunciator visually indicating the location of the elevators and whether they are operational.
5. Status indicators and controls for air handling systems.
6. The fire-fighters control panel required by Section 909.16 for smoke control systems installed in the building.
7. Controls for unlocking stairway doors simultaneously.
8. Sprinkler valve and water-flow detector display panels.
9. Emergency and standby power status indicators.
10. A telephone for fire department use with controlled access to the public telephone system.
11. Fire pump status indicators.
12. Schematic building plans<u>, including a Building Information Card approved by the fire department, which shall provide building statistics including address, height, width and type of construction; stairway access, designation, floors served, pressurization, standpipe availability; elevators bank designation, car numbers, and floors served; ventilation details, including HVAC zones, location of mechanical equipment rooms, and offsite emergency phone numbers; utilities, fuel oil tank locations, gas service locations, electrical service locations; fire protection systems details, including standpipe locations, valve locations, pump room locations; hazardous materials and locations; and, contact phone numbers for building engineers, managers and fire safety directors. The Building Information Card shall also indicate</u> ~~indicating~~ the typical floor plan and detailing the building core, means of egress, fire protection systems, <u>elevator locations</u>, firefighting equipment and fire department access and the location fire walls, fire barriers, fire partitions, smoke barriers and smoke partitions.
13. Work table.
14. Generator supervision devices, manual start and transfer features.
15. Public address system, where specifically required by other sections of this code.
16. Elevator fire recall switch in accordance with ASME A17.1.
17. Elevator emergency or standby power selector switch(es), where emergency or standby power is provided.

Reason: This proposal is a revised follow-up to a similar proposal defeated last cycle. It is part of a package of submittals generated by the ICC's Ad Hoc Committee on Terrorism-Resistant Buildings. The proposal seeks to slightly modify and revise an existing provision of the IBC and a parallel provision in the IFC related to fire command centers in high-rise buildings.

The scope of the proposal has been reduced to simply codifying Item #12 of the list of required fire department support features in the center. There is a need to provide complete, yet concise information to the responding fire service to assist in assessment and management of the rescue and fire fighting efforts.

The Final Report on the Collapse of the World Trade Center contained 30 key recommendations compiled by the National Institute of Standards and Technology designed to address the building vulnerabilities learned in that tragedy. Three of those thirty recommendations (Items #15, 23 and 24) embrace increasing situational awareness and emergency communications of first responders in large-scale emergencies. In fact, the command center was recently doubled in size, and now also contains additional elevator control switching, a relatively new enhancement.

The proposed Building Information Card in #12, as utilized by the NYFD, puts critical response information in a user-friendly format and medium. A simulation of the Building Information Card used in New York City follows:

Bibliography: National Institute of Standards & Technology, Final Report of the National Construction safety Team on the Collapses of the World Trade Center Towers. United States Government Printing Office: Washington, D.C. September 2005.

Cost Impact: The Ad Hoc Committee anticipates no additional cost to construction resulting from this proposal as the bulk of this information must already be provided based on the current code.

ICCFILENAME: LEWIS-F1-508.1.5.DOC

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The committee agreed with the proponent's reason statement and felt that the building information card would be a useful tool that would enable the incident commander to quickly gather critical building information upon arrival at a scene and effectively plan tactics.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Dave Frable, representing U.S. General Services Administration, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

508.1.5 (IBC [F] 911.1.5) Required features. The fire command center shall comply with NFPA 72 and shall contain the following features.

1. The emergency voice/alarm communication system unit.
2. The fire department communications system.
3. Fire-detection and alarm system annunciator system.
4. Annunciator visually indicating the location of the elevators and whether they are operational.
5. Status indicators and controls for air handling systems.
6. The fire-fighters control panel required by Section 909.16 for smoke control systems installed in the building.
7. Controls for unlocking stairway doors simultaneously.
8. Sprinkler valve and water-flow detector display panels.
9. Emergency and standby power status indicators.
10. A telephone for fire department use with controlled access to the public telephone system.
11. Fire pump status indicators.
12. Schematic building plans~~, including a Building Information Card approved by the fire department, which shall provide building statistics including address, height, width and type of construction; stairway access, designation, floors served, pressurization, standpipe availability; elevators bank designation, car numbers, and floors served; ventilation details, including HVAC zones, location of mechanical equipment rooms, and offsite emergency phone numbers; utilities, fuel oil tank locations, gas service locations, electrical service locations; fire protection systems details, including standpipe locations, valve locations, pump room locations; hazardous materials and locations; and, contact phone numbers for building engineers, managers and fire safety directors. The Building Information Card shall also indicate~~ indicating the typical floor plan and detailing the building core, means of egress, fire protection systems, ~~elevator locations,~~ firefighting equipment and fire department access and the location fire walls, fire barriers, fire partitions, smoke barriers and smoke partitions.
13. An approved Building Information Card that contains, but is not limited to, the following information:
    (a) general building information that includes: property name, address, the number of floors in the building (above and below grade), use and occupancy classification (mixed used identify the different types of occupancies on each floor), estimated building population (i.e., day, night, weekend);
    (b) building emergency contact information that includes: a list of the building's emergency contacts (e.g., building manager, building engineer, etc.) and their respective work phone number, cell phone number, e-mail address;
    (c) building construction information that includes: the type of building construction (e.g., floors, walls, columns, and roof assembly);
    (d) exit stair information that includes: number of exit stairs in building, each exit stair designation and floors served, location where each exit stair discharges, exit stairs that are pressurized, exit stairs provided with emergency lighting, each exit stair that allows reentry, exit stairs providing roof access; elevator information that includes: number of elevator banks, elevator bank designation, elevator car numbers and respective floors that they serve, location of elevator machine rooms, location of sky lobby, location of freight elevator banks;
    (e) building services and system information that includes: location of mechanical rooms, location of building management system, location and capacity of all fuel oil tanks, location of emergency generator, location of natural gas service;
    (f) fire protection system information that includes: locations of standpipes, location of fire pump room, location of fire department connections, floors protected by automatic sprinklers, location of different types of sprinkler systems installed (e.g., dry, wet, pre-action, etc.);
    (g) hazardous material information that includes: location of hazardous material, quantity of hazardous material.

14.~~13.~~ Work table.
15.~~14.~~ Generator supervision devices, manual start and transfer features.
16.~~15.~~ Public address system, where specifically required by other sections of this code.
17.~~16.~~ Elevator fire recall switch in accordance with ASME A17.1.
18.~~17.~~ Elevator emergency or standby power selector switch(es), where emergency or standby power is provided.

Commenter's Reason: The intent of the modification is for clarification purposes only and to make the subject information contained on the building information card more user friendly to understand.

Public Comment 2:

Lawrence G. Perry, AIA, representing Building Owners and Managers Association (BOMA) International, requests Disapproval

Commenter's Reason: This code change should be disapproved for the following reasons:

1. The proposal seeks to add a new 'tool' called the Building Information Card to the list of items provided in the Fire Command Center. However, it does so in a way that reduces the overall information provided. Note that item 12 in the current code requires that schematic drawings include each of the existing items listed; as modified by this proposal, the insertion of the Building Information Card language reduces what is required on the schematic drawings. A code change in the 07/08 cycle added a requirement that schematic drawings include the location of fire walls, fire barriers, fire partitions, smoke barriers and smoke partitions; as modified by this change, that requirement is deleted. Only the 'Building Information Card' would have this information.
2. This appears to be a backward-looking proposal. Major jurisdictions, such as Los Angeles, are currently working with building owners to develop appropriate electronic and/or online building information materials for use by responding emergency services. Establishing a new code requirement for a printed 'card' is pushing the IFC in the wrong direction.
3. The proposed change uses terminology not used in the *International Codes.* It requires providing contact information for 'fire safety directors', which is a term used in New York City, from which this card concept was taken, but is not a title used in the I-codes.

Final Action: AS AM AMPC____ D

F27-09/10

510, 502.1, Appendix J, 105.7.12 (New)

Proposed Change as Submitted

Proponent: Tom Lariviere, Chairman, Joint Fire Service Review Committee

1. Revise as follows:

SECTION 510
EMERGENCY RESPONDER RADIO COVERAGE

510.1 Emergency responder radio coverage in new buildings. All new buildings shall have *approved* radio coverage for emergency responders within the building based upon the existing coverage levels of the public safety communication systems of the jurisdiction at the exterior of the building. This section shall not require improvement of the existing public safety communication systems.

Exceptions:

1. Where *approved* by the *building code official* and the *fire code official*, a wired communication system in accordance with Section 907.2.13.2 shall be permitted to be installed or maintained in lieu of an *approved* radio coverage system.
2. Where it is determined by the *fire code official* that the radio coverage system is not needed.

~~**510.3**~~ **510.2** **Emergency responder radio coverage in existing buildings**. Existing buildings that do not have *approved* radio coverage for emergency responders within the building shall be equipped with such coverage according to one of the following:

1. Whenever existing wired communication system cannot be repaired or is being replaced, or where not *approved* in accordance with Section 510.1 Exception 1.
2. Within a time frame established by the adopting authority.

~~**J101.2**~~ **510.3 Permit required.** A construction permit ~~is required~~ for installation of or modification to emergency responder radio coverage systems and related equipment is required as specified in Section 105.7.12. Maintenance performed in accordance with this code is not considered a modification and does not require a permit.

510.4 Technical requirements. Systems, components, and equipment required to provide emergency responder radio coverage system shall comply with Sections 511.4.1 through 511.4.2.5.

~~510.2~~ **510.4.1 Radio signal strength.** The building shall be considered to have acceptable emergency responder radio coverage when signal strength measurements in 95 percent of all areas on each floor of the building meet the signal strength requirements in Sections ~~510.2.1~~ 510.4.1.1 and ~~510.2.2~~ 510.4.1.2.

~~510.2.1~~ **510.4.1.1 Minimum signal strength into the building**. A minimum signal strength of -95 dBm shall be receivable within the building.

~~510.2.2~~ **510.4.1.2 Minimum signal strength out of the building**. A minimum signal strength of -100 dBm shall be received by the agency's radio system when transmitted from within the building.

~~J103.1~~ **510.4.2 System design.** The emergency responder radio coverage system shall be designed in accordance with Sections ~~510.3.2.1~~ 510.4.2.1 through ~~510.3.2.5~~ 510.4.2.5.

~~J103.1.1~~ **510.4.2.1 Amplification systems allowed.** Buildings and structures which cannot support the required level of radio coverage shall be equipped with a radiating cable system, a distributed antenna system with Federal Communications Commission (FCC)-certified signal boosters, or other system approved by the *fire code official* in order to achieve the required adequate radio coverage.

~~J103.1.2~~ **510.4.2.2 Technical criteria.** The *fire code official* shall maintain a document providing the specific technical information and requirements for the emergency responder radio coverage system. This document shall contain, but not be limited to, the various frequencies required, the location of radio sites, effective radiated power of radio sites, and other supporting technical information.

~~J103.1.3~~ **510.4.2.3 Secondary power.** Emergency responder radio coverage systems shall be provided with an *approved* secondary source of power. The secondary power supply shall be capable of operating the emergency responder radio coverage system for a period of at least 12 hours. When primary power is lost, the power supply to the emergency responder radio coverage system shall automatically transfer to the secondary power supply.

~~J103.1.4~~ **510.4.2.4 Signal booster requirements.** If used, signal boosters shall meet the following requirements:

1. All signal booster components shall be contained in a NEMA4-type water proof cabinet.
2. Battery systems used for the emergency power source shall be contained in a NEMA4-type water proof cabinet.
3. The ~~system shall include automatic alarming of malfunctions of the~~ signal booster system and battery system~~. Any resulting trouble alarm shall be automatically transmitted to an approved central station or proprietary supervising station as defined in NFPA 72~~ shall be electrically supervised and monitored by a supervisory service, or when approved by the *fire code official*, shall sound an audible signal at a constantly attended location.
4. Equipment shall have FCC Certification prior to installation.

~~J103.1.5~~ **510.4.2.5 Additional frequencies and change of frequencies.** The emergency responder radio coverage system shall be capable of modification or expansion in the event frequency changes are required by the FCC or additional frequencies are made available by the FCC.

~~J103.2~~ **510.5 Installation requirements.** The installation of the public safety radio coverage system shall be in accordance with Sections ~~J103.2.1~~ 510.5.1 through ~~J103.2.5~~ 510.5.5.

~~J103.2.1~~ **510.5.1 Approval prior to installation**. No amplification system capable of operating on frequencies licensed to any public safety agency by the FCC shall be installed without prior coordination and approval of the *fire code official*.

~~J103.2.3~~ **510.5.3 Minimum qualifications of personnel.** The minimum qualifications of the system designer and lead installation personnel shall include:

1. A Valid FCC issued General Radio Operators License, and
2. Certification of in-building system training issued by a nationally recognized organization, school or a certificate issued by the manufacturer of the equipment being installed.

The agency may waive these requirements upon successful demonstration of adequate skills and experience satisfactory to the *fire code official*.

~~J103.2.4~~ **510.5.4** **Acceptance test procedure**. When an emergency responder radio coverage system is required, and upon completion of installation, the building *owner* shall have the radio system tested to ensure that two-way coverage on each floor of the building is a minimum of 90 percent. The test procedure shall be conducted as follows:

1. Each floor of the building shall be divided into a grid of 20 approximately equal areas.
2. The test shall be conducted using a calibrated portable radio of the latest brand and model used by the agency talking through the agency's radio communications system.
3. A maximum of two nonadjacent areas will be allowed to fail the test.
4. In the event that three of the areas fail the test, in order to be more statistically accurate, the floor may be divided into 40 equal areas. A maximum of four nonadjacent areas will be allowed to fail the test. If the system fails the 40-area test, the system shall be altered to meet the 90 percent coverage requirement.
5. A test location approximately in the center of each grid area will be selected for the test, then the radio will be enabled to verify two-way communications to and from the outside of the building through the public agency's radio communications system. Once the test location has been selected, that location shall represent the entire area. If the test fails in the selected test location, that grid area shall fail, and prospecting for a better spot within the grid area will not be allowed.
6. The gain values of all amplifiers shall be measured and the test measurement results shall be kept on file with the building owner so that the measurements can be verified during annual tests. In the event that the measurement results become lost, the building owner will be required to rerun the acceptance test to reestablish the gain values.
7. As part of the installation a spectrum analyzer or other suitable test equipment shall be utilized to insure spurious oscillations are not being generated by the subject signal booster. This test will be conducted at time of installation and subsequent annual inspections.

~~J103.2.5~~ **510.5.5** **FCC compliance.** The emergency responder radio coverage system installation and components shall also comply with all applicable federal regulations, including but not limited to, FCC 47 CFR 90.219.

~~J103.3~~ **510.6** **Maintenance.** The emergency responder radio coverage system shall be maintained operational at all times in accordance with Sections ~~510.5.1~~ 510.6.1 through ~~510.5.3~~ 510.6.3.

~~**J103.3.1 Maintenance.** The public radio coverage system shall be maintained operational at all times.~~

~~**J103.3.2 Permit required.** A construction permit, as required by Section 105.7.5 of the *International Fire* Code, shall be obtained prior to the modification or alteration of the emergency responder radio coverage system.~~

~~J103.3.3~~ **510.6.1** **Testing and proof of compliance**. The emergency responder radio coverage system shall be inspected and tested annually or whenever structural changes occur including additions or remodels that could materially change the original field performance tests. Testing shall consist of the following:

1. In-building coverage test as described in Section ~~J103.2.4~~ 510.5.4.
2. Signal boosters shall be tested to ensure that the gain is the same as it was upon initial installation and acceptance.
3. Backup batteries and power supplies shall be tested under load of a period of one hour to verify that they will properly operate during an actual power outage. If within the one hour test period the battery exhibits symptoms of failure, the test shall be extended for additional one hour periods until the integrity of the battery can be determined.
4. All other active components shall be checked to verify operation within the manufacturer's specifications.
5. At the conclusion of the testing a report which shall verify compliance with Section ~~J103.3.4~~ 510.5.4 be submitted to the *fire code official*.

~~J103.3.4~~ **510.6.2** **Additional frequencies.** The building *owner* shall modify or expand the emergency responder radio coverage system at their expense in the event frequency changes are required by the FCC or additional frequencies are made available by the FCC. Prior approval of a public safety radio coverage system on previous frequencies does not exempt this section.

~~J103.3.5~~ **510.6.3** **Field testing.** Agency personnel shall have the right to enter onto the property at any reasonable time to conduct field-testing to verify the required level of radio coverage.

~~**J102.1 Definitions.** For the purpose of this appendix, certain terms are defined as follows:~~

<u>502.1</u> Definitions. The following words and terms shall, for the purposes of this chapter and as used elsewhere in this code, have the meanings shown herein.

AGENCY. Any emergency responder department within the jurisdiction that utilizes radio frequencies for communication. This could include, but not be limited to, various public safety agencies such as fire department, emergency medical services and law enforcement.

2. Add new text as follows:

<u>**105.7.12 Radio coverage system.** A construction permit is required for installation of or modification to emergency responder radio coverage systems and related equipment. Maintenance performed in accordance with this code is not considered a modification and does not require a permit.</u>

(Renumber subsequent sections)

3. Delete Appendix J without substitution:

~~APPENDIX J~~
~~EMERGENCY RESPONDER RADIO COVERAGE~~

Reason: This proposal takes the requirements for emergency responder radio coverage made last code cycle and finishes the process. Appendix J was included in the 2009 edition and contains the installation and testing criteria for the emergency responder radio coverage system. In this proposal, the entire appendix is relocated into the code. This action is the result of a request by the Code Development Committee last cycle and can be seen in their Reason Statement in Report on Hearings.

As the appendix is relocated into the code, some minor clarifications occurred. The following revisions are made:

1. 510.1 – the term “new” is included to clarify the difference between Section 510.1 (new construction) and 510.2 (existing construction)
2. 510.3 – this section has been relocated and includes three sections from the appendix which dealt with permits. Sections J101.2, J103.2.2 and J103.3.2 all referenced permits. This revision will provide a single section which covers permits for these systems.
3. 105.7.12 – this permit requirement is added to Chapter 1. Since the appendix is deleted, the permit requirement also needs to be located within the code. This is editorial.
4. 510.4.2.4 – Item 3 is revised to correlate with the new wording used in other sections of the code when referencing monitoring of systems. 510.6 – The two sections from the Appendix J103.3 and J103.3.1 have been combined into one section for simplicity.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: LARIVIERE-F33-510.DOC

<u>Public Hearing Results</u>

Committee Action: **Approved as Modified**

Modify the proposal as follows:

510.2 Emergency responder radio coverage in existing buildings. Existing buildings that do not have approved radio coverage for emergency responders within the building shall be equipped with such coverage according to one of the following:

1. Whenever existing wired communication system cannot be repaired or is being replaced, or where not *approved* in accordance with Section 510.1 Exception 1.
2. Within a time frame established by the adopting authority.

   <u>**Exception:** Where it is determined by the fire code official that the radio coverage system is not needed.</u>

(Portions of the proposed code change not shown remain unchanged.)

Committee Reason:. The committee felt that the specific requirements for emergency responder radio coverage are important enough to warrant relocation into the code text rather than being “hidden” in an appendix. The modification provides the same consideration for existing buildings as Section 510.1 does for new buildings.

Assembly Action: **None**

<u>Individual Consideration Agenda</u>

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Michael E. Dell'Orfano representing Fire Marshal's Association of Colorado, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

510.1 Emergency responder radio coverage in new buildings. All new buildings shall have *approved* radio coverage for emergency responders within the building based upon the existing coverage levels of the public safety communication systems of the jurisdiction at the exterior of the building. This section shall not require improvement of the existing public safety communication systems.

Exceptions:

1. Where *approved* by the *building code official* and the *fire code official*, a wired communication system in accordance with Section 907.2.13.2 shall be permitted to be installed or maintained in lieu of an *approved* radio coverage system.
2. Where it is determined by the *fire code official* that the radio coverage system is not needed.
3. <u>One- and two-family dwellings and townhouses.</u>

510.2 Emergency responder radio coverage in existing buildings. Existing buildings that do not have *approved* radio coverage for emergency responders within the building shall be equipped with such coverage according to one of the following:

1. Whenever existing wired communication system cannot be repaired or is being replaced, or where not *approved* in accordance with Section 510.1 Exception 1.
2. Within a time frame established by the adopting authority.

Exception<u>s</u>:

<u>1.</u> Where it is determined by the fire code official that the radio coverage system is not needed.
<u>2.</u> <u>One- and two-family dwellings and townhouses.</u>

(Portions of proposal not shown, remain unchanged)

Commenter's Reason: This public comment recommends an additional modification to F27-09/10 by adding an exception for new and existing one- and two-family dwellings and townhouses. Installation of an amplification system, when needed to enhance radio coverage, is unreasonable in a one- and two-family dwelling or townhouse due to the inability to verify maintenance Of these systems. Inadequate maintenance may not only decrease reliability of the individual system, but may also degrade the performance of the overall public safety communication system. Critical periodic inspections would need to be performed to verify the system is operational, secondary power is maintained, signal strengths are appropriate, and frequency changes are accommodated. Such inspections, and the corresponding corrections of system deficiencies, would be difficult or impossible to achieve. It is also not common practice in the fire service to conduct code enforcement inspections in one- and two-family dwellings and townhouses.

Public Comment 2:

Michael E. Dell'Orfano representing Fire Marshal's Association of Colorado, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

510.1 Emergency responder radio coverage in new buildings. All new buildings shall have *approved* radio coverage for emergency responders within the building based upon the existing coverage levels of the public safety communication systems of the jurisdiction at the exterior of the building. This section shall not require improvement of the existing public safety communication systems.

Exception~~s~~:

~~1.~~ Where *approved* by the *building code official* and the *fire code official*, a wired communication system in accordance with Section 907.2.13.2 shall be permitted to be installed or maintained in lieu of an *approved* radio coverage system.
~~2. Where it is determined by the *fire code official* that the radio coverage system is not needed.~~

510.2 Emergency responder radio coverage in existing buildings. Existing buildings that do not have *approved* radio coverage for emergency responders within the building shall be equipped with such coverage according to one of the following:

1. Whenever existing wired communication system cannot be repaired or is being replaced, or where not *approved* in accordance with Section 510.1 Exception 1.
2. Within a time frame established by the adopting authority.

~~**Exception:** Where it is determined by the fire code official that the radio coverage system is not needed.~~

(Portions of proposal not shown remain unchanged)

Commenter's Reason: Section 510, as modified by F27-09/10, clearly states that buildings shall have adequate radio coverage by naturally-available signal strengths, wired communication systems, or amplification systems. If the requirements and design options are clear, then under what circumstances would a fire code official determine that radio coverage is not needed in order to apply the exception to 510.1 and 510.2? This exception would imply that the code requirement could arbitrarily be waived without contemplating the practical difficulties or alternate methods allowed in chapter 1. Such an exception is not found in any other IFC construction requirement such as fire sprinklers or fire alarms where the required thresholds and design options are similarly clear. Therefore, it is recommended that the exceptions be removed.

Public Comment 3:

Bob Eugene representing Underwriters Laboratories Inc, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

510.4.1.2 Minimum signal strength out of the building. A minimum signal strength of ~~-100~~ -95 dBm shall be received by the agency's radio system when transmitted from within the building.

(Portions of the proposal not shown remain unchanged.)

Commenter's Reason: Section 24.5.2 of the 2010 edition NFPA 72 National Fire Alarm Code provides different outbound signal strength than specified in 510.4.1.2 as approved by the committee. For consistency, these two companion documents should adopt the same parameters.

Public Comment 4:

Bob Eugene representing Underwriters Laboratories Inc, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

510.4.2.3 Secondary power. Emergency responder radio coverage systems shall be provided with an *approved* secondary source of power. The secondary power supply shall be capable of operating the emergency responder radio coverage system for a period of at least ~~12~~ 24 hours. When primary power is lost, the power supply to the emergency responder radio coverage system shall automatically transfer to the secondary power supply.

(Portions of the proposal not shown remain unchanged.)

Commenter's Reason: Emergency power shall be capable of operating at least 24 hours per NFPA 72 National Fire Alarm Code.

Public Comment 5:

Bob Eugene representing Underwriters Laboratories Inc, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

510.4.2.4 Signal booster requirements. If used, signal boosters shall meet the following requirements:

1. All signal booster components shall be contained in a NEMA4-type water proof cabinet.
2. Battery systems used for the emergency power source shall be contained in a NEMA4-type water proof cabinet.
3. The system shall include automatic alarming of malfunctions of the signal booster ~~system~~ and battery system. Any resulting trouble alarm shall be automatically transmitted to an approved central station or proprietary supervising station as defined in NFPA 72 ~~shall be electrically supervised and monitored by a supervisory service,~~ or when approved by the *fire code official*, shall sound an audible signal at a constantly attended location.
4. Equipment shall have FCC Certification prior to installation.

(Portions of the proposal not shown remain unchanged.)

Commenter's Reason: The existing text is restored and incorporated into Section 510.4.2.4. The original proposal as approved by the committee has the unfortunate consequence of being very vague regarding monitoring troubles off-site.

Public Comment 6:

Paul K. Heilstedt, PE, HonAIA, Chair, representing ICC Code Technology Committee (CTC) and Joe Pierce (Chairman), Dallas Fire Department, representing Joint Fire Service Review Committee, request Approval as Modified by this Public Comment.

Further modify the proposal as follows:

<u>**510.2 Emergency responder radio coverage in existing buildings**. Existing buildings shall be provided with *approved* radio coverage for emergency responders as required in Chapter 46.</u>

<u>**4603.2**</u> ~~**510.2**~~ **Emergency responder radio coverage in existing buildings**. Existing buildings that do not have *approved* radio coverage for emergency responders within the building shall be equipped with such coverage according to one of the following:

1. Whenever existing wired communication system cannot be repaired or is being replaced, or where not *approved* in accordance with Section 510.1 Exception 1.
2. Within a time frame established by the adopting authority.

   Exception: Where it is determined by the *fire code official* that the radio coverage system is not needed.

510.5.1 Approval prior to installation. ~~No~~ Amplification systems capable of operating on frequencies licensed to any public safety agency by the FCC shall <u>not</u> be installed without prior coordination and approval of the *fire code official*.

510.5.3 Minimum qualifications of personnel. The minimum qualifications of the system designer and lead installation personnel shall include:
1. A Valid FCC issued General Radio Operators License, and
2. Certification of in-building system training issued by a nationally recognized organization, school or a certificate issued by the manufacturer of the equipment being installed.

~~The agency may waive~~ These ~~requirements~~ <u>qualifications shall not be required where</u> ~~upon successful~~ demonstration of adequate skills and experience satisfactory to the *fire code official* <u>is provided</u>.

510.5.4 Acceptance test procedure. When an emergency responder radio coverage system is required, and upon completion of installation, the building *owner* shall have the radio system tested to ensure that two-way coverage on each floor of the building is a minimum of 90 percent. The test procedure shall be conducted as follows:

1. Each floor of the building shall be divided into a grid of 20 approximately equal <u>test</u> areas.
2. The test shall be conducted using a calibrated portable radio of the latest brand and model used by the agency talking through the agency's radio communications system.
3. <u>Failure of</u> a maximum of two nonadjacent <u>test</u> areas ~~will be allowed to fail the test~~ <u>shall not result in failure of the test</u>.
4. In the event that three of the <u>test</u> areas fail the test, in order to be more statistically accurate, the floor ~~may~~ <u>shall</u> be <u>permitted to be</u> divided into 40 equal <u>test</u> areas. <u>Failure of</u> a maximum of four nonadjacent <u>test</u> areas ~~will be allowed to fail the test~~ <u>shall not result in failure of the test</u>. If the system fails the 40-area test, the system shall be altered to meet the 90 percent coverage requirement.
5. A test location approximately in the center of each ~~grid~~ <u>test</u> area ~~will~~ <u>shall</u> be selected for the test, ~~then~~ <u>with</u> the radio ~~will be~~ enabled to verify two-way communications to and from the outside of the building through the public agency's radio communications system. Once the test location has been selected, that location shall represent the entire <u>test</u> area. ~~If the test fails~~ <u>Failure</u> in the selected test location <u>shall be considered failure of</u> that ~~grid~~ <u>test</u> area ~~shall fail, and prospecting for a better spot within the grid area will not be allowed~~. <u>Additional test locations shall not be permitted.</u>
6. The gain values of all amplifiers shall be measured and the test measurement results shall be kept on file with the building owner so that the measurements can be verified during annual tests. In the event that the measurement results become lost, the building owner ~~will be required~~ <u>shall</u> to rerun the acceptance test to reestablish the gain values.
7. As part of the installation a spectrum analyzer or other suitable test equipment shall be utilized to insure spurious oscillations are not being generated by the subject signal booster. This test ~~will~~ <u>shall</u> be conducted at time of installation and subsequent annual inspections.

Commenter's Reason: This language originated with code change F87-07/08 last cycle for which the CTC was a co-proponent of the public comment with the Joint Fire Service Review committee. As part of the appendix, this text required the adopting entity to review the language for consideration as a set of mandatory requirements. With the relocation into the body of the code, it is important that all such text be compiled in mandatory, enforceable language. This Public Comment proposes such revisions as editorial.

Additionally, in Section 510.2 the language is relocated in to Chapter 46 to be consistent with the other portions of the IFC. All construction requirements applicable to existing buildings have been compiled in Chapter 46. This is simply an editorial revision to format these requirements in the style of the IFC.

Public Comment 7:

Jeffrey Shapiro, P.E., International Code Consultants, representing National Multi Housing Council, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

510.2 Emergency responder radio coverage in existing buildings. Existing buildings that do not have *approved* radio coverage for emergency responders within the building, <u>based upon the existing coverage levels of the public safety communication systems of the jurisdiction at the exterior of the building, </u>shall be equipped with such coverage according to one of the following:

1. Whenever existing wired communication system cannot be repaired or is being replaced, or where not *approved* in accordance with Section 510.1 Exception 1.
2. Within a time frame established by the adopting authority.

Exception: Where it is determined by the *fire code official* that the radio coverage system is not needed.

(Portions of the proposal not shown remain unchanged.)

Commenter's Reason: The text that is recommended for inclusion in Section 510.2 is currently included in 510.1. In that location, it previously applied to both new and existing buildings. When the section was reformatted by this proposal to split new and existing buildings into two sections, the text was mistakenly omitted from 510.2, unintentionally changing the requirement. Including this text is necessary so that there is a basis of judging the adequacy of the existing radio coverage, and it maintains the existing requirement since there was no apparent intent to delete it.

Final Action: AS AM AMPC____ D

F29-09/10
510.1

<u>Proposed Change as Submitted</u>

Proponent: Ronald Marts, Telecordia, Qwest Communications, AT&T

Revise as follows:

510.1 Emergency responder radio coverage in buildings. All buildings shall have *approved* radio coverage for emergency responders within the building based upon the existing coverage levels of the public safety communication systems of the jurisdiction at the exterior of the building. This section shall not require improvement of the existing public safety communication systems.

Exceptions:

1. Where *approved* by the building official and the *fire code official*, a wired communication system in accordance with Section 907.2.13.2 shall be permitted to be installed or maintained in lieu of an *approved* radio coverage system.
2. Where it is determined by the *fire code official* that the radio coverage system is not needed.
3. <u>In telecommunications buildings, where emergency responder radio coverage is required and such systems, components or equipment required may have a negative impact of radio frequency interference (RFI) on local, regional and/or national telecommunications functions of the facility, it shall be permitted to provide a function switch for the activation of the internal emergency responder radio system. The location of the function switch shall be approved by the fire code official.</u>

Reason: This specific activation of the facilities internal emergency responder radio system will limit potential inference with the vital telecommunications operations of the facility to 24/7 exposure to these signals. The potential for interference with the operations of the telecommunications facility operations is unique to each space and operation of the facility and places in direct risk emergency services, national security and defense, and other critical telecommunications functions of the facility.

To date, studies have suggested that RFI from these transmitters may affect telecommunications equipment and thus telecommunications service.

Cost Impact: The code change proposal will have a small impact on construction cost

ICCFILENAME: MARTS-F1-510.1.DOC

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee felt that exempting a specific type of facility could set up a future trend toward a "laundry list" of facilities that wish to be exempt from the requirement. It also felt that the existing exceptions, reasonably applied, could remedy any such concerns and that IFC Section 104.9 could also be applied. The committee also felt that providing an "on-off" switch for the radio coverage system could place first responders in danger.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Ronald Marts representing Telcordia Technologies, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

510.1 Emergency responder radio coverage in buildings. All buildings shall have *approved* radio coverage for emergency responders within the building based upon the existing coverage levels of the public safety communication systems of the jurisdiction at the exterior of the building. This section shall not require improvement of the existing public safety communication systems.

Exceptions:

1. Where *approved* by the building official and the *fire code official*, a wired communication system in accordance with Section 907.2.13.2 shall be permitted to be installed or maintained in lieu of an *approved* radio coverage system.
2. Where it is determined by the *fire code official* that the radio coverage system is not needed.
3. ~~In telecommunications buildings, where emergency responder radio coverage is required and such systems, components or equipment required may have a negative impact of radio frequency interference (RFI) on local, regional and/or national telecommunications functions of the facility, it shall be permitted to provide a function switch for the activation of the internal emergency responder radio system. The location of the function switch shall be approved by the fire code official.~~ <u>In facilities where emergency responder radio coverage is required and such systems, components or equipment required may have a negative impact on the normal operations of that facility, the fire code official shall have the authority to accept an automatically activated responder system.</u>

Commenter's Reason: Some facilities, such as telecommunications central offices have equipment that may be affected by the radio frequency interference (RFI) of responder radio equipment. Having the emergency responder radio equipment off until needed rectifies the expected interference. The fire official and the building owner can decide on the automatic means of activating the responder system.
To date, studies have suggested that RFI from these transmitters may affect telecommunications equipment and thus telecommunications service to the community, including 911 calls.

Cost Impact: The code change proposal will have a small impact on construction cost.

Final Action: AS AM AMPC____ D

F30-09/10
511 (New)

Proposed Change as Submitted

Proponents: Robert J Davidson, Code Consultant/Alan Shuman, President, representing the National Association of State Fire Marshals (NASFM)

Add new section as follows:

<u>**SECTION 511**</u>
<u>**SOLAR PHOTOVOLTAIC INSTALLATIONS**</u>

511.1 General. The installation of solar photovoltaic installations shall comply with Table 601 and Chapter 16 of the *International Building Code*. The installation shall also comply with Sections 511.2 through 511.11 and NFPA 70.
511.2 Circuit marking. To facilitate identifying energized electrical lines that connect the solar panels to the inverter, to prevent these conduits from being cut when venting for smoke removal, markings shall be provided to give emergency responders appropriate warning that a solar electric system is present.

511.3 Materials. The materials used for marking shall be reflective, weather resistant and suitable for the environment.

511.4 Main service disconnect. For residential occupancies, the marking shall be placed within the main service disconnect. If the main service disconnect is operable with the service panel closed, then the marking shall be placed on the outside cover. For commercial occupancies, the marking shall be placed adjacent to the main service disconnect in a location clearly visible from the location where the lever is operated.
511.4.1. Marking content and format. The marking shall contain the words "CAUTION: SOLAR ELECTRIC CONNECTED" in capital letters a minimum of 3/8 inches in height with white letters on a red background.

511.5 DC conduit, raceways, enclosures, cable assemblies, and junction boxes. Marking shall be provided on all interior and exterior dc conduit, raceways, enclosures, cable assemblies, and junction boxes to alert the fire service to their presence. The marking shall be placed every 10 feet or fraction thereof, at turns and above and below penetrations, and on all dc combiner and junction boxes.

511.5.1 Marking content and format. The marking shall contain the words "CAUTION: SOLAR ELECTRIC CONNECTED" in capital letters a minimum of 3/8 inches in height with white letters on a red background.

511.5.2 Locations of DC conductors. Conduit, wiring systems, and raceways for photovoltaic circuits shall be located as close as possible to the ridge or hip or valley and from the hip or valley as directly as possible to an outside wall to reduce trip hazards and maximize ventilation opportunities. Conduit runs between sub arrays and to DC combiner boxes shall be installed in a manner that minimizes total amount of conduit on the roof by taking the shortest path from the array to the DC combiner box. The DC combiner boxes shall be located such that conduit runs are minimized in the pathways between arrays.

511.6 Power disconnects. A power disconnect shall be located within 3 feet of the photovoltaic array to provide for de-energizing the DC circuit(s) from the array to the inverter. The disconnect shall be label with reflective lettering.

511.7 Access, pathways for smoke ventilation. Roof access and spacing requirements shall be observed in order to ensure access to the roof; provide pathways to specific areas of the roof; provide for smoke ventilation operations; and to provide emergency egress from the roof.

511.8 Roof access points. Roof access points shall be defined as an area that does not place ground ladders over openings such as windows or doors, and are located at strong points of building construction in locations where the access point does not conflict with overhead obstructions such as tree limbs, wires, or signs.

511.9. Residential systems-One- and two-family residential dwellings. Access shall be provided in accordance with Sections 511.9.1 through 511.9.3

511.9.1 Residential buildings with hip roof layouts. Panels shall be located in a manner that provides one (1) three-foot (3') wide clear access pathway from the eave to the ridge on each roof slope where panels are located. The access pathway shall be located at a structurally strong location on the building such as along a underlying bearing wall.

511.9.2 Residential buildings with a single ridge. Panels shall be located in a manner that provides two (2) three-foot (3') wide access pathways from the eave to the ridge on each roof slope where panels are located.

511.9.3 Hips and Valleys: Panels shall be located no closer than one and one half (1.5) feet to a hip or a valley if panels are to be placed on both sides of a hip or valley. If the panels are to be located on only one side of a hip or valley that is of equal length then the panels shall be permitted to be placed directly adjacent to the hip or valley.

511.9.4 Ventilation. Panels shall be located no higher than three feet (3) below the ridge.

> **Exception:** The fire department is authorized to allow panels to be located two (2) feet below the ridge if a product or method acceptable to the fire department has been provided for ventilation.

511.10 All other occupancies. Access shall be provided in accordance with Sections 511.10.1 through 511.10.3

511.10.1 Access. There shall be a minimum six (6) foot wide clear perimeter around the edges of the roof.

Exception: If either axis of the building is 250 feet or less, there shall be a minimum four feet (4') wide clear perimeter around the edges of the roof.

511.10.2 Pathways. The solar installation shall be designed to provide designated pathways. The pathways shall meet the following requirements:

1. The pathway shall be over structural members
2. The center line axis pathways shall be provided in both axis of the roof. Center line axis pathways shall run on structural members or over the next closest structural member nearest to the center lines of the roof
3. Shall be straight line not less than 4 feet clear to skylights and/or ventilation hatches
4. Shall be straight line not less than 4 feet clear to roof standpipes
5. Shall provide not less than 4 feet clear around roof access hatch with at least one not less than 4 feet clear pathway to parapet or roof edge

511.10.3 Ventilation. The solar installation shall be designed to meet the following requirements.

1. Arrays shall be no greater than 150 by 150 feet in distance in either axis
2. Ventilation options between array sections shall be either a pathway 8 feet or greater in width; a 4 feet or greater in width pathway and bordering on existing roof skylights or ventilation hatches; or a 4 feet or greater in width pathway and bordering 4' x 8' "venting cutouts" every 20 feet on alternating sides of the pathway

511.11 Ground mounted photovoltaic arrays. Ground mounted photovoltaic arrays shall comply with Sections 511.1 through 511.6 and this section. Setback requirements do not apply to ground-mounted, free standing photovoltaic arrays. A clear brush area of 10' is required for ground mounted photovoltaic arrays.

Reason: Photovoltaic arrays are increasing in popularity as an alternative energy source. These arrays, which cannot be shut down and retain electrical charges present unique hazards to firefighters operating on roofs with arrays or nearby circuits.

This proposal is intended to provide general requirements to allow for increased safety of firefighters working around and near the arrays.

These provisions were created from a "DRAFT SOLAR PHOTOVOLTAIC INSTALLATION GUIDELINE " prepared by the CAL FIRE, Office of the State Fire Marshal, local California fire departments, and the solar photovoltaic industry.

Cost Impact: The code change proposal will increase the cost of Photovoltaic installations.

Analysis: Code change proposal F238-09/10 proposes similar requirements.

ICCFILENAME: DAVIDSON-SHUMAN-F20-511.DOC

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee recognized the importance of the issues raised by the proposal but felt that it was not sufficiently developed to be included in the code at this time. It was indicated that the California State Fire Marshal's guidelines upon which the proposal was based are still in a draft form and not yet ready for adoption. An issue that the committee noted is that there is no correlation change to the IBC and that there is no IFC permit required for these installations which is important since they are typically done on existing buildings and show up unexpectedly. The proposal is also unclear in Section 511.4 as to where the disconnect would be placed in a mixed occupancy building. It was also noted that walkable pathways cannot always be placed over structural members. The committee indicated some support for placing the proposal in an appendix until the issues of concern are resolved.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Tonya L. Hoover, Acting State Fire Marshal, representing California Office of the State Fire Marshal and Robert J. Davidson, Davidson Code Concepts, LLC representing self, request Approval as Modified by this Public Comment.

Modify the proposal as follows:

~~SECTION 511~~ 605.11 Solar Photovoltaic Power Systems. Solar photovoltaic power systems shall be installed in accordance with this code, the *International Building Code* and NFPA 70.

> **Exception:** Detached Group U non-habitable structures such as parking shade structures, carports, solar trellises, and similar type structures are not subject to the requirements of this section.

~~511.1 General.~~ ~~The installation of solar photovoltaic installations shall comply with Table 601 and Chapter 16 of the *International Building Code*. The installation shall also comply with Sections 511.2 through 511.11 and NFPA 70~~.

~~511.2~~ 605.11.1 ~~Circuit~~ Marking. ~~To facilitate identifying energized electrical lines that connect the solar panels to the inverter, to prevent these conduits from being cut when venting for smoke removal, markings shall be provided to give emergency responders appropriate warning that a solar electric system is present.~~ Marking is required on all interior and exterior dc conduit, enclosures, raceways, cable assemblies, junction boxes, combiner boxes, and disconnects.

~~511.3~~ 605.11.1.1 Materials. The materials used for marking shall be reflective, weather resistant and suitable for the environment. Marking as required in sections 605.11.1.2 through 605.11.1.4 shall have all letters capitalized with a minimum height of 3/8 inch (9.5 mm) white on red background.

~~511.4.1~~ 605.11.1.2 Marking content ~~and format~~. The marking shall contain the words "~~CAUTION~~: ~~SOLAR ELECTRIC CONNECTED~~ WARNING: PHOTOVOLTAIC POWER SOURCE" ~~in capital letters a minimum of 3/8 inches in height with white letters on a red background~~.

~~511.4~~ 605.11.1.3 Main service disconnect. ~~For residential occupancies, the marking shall be placed within the main service disconnect. If the main service disconnect is operable with the service panel closed, then the marking shall be placed on the outside cover. For commercial occupancies, t~~ The marking shall be placed adjacent to the main service disconnect in a location clearly visible from the location where the ~~lever~~ disconnect is operated.

~~511.5~~ 605.11.1.4 ~~DC conduit, raceways, enclosures, cable assemblies, and junction boxes.~~ ~~Marking shall be provided on all interior and exterior dc conduit, raceways, enclosures, cable assemblies, and junction boxes to alert the fire service to their presence. The marking shall be placed every 10 feet or fraction thereof, at turns and above and below penetrations, and on all dc combiner and junction boxes~~. **Location of Marking.** Marking shall be placed on all interior and exterior dc conduit, raceways, enclosures and cable assemblies every 10 feet (3048 mm) within 1 foot (305 mm) of all turns or bends and within 1 foot (305 mm) above and below all penetrations of roof/ceiling assemblies and all walls and /or barriers.

~~**511.5.1. Marking content and format**. The marking shall contain the words "CAUTION: SOLAR ELECTRIC CONNECTED" in capital letters a minimum of 3/8 inches in height with white letters on a red background.~~

~~511.5.2~~ 605.11.2 Locations of DC conductors. Conduit, wiring systems, and raceways for photovoltaic circuits shall be located as close as possible to the ridge or hip or valley and from the hip or valley as directly as possible to an outside wall to reduce trip hazards and maximize ventilation opportunities. Conduit runs between sub arrays and to DC combiner boxes shall be installed in a manner that minimizes total amount of conduit on the roof by taking the shortest path from the array to the DC combiner box. The DC combiner boxes shall be located such that conduit runs are minimized in the pathways between arrays. DC wiring shall be installedn in metallic conduit or raceways when located within enclosed spaces in a building. Conduit shall run along the bottom of load bearing members.

~~**511.6 Power disconnects**. A power disconnect shall be located within 3 feet of the photovoltaic array to provide for de-energizing the DC circuit(s) from the array to the inverter. The disconnect shall be label with reflective lettering.~~

~~511.7~~ 605.11.3 Access ~~,~~ and pathways ~~for smoke ventilation~~. Roof access, pathways, and spacing requirements shall be ~~observed~~ provided in order to ensure access to the roof; provide pathways to specific areas of the roof; provide for smoke ventilation operations; and to provide emergency egress from the roof.

Exceptions:

1. Requirements relating to ridge, hip, and valleys do not apply to roofs slopes of two units vertical in twelve units horizontal (2:12) or less.
2. Residential structures shall be designed so that each array is no greater than 150 feet (45 720 mm) by 150 feet (45 720 mm) in either axis.
3. The fire chief may allow panels/modules to be located up to the ridge when an alternative ventilation method acceptable to the fire chief has been provided or where the fire chief has determined vertical ventilation techniques will not be employed.

~~511.8~~ 605.11.3.1 Roof access points. Roof access points shall be defined as an area that does not place ground ladders over openings such as windows or doors, and are located at strong points of building construction in locations where the access point does not conflict with overhead obstructions such as tree limbs, wires, or signs.

~~511.9~~ 605.11.3.2 Residential systems for one- and two-family residential dwellings. Access shall be provided in accordance with Sections ~~511.9.1~~ 605.11.3.2.1 through ~~511.9.3~~. 605.11.3.2.4

~~511.9.1~~ 605.11.3.2.1 Residential buildings with hip roof layouts. Panels /modules shall be located in a manner that provides a 3 foot (914 mm) wide clear access pathway from the eave to the ridge on each roof slope where panels/modules are located. The access pathway shall be located at a structurally strong location on the building ~~such as along a underlying bearing wall~~ capable of supporting the live load of fire fighters accessing the roof.

~~511.9.2~~ 605.11.3.2.2 Residential buildings with a single ridge. Panels/modules shall be located in a manner that provides two 3 foot (914 mm) ~~(2) three foot (3')~~ wide access pathways from the eave to the ridge on each roof slope where panels/modules are located.

~~511.9.3~~ **605.11.3.2.3 Hips and Valleys:** Panels/modules shall be located no closer than ~~one and one half (1.5) feet~~ 18 inches (457 mm) to a hip or a valley if panels/modules are to be placed on both sides of a hip or valley. If the panels are to be located on only one side of a hip or valley that is of equal length then the panels shall be permitted to be placed directly adjacent to the hip or valley.

~~511.9.4~~ **605.11.3.2.4 Smoke Ventilation**. Panels/modules shall be located no higher than ~~three feet (3)~~ 3 feet (914 mm) below the ridge in order to allow for fire department smoke ventilation operations.

~~**Exception:** The fire department is authorized to allow panels to be located two (2) feet below the ridge if a product or method acceptable to the fire department has been provided for ventilation.~~

~~511.10~~ **605.11.3.3 All other occupancies**. Access shall be provided in accordance with Sections ~~511.10.1~~ 605.11.3.3.1 through ~~511.10.3~~ 605.11.3.3.3.

Exception: Where it is determined by the *fire code official* that the roof configuration is similar to a one- or two-family dwelling, the *fire code official* may *approve* the residential access and ventilation requirements provided in 605.11.3.2.1 through 605.11.3.2.4.

~~511.10.1~~ **605.11.3.3.1 Access**. There shall be a minimum ~~six (6) foot~~ 6 foot (1829 mm) wide clear perimeter around the edges of the roof.

Exception: If either axis of the building is 250 feet (76 200 mm) or less, there shall be a minimum ~~four feet (4')~~ 4 foot (1290 mm) wide clear perimeter around the edges of the roof.

~~511.10.2~~ **605.11.3.3.2 Pathways**. The solar installation shall be designed to provide designated pathways. The pathways shall meet the following requirements:

1. The pathway shall be over ~~structural members~~ areas capable of supporting the live load of fire fighters accessing the roof
2. The center line axis pathways shall be provided in both axis of the roof. Center line axis pathways shall run ~~on structural members or over the next closest structural member nearest to the center lines of the roof~~ where the roof structure is capable of supporting the live load of firefighters accessing the roof.
3. Shall be straight line not less than 4 feet (1290 mm) clear to skylights and/or ventilation hatches
4. Shall be straight line not less than 4 feet (1290 mm) clear to roof standpipes
5. Shall provide not less than 4 feet (1290 mm) clear around roof access hatch with at least one not less than 4 feet (1290 mm) clear pathway to parapet or roof edge

~~511.10.3~~ **605.11.3.3.3 Smoke Ventilation**. The solar installation shall be designed to meet the following requirements:

1. Arrays shall be no greater than 150 feet (45 720 mm) by 150 feet (45 720 mm) in distance in either axis in order to create opportunities for smoke ventilation operations.
2. Smoke ~~V~~ventilation options between array sections shall be ~~either~~ one of the following:
   2.1. ~~a~~A pathway 8 feet (2438 mm) or greater in width~~;~~
   2.2. ~~a~~A 4 feet (1290 mm) or greater in width pathway and bordering ~~on existing~~ roof skylights or ~~ventilation hatches~~ smoke and heat vents~~;~~
   2.3. ~~or a~~A 4 feet (1290 mm) or greater in width pathway and bordering 4 foot (1290 mm) x 8 foot (2438 mm) "venting cutouts" every 20 feet (6096 mm) on alternating sides of the pathway

~~511.11~~ **605.11.4 Ground mounted photovoltaic arrays**. Ground mounted photovoltaic arrays shall comply with Sections ~~511.1~~ 605.11 through ~~511.6~~ 605.11.2 and this section. Setback requirements do not apply to ground-mounted, free standing photovoltaic arrays. A clear brush area of 10 feet (3048 mm) is required for ground mounted photovoltaic arrays.

105.7.14 Solar photovoltaic power systems. A construction permit is required to install or modify Solar photovoltaic power systems.

IBC Section 1511
Solar Photovoltaic Panels/Modules

IBC 1511.1 Solar photovoltaic panels/modules. Solar photovoltaic panels/modules installed upon a roof or as an integral part of a roof assembly shall comply with the requirements of this code and the *International Fire Code*.

IBC 1511.1.1 Structural fire-resistance. The structural frame and roof construction supporting the load imposed upon the roof by the photovoltaic panels/modules shall comply with the requirements of Table 601.

IBC Section 3111
Solar Photovoltaic Panels/Modules

IBC 3111.1 Solar photovoltaic panels/modules. Solar photovoltaic panels/modules shall comply with the requirements of this code and the *International Fire Code*.

Commenter's Reason: The California Office of the State Fire Marshal (CSFM) supports the National Association of State Fire Marshals (NASFM) proposed changes to the 2009 Edition of the International Fire Code (IFC), F30-09/10 Section 511 Solar Photovoltaic Installations. The CSFM formed a small work group with representatives from the fire service, building officials, and solar industry to develop this public comment proposal base on the CSFM "Guidelines". This proposal seeks to address the ICC Fire Code Committees comments as well as other comments made during and after the ICC code hearings in Baltimore November 2009.

To address the Fire Code Committees comments the CSFM offers the following:

The CSFM/work group disagrees in part with the committees comment that these provisions are "…not sufficiently developed to be in the code…" as these provisions (through the CSFM "Guidelines") are being widely implemented throughout the state to address provisions missing from the IFC. This proposal fills that missing element/provisions for Solar Photovoltaic Installations and further provides for uniform design and enforcement.

The CSFM's "Guidelines" are still in draft form at this time due to specific California rulemaking procedures that have a process to follow to adopt into regulations. The "Guidelines" would be in draft until the regulations were adopted and approved for statewide application.

The CSFM added IFC Section 105.7.14 to address that a permit is required to install or modify solar photovoltaic systems (see part 2 of this public comment proposal).

Section 605.11.1.3 addresses the main service disconnect in a location clearly visible from the location where the lever disconnect is operated regardless if it is for a residential, commercial or mixed occupancy building.

Sections 605.11.3.2.1 and 605.11.3.3.2 both addresses the walkable pathways over structural members for residential and all other occupancies.

The CSFM/work group feel there is not a need to put the proposal in the appendix, it is in the best interest of both the industry and the fire service to have uniform minimum provisions for application and effective. Additional response below regarding relocation to chapter 6.

Additional modifications to address other comments, alignment with the original "Guidelines", coordination with NFPA 70 and OSHA provisions.

The CSFM/work group recommends that the appropriate area for this proposal should be moved to the IFC Chapter 6 Building Services and Systems; Section 605.11 since 605 addresses electrical equipment, wiring and hazards.

The CSFM removed Section 511.6 for power disconnects because it was not provided for and/or addressed the in the "Guidelines" and the CSFM believes that this issue be address by the individual adopting jurisdictions.

Modifications for the marking content and color scheme are made top avoid conflict the OSHA sign and tag requirements.

Other minor changes made are to give clear and specific requirements for Solar Photovoltaic Power Systems.

This public comment also addresses the need expressed by the committee for references to the IFC in the International Building Code (IBC). IBC Section 1511 and Section 3111 are being added so solar systems are referenced to address roofing requirements, such as supporting the load of these systems to roofs and to structural roof frame and pedestrian walkways, awnings and canopies. Additionally these references are located in both chapter 15 and 31 where the user may look to find provisions for either roof mounted, stand alone or ground mounted solar photovoltaic panels/modules.

Final Action: AS AM AMPC____ D

F36-09/10
605.1

Proposed Change as Submitted

Proponent: Philip M. Chandler, representing New York State Department of State, Office of Fire Protection & Control

Revise as follows:

605.1 Abatement of electrical hazards. ~~Identified electrical hazards shall be abated. Identified hazardous electrical conditions in permanent wiring shall be brought to the attention of the responsible code official.~~ <u>Where it is found that the electrical system in a structure constitutes a hazard to the occupants or the structure by reason of inadequate service, improper fusing, insufficient receptacle and lighting outlets, improper wiring or installation, deterioration or damage, or for similar reasons, the fire code official shall require the defects to be corrected to eliminate the hazard.</u> Electrical wiring, devices, appliances and other equipment that is modified or damaged and constitutes an electrical shock or fire hazard shall not be used.

Reason: The proposed revision will make this section consistent with the requirements of the *International Property Maintenance* Code (IPMC), Section 604.3. The new language clearly identifies important electrical hazards that create a risk of fire and eliminates much ambiguity found in the old language.

Cost Impact: The code change proposal will not increase the cost of construction

ICCFILENAME: CHANDLER-F1-605.1.DOC

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The proposal contains vague language (e.g., "...or for similar reasons...") and includes a "laundry list" of electrical hazards that is not exhaustive and provides no guidance as to what standards are to be used to judge electrical systems as being deficient. The committee was also concerned that the proposal would put the fire code official and/or the fire department in the role of being an electrical expert.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Philip M. Chandler, representing New York State Department of State, Office of Fire Prevention & Control, requests Approval as Submitted.

Commenter's Reason: It is urged that Code change Proposal F36-09/10 be approved as submitted for the following reasons:

Electrical fires area problem in America. The U.S. Fire Administration estimates that electrical fires in residential occupancies alone take the lives of 360 people each year, injure 1,000, and do $995 million dollars of damage. [1]The Administration further reports that "most electrical fires result from problems with faulty electrical outlets and old wiring, "[2] Surprisingly, however, the IFC barely addresses the issue of defects in permanent wiring. The weak language of IFC 605.1, "Identified electrical hazards shall be abated," gives little support or guidance to fire code officials conducting safety inspections of existing buildings. Why not, therefore, provide fire code officials with the precise and informative code language needed to identify and address electrical deficiencies before they cause a fire?

Accordingly, it is proposed that IFC 605.1 be modified and strengthened by importing the provisions of IPMC 604.3. This descriptive language provides a useful set of criteria for the fire code official. Inasmuch as the USFA has specifically identified "old wiring" as a fire hazard, it is certainly appropriate that the IFC also recognizes and specifies the dangerous conditions indicative of electrical systems that have outlived their safe and useful life as well as systems and components that have been improperly installed, modified or have become damaged.

The IFC Committee has criticized the language of IPMC 604.3, calling it a "laundry list," and has denigrated the use of the explanatory expression "or for similar reasons," as being "vague." The Committee's objections are misplaced in this instance, as the language of IPMC 604.3 has not only been vetted through the same process to which this code change proposal is being subjected, but has also proven itself in the field. Further, so-called "laundry lists" are still used to great effect throughout the IFC, including in the remainder of IFC 605.1 not modified by this proposal("…devices, appliances, and other devices…"). Certainly a referenced standard adds clarity, but there is no one standard, or set of standards presently out there that will adequately do the job here in regards to existing electrical systems and components. NFPA 70, *National Electric Code*, is ostensibly a standard for new construction. NFPA 73, *Electrical Inspection Code for Existing Dwellings*, is just that, a code for dwellings. Until such time as a comprehensive standard for evaluating existing electrical conditions across the full range of occupancy classifications is developed, the tried and true language of IPMC 604.3 proposed for insertion into the IFC is the next best thing.

The Committee has also objected to the strengthening of IFC 605.1 worrying that by so doing, "it would put the fire code official and/or the fire department in the role of being an electrical expert." This line of reasoning, if followed to its logical conclusion, would disqualify all but engineers, physicists and chemists from conducting life safety inspections. Are we worried that Chapter 27 puts the fire inspector in the role of a chemist, able to identify incompatible materials? Are we worried that Chapter 9 puts the fire inspector in the role as a fire protection engineer, able to determine if a complex system is properly functioning? The truth is that the fire code official or firefighter of today must have advanced training and education to function effectively in a rapidly changing, highly technical environment. Obviously they cannot have expertise in every single topic covered by the IFC, but they can, as authorized in IFC 104.7.2, obtain the technical assistance or inspection reports that they need to complete their inspection. But honestly, rocket science is not required to determine that a 15 amp electrical circuit protected by a 30 amp fuse is overloaded and is a fire waiting to happen!

The Committee is apparently quite content that fire code inspectors simply pass off suspected electrical fire hazards to the appropriate building code official. What about those jurisdictions where the fire code official is the building code official as well? What about those jurisdictions where the appropriate building code official only inspects new permitted construction? What about those jurisdictions where as a result of budgetary constraints the building department is unable to respond in a timely fashion to complaints of electrical hazards in existing occupancies? Keep in mind, in many communities, it is the fire code official alone, or for that matter, the fire department alone, that conducts life safety inspections of existing buildings, including occupancies as diverse as high-rise hotels and chip-fabrication facilities. If we as fire protection specialists have only one shot at preventing the next fire, why not make it count! It is quite possible that these inspections constitute the best hope that occupants have of escaping a deadly blaze; why pass the buck?

F37-09/10
605.1.1 (New)

Proposed Changes as Submitted

Proponent: Philip M. Chandler, representing New York State Department of State, Office of Fire Protection & Control

Add new text as follows:

605.1.1 Electrical inspection. In accordance with the provisions of Section 104.7.2, the fire code official is authorized to require an inspection and report on the safety of a structure's electrical system, wiring, devices, appliances and equipment. The inspection and report shall be prepared by a qualified engineer, specialist, laboratory or fire safety specialty organization acceptable to the fire code official.

Reason: The fire code official may have reason to believe that the electrical safety of a structure is compromised, yet lack the highly technical knowledge or specialized skills to make a final determination. Inasmuch as the risk of shock or hazard of fire are very real consequences of defective electrical systems and equipment, this authorization of the fire code official to obtain technical assistance is warranted.

Cost Impact: The code change proposal will not increase the cost of construction

ICCFILENAME: CHANDLER-F2-605.1.1.DOC

<u>Public Hearing Results</u>

Committee Action: **Disapproved**

Committee Reason: The committee felt that the proposal would leave out the building official and the electrical inspector. The committee also felt that the proposal is redundant since the code already contains provisions for referring electrical hazards to the appropriate code official

Assembly Action: **None**

<u>Individual Consideration Agenda</u>

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Philip M. Chandler, representing New York State Department of State, Office of Fire Prevention & Control, requests Approval as Submitted.

Commenter's Reason: It is urged that this code change proposal be adopted as submitted for the following reasons:

All across America, fire code officials, building code officials, and firefighters conduct life safety inspections of existing occupancies of every type. Frequently, they may have reason to believe by virtue of the presence of certain telltale signs that a building's electrical wiring or components are unsafe, posing an unacceptable life safety risk. Yet often because they lack sufficient technical expertise, appropriate tools or personal protective equipment, those conducting inspections are unable to make a final determination without recourse to specialized outside resources. This often is the case when it comes to assessing obsolescence, a leading cause of electrical fires (see comments of Philip M. Chandler on F36 above). This proposal unambiguously grants the authority to fire inspectors to obtain the necessary assistance to get the job done right.

The intention of this proposal is not as the committee has suggested, to "leave out the building code official or electrical inspector," but rather to give the inspector of existing electrical systems and components access to all the technical assistance required to adequately assess conditions where hazards are suspected. Even building code officials or electrical inspectors may need additional information or knowledge to complete their inspection. It is true that this authority to obtain outside assistance is already granted by IFC 104.7.2. It is repeated here because the incidence of electrical fires and their human toll warrant a second mention. It is also important to note that the invaluable provisions of IFC 104.7.2 may be inadvertently lost by those jurisdictions that choose to rewrite Chapter One to better reflect local policy and procedures. The option of getting a second opinion is a right we all cherish when it comes to clarifying issues of our own health, the same option should be available in all jurisdictions when it comes to identifying electrical life safety hazards.

Final Action: AS AM AMPC____ D

F46-09/10
703.2

<u>Proposed Change as Submitted</u>

Proponent: John Woestman, The Kellen Company, representing the Door Safety Council (DSC)

Revise as follows:

703.2 Opening protectives. Opening protectives shall be maintained in an operative condition in accordance with NFPA 80. <u>Where required by the fire code official, the application of field applied labels associated with the maintenance of opening protectives shall follow the requirements of the *approved* third-party certification organization accredited for *listing* the opening protective.</u> Fire doors and *smoke barrier* doors shall not be blocked or obstructed or otherwise made inoperable. Fusible links shall be replaced promptly whenever fused or damaged. Fire door assemblies shall not be modified.

Reason: This code proposal addresses the very real issue of maintaining labeled opening protectives by requiring field applied labels to follow the requirements of the third-party certification organization which is accredited for listing the specific opening protective. Ongoing maintenance is now an IFC requirement, and this code change provides an enforceable method of allowing maintenance of labeled protectives.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: WOESTMAN-F3-1030.2-2.DOC

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The relabeling of existing fire doors is a common practice and due to the importance of the rating requirements a level of monitoring by a third party to ensure the labeling matches the rating of the door assembly is necessary. It was suggested that the new language could be better located in its own subsection.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Joe Pierce (Chairman), Dallas Fire Department, representing Joint Fire Service Review Committee, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

703.2 Opening protectives. Opening protectives shall be maintained in an operative condition in accordance with NFPA 80. Where ~~required~~ allowed by the fire code official, the application of field applied labels associated with the maintenance of opening protectives shall follow the requirements of the *approved* third-party certification organization accredited for *listing* the opening protective. Fire doors and *smoke barrier* doors shall not be blocked or obstructed or otherwise made inoperable. Fusible links shall be replaced promptly whenever fused or damaged. Fire door assemblies shall not be modified.

Commenter's Reason: The issue is not whether the fire code official "requires" field applied labels, the actual issue is whether the fire code official "allows" field applied labels.

In the listing documentation there are specific criteria for field application of labels. One of the criteria is whether the local code officials allow this practice. IBC 715.4.6.1 states that fire doors must be labeled at the factory. This would apply to new doors or new installations. Now that existing door either has a damaged label, the label is painted over, or the label is gone. The fire code official needs to make a determination as to whether field application of the label is acceptable or not. If field application is allowed, then the certification organization can follow the proper criteria for labeling the opening protective.

Proper maintenance necessitates that the manufacturer's instructions are followed and the listing organization's instructions are followed. The fact is that following proper procedures is required by the code to maintain proper operation of the assemblies and devices; it is required by the manufacturer; and it is required by the listing organization in order to maintain the listing.

Therefore, the phrase of "where required" is proposed to be replaced with "when allowed".

Final Action: AS AM AMPC____ D

F50-09/10
803.6.1, 803.6.2

Proposed Change as Submitted

Proponent: Marcelo M. Hirschler, GBH International, representing American Fire Safety Council

Revise as follows:

803.6.1 General. Expanded vinyl wall or ceiling coverings shall comply with the requirements of Section 803.1.2 using the product mounting system (including adhesive) of actual use. Expanded vinyl wall or ceiling coverings complying with Section 803.1.2 shall not be required to comply with Section 803.1.1.

803.6.2 Compliance alternative. Expanded vinyl wall or ceiling coverings shall be allowed to comply with ~~the requirements for textile wall or ceiling coverings in Section 803.5. When tested in accordance with ASTM E 84 or UL 723, test specimen preparation shall be in accordance with ASTM E 2404~~ one of the following:

1. The wall or ceiling covering shall have a class A flame spread index in accordance with ASTM E 84 or UL 723 and be protected by automatic sprinklers installed in accordance with Section 903.3.1.1 or 903.3.1.2. Test specimen preparation and mounting shall be in accordance with ASTM E 2404.
2. The wall covering shall meet the criteria of Section 803.5.1.2 when tested in the manner intended for use in accordance with NFPA 265 using the product mounting system (including adhesive) of actual use.
3. The wall or ceiling covering shall meet the criteria of Sections 803.1.2.1 when tested in accordance with NFPA 286 using the product mounting system (including adhesive) of actual use.

Reason: Instead of sending code users to another section, it is best simply to state the requirements for expanded vinyl wall or ceiling covering materials directly. The correct specimen preparation and mounting method for textile, paper and vinyl wall and ceiling coverings tested in accordance with ASTM E 84 (Steiner tunnel) test is ASTM E 2404. The revised text addresses the requirements for wall and ceiling coverings, as appropriate:

1. They point out again that expanded vinyl wall and ceiling coverings are only permitted to be installed when tested in accordance with ASTM E 84 if the compartment is fully protected by sprinklers.
2. The new text also makes it clear that NFPA 265 is inappropriate for testing ceiling coverings since the burner flame does not reach the ceiling.
3. The new text eliminates reference to Method A of NFPA 265, which has been eliminated from the body of the standard. Method A applies only to materials tested in the past.
4. The text also clarifies that testing to NFPA 286 needs to use the correct product mounting system, including adhesive.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: HIRSCHLER-F1-803.6.1.DOC

Public Hearing Results

Committee Action: Approved as Submitted

Committee Reason: The committee approved the provisions adding a separate section detailing the testing requirements for expanded vinyl wall coverings to help clarify when and how the various tests apply to these materials. These provisions would apply to existing and newly introduced expanded vinyl wall or ceiling coverings. The provisions correlate with the IBC.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Marcelo M. Hirschler (GBH International), requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

803.6 Expanded vinyl wall or ceiling coverings. Expanded vinyl wall or ceiling coverings shall comply with ~~the requirements of either Section 803.6.1 or 803.6.2.~~

~~**803.6.1 General.** Expanded vinyl wall or ceiling coverings shall comply with the requirements of Section 803.1.2 using the product mounting system (including adhesive) of actual use. Expanded vinyl wall or ceiling coverings complying with Section 803.1.2 shall not be required to comply with Section 803.1.1.~~

~~**803.6.2 Compliance alternative.** Expanded vinyl wall or ceiling coverings shall be allowed to comply with~~
one of the following:

1. The wall or ceiling covering shall have a class A flame spread index in accordance with ASTM E 84 or UL 723 and be protected by automatic sprinklers installed in accordance with Section 903.3.1.1 or 903.3.1.2. Test specimen preparation and mounting shall be in accordance with ASTM E 2404.
2. The wall covering shall meet the criteria of Section 803.5.1.2 when tested in the manner intended for use in accordance with NFPA 265 using the product mounting system (including adhesive) of actual use.
3. The wall or ceiling covering shall meet the criteria of Sections 803.1.2.1 when tested in accordance with NFPA 286 using the product mounting system (including adhesive) of actual use.

Commenter's Reason: This public comment is simply reformatting the section in an effort to simplify the language as the revised wording in Section 803.6.1 is also addressed within item 3 of the revised section 803.6.2. This will streamline the language from three sections into one.

Final Action: AS AM AMPC____ D

F51-09/10
804.3 (New), Chapter 47

Proposed Change as Submitted

Proponent: Marcelo M. Hirschler, GBH International, representing American Fire Safety Council

1. Add new text as follows:

804.3 Interior floor finish Newly introduced interior floor finish and floor covering materials shall comply with Sections 804.3.1 through 804.3.3.

> **Exception:** Floor finishes and coverings of a traditional type, such as wood, vinyl, linoleum or terrazzo, and resilient floor covering materials that are not comprised of fibers.

804.3.1 Classification. Interior floor finish and floor covering materials required by Section 804.3.3 to be of Class I or II materials shall be classified in accordance with NFPA 253. The classification referred to herein corresponds to the classifications determined by NFPA 253 as follows: Class I, 0.45 watts/cm^2 or greater; Class II, 0.22 watts/cm^2 or greater.

804.3.2 Testing and identification. Interior floor finish and floor covering materials shall be tested by an approved agency in accordance with NFPA 253 and identified by a hang tag or other suitable method so as to identify the manufacturer or supplier and style, and shall indicate the interior floor finish or floor covering classification according to Section 804.3.1. Carpet-type floor coverings shall be tested as proposed for use, including underlayment. Test reports confirming the information provided in the manufacturer's product identification shall be furnished to the building official upon request.

804.3.3 Interior floor finish requirements. Interior floor covering materials shall comply with Sections 804.3.3.1 and 804.3.3.2 and interior floor finish materials shall comply with Section 804.3.4.2.

804.3.3.1 Pill test. In all occupancies, interior floor covering materials shall comply with the requirements of the DOC FF-1 Apill test@ (CPSC 16 CFR, Part 1630) or of ASTM D 2859.

804.3.3.2 Minimum critical radiant flux. In all occupancies, interior floor finish and floor covering materials in exit enclosures, exit passageways, corridors and rooms or spaces not separated from corridors by full-height partitions extending from the floor to the underside of the ceiling shall withstand a minimum critical radiant flux. The minimum critical radiant flux shall not be less than Class I in Groups I-1, I-2 and I-3 and not less than Class II in Groups A, B, E, H, I- 4, M, R-1, R-2 and S.

> **Exception:** Where a building is equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 or 903.3.1.2, Class II materials are permitted in any area where Class I materials are required and materials complying with DOC FF-1 A pill test@ (CPSC 16 CFR, Part 1630) or with ASTM D 2859 are permitted in any area where Class II materials are required.

(Renumber subsequent section)

2. Add new standard to Chapter 47 as follows:

ASTM D 2859 (2006) Standard Test Method for Ignition Characteristics of Finished Textile Floor Covering Materials

Reason: Somehow, requirements for interior floor finish are missing in the IFC, while such requirements exist in the IBC as well as in the Life Safety Code and the Uniform Fire Code. In this proposal the wording has been taken from the IBC, with four changes. The key change is that this section applies only to "newly introduced" interior floor finish materials, in view of the fact that the IFC is for existing buildings. The other changes are as shown below:

1. The "pill test" is applied to all newly introduced carpets and carpet-like floor finish materials, in view of the fact that the federal government, through CPSC, regulates all carpets and rugs based on 16 CFR 1630 since the 1970s.
2. In the IBC there is confusion because section 804.4 states that "interior floor finish and floor covering materials in exit enclosures, exit passageways, corridors and rooms or spaces not separated from corridors by full-height partitions extending from the floor to the underside of the ceiling shall withstand a minimum critical radiant flux" and then section 804.4.1 states that "interior floor finish and floor covering materials in exit enclosures, exit passageways and corridors shall not be ...". This leaves undefined what minimum critical radiant flux is required for "interior floor finish and floor covering materials in rooms or spaces not separated from corridors by full-height partitions extending from the floor to the underside of the ceiling". Since section 804.2 only distinguishes two classes for NFPA 253, the logical conclusion is that the words are missing and that these rooms or spaces have to meet the same requirements as the corridors from which they are not separated. A proposal has been submitted to the IBC to make this correction.

3. ASTM D 2859, which is equivalent to 16 CFR 1630 and is used extensively outside of the US, while 16 CFR 1630 is only a federal mandate, is added as an alternate. In fact, ASTM D 2859 is the standard that complies with the ICC policy on referenced standards. A proposal has been submitted to the IBC to allow ASTM D 2859 as an alternate test method to 16 CFR 1630.

The fire hazard of newly introduced floor coverings (which basically means carpets only) is the same in new buildings and in existing buildings. Therefore the IFC should be consistent with the IBC.

An alternate approach: If the addition of ASTM D 2859 is not desired by the committee, please use the following text:

804.3 Interior floor finish.

804.3.1 General. Newly introduced interior floor finish and floor covering materials shall comply with Sections 804.3.2 through 804.3.4.

Exception: Floor finishes and coverings of a traditional type, such as wood, vinyl, linoleum or terrazzo, and resilient floor covering materials that are not comprised of fibers.

804.3.2 Classification. Interior floor finish and floor covering materials required by Section 804.3.4 to be of Class I or II materials shall be classified in accordance with NFPA 253. The classification referred to herein corresponds to the classifications determined by NFPA 253 as follows: Class I, 0.45 watts/cm^2 or greater; Class II, 0.22 watts/cm^2 or greater.

804.3.3 Testing and identification. Interior floor finish and floor covering materials shall be tested by an approved agency in accordance with NFPA 253 and identified by a hang tag or other suitable method so as to identify the manufacturer or supplier and style, and shall indicate the interior floor finish or floor covering classification according to Section 804.3.2. Carpet-type floor coverings shall be tested as proposed for use, including underlayment. Test reports confirming the information provided in the manufacturer's product identification shall be furnished to the building official upon request.

804.3.4 Interior Floor Finish R**equirements.**

804.3.4.1 Pill test. In all occupancies, newly introduced floor covering materials shall comply with the requirements of the DOC FF-1 "pill test" (CPSC 16 CFR, Part 1630).

804.3.4.2 Minimum critical radiant flux. In all occupancies, newly introduced interior floor finish and floor covering materials in exit enclosures, exit passageways, corridors and rooms or spaces not separated from corridors by full-height partitions extending from the floor to the underside of the ceiling shall withstand a minimum critical radiant flux. The minimum critical radiant flux shall not be less than Class I in Groups I-1, I-2 and I-3 and not less than Class II in Groups A, B, E, H, I- 4, M, R-1, R-2 and S.

Exception: Where a building is equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 or 903.3.1.2, Class II materials are permitted in any area where Class I materials are required and materials complying with DOC FF-1 "pill test" (CPSC 16 CFR, Part 1630) are permitted in any area where Class II materials are required.

(Renumber subsequent section)

Cost Impact: The cost of carpets that meet Class I or Class II in accordance with NFPA 253 is higher than the cost of carpets that are not classified.

Analysis: A review of the standard(s) proposed for inclusion in the code, ASTM D 2859-2006, for compliance with ICC criteria for referenced standards given in Section 3.6 of Council Policy #CP 28 will be posted on the ICC website on or before September 24, 2009.

CPSC 16 CFR, Part 1630 is already referenced in the IBC and NFPA 253 is already referenced in the IFC.

ICCFILENAME: HIRSCHLER-F10-804.3.DOC

Public Hearing Results

Note: The following analysis was not in the Code Change monograph but was published on the ICC website at http://www.iccsafe.org/cs/codes/Documents/2009-10cycle/ProposedChanges/Standards-Analysis.pdf :

Analysis: Review of the proposed new standard ASTM D2859 (2006) indicated that, in the opinion of ICC staff, the standard did comply with ICC standards criteria.

Committee Action: Disapproved

Committee Reason: There were a couple concerns with this proposal including the inconsistencies between the current sections within the IBC and the language proposed for the IFC. In addition there were several typographical errors and the new standard being introduced was not currently referenced in that portion of the IBC.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Marcelo M. Hirschler (GBH International) representing American Fire Safety Council, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

804.3 New Interior Floor Finish ~~Newly introduced~~ New interior floor finish and floor covering materials shall comply with Sections 804.3.1 through 804.3.3.

> **Exception:** Floor finishes and coverings of a traditional type, such as wood, vinyl, linoleum or terrazzo, and resilient floor covering materials that are not comprised of fibers.

804.3.1 Classification. Interior floor finish and floor covering materials required by Section 804.3.3.2 to be of Class I or II materials shall be classified in accordance with NFPA 253. The classification referred to herein corresponds to the classifications determined by NFPA 253 as follows: Class I, 0.45 watts/cm^2 or greater; Class II, 0.22 watts/cm^2 or greater.

804.3.2 Testing and identification. Interior floor finish and floor covering materials shall be tested by an approved agency in accordance with NFPA 253 and identified by a hang tag or other suitable method so as to identify the manufacturer or supplier and style, and shall indicate the interior floor finish or floor covering classification according to Section 804.3.1. Carpet-type floor coverings shall be tested as proposed for use, including underlayment. Test reports confirming the information provided in the manufacturer's product identification shall be furnished to the building official upon request.

804.3.3 Interior Floor Finish Requirements. New Interior floor coverings materials shall comply with Sections 804.3.3.1 and 804.3.3.2 and interior floor finish materials shall comply with Section 804.3.1.

804.3.3.1 Pill test. In all occupancies, new floor covering materials shall comply with the requirements of the DOC FF-1 "pill test" (CPSC 16 CFR, Part 1630) or of ASTM D 2859.

804.3.3.2 Minimum critical radiant flux. In all occupancies, new interior floor finish and floor covering materials in exit enclosures, exit passageways, corridors and rooms or spaces not separated from corridors by full-height partitions extending from the floor to the underside of the ceiling shall withstand a minimum critical radiant flux. The minimum critical radiant flux shall not be less than Class I in Groups I-1, I-2 and I-3 and not less than Class II in Groups A, B, E, H, I- 4, M, R-1, R-2 and S.

> **Exception:** Where a building is equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 or 903.3.1.2, Class II materials are permitted in any area where Class I materials are required and materials complying with DOC FF-1 "pill test" (CPSC 16 CFR, Part 1630) or with ASTM D 2859 are permitted in any area where Class II materials are required.

804.4 ~~804.3~~ Interior Floor Wall base. Interior floor wall base that is 6 inches (152 mm) or less in height shall be tested in accordance with NFPA 253 and shall not be less than Class II. Where a Class I floor finish is required, the floor-wall base shall be Class I. The classification referred to herein corresponds to the classifications determined by NFPA 253 as follows: Class I, 0.45 watts/cm^2 or greater; Class II, 0.22 watts/cm^2 or greater.

> **Exception:** Interior trim materials that comply with Section 804.1.

(Portions of the proposal not shown remain unchanged)

Commenter's Reason: The technical committee was concerned about two issues: (a) that the new language was inconsistent with the language in the IBC and (b) that this could be considered to apply to used carpets/floor coverings that are being brought in from a relative or into a new occupancy (apartment to apartment) could be covered. The first concern was addressed by the IBC-FS committee, which met after the IFC committee, and approved both FS137 and FS 138. By approving these proposals the IBC-FS committee incorporated the language that was missing in both the IBC and the IFC (probably via typographical errors) and the new standard. The second concern is addressed in this comment by the language change.

Therefore, the code language proposed for the IFC in this proposal, as modified by the comment, addresses both issues: instead of "newly introduced" the language would now read "new" (in three places) and the remaining language is fully consistent with the IBC, except that it applies only to "new" interior floor finish.

For information, as a result of the approval of FS137 and FS138, the section of the IBC reads as follows.

Section 804 – Interior Floor Finish

804.1 General. *Interior floor finish* and floor covering materials shall comply with Sections 804.2 through 804.4.1.

> **Exception:** Floor finishes and coverings of a traditional type, such as wood, vinyl, linoleum or terrazzo, and resilient floor covering materials that are not comprised of fibers.

804.2 Classification. *Interior floor finish* and floor covering materials required by Section 804.4.1 to be of Class I or II materials shall be classified in accordance with NFPA 253. The classification referred to herein corresponds to the classifications determined by NFPA 253 as follows: Class I, 0.45 watts/cm^2 or greater; Class II, 0.22 watts/cm^2 or greater.

804.3 Testing and identification. *Interior floor finish* and floor covering materials shall be tested by an agency in accordance with NFPA 253 and identified by a hang tag or other suitable method so as to identify the manufacturer or supplier and style, and shall indicate the *interior floor finish* or floor covering classification according to Section 804.2. Carpet-type floor coverings shall be tested as proposed for use, including underlayment. Test reports confirming the information provided in the manufacturer's product identification shall be furnished to the building official upon request.

804.4 Interior floor finish requirements.

804.4.1 Pill test. In all occupancies, floor covering materials shall comply with the requirements of the DOC FF-1 "pill test" (CPSC 16 CFR, Part 1630) or with ASTM D 2859.

804.4.2 Minimum critical radiant flux. In all occupancies, interior floor finish and floor covering materials in exit enclosures, exit passageways, corridors and rooms or spaces not separated from corridors by full-height partitions extending from the floor to the underside of the ceiling shall withstand a minimum critical radiant flux. The minimum critical radiant flux shall not be less than Class I in Groups I-1, I-2 and I-3 and not less than Class II in Groups A, B, E, H, I- 4, M, R-1, R-2 and S.

~~**804.4 Interior Floor Finish Requirements** In all occupancies, interior floor finish and floor covering materials in exit enclosures, exit passageways, corridors and rooms or spaces not separated from corridors by full-height partitions extending from the floor to the underside of the ceiling shall withstand a minimum critical radiant flux as specified in Section 804.4.1.~~

~~**804.4.1 Minimum critical radiant flux.** Interior floor finish and floor covering materials in exit enclosures, exit passageways and corridors shall not be less than Class I in Groups I-1, I-2 and I-3 and not less than Class II in Groups A, B, E, H, I- 4, M, R-1, R-2 and S. In all areas, floor covering materials shall comply with the DOC FF-1 "pill test" (CPSC 16 CFR, Part 1630).~~

> **Exception:** Where a building is equipped throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 or 903.3.1.2, Class II materials are permitted in any area where Class I materials are required and materials complying with DOC FF-1 "pill test" (CPSC 16 CFR, Part 1630) or with ASTM D 2859 are permitted in any area where Class II materials are required.

Final Action: AS AM AMPC____ D

F52-09/10
805.1 (New)

Proposed Change as Submitted

Proponent: Marcelo M. Hirschler, GBH International

Add new text as follows:

805.1 Ignition by cigarettes. Upholstered furniture newly introduced into occupancies regulated by this code shall comply with 805.1.1. Mattresses newly introduced into occupancies regulated by this code shall comply with 805.1.2.

805.1.1 Upholstered furniture. Newly introduced upholstered furniture shall be shown to resist ignition by cigarettes as determined by tests conducted in accordance with one of the following:

1. Mocked-up composites of the upholstered furniture shall have a char length not exceeding 1.5 inches (38 mm) when tested in accordance with NFPA 261.
2. The components of the upholstered furniture shall meet the requirements for Class I when tested in accordance with NFPA 260.

805.1.2 Mattresses. Newly introduced mattresses shall be shown to resist ignition by cigarettes as determined by tests conducted in accordance with DOC 16 CFR Part 1632 and shall have a char length not exceeding 2 inches (51 mm).

(Renumber subsequent sections)

Reason: Mattresses in the United States have been required to meet 16 CFR 1632 by the Consumer Product Safety Commission since the 1970s. There are no new mattresses sold legally in the US that are not compliant with 16 CFR 1632. As an example, the web site by ISPA (International Sleep Products Association)

(http://www.sleepproducts.org/Content/NavigationMenu/Advocacy_Issues/ISPA_Position_Papers/Flammability_Position_Paper.htm) states as follows: "ISPA Position: ISPA supports the national flammability standards for mattresses codified at 16 C.F.R. Parts 1632 and 1633 promulgated by the U.S. Consumer Product Safety Commission (CPSC) [linked text]. Part 1632 requires that mattresses resist a smoldering cigarette ignition, which has been in place since the mid-1970s. Part 1633, which will become effective July 1, 2007, requires that mattresses resist an open-flame ignition. ISPA also seeks a national standard that addresses the flammability of bedclothes (top-of-the-bed products such as pillows, comforters and mattress pads), given that these are usually the first items ignited in a bedroom fire. Background: The mattress industry takes its product stewardship responsibilities seriously. For over 30 years, the mattress industry has actively supported regulatory efforts to develop flammability standards, public education initiatives and basic scientific research targeted at reducing residential fire casualties and property loss. In the early 1970s, we participated in the development of 16 C.F.R. Part 1632."

There is no mandatory federal flammability regulation for upholstered furniture in the US. However basically, manufacturers of both residential and contract upholstered furniture support the need for their products to meet cigarette ignition resistance requirements.

Residential upholstered furniture: the UFAC (Upholstered Furniture Action Council) web site (www.ufac.org) states: "The Upholstered Furniture Action Council was founded in 1978 to make upholstered furniture more resistant to ignition from smoldering cigarettes which are the leading cause of upholstery fires in the home. Household fires from smoldering ignition have been reduced substantially since its inception. According to the latest figures there has been a 79.3% decline in the number of upholstered furniture fires from cigarette ignition." The web site also states: "Background: In 1970, federal government agencies proposed mandatory safety standards to reduce the potential fire hazards posed by the cigarette ignition of mattresses, carpeting and upholstered furniture. Mandatory standards were imposed for mattresses and carpeting. When the Consumer Product Safety Commission, (CPSC) began looking at upholstered furniture, UFAC was formed to allow upholstered furniture manufacturers the opportunity to work with CPSC in a meaningful way to design safety standards which are effective, cost effective and workable from a manufacturing standpoint. The only logical course of action for the furniture industry was to create a voluntary program that would develop a better safety record for the industry, at a lower cost, than the proposed government regulations." UFAC administers the program that is responsible for the golden hangtags that are found on residential upholstered furniture and indicate that the furniture has passed the UFAC test. The UFAC web site lists the manufacturers (http://www.ufac.org/mfglist.htm) and the retailers (http://www.ufac.org/retailerslist.htm) that comply with their test. UFAC represents the major manufacturers of residential upholstered furniture. Their web site indicates that the UFAC test is identical to NFPA 260 (http://www.ufac.org/method11.htm).

Institutional upholstered furniture: The Business & Institutional Home Furnishings Alliance (BIFMA) was the developer of the standard test that became NFPA 261 (originally known as the BIFMA test). Contract or institutional upholstered furniture now meets either NFPA 260 (UFAC test) or NFPA 261 and is resistant to cigarette ignition resistance. BIFMA is listed in the UFAC web site as a UFAC supporting organization.

Therefore, all newly introduced mattresses and upholstered furniture should be required to meet the appropriate smoldering ignition resistance tests.

Cost Impact: The code change proposal will not increase the cost of construction, as this is normal use.

Analysis: Standards NFPA 260 and 261 and DOC 16 CFR Part 1632 are currently referenced in the IFC.

ICCFILENAME: HIRSCHLER-F17-805.1.DOC

Public Hearing Results

Committee Action: Disapproved

Committee Reason: The proposal was disapproved related to concerns with enforceability. These provisions would be applicable to all occupancies which seemed too be broad and application. The proposed text would require that anytime furniture is taken from one building to another, such as one apartment building to another, that the furniture would need to meet this requirement.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment 1:

Marcelo M. Hirschler (GBH International) representing American Fire Safety Council, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

805.1 Ignition by cigarettes. <u>New</u> upholstered furniture ~~newly~~ introduced into occupancies regulated by this code shall comply with 805.1.1. ~~Mattresses newly introduced into occupancies regulated by this code shall comply with 805.1.2.~~

805.1.1 Upholstered furniture. ~~Newly introduced~~ <u>New</u> upholstered furniture shall be shown to resist ignition by cigarettes as determined by tests conducted in accordance with one of the following<u>:</u>

1. Mocked-up composites of the upholstered furniture shall have a char length not exceeding 1.5 inches (38 mm) when tested in accordance with NFPA 261.
2. The components of the upholstered furniture shall meet the requirements for Class I when tested in accordance with NFPA 260.

~~**805.1.2 Mattresses.** Newly introduced mattresses shall be shown to resist ignition by cigarettes as determined by tests conducted in accordance with DOC 16 CFR Part 1632 and shall have a char length not exceeding 2 inches (51 mm).~~

(Renumber subsequent sections)

Commenter's Reason: The technical committee was concerned that this could be considered to apply to used upholstered furniture that is being brought in from a relative or into a new occupancy (apartment to apartment). Such used items would not be covered with this language. The concern about used items is addressed in this comment by the language change from "newly introduced" to "new". This comment addresses upholstered furniture only.

It needs to be pointed out that the test for addressing cigarette ignition of residential furniture (NFPA 260) is the same test as the UFAC test (Upholstered Furniture Action Council test) that residential furniture manufacturers have been required by their trade association to comply with, on a voluntary basis, since 1978 and that such compliance is shown by the golden hangtags.

Also, NFPA 261 is the test that was originally developed by BIFMA (the Business & Institutional Furniture Manufacturer's Association, note that the original proposal misidentified the name of this association) for compliance by institutional upholstered furniture, on a voluntary basis.

Public Comment 2:

Marcelo M. Hirschler (GBH International) representing American Fire Safety Council, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

805.1 Ignition by cigarettes. ~~Upholstered furniture newly introduced into occupancies regulated by this code shall comply with 805.1.1.~~ New mattresses ~~newly~~ introduced into occupancies regulated by this code shall comply with 805.1.2.

~~**805.1.1 Upholstered furniture.** Newly introduced upholstered furniture shall be shown to resist ignition by cigarettes as determined by tests conducted in accordance with one of the following:~~

1. ~~Mocked-up composites of the upholstered furniture shall have a char length not exceeding 1.5 inches (38 mm) when tested in accordance with NFPA 261.~~
2. ~~The components of the upholstered furniture shall meet the requirements for Class I when tested in accordance with NFPA 260.~~

805.1.2 Mattresses. New~~ly~~ ~~introduced~~ mattresses shall be shown to resist ignition by cigarettes as determined by tests conducted in accordance with DOC 16 CFR Part 1632 and shall have a char length not exceeding 2 inches (51 mm).

(Renumber subsequent sections)

Commenter's Reason: The technical committee was concerned that this could be considered to apply to used mattresses that are being brought in from a relative or into a new occupancy (apartment to apartment). Such used items would not be covered with this language. The concern about used items is addressed in this comment by the language change from "newly introduced" to "new". This comment addresses mattresses only.

It needs to be pointed out that DOC 16 CFR Part 1632 is a requirement for all mattresses sold in the United States since the 1970s, as administered by the Consumer Product Safety Commission, for resistance to cigarette ignition. Therefore all new mattresses introduced in the US now would meet this requirement.

Final Action: AS AM AMPC____ D

F54-09/10

805.5 (New)

Proposed Change as Submitted

Proponent: Carl Ogburn, Chestnut Ridge Foam

Add new text as follows:

805.5 Group A-2 occupancies intended for food or drink consumption. The requirements of Sections 805.5.1 through 805.5.1.3 shall apply to Group A-2 occupancies intended for food or drink consumption.

805.5.1 Upholstered furniture. Newly introduced upholstered furniture shall meet the requirements of Sections 805.5.1.1 through 805.5.1.3

805.5.1.1 Ignition by cigarettes. Newly introduced upholstered furniture shall be shown to resist ignition by cigarettes as determined by tests conducted in accordance with one of the following:

1. Mocked-up composites of the upholstered furniture shall have a char length not exceeding $1^1/_2$ inches (38 mm) when tested in accordance with NFPA 261, or
2. The components of the upholstered furniture shall meet the requirements for Class I when tested in accordance with NFPA 260.

805.5.1.2 Heat release rate. Newly introduced upholstered furniture shall have limited rates of heat release when tested in accordance with ASTM E 1537 or California Technical Bulletin 133, as follows:

1. The peak rate of heat release for the single upholstered furniture item shall not exceed 80 kW.

   Exception: Upholstered furniture in rooms or spaces protected by an approved automatic sprinkler system installed in accordance with Section 903.3.1.1.

2. The total energy released by the single upholstered furniture item during the first 10 minutes of the test shall not exceed 25 MJ.

   Exception: Upholstered furniture in rooms or spaces protected by an approved automatic sprinkler system installed in accordance with Section 903.3.1.1.

805.5.1.3 Identification. Upholstered furniture shall bear the label of an approved agency, confirming compliance with the requirements of Sections 805.5.1.1 and 805.5.1.2.

Reason: CA TB 133, which is referenced in the IFC, is a standard issued by the California Bureau of Home Furnishings and Thermal Insulation (CBHF) and is equivalent to ASTM E 1537, with the pass/fail criteria contained in the proposal. This proposal would make the same requirements for bars and night clubs than is now used for some other occupancies, such as Groups I-1, I-2, I-3 and R-2. Experience shows that if a bar or night club is not sprinklered the potential for big fires is large. Approval of this proposal would ensure that furniture is not the cause of a big fire with many fatalities.

Cost Impact: CA TB 133 furniture is more expensive than standard furniture.

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The proposal was disapproved as it was felt that regulating furniture in this way in Group A occupancies intended for food or drink was overly restrictive and would be difficult to enforce. This would prohibit the use of antique furniture. Many of the occupancies would be required to be sprinklered and the phrase "food or drink" would include Group A-2 occupancies serving both alcoholic and non-alcoholic beverages.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Marcelo M. Hirschler (GBH International), requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

805.5 Group A-2 occupancies intended for ~~food or drink~~ consumption of alcoholic drinks. The requirements of Sections 805.5.1 through 805.5.1.3 shall apply to Group A-2 occupancies intended for ~~food or drink~~ consumption of alcoholic drinks.

805.5.1 Upholstered furniture. New ~~Newly introduced~~ upholstered furniture shall meet the requirements of Sections 805.5.1.1 through 805.5.1.3

805.5.1.1 Ignition by cigarettes. New ~~Newly introduced~~ upholstered furniture shall be shown to resist ignition by cigarettes as determined by tests conducted in accordance with one of the following:

1. Mocked-up composites of the upholstered furniture shall have a char length not exceeding $1^{1}/_{2}$ inches (38 mm) when tested in accordance with NFPA 261, or
2. The components of the upholstered furniture shall meet the requirements for Class I when tested in accordance with NFPA 260.

805.5.1.2 Heat release rate. New ~~Newly introduced~~ upholstered furniture shall have limited rates of heat release when tested in accordance with ASTM E 1537 or California Technical Bulletin 133, as follows:

1. The peak rate of heat release for the single upholstered furniture item shall not exceed 80 kW.

   Exception: Upholstered furniture in rooms or spaces protected by an approved automatic sprinkler system installed in accordance with Section 903.3.1.1.

2. The total energy released by the single upholstered furniture item during the first 10 minutes of the test shall not exceed 25 MJ.

Exception: Upholstered furniture in rooms or spaces protected by an approved automatic sprinkler system installed in accordance with Section 903.3.1.1.

805.5.1.3 Identification. Upholstered furniture shall bear the label of an approved agency, confirming compliance with the requirements of Sections 805.5.1.1 and 805.5.1.2.

Commenter's Reason: The technical committee was concerned about two key issues: (a) that this could be considered to apply to antique or used upholstered furniture that are being brought in from elsewhere and (b) that this would apply to Group A2 occupancies such as fast-food places and other occupancies that do not serve alcoholic beverages. Both concerns are addressed by the comment. Such antique or used items would not be covered with this language. The concern is addressed in this comment by the language change from "newly introduced" to "new". The concern about food and non alcoholic drinks is addressed in this comment by the language change to specifically address assembly occupancies intended for consumption of alcoholic drinks.

As stated by the proponent, experience shows that if a bar or night club is not sprinklered the potential for big fires is large. Approval of this proposal, as amended, would ensure that furniture is not the cause of a big fire with many fatalities.

Final Action: AS AM AMPC____ D

F55-09/10

805.5 (New)

Proposed Change as Submitted

Proponent: Carl Ogburn, Chestnut Ridge Foam

Add new text as follows:

805.5 Group E Occupancies other than day care facilities. The requirements of Sections 805.5.1 through 805.5.1.3 shall apply to Group E occupancies other than Group E day care facilities.

805.5.1 Upholstered furniture. Newly introduced upholstered furniture shall meet the requirements of Sections 805.5.1.1 through 805.5.1.3

805.5.1.1 Ignition by cigarettes. Newly introduced upholstered furniture shall be shown to resist ignition by cigarettes as determined by tests conducted in accordance with one of the following:

1. Mocked-up composites of the upholstered furniture shall have a char length not exceeding $1^1/_2$ inches (38 mm) when tested in accordance with NFPA 261; or
2. The components of the upholstered furniture shall meet the requirements for Class I when tested in accordance with NFPA 260.

805.5.1.2 Heat release rate. Newly introduced upholstered furniture shall have limited rates of heat release when tested in accordance with ASTM E 1537 or California Technical Bulletin 133, as follows:

1. The peak rate of heat release for the single upholstered furniture item shall not exceed 80 kW.

   Exception: Upholstered furniture in rooms or spaces protected by an *approved automatic sprinkler system* installed in accordance with Section 903.3.1.1.

2. The total energy released by the single upholstered furniture item during the first 10 minutes of the test shall not exceed 25 MJ.

   Exception: Upholstered furniture in rooms or spaces protected by an *approved automatic sprinkler system* installed in accordance with Section 903.3.1.1.

805.5.1.3 Identification. Upholstered furniture shall bear the label of an *approved* agency, confirming compliance with the requirements of Sections 805.5.1.1 and 805.5.1.2.

Reason: CA TB 133, which is referenced in the IFC, is a standard issued by the California Bureau of Home Furnishings and Thermal Insulation (CBHF) and is equivalent to ASTM E 1537, with the pass/fail criteria contained in the proposal. This proposal would make the same requirements for educational establishments (other than day care occupancies) than is now used for some other occupancies, such as Groups I-1, I-2, I-3 and R-

2. Educational facilities are ones where so many young people are potentially exposed and vulnerable. Approval of this proposal would ensure that furniture is not the cause of a big fire with many fatalities.

Cost Impact: CA TB 133 furniture is more expensive than standard furniture.

ICCFILENAME: OGBURN-F2-805.5-2.DOC

Public Hearing Results

Committee Action: Disapproved

Committee Reason: The proposal was disapproved as loss data was not presented to justify the regulation of furnishings in Group E occupancies. In addition, the more vulnerable occupants in Group E occupancies are excluded which are those found in Group E Daycare facilities. The committee also felt that the enforcement of these requirements would be difficult.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Marcelo M. Hirschler (GBH International), requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

805.5 Group E ~~Occupancies other than~~ day care facilities. The requirements of Sections 805.5.1 through 805.5.1.3 shall apply to ~~Group E occupancies~~ ~~**other than**~~ Group E day care facilities.

805.5.1 Upholstered furniture. New ~~Newly introduced~~ upholstered furniture shall meet the requirements of Sections 805.5.1.1 through 805.5.1.3

805.5.1.1 Ignition by cigarettes. New ~~Newly introduced~~ upholstered furniture shall be shown to resist ignition by cigarettes as determined by tests conducted in accordance with one of the following:

1. Mocked-up composites of the upholstered furniture shall have a char length not exceeding $1^1/_2$ inches (38 mm) when tested in accordance with NFPA 261; or
2. The components of the upholstered furniture shall meet the requirements for Class I when tested in accordance with NFPA 260.

805.5.1.2 Heat release rate. New ~~Newly introduced~~ upholstered furniture shall have limited rates of heat release when tested in accordance with ASTM E 1537 or California Technical Bulletin 133, as follows:

1. The peak rate of heat release for the single upholstered furniture item shall not exceed 80 kW.

   Exception: Upholstered furniture in rooms or spaces protected by an *approved automatic sprinkler system* installed in accordance with Section 903.3.1.1.

2. The total energy released by the single upholstered furniture item during the first 10 minutes of the test shall not exceed 25 MJ.

   Exception: Upholstered furniture in rooms or spaces protected by an *approved automatic sprinkler system* installed in accordance with Section 903.3.1.1.

805.5.1.3 Identification. Upholstered furniture shall bear the label of an *approved* agency, confirming compliance with the requirements of Sections 805.5.1.1 and 805.5.1.2.

Commenter's Reason: The technical committee was concerned about two key issues: (a) that this could be considered to apply to used upholstered furniture that are being brought in from elsewhere and (b) that this would apply to Group E occupancies that had lower risk factors than day-care facilities. Both concerns are addressed by the comment. Such used items would not be covered with this language. The concern is addressed in this comment by the language change from "newly introduced" to "new". The concern about day-care centers is addressed in this comment by the language change to restricting the application specifically to day-care facilities.

Final Action: AS AM AMPC____ D

F64-09/10
901.9 (New)

Proposed Change as Submitted

Proponent: Rick Sheets, Fire Committee Chair, Brinks Home Security, representing National Burglar and Fire Alarm Association

Add new text as follows:

901.9 Discontinuation or change of service. Notice shall be made to the fire code official whenever contracted alarm services for monitoring or testing or inspection of an existing fire alarm system are terminated for any reason, or a change in alarm monitoring provider or other service provider is made. Notice shall be made in writing, to the fire code official by the building owner and where required, by the alarm service provider being terminated.

Reason: It is, and should always remain, the responsibility of the commercial property owner to maintain their building(s) to code. The code prohibits the "removal of or tampering with equipment" and "appurtenances", and in 901.4 of this code states that "fire protection systems shall be maintained in accordance with the original installation standards for that system", yet no such language is provided for non-tangible services. Any contracted services for remote station monitoring and the required testing of equipment in place at the time of acceptance, could be cancelled after the Acceptance Test without notifying the code official. This is of concern for many reasons:

1. The alarm service provider of record may be replaced with non-licensed, non-registered, non-qualified and non-approved personnel or methods.
2. Due to non-payment of fees by the property owner, the alarm service provider may have stopped (or will soon stop) monitoring, repairing and testing of the fire alarm system.
3. If an alarm service provider no longer provides monitoring, repairing or testing services due to non-payment they cannot be seen by the code official as being at fault.

Since by code, the building owner is responsible for keeping their building and fire alarm system in proper working condition, part of that responsibility lies in the fact that they are paying their bills to their alarm service provider. In any other circumstance nonpayment is merely a contract dispute between customer and provider. However, since the service being provided is mandated by code (monitoring and testing) the service provider gets caught in the middle of a complex situation. The addition of this rule will provide the proper notifications to be made before discontinuance of required services.

While the impairment coordinator should be the one to inform the fire official of these types of changes, they may be reluctant to do so because they'd be admitting that these services have been stopped as a cost cutting measure. Allowing the alarm service provider to also notify the fire code official of imminent cessation of service provides a cross-check to ensure the proper continuation of services present at the time of acceptance remain in effect. If another service provider has been procured by the building owner this notification allows the fire code official an opportunity to make sure any required licenses and permits are in place.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: SHEETS-F6-901.8.2.DOC

Public Hearing Results

Committee Action: **Approved as Modified**

Modify the proposal as follows:

901.9 Discontinuation or change of service. Notice shall be made to the fire code official whenever contracted alarm services for monitoring or testing or inspection of an existing fire alarm system are terminated for any reason, or a change in alarm monitoring provider or other service provider is made. Notice shall be made in writing, to the fire code official ~~by the building owner and where required,~~ by the alarm service provider being terminated.

Committee Reason: The committee felt that it was necessary for the fire official to be notified when the alarm system was no longer being maintained or monitored. One concern was that the language as proposed would put this responsibility on the building owner which may be the one who does not understand the significance of the problem and would not notify the fire code official. Therefore a modification was made to remove the building owner and place the responsibility to contact the Fire official on the alarm service provider. This concept was equated to auto insurance companies notifying states when drivers fail to pay their premiums on their insurance.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Steve Orlowski representing National Association of Home Builders (NAHB), requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

901.9 Discontinuation or change of service. Notice shall be made to the fire code official whenever contracted alarm services for monitoring or testing or inspection of an existing fire alarm system are terminated for any reason, or a change in alarm monitoring provider or other service provider is made. Notice shall be made in writing, to the fire code official by the building owner. ~~by the alarm service provider being terminated.~~

Commenter's Reason: Since the beginning of most model codes, the owner has been the primary person responsible for the maintenance of all life safety and property protection systems within their building. This proposed change, based on the supporting reason statement had little to do with safety and continued service, but more so as a means for the service provider to utilize the code to force the owner to make payments. As for the modification made by the fire committee, taking the building owner out of the equation does little to support the responsibilities put upon the building owner in other sections of this code. If the building owner terminates service or hires another service provider, then it should be the responsibility of the building owner to insure that the local fire department or authority having jurisdiction is notified.

Public Comment 2:

Jeffrey M. Shapiro, PE, International Code Consultants, representing National Multi Housing Council, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

901.9 Discontinuation or change of service. For fire alarm systems required to be monitored by this code, notice shall be made to the fire code official whenever ~~contracted~~ alarm monitoring services ~~for monitoring or testing or inspection of an existing fire alarm system~~ are terminated ~~for any reason, or a change in alarm monitoring provider or other service provider is made~~. Notice shall be made in writing~~,~~ to the fire code official by the ~~alarm~~ monitoring service provider being terminated.

Commenter's Reason: The code does not require all fire alarm systems to be monitored, and for systems that are not required to be monitored, there is no reason that monitoring cannot be terminated without notifying the fire code official. When in doubt about whether monitoring is required, the alarm monitoring company could err on the side of conservatism and send a notice.

Likewise, because there is no requirement in the code that an owner contract with a fire alarm service provider to test or inspect a fire alarm system, requiring notice of terminating such a contract is beyond the scope of the code. Accordingly, the revised section has been limited to notification of discontinuance of required alarm monitoring services.

Final Action: AS AM AMPC____ D

F70-09/10
903.2.6 (IBC [F] 903.2.6)

Proposed Change as Submitted

Proponent: Roland J. Huggins, PE, American Fire Sprinkler Association, representing self

Revise as follows:

903.2.6 Group I. An *automatic sprinkler system* shall be provided throughout buildings with a Group I *fire area*.

> **Exception:** An *automatic sprinkler system* installed in accordance with Section 903.3.1.2 or 903.3.1.3 shall be allowed in Group I-1 facilities provided that:
>
> 1. A hydraulic design information sign is located on the system riser
> 2. Exception 1 of Section 903.4 is not applied
> 3. Systems installed in accordance with Section 903.3.1.3 shall be maintained in accordance with the requirements of Section 903.3.1.2.

Reason: This exception provides a very cost efficient system but an institutional facility is still a commercial facility and warrants a higher level of assurance that the system will work. An NFPA 13D system does not require any identification for the design basis of the system so others working on the system after installation need this information. Granted, building plans are supposed to be maintained, but often aren't and a system riser sign is often the only guidance available. Section 903.4 requires the system to be monitored so in case of fire the fire department is automatically notified. Exception #1 excludes systems in one-and two-family dwellings. Since Section 903.3.1.3 explicitly links NFPA 13D systems and one- and two-family dwellings, it is interpreted that Exception #1 applies to all 13D systems. Clarification is needed. As a final item, if the intent of the ICC is that these facilities be maintained to ensure adequate operation, guidance must be provided. Simply referencing Section 903.5 will not work since it references IFC which references NFPA 25. NFPA 13D systems are outside the scope of NFPA 25. The only maintenance and testing performed on an NFPA 13D system is provided by the homeowner.

Cost Impact: The code change proposal will have minimal impact on the cost of construction.

ICCFILENAME: HUGGINS-F1-903.2.5.DOC

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The committee felt that in order for a 13D system to be used in this application for Group I-1 occupancies that additional controls were necessary to increase the integrity of the system, therefore the proposal was approved as submitted.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Roland J. Huggins, American Fire Sprinkler Association, representing self, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

903.2.6 Group I. An *automatic sprinkler system* shall be provided throughout buildings with a Group I *fire area*.

Exceptions:

1. An *automatic sprinkler system* installed in accordance with Section 903.3.1.2 ~~or 903.3.1.3~~ shall be allowed in Group I-1 facilities ~~provided that:~~

   ~~1. A hydraulic design information sign is located on the system riser~~
   ~~2. Exception 1 of Section 903.4 is not applied~~
   ~~3. Systems installed in accordance with Section 903.3.1.3 shall be maintained in accordance with the requirements of Section 903.3.1.2.~~

2. An *automatic sprinkler system* installed in accordance with Section 903.3.1.3 shall be allowed in Group I-1 facilities when in compliance with all of the following:

   2.1. A hydraulic design information sign is located on the system riser
   2.2. Exception 1 of Section 903.4 is not applied, and
   2.3. Systems shall be maintained in accordance with the requirements of Section 903.3.1.2.

Commenter's Reason: This is just an editorial change to better comply with the standard format.

Final Action: AS AM AMPC____ D

F76-09/10
903.2.11.1.3 (IBC [F] 903.2.11.1.3)

Proposed Change as Submitted

Proponents: Tom Lariviere, Chairman, Joint Fire Service Review Committee; Alan Shuman, President, representing the National Association of State Fire Marshals (NASFM)

Revise as follows:

903.2.11.1.3 (IBC [F] 903.2.11.1.3) Basements. Where any portion of a *basement* is located more than 75 feet (22 860 mm) from openings required by Section 903.2.11.1, <u>or where walls, partitions or other obstructions are installed that restrict the application of water from hose streams,</u> the *basement* shall be equipped throughout with an *approved automatic sprinkler system*.

Reason: The purpose of the openings under Section 903.2.11.1 are for firefighting operations.

The firefighting purpose of these openings is to provide the ability to confine the fire in the basement from the exterior of the building. A basement fire can be especially dangerous to enter under fire conditions. Firefighters must be able to apply hose stream water from the exterior of the structure through these openings provided. This is particularly important in basements (below grade floors) since entry through a stairway would require firefighters to travel down into the heat and smoke that is trying to escape up and out the stairway.

When obstructions such as walls or partitions are installed in the basement, the ability to apply hose streams through these openings and reach the basement area is reduced or eliminated. The configuration and clear-opening requirements become useless when an interior wall or other obstruction is placed inside the basement. In that case, it is reasonable to require automatic fire sprinklers to provide adequate protection in the basement. This proposal requires that in the case of obstructions, the basement shall be provided with an approved automatic sprinkler system.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: LARIVIERE-F11-SHUMAN-F3-903.2.11.1.3.DOC

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The committee felt that this proposal clarified the intent of the code with regard to obstructions in the basement causing challenges to fire fighting operations. It should be noted that there was some concern from committee members that the present code language already addresses this hazard and this language is unnecessary.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Marshall A. Klein, requests Disapproval.

Commenter's Reason: There was no fire data submitted with this code proposal to justify that the existing code language, or its existing enforcement, under the present wording in the Code has been a problem. Even the Committee's reason stated a concern from the "…committee members that the present code language already addresses this hazard and this language is unnecessary…", so why change the Code?

This section was originally from the UBC Section 3802(b)(1) that goes back to the 1976 edition of the UBC/UFC. The UBC/UFC did not consider hose stream an issue. The 1997 UBC Commentary stated:

> **"The provisions requiring openings in the exterior walls do not extend beyond the exterior wall line into the building. Thus, the code does not dictate specific openings for interior partition arrangements because the normal openings provided through interior partitions provide adequate accessibility to all interior portions of the building"**

The IFC/IBC Commentary Handbooks further explains the application of this requirement very clearly as follows:

> **"Where obstructions such as walls or other partitions are present in any given story or basement, *the* walls *and partitions enclosing any room or space must have openings* that provide an equivalent degree of fire department access to that provided by the openings prescribed in Section 903.2.10.1 for exterior walls. If an equivalent degree of fire department access to all portions of the floor area is not provided, the story or basement would require an automatic sprinkler system."**

The added language to the code text could cause many of the code complying small basements in existing buildings, to now become non-compliant if renovated because one could argue that an existing opening in an interior wall with any door or window arrangement would not necessarily "…restrict the application of water from hose streams…". Therefore, the adoption of this proposal will adversely affect previously approved code complying small basements during later interior remodels.

With no supporting documentation of fire problems in existing buildings to show a need that the existing code language is not adequate, the new wording for application of hose streams will only create added code interpretation issues for code compliance in small basements in buildings. This is a solution to a problem that does not exist with the present code text as was even stated in the Committee's "soft" approval recommendation. This code proposal should be disapproved.

Final Action: AS AM AMPC____ D

F81-09/10

903.3.1.1.2 (New) [IBC [F] 903.3.1.1.2 (New)]

Proposed Change as Submitted

Proponent: Jeff Hugo, CBO, National Fire Sprinkler Association

Add new text as follows:

903.3.1.1.2 (IBC [F] 903.3.1.1.2) Sprinkler omissions Automatic sprinklers shall not be required to be installed in locations where NFPA 13 permits sprinklers to be omitted. The building shall still be considered equipped throughout.

Reason: The IBC requires that buildings using sprinklers for height/area increases and trade-offs (exceptions) to be sprinklered throughout. NFPA 13 also requires that the structure be sprinklered throughout (Section 8.1.1), unless specifically exempted by the standard. These areas that do not require sprinklers are commonly found in Chapter 8 of NFPA 13, and with these excepted areas, the building is still considered by the standard to be sprinklered throughout, which would comply with the requirements of the IBC.

One of the most common misinterpretations seen are canopies, exterior roofs and porte-cocheres being considered as a part of the main portion of the structure and therefore are being required to be sprinklered. The 2007 NFPA 13 clearly defines when sprinklers are required under the exterior roofs, canopies and porte-cocheres.

NFPA 13 (Section 8.15.7) is very specific on the sprinklering requirements in these appendages. All canopies, exterior roofs and porte-cocheres over 4' in width are required to be sprinklered unless:

- The canopy, roof, or porte-cochere is constructed with non-combustible, limited combustible, or fire retardant treated wood. (all fire retardant treated wood shall comply with NFPA 703)
- The underside (ceiling/eaves) of the canopy, roof, and porte-cochere of combustible construction provided the exposed finish material on the roof, canopy, or porte-cochere is non-combustible, limited combustible, or fire retardant treated wood, and the combustible concealed spaces (attic) is sprinklered, unless:
- The combustible concealed space is filled entirely with noncombustible insulation, or
- Ceilings that are noncombustible or limited combustible connected directly to joists with joist spaces not - exceeding 160 cubic feet, or
- If concealed spaces do not exceed 55 square feet in area.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: HUGO-F3-903.3.1.1.2.DOC

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee disapproved this item as they felt that the language explaining what is considered as fully sprinklered appeared unnecessary for the code. The committee noted that such issues are better addressed within the standard and in the commentary for the IBC and IFC.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Joseph Holland and Dave Bueche representing Hoover Treated Wood Products, Inc, request Approval as Submitted.

Commenter's Reason: Committee decision rested on their belief this belonged in the commentary. We disagree. This is an important issue. Obviously, proponent has been questioned about the term "fully sprinklered". That term is could cause confusion. This proposal clarifies the intent of the code and the NFPA 13 standard.

Final Action: AS AM AMPC____ D

F83-09/10

903.3.5.2 (IBC [F] 903.3.5.2)

Proposed Change as Submitted

Proponent: Phillip A. Brown, American Fire Sprinkler Association

Revise as follows:

903.3.5.2 (IBC [F] 903.3.5.2) Secondary water supply. ~~A~~ An automatic secondary on-site water supply equal to the hydraulically calculated sprinkler demand, including the hose stream requirement, shall be provided for high-rise buildings in Seismic Design Category C, D, E or F as determined by the *International Building Code*. An additional fire pump is not required. The secondary water supply shall have a duration of not less than 30 minutes as determined by the occupancy hazard classification in accordance with NFPA 13.

Exception: Existing buildings.

Reason: A statement needs to be added to this section clarifying that the secondary water supply must be automatic and cannot be from a source that has to be manually activated. The Commentary clarification that an additional fire pump is not required should also be brought forward into this section.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: BROWNP-F1-903.3.5.2.DOC

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The proposal was approved as the existing language could be interpreted as being a manual water supply when the intent is for an automatic water supply. This additional language will clarify the need for an automatic secondary water supply.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Lawrence G. Perry, AIA, representing Building Owners and Managers Association (BOMA) International, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

903.3.5.2 (IBC [F] 903.3.5.2) Secondary water supply. A ~~An automatic~~ secondary on-site water supply equal to the hydraulically calculated sprinkler demand, including the hose stream requirement, shall be provided for high-rise buildings in Seismic Design Category C, D, E or F as determined by the *International Building Code*. An additional fire pump is not required. The secondary water supply shall have a duration of not less than 30 minutes as determined by the occupancy hazard classification in accordance with NFPA 13.

Exception: Existing buildings.

Commenter's Reason: This code change should be modified as proposed for the following reasons:

1. The intent of the change is not clear. It appears that perhaps the intent is that the sprinkler water supply would automatically switch to the secondary supply upon loss of the primary water supply, but that is not at all clearly stated.
2. It is not clear that this has always been the intent of the code, if it has been the standard practice for secondary water supplies, or if it is even a wise design choice.
3. In the event of a significant earthquake that causes a break in the main water supply, the primary water supply will be lost, and it is possible that the building system could as least partially drain. If the secondary water supply is 'automatically' tapped, it appears to be quite possible that the secondary supply would then be lost through the same break.
4. Secondary water supply sources historically have included swimming pools, on-site ponds, and gravity tanks in buildings. "Automatically" tapping that supply upon any interruption (regardless of the time frame of the interruption or the current conditions in the building) appears to open the door to all kinds of potential problems.
5. The second portion of the change, clarifying that a second fire pump is not required for a secondary water supply, is good clarification of the intent of the code.

Public Comment 2:

Rick Thornberry, PE, The Code Consortium Inc, representing self, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

903.3.5.2 (IBC [F] 903.3.5.2) Secondary water supply. An automatic secondary on-site water supply ~~equal to~~ having a capacity not less than the hydraulically calculated sprinkler demand, including the hose stream requirement, shall be provided for high-rise buildings in Seismic Design Category C, D, E or F as determined by the International Building Code. An additional fire pump shall ~~is~~ not be required for the secondary water supply unless needed to provide the minimum design intake pressure at the suction side of the fire pump supplying the automatic sprinkler system. The secondary water supply shall have a duration of not less than 30 minutes as determined by the occupancy hazard classification in accordance with NFPA 13.

Exception: Existing buildings.

Commenter's Reason: The purpose of this Public Comment is to further clarify the intent of the original code change proposal, as well as the current Section 903.3.5.2, requiring the on-site water storage for automatic sprinkler/standpipe systems in high-rise buildings in Seismic Design Categories C, D, E, and F. We certainly agree that the on-site water storage needs to be automatically available should the normal water supply to the fire protection system be interrupted for whatever reason. And we also agree that there should be no need to provide an additional fire pump with the automatic water supply since it is intended to directly supply the existing fire pump provided as required by code. However, there may be cases where the on-site water supply is located such that a pump is required in order for the necessary flow and pressure to be maintained to the suction side of the fire pump provided for the original design of the automatic sprinkler/standpipe system so that the fire pump can function properly in order to provide the required flows and pressures to adequately support the system. So the code text should be revised as indicated in this Public Comment to make it clear that, generally, an additional fire pump is not required but may be necessary for the automatic secondary on-site water supply to adequately supply the fire pump provided for the original system design.

Public Comment 3:

Dave Frable, representing U.S. General Services Administration, requests Disapproval.

Commenter's Reason: A water supply is a source of water (e.g., a tank, lake, reservoir, well, etc. or a connection to a municipal water distribution system). Though the means for delivering water from a secondary supply source to where it's needed can be (and maybe should be) automatic (e.g., a fire pump that starts upon loss of pressure), the water supply itself can not be automatic. Regardless of the intent, we believe the new text confuses the issue, more than it helps convey the proponent's intent. If there is a desire to require the means for delivering the water supply from the secondary source be automatic, code language needs to be stated differently. Therefore, it's critical that this comment be accepted so the code change proposal as written is rejected.

Final Action: AS AM AMPC____ D

F87-09/10
904.1.1 (New) [IBC [F] 904.1.1 (New)]

Proposed Change as Submitted

Proponent: Tom Lariviere, Chairman, Joint Fire Service Review Committee

Add new text as follows:

904.1.1 (IBC [F] 904.1.1) Certification of service personnel for fire extinguishing equipment. Service personnel providing or conducting maintenance on *automatic fire extinguishing systems*, other than *automatic sprinkler systems*, shall possess a valid Certificate issued by an *approved* third party certification organization, an *approved* governmental agency, or other *approved* organization for the type of system and work performed.

Reason: This proposal will allow the code official to specify a minimum level of qualifications for servicing fire extinguishing systems. Ensuring technicians are qualified will enable communities to stay in compliance with the latest code regulations for fire extinguishing systems.

This proposal allows several options for the code official. The code official could choose to accept certification from a third party organization, a governmental agency, or any other organization. Formal certification for automatic fire extinguishing system technicians provides a mechanism for the technicians to demonstrate their knowledge of codes, standards, and related practices. The code official only needs to ascertain that the service technician has the proper certification.

Third party certification programs must meet a minimum acceptable standard that ensures a proper examination preparation. Certification programs provide a mechanism for fire code officials to use to evaluate individuals for the necessary knowledge. Certification programs from third party certification agencies should comply with Regulations and National Standards, such as:

- Uniform Guidelines on Employee Selection Procedures
- US Equal Employment Opportunity Commission (EEOC)
- Standards for Educational & Psychological Testing
- National Council on Measurement in Education (NCME)
- American Educational Research Association (AERA)
- American Psychological Association (APA)

Certification by governmental agency quite often is a certificate issued by a state agency. Similar to third party certifications, governmental certification must be specific to the type of work to be performed.

Certification by other organizations could consist of manufacturer training and certification programs. These certifications typically are only valid for the products from the specific manufacturer.

The code official has the option to determine which certification methods are acceptable, or even if multiple certifications are necessary. Requiring certified technicians helps protect public safety and promotes professionalism and expertise and helps ensure the competency of those individuals involved in the service industry.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: LARIVIERE-F12-904.1.1.DOC

Public Hearing Results

Committee Action: **Approved as Modified**

Modify proposal as follows:

904.1.1 (IBC [F] 904.1.1) Certification of service personnel for fire extinguishing equipment. Service personnel providing or conducting maintenance on *automatic fire extinguishing systems*, other than *automatic sprinkler systems*, shall possess a valid Certificate issued by ~~an *approved* third party certification organization,~~ an *approved* governmental agency, or other *approved* organization for the type of system and work performed.

Committee Reason: This proposal was approved as it was felt that certification programs are necessary and with this requirement such certification will be created. The modification simply removed the phrase "an approved third party certification organization" to provide more control to the jurisdiction.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Lawrence G. Perry, AIA, representing Building Owners and Managers Association (BOMA) International, requests Disapproval.

Commenter's Reason: This proposal should be disapproved for the following reasons:

1. There are currently no widely-recognized certification programs in place to be utilized for this proposed certification requirement. The Code Development Committee notes that 'with this requirement, such certification will be created'. Without programs already in place, with criteria that has been vetted and accepted, it is premature to add such a code requirement.
2. Existing 'certifications' run the gamut from short written programs to extensive hands-on training.
3. The proposed text would open the door to allowing inadequate certification programs being accepted, while they might not provide adequate levels of training.

Final Action: AS AM AMPC____ D

F94-09/10
906.1 (IBC [F] 906.1)

Proposed Change as Submitted

Proponent: Robert J Davidson, Code Consultant/Alan Shuman, President, representing the National Association of State Fire Marshals (NASFM)

Revise as follows:

906.1 (IBC [F] 906.1) Where required. Portable fire extinguishers shall be installed in the following locations.

1. In new and existing Group A, B, E, F, H, I, M, R-1, R-2, R-4 and S occupancies.

   ~~**Exception:** In new and existing Group A, B and E occupancies equipped throughout with quick response sprinklers, portable fire extinguishers shall be required only in locations specified in Items 2 through 6.~~

2. Within 30 feet (9144 mm) of commercial cooking equipment.
3. In areas where flammable or *combustible liquids* are stored, used or dispensed.
4. On each floor of structures under construction, except Group R-3 occupancies, in accordance with Section 1415.1.
5. Where required by the sections indicated in Table 906.1.
6. Special-hazard areas, including but not limited to laboratories, computer rooms and generator rooms, where required by the *fire code official*.

Reason: Fire extinguishers have historically been the first line of defense for small, controllable fires. They are intended to be used for fires of limited size and easily controlled. If a fire is discovered in its early stages the most effective means of protecting life and preventing property loss is to sound an alarm and then to control and/or extinguish the incipient stage fire with a portable fire extinguisher. To simply wait for the fire to grow to size large enough for a sprinkler head to activate is contrary to lessons and guidance from the fire service and fire protection professionals. Since fire extinguishers provide a first line of defense vs. sprinklers, it remains unclear as to the justification for this exception .In that light, the Exception 1 to Section 906.1 should be deleted.

This exception was not in the original draft of the International Fire Code and it did not exist in any of the legacy fire codes. It currently does not exist in NFPA 1 Uniform Fire Code, NFPA 10 Standard for Portable Fire Extinguishers or NFPA 5000 Building Construction and Safety Code. It first appeared in the Final Draft of the 2000 editions of the IFC/IBC. Since the first publication of the International Fire Code, some fire service and fire protection professionals have expressed concern over the inclusion of an exception.

As a result a number of states have deleted the exception upon adoption of the IFC/IBC.

12 States plus Washington D.C. and New York City have Deleted Line 1 Exception.
2 States have amended Section 906.1 and the exception to require more extinguishers
2 States use both NFPA 1 and the IFC with more stringent code applicable.
17 additional States have adopted NFPA 1 as their fire code instead of the IFC.

A total of 33 State jurisdictions and an unknown number of local jurisdictions have chosen to delete the exception in favor of providing the ability to control a fire at its earliest stages.

There are other issues with this exception that have arisen since states have now been adopting the IFC and enforcing it within their state. Some examples are:

The exception is not being interpreted correctly and as a result is not being limited to occupancies with “QUICK RESPONSE” sprinklers installed. Instead, it is being applied in all cases where “REGULAR” sprinklers are installed.

When an occupancy is being renovated and the sprinkler system is updated, presently installed extinguishers are being removed, lessening the level of protection available.

Fire code officials do not all see hazard areas the same and as a result Section 906.1, Item 6 is not consistently applied jurisdiction to jurisdiction.

Some officials are exempting all extinguishers from being required thereby placing the occupants in danger at the time of a fire.

An added detriment is that if a building is occupied without fire extinguishers the ability of the building owner to properly and effectively place fire extinguishers is negatively impacted by the practical difficulty of installing fire extinguisher cabinets. Walls may not be thick enough for recessing the cabinets to keep the fire extinguishers from being obstructions to travel or from being hit and damaged themselves. If the walls and partitions can handle the recessed cabinets, design drawings and permits may be required to modify the walls and partitions.

This proposal will eliminate the exception and provide for the proper placement of an important firefighting tool.

Cost Impact: The code change proposal will cause a cost increase in new construction.

ICCFILENAME: DAVIDSON-SHUMAN-F8-906.1.DOC

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The committee felt that even within sprinklered buildings fire extinguishers have made a difference in fighting fires therefore the exception for quick response sprinklers in Groups A, B and E occupancies was deleted. In addition people are used to seeing extinguishers within buildings and having them available for use.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Gene Boecker, Code Consultants Inc. representing the National Association of Theatre Owners, requests Disapproval.

Commenter's Reason: The proponent has not provided any indication of the number of jurisdictions that do not delete this exception, which can be assumed to be far greater than those that delete it. As a base code allowance, this has been in the codes for many years, and should not be deleted, since it is obviously adopted in many jurisdictions without problems.

Further, to address the following points from the original proponent:

• The exception is not being interpreted correctly and as a result is not being limited to occupancies with “QUICK RESPONSE” sprinklers installed. Instead, it is being applied in all cases where “REGULAR” sprinklers are installed.

Response: This is not a valid argument. If the exception is being misapplied to areas where ““REGULAR” sprinklers are installed”, changing the code is not a rational response. If the answer to each misapplied code exception is to delete it, then it follows that all exceptions should be removed from the code, since <u>any</u> exception could be misapplied. In fact, most of the code should be deleted if potential misapplication is a reason for deletion of text.

• When an occupancy is being renovated and the sprinkler system is updated, presently installed extinguishers are being removed, lessening the level of protection available.

Response: The protection is not being “lessened”. It is being addressed appropriately, since the current code language clearly allows this exception for existing buildings, based on the equivalent protection provided by the quick response sprinklers.

• Fire code officials do not all see hazard areas the same and as a result Section 906.1, Item 6 is not consistently applied jurisdiction to jurisdiction.

Response: The code clearly states the exception. As stated above, if the answer to each misapplied code exception is to delete it, then it follows that all exceptions should be removed from the code.

• Some officials are exempting all extinguishers from being required thereby placing the occupants in danger at the time of a fire.

Response: As stated above, if the answer to each misapplied code exception is to delete it, then it follows that all exceptions should be removed from the code. If there is a question regarding application, ICC can be contacted and the Code commentary can be reviewed for help.

As a base allowance, this has been in the codes for many years, since it is obviously adopted in many jurisdictions without problems. Based on this alone, the current exception should be retained.

Public Comment 2:

Dave Frable representing the US General Service Administration, requests Disapproval.

Commenter's Reason: We are strongly opposed to deleting the exception that permits new and existing Group A, B, and E occupancies protected throughout by quick response sprinklers, the exemption for installing portable fire extinguishers in certain areas of a building. It should be noted that this exception has been in the International Fire Code since 2000. Please see the Fire Code Committee's reason statement and note that the basis for the Fire Code Committee approving this code change proposal was strictly based on how they "Felt" and not based on any technical justification of fire loss data provided by the proponent. We also strongly believe that evacuation of the building should be the first action of the occupants in the subject occupancies, not fighting the fire.

The exception acknowledges the reliable advantages of an automatic sprinkler system designed to comply with NFPA 13. Group A, B and E occupancies are considered light hazard occupancies in NFPA 13. Light hazard occupancies must be protected with quick-response sprinklers (see Section 903.3.2). The faster-acting sprinklers and lower fuel load associated with Group A, B and E occupancies counter the need for portable fire extinguishers. Our desire is to have occupants evacuate the building whenever possible rather than having them put themselves in harms way in trying to fight the fire with a portable fire extinguisher. It should be noted that portable fire extinguishers are still required to be installed in specific areas within these occupancies where the fire risk warrants.

As stated earlier, no technical substantiation or fire loss data that justifies the need to delete this exception has been provided. In addition, I totally disagree with the proponent's inference that this exception alone is the single primary reason why 19 States have not adopted the IFC. We also disagree with the proponent's statement that this exception is placing occupants in danger at the time of a fire. On the contrary, we feel eliminating this exception the risk of injury of occupants attempting to extinguish a fire will increase.

It should also be noted that the Occupational Safety and Health Administration (OSHA), 29 CFR 1910.157(g)(1) , also addresses portable fire extinguishers by specifically stating: "Where the employer has provided portable fire extinguishers **<u>for employee use</u>** in the workplace, the employer shall also provide an educational program to familiarize employees with the general principles of <u>fire extinguisher use</u> and the hazards involved with incipient stage fire fighting." Therefore, if portable fire extinguishers have been installed in a building and have been designated for occupant use and incorporated into the building's fire safety plan, training would be required. However, if this protocol for occupants using portable fire extinguishers is not incorporated in the building's fire safety plan, no training would be required. Hence, the occupants will not be properly trained to use the subject portable fire extinguishers as the proponent and Fire Code Committee has suggested. Also, we have been informed by several fire department personnel that they also do not utilize the subject building's portable fire extinguishers for suppression purposes based on reliability issues.

As everyone knows, fire is a rare event; however, should a fire occur in these occupancies, the probability that all occupants are knowledgeable and have been trained proficiently in the use of portable fire extinguishers to effectively extinguish a fire is low. We also believe the cost associated with the installation of portable fire extinguishers in these occupancies is unjustified, taking into consideration maintaining the subject fire extinguishers for the life of the building. We believe these costs savings would be better expended active fire detection and suppression system.

Lastly, it should be pointed out that all previous Fire Code Committees disapproved similar proposed code changes in the past by stating there has been no technical justification presented indicating that the current exception presents an increased hazard to safety. Evacuation of the building should be the first action of the occupants in the subject occupancies, not fighting the fire.

Public Comment 3:

Rob Geislinger representing the Fire Marshals Association of Colorado, requests Disapproval.

Commenter's Reason: The exception which would be deleted by F94 has been in the International Fire Code since 2000. While the proponents identified a number of entities which have amended this exception out, many more have not. In fact, many jurisdictions believe the exception has significant merit by providing an additional economic incentive to a building owner who might not otherwise install fire sprinklers.

The proponents also indicated that this provision did not exist in the legacy codes. This is true. However, the legacy Uniform Fire Code required fire extinguishers in far less locations than the IFC. That Code required extinguishers only in proximity to specific hazards (I.e. asphalt kettles, motor vehicle fuel dispensing facilities, and temporary membrane structures). That Code contained no general requirement for fire extinguishers in A, B, or E occupancies unless specifically mandated for specific hazards. The IFC as written is thus more restrictive than UFC.

The proponents also brought up other reasons for deleting the section:

• "The exception is not being interpreted correctly and as a result is not being limited to occupancies with "QUICK RESPONSE" sprinklers installed. Instead, it is being applied in all cases where "REGULAR" sprinklers are installed." **Answer: This is a training issue for fire code officials. The fact is that many sections of the Code may be misinterpreted or misapplied.**

• "When an occupancy is being renovated and the sprinkler system is updated, presently installed extinguishers are being removed, lessening the level of protection available." **Answer: The lower RTI and faster response of QR sprinklers have been demonstrated to protect people even in the room of origin. Standard response sprinklers generally do not activate in time to protect people intimate with a fire. Also, any building being renovated with a quick response automatic fire sprinkler system is obviously safer than it was when it only had manual firefighting devices.**

• "Fire code officials do not all see hazard areas the same and as a result Section 906.1, Item 6 is not consistently applied jurisdiction to jurisdiction." **Answer: The Code includes many provisions that are not consistently applied between jurisdictions. Rather than a laundry list of hazardous locations, the exception provides reasonable guidance to a fire code official based upon specific hazards within an occupancy and jurisdiction.**

• "Some officials are exempting all extinguishers from being required thereby placing the occupants in danger at the time of a fire." **Answer: This would also be a training issue. Fire extinguishers are a necessary safety component where superior automatic suppression systems do not exist.**

The proponents' last justification was that building owners later choosing to voluntarily add fire extinguishers would be at a disadvantage and could compromise necessary fire separations and exiting. In fact, by removing this exception, the proponents will be creating these problems throughout the country as now extinguishers will be required in "new and *existing* Group A, B, E…, occupancies". Also, while some building owners choose to spend their money to exceed the requirements of the Code, most do not. If they so choose, the exception doesn't prohibit them from doing so.

Despite the fact that this provision has been in the Code since its inception, the proponents did not identify any cases where individuals were injured or killed by the lack of fire extinguishers in buildings with quick response sprinklers. On the other hand, NFPA documents numerous cases where individuals are injured or killed in attempting to extinguish fires. It is counterproductive to place a device for property protection in a building where most occupants have not been trained, the likelihood of injury is high, and a building system itself will respond to mitigate the hazard. The proponents' state: "To simply wait for the fire to grow to a size large enough for a sprinkler head to activate is contrary to lessons and guidance from the fire service and fire protection professionals." However, as fire professionals we should not be expecting untrained citizens to extinguish incipient fires. In fact, our message should be, "Get out!"

Public Comment 4:

Lawrence Perry representing the Building Owners and Managers Association, requests Disapproval.

Commenter's Reason: This code change should be disapproved for the following reasons.

1. The Committee reason states "the committee felt that even within sprinklered buildings, fire extinguishers have made a difference in fighting fires before the exception." What does that mean? The committee neither received nor presented any data showing lesser loss of life or lesser property damage in sprinklered buildings that also had portable fire extinguishers installed throughout.
2. The current code provides a safe workplace, and the proponents provide no evidence of an improvement in life safety by adding portable fire extinguishers; they would be hard pressed to do so, based on the excellent life-safety record of fully-sprinkiered office buildings. The proponents want you to support the initial expenditure for large quantities of portable fire extinguishers, possibly large quantities of cabinets to store them, and possibly alarm/monitoring devices to prevent tampering. In addition, they either anticipate that businesses will suddenly choose to then voluntarily choose to opt for the OSHA 'fight-the-fire' approach (contrary to current widespread practice), absorb the costs for training some/most/all of the buildings occupants, and also foot the ongoing costs of maintaining both the equipment and the training program. At what additional benefit?
3. Perhaps the proponents will claim that there are no training costs to be incurred, since the proposal doesn't require occupants to be trained. If that is the case, and large numbers of businesses continue to instruct their employees, as permitted by OSHA, to simply flee the building in the event of any fire, what exactly is the point of this code change? Besides selling a bunch of expensive equipment that comes with an ongoing upkeep fee, there appears to be none.
4. The Committee and the proponents ignore the fact that in many of the affected buildings, there is either a lack of opportunity to train building occupants in the use of portable fire extinguishers, or a significant risk in assigning a fire suppression obligation to building occupants. OSHA regulations require that if employees are expected to perform fire suppression duties, that they be properly trained; however, OSHA also allows a workplace to have a policy that employees are to EVACUATE and not perform any suppression activities. The 'evacuate' approach is widely used in the modern workplace. In a multi-tenant office building, building management has no mechanism to train every employee of every tenant space.
5. The potential risk to property due to some minor water damage from sprinkler activation to control a small fire is a preferred, and an acceptable, risk to the option of either providing equipment that occupants will be instructed not to use, or providing the equipment and then needing to 'deputize' every building occupant as a fire fighter.
6. For both A and E occupancies, also affected by this change, training of building occupants in the proper use of extinguishers is even more impractical, if not impossible.

Final Action: AS AM AMPC____ D

F95-09/10
906.1 (IBC [F] 906.1)

<u>Proposed Change as Submitted</u>

Proponent: Steven Orlowski, National Association of Home Builders

Revise as follows:

906.1 (IBC [F] 906.1) Where required. Portable fire extinguishers shall be installed in the following locations.

1. In new and existing Group A, B, E, F, H, I, M, R-1, R-2, R-4, and S Occupancies.

   Exception: In new and existing Group A, B, ~~and~~ E <u>and R-2</u> occupancies equipped with quick response sprinklers, portable fire extinguishers shall be required only in locations specified in Items 2 through 6.

2. Within 30 feet (9144 mm) of commercial cooking equipment.
3. In areas where flammable or *combustible liquids* are stored, used, or dispensed.
4. On each floor of structures under construction, except R-3 occupancies, in accordance with Section 1415.1.
5. Where required by the sections indicated in Table 906.1.
6. Special-hazard areas, including but not limited to, laboratories, computer rooms and generator rooms where required by the *fire code official*.

Reason: Both the International Building Code and the International Fire Code specifically require that all new R occupancies, which are considered light hazard according to NFPA 13, are equipped with quick-response or residential type automatic sprinklers. In addition, NFPA 13 permits some R occupancies to install an automatic suppression system in accordance to NFPA 13 R, when the structure does not exceed 4 stories in height. The purpose for requiring the quick response heads in group A, B, E and R-2 occupancies is to lower the operating temperature for the suppression system to react during the incipient stage of a fire emergency. This provides additional time for the occupants to evacuate the structure and achieve the overall desire for the occupant to evacuate the structure rather than fight the fire and put themselves at unnecessary risk.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: ORLOWSKI-F1-906.1.DOC

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The proposal was disapproved to be consistent with the action on code change F94-09/10 that deleted the exception for quick response sprinklers. In addition, it was felt that there have been many situations in Group R-2 dormitories where extinguishers have been necessary.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jeffrey Shapiro, International Code Consultants, representing National Multi Housing Council, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

906.1 Where required. Portable fire extinguishers shall be installed in the following locations.

1. In new and existing Group A, B, E, F, H, I, M, R-1, R-2, R-4 and S occupancies.

   Exception<u>s</u>:

   1. In new and existing Group A, B <u>and</u> E ~~and R-2~~ occupancies equipped throughout with quick-response sprinklers, portable fire extinguishers shall be required only in locations specified in Items 2 through 6.
   2. <u>In R-2 occupancies, portable fire extinguishers shall be required only in locations specified in Items 2 through 6 where each dwelling unit is provided with a portable fire extinguisher having a minimum rating of 1-A:10-B:C.</u>

2. Within 30 feet (9144 mm) of commercial cooking equipment.
3. In areas where flammable or combustible liquids are stored, used or dispensed.
4. On each floor of structures under construction, except Group R-3 occupancies, in accordance with Section 1415.1.
5. Where required by the sections indicated in Table 906.1.
6. Special-hazard areas, including but not limited to laboratories, computer rooms and generator rooms, where required by the fire code official.

Commenter's Reason: Existing IFC Table 906.3(1) would require fire extinguishers in an R-2 occupancy (considered a Light Hazard Occupancy for fire extinguisher design) to be a minimum of 2A rated (maximum floor area per unit of A is 3000 sq. ft) and no more than 75' to reach the fire extinguisher. Some jurisdictions measure the travel distance to a fire extinguisher from within the dwelling unit to the fire extinguisher placed in the common corridor of the building, and others from the dwelling unit's entrance door to the fire extinguisher placed in the common corridor of the building. Either way the fire extinguishers are placed in the common corridor that would require the occupant to leave the dwelling unit to get the fire extinguisher to use.

Based on NFPA Fire Reports for fires in apartment buildings (2003-2007 Annual Averages), out of the 38,000 fires/year in apartment buildings, 60% of the fires originate within the dwelling unit, and only about 14% in the common areas of the building that would not be covered by Item #3 or #6 in current Section 906.1. The largest numbers of fires in apartment buildings originate in the kitchen, bedrooms, and living rooms so it makes more sense to locate the fire extinguisher closer to the areas within the dwelling unit where the great majority of the fires occur than outside the dwelling unit. Even if a fire is outside the dwelling unit, it seems more likely that the occupant will be able to get to, and use, the fire extinguisher located in his/her dwelling unit, than finding the fire extinguisher in the common corridor.

In addition, there has always been a problem with vandalism and pilfering of fire extinguishers in common corridors of apartment buildings, as well as issues involving the size and weight of such fire extinguishers if an elderly apartment resident were to attempt using one.

This proposed public comment would permit the placement of a fire extinguisher within each dwelling unit to provide rapid access and use by the dwelling unit occupants to an incipient fire in the dwelling unit where a fire would more likely occur. The size and rating of the fire extinguisher would be appropriate for the residential environment. The size of a dwelling unit is typically well under the 3000 sq. ft. rating for a 1A rated fire extinguisher (most dwelling units are in the 750-1000 sq. ft. range) so there is a large safety factor for justifying the minimum 1A-10B:C rating.

Finally, it makes more sense to put extinguishers in dwelling units, as opposed to common areas, because we don't want occupants re-entering a unit that is on fire after they've already left. It's preferable to provide an extinguisher for ready access in the unit, versus encouraging someone to leave the unit to get an extinguisher and then return to fight a fire.

Final Action: AS AM AMPC____ D

F96-09/10
906.3 (New) [IBC [F] 906.3 (New)]

Proposed Change as Submitted

Proponent: Tom Lariviere, Chairman, Joint Fire Service Review Committee

Add new text as follows:

<u>**906.3 (IBC [F] 906.3) Certification of service personnel.** Service personnel providing or conducting maintenance shall possess a valid Certificate issued by an *approved* third party certification organization, an *approved* governmental agency, or other *approved* organizations for the type of work performed.</u>

(Renumber subsequent sections)

Reason: This proposal will allow the code official to specify a minimum level of qualifications for servicing portable fire extinguishers. Ensuring technicians are qualified will enable communities to stay in compliance with the latest code regulations for portable fire extinguishers.

This proposal allows several options for the code official. The code official could choose to accept certification from a third party organization, a governmental agency, or any other organization. Formal certification for portable fire extinguisher technicians provides a mechanism for the technicians to demonstrate their knowledge of codes, standards, and related practices. The code official only needs to ascertain that the service technician has the proper certification.

Third party certification programs must meet a minimum acceptable standard that ensures a proper examination preparation. Certification programs provide a mechanism for fire code officials to use to evaluate individuals for the necessary knowledge. Certification programs from third party certification agencies should comply with Regulations and National Standards, such as:

- Uniform Guidelines on Employee Selection Procedures
- US Equal Employment Opportunity Commission (EEOC)
- Standards for Educational & Psychological Testing
- National Council on Measurement in Education (NCME)
- American Educational Research Association (AERA)
- American Psychological Association (APA)

Certification by governmental agency quite often is a certificate issued by a state agency. Similar to third party certifications, governmental certification must be specific to the type of work to be performed.

Certification by other organizations could consist of manufacturer training and certification programs. These certifications typically are only valid for the products from the specific manufacturer.

The code official has the option to determine which certification methods are acceptable, or even if multiple certifications are necessary. Requiring certified technicians helps protect public safety and promotes professionalism and expertise and helps ensure the competency of those individuals involved in the service industry.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: LARIVIERE-F15-906.3.DOC

Public Hearing Results

Committee Action: **Approved as Modified**

Modify the proposal as follows:

906.3 (IBC [F] 906.3) Certification of service personnel. Service personnel providing or conducting maintenance shall possess a valid Certificate issued by ~~an *approved* third party certification organization,~~ an *approved* governmental agency, or other *approved* organizations for the type of work performed.

Committee Reason: The committee approved this proposal to be consistent with the action taken on code change F87-09/10. In addition, it will provide more leeway for the jurisdiction to ask for a certain level of qualifications. The modification was the same as that made for code change F87-09/10 which deleted the phrase “”an approved third party certification organization” to provide more control to the jurisdiction.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Lawrence G. Perry, AIA, representing Building Owners and Managers Association (BOMA) International, requests Disapproval.

Commenter's Reason: This proposal should be disapproved for the following reasons:
1. There are currently no widely-recognized certification programs in place to be utilized for this proposed certification requirement. The Code Development Committee, in their approval of similar item F87-09/10, notes that 'with this requirement, such certification will be created'. Without programs already in place, with criteria that has been vetted and accepted, it is premature to add such a code requirement.
2. Existing 'certifications' run the gamut from short written programs to extensive hands-on training. The proposed text would open the door to allowing inadequate certification programs being accepted, while they might not provide adequate levels of training.
3. For this item, part of the Committee reason for approval was that "it will provide more leeway for the jurisdiction to ask for a certain level of qualifications'. This works both ways: while some jurisdictions may develop a very high 'certification' requirement, "certified" to an inappropriate standard will lead to nothing more than an appearance of appropriately trained personnel.

Final Action: AS AM AMPC____ D

F102-09/10
907.2.1.1 (IBC [F] 907.2.1.1)

Proposed Change as Submitted

Proponent: Gene Boecker, Code Consultants, Inc., representing self

Revise as follows:

907.2.1.1 (IBC [F] 907.2.1.1) System initiation in Group A occupancies with an occupant load of 1,000 or more. Activation of the fire alarm in Group A occupancies ~~with an~~ <u>where the</u> occupant load ~~of~~ <u>due to the assembly occupancy</u> is 1,000 or more shall initiate a signal using an emergency voice/alarm communications system in accordance with Section 907.6.2.2. <u>Group A occupancies not separated from one another in accordance with Section 707.3.9 of the *International Building* Code shall be considered as a single occupancy for the purposes of applying this section.</u>

> **Exception:** Where *approved*, the prerecorded announcement is allowed to be manually deactivated for a period of time, not to exceed 3 minutes, for the sole purpose of allowing a live voice announcement from an *approved*, constantly attended location.

Reason: Section 508 of the IBC already addresses the extent of application for conditions where there are differing occupancy groups. The revised language recognizes that and makes reference back to that section of the code. There has been a question about how to apply the 1,000 occupants. If the 1,000 occupants are all in a single room, it is clear. However, it is not clear how the people in different parts of the building are combined to reach the threshold of 1,000.

For example: There are 250 assembly occupants in a small restaurant at one end of a hotel and sports bar with an occupant load of 120 in a separate location. At the other end of the hotel is a conference center with an occupant load of 700. It is not clear from the code whether those people should be added together or not; and, if not, under what conditions. The code will now be clear that the areas must be separated using the mixed occupancy provisions if there are other occupancies between them or by a fire barrier if the areas adjoin one another.

The exception is unaffected by the proposal.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: BOECKER-F2-907.2.1.1.DOC

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee disapproved the proposal with concern that this approach, which was used in code change F100-09/10, is not considered appropriate due to the large occupant loads addressed by this section.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Gene Boecker, Code Consultants Inc, representing The National Association of Theatre Owners, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

907.2.1.1 (IBC [F] 907.2.1.1) System initiation in Group A occupancies with an occupant load of 1,000 or more. Activation of the fire alarm in Group A occupancies where the occupant load due to the assembly occupancy is 1,000 or more shall initiate a signal using an emergency voice/alarm communications system in accordance with Section 907.6.2.2~~. Group A occupancies not separated from one another in accordance with Section 707.3.9 of the *International Building* Code shall be considered as a single occupancy for the purposes of applying this section.~~

Exception<u>s :</u>

1. <u>Group A occupancies that do not share any portion of the same exit access system shall not be required to be considered as a single occupancy for the purposes of applying this section.</u>
2. Where *approved*, the prerecorded announcement is allowed to be manually deactivated for a period of time, not to exceed 3 minutes, for the sole purpose of allowing a live voice announcement from an *approved*, constantly attended location.

Commenter's Reason: The committee felt that the missing concept in this proposal was the issue of assembly occupancies that share the exit access portions of the means of egress. Where such occupancies share exit access, and the aggregate occupant loads of such occupancies exceed 1,000, the committee felt that the requirements for voice alarm should be applied. However, should such occupancies use separate exit access components, the committee felt that each occupancy would be permitted to be evaluated separately. This proposal addresses these concerns and comments.

Final Action: AS AM AMPC____ D

F106-09/10
907.2.2.1 (IBC [F] 907.2.2.1)

Proposed Change as Submitted

Proponent: Rick Sheets, Fire Committee Chair, Brinks Home Security, representing National Burglar and Fire Alarm Association

Revise as follows:

907.2.2.1 (IBC [F]907.2.2.1) Group B ambulatory health care facilities. *Fire areas* containing Group B ambulatory health care facilities shall be provided with an electronically supervised automatic smoke detection system installed within the ambulatory health care facility and in public use areas outside of tenant spaces, including public *corridors* and elevator lobbies.

> ~~**Exception:** Buildings equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1 provided the occupant notification appliances will activate throughout the notification zones upon sprinkler water flow.~~

Reason: Delete Exception.

Another new occupancy has been defined under the "B" Business category, called "Ambulatory Health Care Facilities". (304.1) These facilities are defined as buildings or portions of buildings providing medical, surgical, psychiatric or nursing care less than 24 hours a day to persons incapable of self-preservation (i.e. 'put under' for minor surgery etc.). These occupancies, covered in 907.2.2.1, need an automatic smoke detection system installed in the Ambulatory Health Care Facility plus in their public use areas, corridors and elevator lobbies including all the public areas on other floors outside the AHCF area, ...except if the building is sprinkled and its activation causes the (required) occupant notification appliances to activate.

The problem with allowing this exception is that by code, heat detectors (which is what a sprinkler head is) are not, and never have been, permitted to replace smoke detectors for protection of life. Heat detectors are not life-safety devices in any code or standard because they do not provide the early warning needed for the safe evacuation of occupants. Sprinklers have a great reputation for saving lives only when used along with early detection provided by smoke detectors.

Cost Impact: The code change proposal will increase the cost of construction $.30 per square foot.

ICCFILENAME: SHEETS-F1-907.2.2.1.DOC

Public Hearing Results

Committee Action: Disapproved

Committee Reason: The proposal which would have removed the exception allowing sprinklers in lieu of smoke detection was disapproved as it would take away the incentive for sprinklers. In addition since the section is so new it should first have a chance to be applied before being revised.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Rick Sheets representing National Burglar and Fire Alarm Association, requests Approval as Submitted.

Commenter's Reason: The committee action was to disapprove F106 because it was felt that removing the exception took away the sprinkler incentive. The proposal did not ask to remove the sprinklers, just to provide smoke detectors in addition to the sprinklers. Smoke detectors provide much earlier warning of a fire emergency than sprinklers. While sprinklers will certainly reduce the fire growth, since many occupants of the AHCF occupancy may need assistance in evacuating if necessary, staff should be given the maximum amount of warning. Life safety can be greatly improved by providing both smoke detection and fire sprinklers.

A number of studies validate this, such as:

"Measurement of Room Conditions and Response of Sprinklers and Smoke Detectors During a Simulated Two-Bed Hospital Patient Room Fire", Notarianni, Kathy A., 1993, NISTIR 5240, Gaithersburg, MD: National Institute of Standards and Technology, July.

Notarianni noted:

> *"Sprinklers in all locations tested actuated before the patient's life would be threatened by this nominally 65 kW fire for the closed door, closed door privacy curtain, and open door privacy curtain tests. However, in the shielded fire test, the sprinklers at locations S6 and S1, the standard sidewall across from the foot of patient bed #2, and the EC sidewall, on the east wall near the bathroom, respectively, activated after the life safety criterion in HAZARD I with regard to temperature was exceeded. Ionization and photoelectric detectors in all locations alarmed before the patient's life would be threatened."*

Structure Fires in Residential Board and Care, Jennifer Flynn, NFPA Fire Analysis and Research, Quincy, MA, December 2009
U.S. Fire departments responded to an estimated average of 2,070 structure fires in residential board and care facilities annually during 2003-2007. These fires caused annual averages of:
• 10 civilian deaths
• 70 civilian injuries
• $10.9 million in direct property damage

Smoking materials caused 3% of fires but 63% of the civilian deaths.
• Fires that started on mattress or bedding material caused 44% of the civilian deaths in these properties.
• Structure fires in these properties peak between 4 and 7 p.m.
• Saturday was the peak day for fires in these properties.

Public Comment 2:

Thomas Hammerberg representing Automatic Fire Alarm Association, requests Approval as Submitted.

Commenter's Reason: The committee action was to disapprove F106 because it was felt that removing the exception took away the sprinkler incentive. The proposal did not ask to remove the sprinklers, just to provide smoke detectors in addition to the sprinklers. Smoke detectors provide much earlier warning of a fire emergency than sprinklers. While sprinklers will certainly reduce the fire growth, since many occupants of the AHCF occupancy may need assistance in evacuating if necessary, staff should be given the maximum amount of warning. Life safety for fire fighters and occupants can be greatly improved by providing both smoke detection and fire sprinklers.

F107-09/10
907.2.3 (IBC [F] 907.2.3)

Proposed Change as Submitted

Proponent: Robert J Davidson, Code Consultant/Alan Shuman, President, representing the National Association of State Fire Marshals (NASFM)

Revise as follows:

907.2.3 (IBC [F] 907.2.3) Group E. A manual fire alarm system that ~~activates~~ initiates the occupant notification signal utilizing an emergency voice/alarm communication system meeting the requirements of Section 907.6.2.2 and installed in accordance with Section 907.6 shall be installed in Group E occupancies. When automatic sprinkler systems or smoke detectors are installed, such systems or detectors shall be connected to the building fire alarm system.

Exceptions:

1. A manual fire alarm system is not required in Group E occupancies with an occupant load of ~~less than 50~~ 30 or less.
2. Manual fire alarm boxes are not required in Group E occupancies where all of the following apply:
   - 2.1. Interior corridors are protected by smoke detectors.
   - 2.2. Auditoriums, cafeterias, gymnasiums and similar areas are protected by heat detectors or other approved detection devices.
   - 2.3. Shops and laboratories involving dusts or vapors are protected by heat detectors or other approved detection devices.
   - ~~2.4. The capability to activate the evacuation signal from a central point is provided.~~
   - ~~2.5. In buildings where normally occupied spaces are provided with a two-way communication system between such spaces and a constantly attended receiving station from where a general evacuation alarm can be sounded, except in locations specifically designated by the fire code official.~~
3. Manual fire alarm boxes shall not be required in Group E occupancies where the building is equipped throughout with an approved automatic sprinkler system installed in accordance with Section 903.3.1.1, the ~~notification appliances~~ emergency voice/alarm communication system will activate on sprinkler waterflow and manual activation is provided from a normally occupied location.

Reason: Group E occupancies mix a high concentration of children with fuel loads on a daily basis. As budgets shrink, so do the number of adult supervisors. Our children are in schools because they are required to be there. We owe them a duty to ensure they are safe from the risk of fire while in school. We simply cannot wait for a catastrophe to protect children while at school.

Unfortunately the world of elementary, secondary and higher education learning has gone through tremendous changes in security measures undertaken, both operationally and hardware installations, due to the threat of violent acts committed against students and staff. Where we had educational facilities with highly effective fire drill evacuation procedures and actions during system activation, we now have written plans and training in place to ignore the activation of the fire alarm system if a "lockdown" has been declared because the activation of the fire alarm system may be a diversion to bring staff and students out into the open to serve as victims.

This is not a possible situation. This is a very real situation that occurs throughout the country in response to the acts of violence that have occurred at educational facilities. Though the exact procedure may vary site to site, the main premise of a "lockdown" is to gather staff and students into classrooms and offices and to lock the doors, preventing intruders from getting into the room and preventing staff and students from leaving the rooms until an all clear is announced. The staff and students are trained to ignore a fire alarm activation during a lockdown until they are ordered to evacuate after someone in authority, (could be a Principal or could be a Police Commander), makes a determination that the fire threat is real and that they must evacuate to survive the fire.

Once the students and staff ignore the fire alarm, there needs to be a reliable method of communicating the message that now is the time to evacuate. PA systems that do not meet appropriate standards of care for installation or maintenance related to reliability at the time of a fire emergency do not satisfy that need. To address this issue this proposal would require the installation of a emergency voice/alarm communications system installed in accordance with the code and referenced standards. Recognizing that there is a related increase in the cost of construction Section 907.5.2.2 allows that system to be used for other announcements to eliminate the need for a public address system for that purpose.

Section 907.2.3, Exception one has been modified to correlate the occupant load triggers, Items 2.4 and 2.5 would be redundant since the emergency voice/alarm communications system would meet those two requirements and Exception 3 was modified to correlate with the new language in 907.2.3.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: DAVIDSON-SHUMAN-F2-907.2.3.DOC

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The committee felt that this proposal was necessary as schools are dealing with a host of threats such as fires and tornados and in more recent history an increase in school lockdown situations. This provides a better method of communication during emergencies than traditional fire alarm and occupant notification systems

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Lawrence G. Perry, AIA, representing Building Owners and Managers Association (BOMA) International, requests Disapproval.

Commenter's Reason: This code change proposal, which would require emergency voice alarm systems in any Group E occupancy with more than 30 occupants, should be disapproved for the following reasons:

1. This is an onerous requirement for small schools, with no sensible rationale. A school of 30 or so students could be as small as 1000 square feet or so. What is the point of an emergency voice alarm system in such a small building? Are you going to have one zone at the fingerpaint station and a separate one at the snack table?
2. In larger schools, a two-way communication system is typically installed between each classroom and a central control point (typically the main office), so that administrative staff can communicate with teachers (and vice versa), summon students, make and announcements on a classroom or school-wide basis. Current code recognizes this system, allowing the deletion of manual pull stations in spaces served by such a system. This code change deletes the exception, and removes any incentive for providing these two-way communication systems. What is the increase in protection provided by replacing a two-way system with a one-way system?
3. This change adds a significant cost to all affected Group E buildings. In the current economic climate, with jurisdictions faced with significant budget shortfalls, code changes that add to the cost of new (or renovated) school buildings will simply lead to less new construction and less modernization of existing buildings. This change has not been shown to offer any significant increase to life safety in Group E occupancies, and should therefore, not be a financial burden passed on to local communities.
4. One of the primary reasons given in support of this change was that in some cases, schools have put in place policies that instruct staff and students not to immediately evacuate upon activation of the fire alarm signal. First, a decision by some unclear number of facilities should not become the basis of a major change to all future construction. Second, this concern has been more appropriately been addressed by changes that were processed last cycle, and are already contained in Section 404.3.3 of the IFC. Any facility wishing to put in place any sort of 'lockdown plan' is required to receive approval of the fire department. This package of provisions includes a requirement that any lockdown plan include a means of 'two-way communication' between each secured area and a central control point. With this provision in the code already, what is the purpose of adding an expensive 'one-way' communication system to the same buildings?

Final Action: AS AM AMPC____ D

F109-09/10

907.2.9 (IBC [F] 907.2.9), 907.2.9.3 (New) [IBC [F] 907.2.9.3 (New)]

Proposed Change as Submitted

Proponent: William Freer, Fire Protection Specialist, NYS Office of Fire Prevention and Control

1. Revise as follows:

907.2.9 (IBC [F] 907.2.9) Group R-2. Fire alarm systems and smoke alarms shall be installed in Group R-2 occupancies as required in Section 907.2.9.1 ~~and 907.2.9.2~~ through 907.2.9.3.

907.2.9.3 ([F] 907.2.9.3) Group R-2 college and university buildings. An automatic smoke detection system that activates the occupant notification system in accordance with Section 907.6 shall be installed in Group R-2 college and university buildings in the following locations:

1. Common spaces outside of dwelling units and sleeping units
2. Laundry rooms, mechanical equipment rooms, and storage rooms
3. All interior corridors serving sleeping units or dwelling units.

Required smoke alarms in dwelling units and sleeping units in Group R-2 college and university buildings shall be interconnected with the fire alarm system in accordance with NFPA 72.

Exception: An automatic smoke detection system is not required in buildings that do not have interior corridors serving sleeping units or dwelling units and where each sleeping unit or dwelling unit either have a *means of egress* door opening directly to an exterior *exit access* that leads directly to an *exit* or a *means of egress* door opening directly to an exit.

Reason: This code change would add new requirements to the code. The current code only requires single and multiple station smoke alarms in new R-2 student housing. Single and multiple station smoke alarms are not required to be connected to a building fire alarm which would evacuate the building in event of a fire or smoke condition. They are also not required to be in all areas of the building which have been shown to be frequent areas of ignition. In a study completed by the New York State Governor's Task Force on Campus Fire Safety it was cited that 43% of fires in college dormitories are located in dorm rooms or kitchens, leaving the other 57% to be located in areas that would not require smoke detection under the current code. The study also showed that there were approximately 300 fires on college campus over a 3 year period while only 160 and were reported to the Fire Department. The Center for Campus Fire Safety reports 99 deaths have been "reported" in fires in student housing since 2000. An NFPA study on student housing showed 3,300 structural fires in Dormitories, Fraternities, Sororities and Barracks between 2002-2005. Since 1980 there has been an increase of 3% in reported fires in dormitory type occupancies, while there has been a 52% decrease in overall reported structural fires. New York State has required Fire Alarm and detection system in new dormitories since 2003 and has not had any deaths reported in these buildings since that change.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: FREER-F2-907.2.9.DOC

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The committee approved the proposal due to the unique hazards that are present in Group R-2 college and university buildings. More specifically, there are often more common areas than found in other types of Group R-2 occupancies where occupants congregate. Also it is not uncommon to have activities such as cooking in these common areas.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jeffrey Shapiro, International Code Consultants, representing National Multi Housing Council, requests Disapproval.

Commenter's Reason: The justification for approving this proposal failed to consider the inclusion of residential fire sprinkler systems in cited fire statistics, and it failed to look at whether the existing requirement for manual fire alarm systems adequately addresses the need for a supplemental evacuation warning.

Of greater concern however, is the lack of consideration for the increased number of alarms that will be associated with placing smoke detectors in common areas and dorm rooms that will ultimately lead students to ignore the alarm system. Consider that small dorm rooms with cooking equipment (microwaving popcorn being one example) will take very little time to fill with enough smoke to activate the alarm system.

Finally, there is a concern with respect to defining exactly what constitutes "college and university buildings." Are these only buildings that are owned by the school, or do they include off-campus housing. If off-campus housing is included, at what point does the tenant population's student percentage cause the building to differ from any other apartment building? Granted, the code already uses this text in Chapter 4 for emergency planning, but that is a far less ominous requirement to leave vague than what is proposed here.

With all of these concerns and the lack of a comprehensive basis of justification, the proposal should be rejected.

Final Action: AS AM AMPC____ D

F110-09/10

907.2.9.2 (New) [IBC [F] 907.2.9.2 (New)]

Proposed Change as Submitted

Proponent: Ken Kraus, Los Angeles Fire Department

Add new text as follows:

907.2.9.2 (IBC [F] 907.2.9.2) Automatic smoke detection system. An automatic smoke detection system that activates the occupant notification system in accordance with Section 907.6 shall be installed through out all interior corridors serving 10 or more dwelling units.

> **Exception:** An automatic smoke detection system is not required in buildings that do not have interior *corridors* serving *dwelling units* and where each *dwelling unit* has a *means of egress* door opening directly to an *exit* or to an exterior *exit access* that leads directly to an *exit*.

Reason: Automatic fire alarm systems are currently required, with exception, within interior corridors in R-1 Occupancies, e.g., Hotels and Motels. While Apartment buildings represent, in some respects, hazards similar to those found in R-1 Occupancies, they represent distinct and extenuating conditions that warrant similar protectives. Specifically:

Non transient occupants in R-2 Occupancies utilize cooking appliances to a much greater extent than R-1 Occupants.
R-2 occupants disable smoke alarms since low voltage and false alarms represent a continual nuisance.
R-2 occupants are much more likely to prop open required fire protection assemblies (for ventilation) than occupants in hotels and motels.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: KRAUS-F1-907.2.9.2.DOC

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: This proposal to add an automatic smoke detection system to Group R-2 occupancies was disapproved as it appeared to be too restrictive. In addition, these requirements would be applicable more often than the manual fire alarm requirements. Group R-1 occupancies require both manual and automatic fire alarm systems but the occupants found in such occupancies are generally more unfamiliar with the building and necessitate this higher level of protection.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Thomas P. Hammerberg, Automatic Fire Alarm Association Inc, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

907.2.9.2 (IBC [F] 907.2.9.2) Automatic smoke detection system. An automatic smoke detection system that activates the occupant notification system in accordance with Section 907.6 shall be installed throughout all interior corridors serving ~~10~~ 16 or more dwelling units.

> **Exception:** An automatic smoke detection system is not required in buildings that do not have interior *corridors* serving *dwelling units* and where each *dwelling unit* has a *means of egress* door opening directly to an *exit* or to an exterior *exit access* that leads directly to an *exit*.

Commenter's Reason: One of the reasons the committee action was to disapprove F110 was because it would have been more restrictive than the manual fire alarm box requirements. Changing the number of dwelling units from 10 to 16 corrects that. Smoke detectors provide early warning of a fire emergency. Apartments with interior corridors are not that much different than hotels with interior corridors. The IFC requires smoke detectors in corridors of hotels regardless of whether or not the building is sprinklered. It is a known fact that sleeping occupants need more time to react to an alarm, regardless of whether they are sleeping in an apartment or a hotel. Due to the slower response to a fire emergency by occupants who are sleeping, the earliest possible warning must be provided to save more lives. Other factors to consider include the fact that escape time has decreased from approximately 17 minutes to 3 minutes in residential applications and recent studies showing difficulty in awakening the elderly and young children. The more time we allow for reaction, the safer it will be.

There are numerous studies on human behavior during fires. A couple of examples are:

“Evacuation Time and Movement in Apartment Buildings”, Guylene Proulx, Fire Safety Journal, 1995.
“Awakening of Sleeping People – a Decade of Research”, Ian Thomas & Dorothy Bruck, Fire Technology, 2008.

Public Comment 2:

Thomas P. Hammerberg, Automatic Fire Alarm Association Inc, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

907.2.9.2 (IBC [F] 907.2.9.2) Automatic smoke detection system. <u>In addition to smoke alarms required by Section 907.2.11.2,</u> an automatic smoke detection system that activates the occupant notification system in accordance with Section 907.6 shall be installed throughout all interior corridors serving 10 or more dwelling units.

> **Exception:** An automatic smoke detection system is not required in buildings that do not have interior *corridors* serving *dwelling units* and where each *dwelling unit* has a *means of egress* door opening directly to an *exit* or to an exterior *exit access* that leads directly to an *exit*.

Commenter’s Reason: The additional language to the beginning of this proposed section was added to ensure there were no interpretation issues. More specifically, the language is intended to clarify that the smoke detection system in the corridors was in addition to smoke alarms in the rooms, not a replacement for them.

Final Action: AS AM AMPC____ D

F111-09/10
907.2.10.2 (IBC [F] 907.2.10.2)

<u>Proposed Change as Submitted</u>

Proponent: Rick Sheets, Fire Committee Chair, Brinks Home Security, representing National Burglar and Fire Alarm Association

Revise as follows:

907.2.10.2 (IBC [F] 907.2.10.2) Automatic smoke detection system. An automatic smoke detection system that activates the occupant notification system in accordance with Section 907.6 shall be installed in corridors, waiting areas open to corridors and habitable spaces other than sleeping units and kitchens.

Exception~~s~~:

~~1.~~ ~~Smoke detection in habitable spaces is not required where the facility is equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1.~~

~~2.~~ An automatic smoke detection system is not required in buildings that do not have interior corridors serving sleeping units and where each sleeping unit has a means of egress door opening directly to an exit or to an exterior exit access that leads directly to an exit.

Reason: Exception #1 should be deleted.

Background: A new R-4 occupancy has been defined under the “B” Business category, called “Ambulatory Health Care Facilities”. (AHCF, 304.1) These facilities provide medical, surgical, psychiatric or nursing care less than 24 hours a day to persons incapable of self-preservation (i.e. ‘put under’ for minor surgery etc.). These occupancies, covered in 907.2.2.1, need an automatic smoke detection system installed in the Ambulatory Health Care Facility area, plus in their public use areas, corridors and elevator lobbies for all the public areas located outside the AHCF area. While we see the need for a new occupancy type, we cannot see where sprinklers are permitted to replace required smoke detection.

Problem:

First, it seems that this exception doesn’t simply allow smoke detection to be omitted; it seems to allow the “smoke detection” to be omitted from an “automatic smoke detection system.” Doesn’t this mean that virtually no system will be installed, since the manual boxes required by 907.2.10.1 are also allowed to be omitted in sprinklered buildings? Isn’t this pushing the sprinkler reliance a little too far?

Secondly, sprinkler heads are essentially fixed-temperature heat detectors. Smoke detectors required in other parts of the ICC codes only permit heat detectors to be used where the environment is not suitable for the use of smoke detectors. It is not reasonable to expect the occupants and staff of these facilities to wait until a smoldering/small fire generates enough heat to activate a sprinkler head, when the environment allows early warning to be used. Section 907.2.10.1 indicates there won’t even be manual pull boxes at the exits, even if the fire is soon discovered by an occupant. We are also confident most fire departments would rather be informed of smoke rather than told that a sprinkler system is currently trying to control a fire.

The fire alarm and detection community has watched as manual pull boxes are permitted to be omitted, but this is the first time automatic smoke detection is permitted to be omitted. Please stop this dangerous trend and provide the early warning needed for the safe evacuation of these occupants. Sprinkler are not perfect and they do have a great reputation for saving lives, but they provide the best chances for survival when used along with the early warning provided by smoke detectors.

Cost Impact: This code change proposal would increase the cost by $0.15 to $0.30 per square foot.

ICCFILENAME: SHEETS-F2-907.2.10.2.DOC

Public Hearing Results

Committee Action: Disapproved

Committee Reason: The reason provided by the proponent for this revision did not correlate well with the proposal and adequate justification for elimination of the exception when the facility is sprinklered throughout in accordance with NFPA 13 was not provided. Additionally, it was felt that the resulting level of protection if the exception was eliminated appeared to be overly restrictive.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Rick Sheets, SET National Burglar and Fire Alarm Association, requests Approval as Submitted.

Commenter's Reason: The committee action was to disapprove F111 because it was felt that removing the exception took away the sprinkler incentive. The proposal did not ask to remove the sprinklers, just to provide smoke detectors in addition to the sprinklers. Smoke detectors provide much earlier warning of a fire emergency than sprinklers. While sprinklers will certainly reduce the fire growth, since many occupants of the AHCF occupancy may need assistance in evacuating if necessary, staff should be given the maximum amount of warning. Life safety can be greatly improved by providing both smoke detection and fire sprinklers.

A number of studies validate this, such as:

"Measurement of Room Conditions and Response of Sprinklers and Smoke Detectors During a Simulated Two-Bed Hospital Patient Room Fire", Notarianni, Kathy A., 1993, NISTIR 5240, Gaithersburg, MD: National Institute of Standards and Technology, July.

Notarianni noted:

> *"Sprinklers in all locations tested actuated before the patient's life would be threatened by this nominally 65 kW fire for the closed door, closed door privacy curtain, and open door privacy curtain tests. However, in the shielded fire test, the sprinklers at locations S6 and S1, the standard sidewall across from the foot of patient bed #2, and the EC sidewall, on the east wall near the bathroom, respectively, activated after the life safety criterion in HAZARD I with regard to temperature was exceeded. Ionization and photoelectric detectors in all locations alarmed before the patient's life would be threatened."*

Structure Fires in Residential Board and Care, Jennifer Flynn, NFPA Fire Analysis and Research, Quincy, MA, December 2009
U.S. Fire departments responded to an estimated average of 2,070 structure fires in residential board and care facilities annually during 2003-2007. These fires caused annual averages of:
• 10 civilian deaths
• 70 civilian injuries
• $10.9 million in direct property damage

Smoking materials caused 3% of fires but 63% of the civilian deaths.
• Fires that started on mattress or bedding material caused 44% of the civilian deaths in these properties.
• Structure fires in these properties peak between 4 and 7 p.m.
• Saturday was the peak day for fires in these properties.

Public Comment 2:

Thomas Hammerberg, Automatic Fire Alarm Association, requests Approval as Submitted.

Commenter's Reason: The committee action was to disapprove F111 because it was felt the resulting level of protection was overly restrictive with the exception removed. Smoke detectors provide much earlier warning of a fire emergency than sprinklers. While sprinklers will certainly reduce the fire growth, since many occupants of the R-4 occupancy may need assistance in evacuating if necessary, staff should be given the maximum amount of warning. Life safety for both fire fighters and occupants can be greatly improved by providing both smoke detection and fire sprinklers.

A number of studies validate this, such as:

"Measurement of Room Conditions and Response of Sprinklers and Smoke Detectors During a Simulated Two-Bed Hospital Patient Room Fire", Notarianni, Kathy A., 1993, NISTIR 5240, Gaithersburg, MD: National Institute of Standards and Technology, July.

Notarianni noted:

• Fires that started on mattress or bedding material caused 44% of the civilian deaths in these properties.
• Structure fires in these properties peak between 4 and 7 p.m.
• Saturday was the peak day for fires in these properties.

Koffel, William E., 2005, "Reliability of Automatic Sprinkler Systems," SUPDET Conference, Quincy, MA: Fire Protection Research Foundation. Sprinklers operated in almost 88% of 50,000 fire incidents in apartments. These did not include fires where the fire was deemed to be too small or where sprinklers were absent from the area of fire origin. In the residential fires where the sprinklers operated, they extinguished the fire in 19% of the incidents, providing support for Koffel's following statement:

> *"While property loss and life loss are greatly reduced in buildings protected with an automatic sprinkler system, the sprinkler system alone is not providing the entire increased protection."*

907.2.11 (IBC [F] 907.2.11)

Proposed Change as Submitted

Proponents: Joseph Fleming, Deputy Chief, Boston Fire Department, representing The Boston, MA Fire Department; Sean DeCrane, Cleveland Fire Department representing the Cleveland, OH Fire Department and the International Association of Fire Fighters

PART I – IFC

Revise as follows:

907.2.11 (IBC [F] 907.2.11) Single and multiple-station smoke alarms. *Listed* single- and multiple-station photoelectric smoke alarms complying with UL 217 shall be installed in accordance Sections 907.2.11.1 through 907.2.11.4 and NFPA 72.

Reason: (**Fleming)** According to the United States Fire Administration (http://www.usfa.dhs.gov/downloads/pdf/tfrs/v5i1.pdf) 37% of fire fatalities occur with operational smoke alarms and another 21% occur with disabled alarms. The use of photoelectric alarms, as opposed to alarms using ionization technology could reduce both by ½. This would reduce fire deaths in the U.S. by approximately 25% which translates into over 750 lives saved each year. The following information supports this estimated benefit.

1. There are some fires were smoke alarms/detectors cannot provide a benefit: arson fires in egress paths, victims intimate with flaming fires, explosions, etc. In addition, it is unlikely that smoke alarms/detectors provide the critical warning to occupants who are awake. As a consequence, when discussing smoke alarms, we should focus our attention on the types of fires where the smoke alarm can provide a crucial benefit to occupants not on all the types of fires that occur. The vast majority of fires where a smoke alarm/detector can help occupants are smoldering fires started when the victim is asleep.

> *Smoke detectors should be able to save at least 60% and possibly 75% of sleeping victims, but only 13% of victims who were awake.* (McGuire, J., Ruscoe, B., The Value of a Fire Detectors in the Home, Fire Study No. 9, National Research Council of Canada, Division of Building Research, Ottawa, Ont., Canada, December, 1962.)
> *"Delayed discovery, typically associated with fires that occur at night when everyone is asleep, also tends to be a characteristic of the smoldering fire caused by discarded smoking material. These smoldering fires are the leading causes of US fire fatalities and detectors are ideally designed to deal with them.* ("A Decade of Detectors", Fire Journal 09/85, John Hall - NFPA.)

2. In flaming fires the ionization alarm/detector is faster than the photoelectric by 30-50 seconds. This extra time is virtually irrelevant to alert occupants. For example, in the recent smoke alarm testing involving flaming cooking fires (http://smokealarm.nist.gov/pdf_files/SmokeDetectors_Q&As_Feb2008.pdf), which is the most common type of flaming fire, although the photo was 30-50 seconds slower than the ionization it still provided on average over 10 minutes warning. It has often been said that in a fire "seconds count." However it is hard to imagine a scenario were the extra seconds provided by the ionization in the most common type of flaming fires makes a difference for life safety, when the photoelectric is already providing on average over 10 minutes of Available Safe Egress Time. As a consequence, although photoelectric alarms/detectors respond later in flaming fires this is a quantitative as opposed to a qualitative advantage. Here are some quotes from researchers.

> *The advantage of ionization smoke detectors during flaming fires is only about a 15-20 second earlier warning. This margin will only be decisive for the loss of human life in extraordinary circumstances. In general the difference between the alarm times for the optical and the ionization detectors are reduced when the detection is made from an adjacent room. (*Meland, Oysten, and Lonuik, Lars, "Detection of Smoke - Full Scale Tests with Flaming and Smouldering Fires, "Fire Safety Science," - Proceedings of the Third International Symposium, July, 1991,)
>
> *Under the conditions of ignition from flames, the ionization chamber type detector exhibited a greater sensitivity to the smoke produced than the photoelectric system. However, the rate of generation of smoke was so great that the extra time given by the ionization chamber as a result may be of little practical use. (*R., (Riley, K., and Rogers, S., "A Study of the Operation and Effectiveness of Fire Detectors Installed in the Bedrooms and Corridors of Residential Institutions", Fire Research Station, Fire Research Current Paper 26/78, Borehamwood, England, April 1978.)

3. In smoldering fires the photoelectric is faster than the ionization by 30 minutes or more. This extra time is critical for sleeping occupants. If the ionization was consistently providing adequate warning, it would not matter that it was slower than the photoelectric. Unfortunately it doesn't. According to NIST's testimony to the Boston City Council), *"ionization alarms may not always alarm even when a room is filled with smoke from a smoldering fire."* In addition, according to data collected by NIST Report during smoldering fires the ionization smoke alarm often provided less than 1-2 minutes of Available Safe Egress Time. (1-2 minutes is the minimum time needed for sleeping occupants to escape.) In fact the ionization, in many cases, was providing negative available safe egress time. (http://smokealarm.nist.gov/pdf_files/StatementfortheRecordWG1finalsmokealarmstatement.pdf

   This finding has been noted by many other researchers.

> *Ionization chamber type detectors, in the room of origin and the corridor, did not, in the smoldering fire tests, provide adequate warning that the escape route was impassable or that conditions in the room were potentially hazardous to life. (*R., Riley, K., and Rogers, etc.)
>
> *"This test will show that most photoelectric detectors, operated by battery will detect smoke at about 1.5-3% smoke, which is good. The test will show that the photoelectric detectors operated by household current will activate between 2 and 4 %, which is still good. But, the test also will show that many ionization detectors will not activate until the smoke obscuration reaches 10-20 and sometimes 25%. … Therefore, because of the present state of the art in detecting smoke, the Subcommittee on Smoke Detectors can take no other course but to recommend the installation of photoelectric detectors."* ("Residential Smoke Alarm Report - Prepared by Special Automatic Detection Committee of the International Association of Fire Chiefs," The International Fire Chief, September 1980.)
>
> The tests i.e. the CALCHIEFS Tests, being commented upon in the previous quote were conducted by the Los Angeles Fire Dept. They concluded that photoelectrics were the preferred smoke alarm for all hallways and bedrooms. ("An Evaluation of Fire Detectors for Residential Placement," Los Angeles City Fire Dept., Fire Prevention Bureau – Research Unit, August 1981.)
>
> *"Photoelectric detectors sighted in the hallway are more effective for detecting smoldering smoke than ionization detectors, providing adequate escape time for most conditions of size and location of the smoke sources. Ionization detectors sited in the hallway generally provide inadequate escape times unless smoke movement into the hallway is slowed down by narrow door openings, causing a slower loss of visibility, or unless they are sited close to the smoke source." (* P.F. Johnson and S. K. Brown, "Smoke Detection of Smoldering Fires in a Typical Melbourne Dwelling," *Fire Technology,* Vol. 22, No. 4, 1986, pp. 295-340.)
>
> *"The ionization detectors detected smoke from a smoldering fire much later than optical (photoelectric) detectors. When the particular conditions during the fire development are taken into consideration there are reasons to indicate that this detection principle would not provide adequate safety during this type of fire".* (Meland, Oysten, and Lonuik, Lars, "Detection of Smoke - Full Scale Tests with Flaming and Smouldering Fires, "Fire Safety Science," - Proceedings of the Third International Symposium, July, 1991, pp. 975-984.)

4. In addition to being inadequate at providing adequate warning in smoldering fires, several researchers have identified that the ionization smoke alarm is far more susceptible to disablement due to nuisance alarms than is the photoelectric. Here are some quotes from the recent NIST Smoke Alarm Report. http://smokealarm.nist.gov/

   Additionally a separate study of nuisance alarm sources was conducted because this was identified as an important issue in a prior study by the U.S. Consumer Product Safety Commission. It was observed that ionization alarms had a propensity to alarm when exposed to nuisance aerosols produced in the early stages of some cooking activities, prior to noticeable smoke production. This phenomenon could be particularly vexing to homeowners who experience such nuisance alarms. … While one third of the smoke detectors did not work on the initial test, half of these were made operational by restoring power. Homeowners interviewed revealed that most of these were intentionally disconnected due to nuisance alarms, mostly from cooking.

   For the Toasting Scenario the ionization located near the kitchen responded in about 130-150 seconds. The photoelectric responded in 225-300. In fact according to NIST, *"Photoelectric alarm thresholds were met only after item started to char and produce visible smoke."* So although both responded, it is much more likely that the ionization will repeatedly respond to most normal toasting and be more likely to be disabled..

   Here are some recent quotes by other researchers on nuisance alarms.

> *"Homes with ionization alarms had more than 8 times the rate of false alarms as those with photoelectric. In small rural residences, photoelectric smoke alarms have lower rates of false alarms and disconnections." (*Perkins, M., "Ionization and

photoelectric smoke alarms in rural Alaskan homes," Western Journal of Medicine, 2000;173:89-92 (Contact: Alaska Injury Prevention Center, Anchorage, AK.))

*"We favor photoelectric detectors to reduce rates of nuisance alarms from cooking and to provide optimal protection from cigarette related fires." (*Kuklinski, D., Berger, L., Weaver, J., "Smoke detector Nuisance Alarms: A Field Study in a Native American Community," NFPA Journal; Sept/Oct. 1995.)

*"On direct observation at first follow-up, ionization study alarms were more likely to be non-functional, 20% ionization vs. 5% photoelectric, with the most common reason being a disconnected or absent battery." (*Mueller, B., et al, "Randomized controlled trial of ionization and photoelectric smoke alarm functionality," Injury Prevention, 2008; 14:80-86.)

Even smoke alarm manufacturers are aware of the benefits of photoelectric technology. (They just do a very poor job of communicating this to consumers.)

*"The optical smoke alarm therefore is less likely to react to the results of cooking and this makes it far more suitable for installation near kitchens or in confined spaces such as bed sits. The slight price differential between the two types of alarms can be balanced out by the elimination of false alarms being triggered by nearby kitchens and bathrooms." "*Domestic smoke alarms – a guide for specifiers," Bendall, D. (BFK Brands Europe), Fire Prevention 281 July/August 1995.

"Never install ionization smoke alarms in areas where cooking fumes, open fires and products of combustion are present. Where these conditions occur and a smoke alarm must be installed, a photoelectric alarm is the best option."
http://www.kidde.com.au/utcfs/kid/How+Smoke+Alarms+Work.html

5. Combination alarms/detectors have the potential to provide the quickest response to both smoldering and flaming fires but due to the excessive nuisance alarms from the ionization part of the alarm/detector, they should not be allowed near kitchens and bathrooms. In addition, the minor advantage that ionization or combination have over photoelectric in flaming fires is marginal and probably not critical.

   To quote a study (Mueller et al) cited earlier, *"An alarm containing both technologies is more expensive; it may also be more likely rendered non-functional if either technology causes frequent nuisance alarms. Our results suggest that installing photoelectric alarms on main floors of homes similar to those in our study may increase the proportion of functioning alarms and therefore provided longer term protection,"*

   Other items to consider:

   I am not aware of any "wireless alarms" that come as combination (photo/ion).

   Both ion and photo are sold with 10 year batteries. Are Combination (ion/photo)?

   Combination CO/Smoke come with CO/Ion or CO/Photo. Is there a Combo Smoke Alarm/CO?

   Why require dual in sprinkled occupancies when, according to the USFA, the only type of fire that can kill someone is a smoldering fire? "*Even though fire sprinklers are effective life safety devices you still need smoke alarms. Some fires can begin as smoldering fires that produce smoke and gases but don't generate enough heat to activate the sprinklers. Smoke alarms are needed to provide warning for these situations."*
   (http://www.usfa.dhs.gov/citizens/all_citizens/home_fire_prev/manufactured/sprinklers-mh.shtm)

6. I would like to mention that based on this research the Australasian Fire Authorities Council has recommended the use of photoelectric smoke alarms as opposed to ionization or combination.

   http://www.afac.com.au/__data/assets/pdf_file/0020/3674/AFACSmokeAlarmposition1June2006.pdf

7. Precedents for this action.

   a. Since 1998 the Massachusetts State Building Code has mandated photoelectric smoke alarm within 20 feet of a kitchen or bathroom due to the propensity of ionization smoke alarms to experience nuisance alarms.
   b. Since 2002 **NFPA 72 (the National Fire Alarm Code)** has only allowed ionization smoke alarms near kitchens if they were equipped with a silence button. The NFPA 72 committee has finally recognized the advantage that photoelectric smoke alarms have in regards to nuisance alarms. However I take exception to their assumption that a "hush button" neutralizes the ionizations propensity for nuisance alarms. No study has shown these to be effective at reducing disablement of ionization alarms. http://www.nfpa.org/assets/files/PDF/ROP/72-A2009-ROC.pdf (Page 72-249)
   c. **New Vermont Law** – Photoelectric-only type of smoke alarms are required to be installed in the vicinity of any bedrooms and on each level of a dwelling, for all new dwellings and dwellings that are sold or transferred, beginning January 1, 2009. http://www.dps.state.vt.us/fire/heating/photoelectric.html
   d. **Massachusetts has voted to Change the State Fire Code** so that as of January 1, 2010, smoke alarms with only ionization technology will not be allowed to meet the code. http://www.realtown.com/massachusettsrealestate/blog/massachusetts-smoke-detector-laws-changing
   e. **The 7th Edition of the Massachusetts State Building Code** was updated so that as of January 1, 2008 smoke alarms with only ionization technology will not be allowed to meet the code. http://www.ludlow.ma.us/building/permit_applications/life-safety-systems-app.pdf

This presentation included analyses of: 1) 30 years of smoke detector studies, 2) the National Institute of Standards Smoke Detector Project, 3) statistic regarding the effectiveness of smoke detectors, ands 4) the effectiveness of Underwriter's Labs Smoke Detector Approval Standard, UL217.)
3. Fleming, J., *"Smoke Detectors and the Investigation of Fatal Fires,"* Published in May 2000 issue of "Fire & Arson Investigator", the official magazine of International Association of Arson Investigators. (Also published on Interfire.org, an Arson Resource Website – posted 02/01.)

Reason: (DeCrane) I do not want to get into me too testimony, even during the reason statement, and my colleague Joseph Fleming from the Boston Fire Department has written an extensive Reason Statement. This will make it difficult to go in depth referencing various reports as Chief Fleming has provided the technical substantiation for this code change.

As a representative of the International Association of Fire Fighters (IAFF), I represent the professional fire fighters of North America. At the IAFF's most recent convention, the Union representatives of over 280,000 professional fire fighters across the United States and Canada, with representatives from the United Kingdom, Australia and New Zealand, voted unanimously to support he requirement of photoelectric smoke detectors.

The representatives, of those who respond to difficult fire scenes involving thousands of fatalities, have determined it is time to move forward with the requirement of photoelectric smoke detectors. Countless times our members have responded to residential fires and removed victims who had disabled their detectors due to nuisance alarms. Tragically many of these families forgot to replace the batteries or reinstall the hard wire detector when they were finished cooking. Unfortunately in many incidents these occupants, or a loved one, ended up paying the ultimate price for their forgetfulness, or some may argue, the lack of the detector industry addressing the problem.

On behalf of the nation's professional fire fighters we request your support for this code change.

Cost Impact: (**Fleming)** The code change proposal will not increase construction costs in any meaningful manner. The cost difference between ionization and photoelectric is minimal, particularly when one considers the benefit.

Cost Impact: (DeCrane) The code change proposal will minimally increase construction costs.

ICCFILENAME: FLEMING-DECRANE-F1-907.2.11

Public Hearing Results

PART I- IFC
Committee Action: Disapproved

Committee Reason: The committee disapproved the code change as they felt that the standards development process should address concerns with the performance of smoke alarms. There was also a concern that by stating a specific type of technology, future technologies could potentially be limited. Finally, there appeared to be conflicting data on the performance of ionization and photoelectric smoke alarms with the reason statement.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Joseph Fleming, Deputy Chief, Boston Fire Department, representing The Boston, MA Fire Department, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

907.2.11 (IBC [F] 907.2.11) Single and multiple-station smoke alarms. *Listed* single- and multiple-station ~~photoelectric~~ smoke alarms complying with UL 217 shall be installed in accordance with Sections 907.2.11.1 through 907.2.11.4 and NFPA 72. <u>New installations of smoke alarms shall not rely solely on ionization technology to detect a fire.</u>

<u>Any smoke alarm newly installed within 20 feet of a kitchen or bathroom cannot include ionization technology even if used in combination with other detection technology</u>

Commenter's Reason: There were 4 reasons that appeared to concern the Committee about the original proposal: 1) it would apply to existing alarms, 2) it would limit new technology, 3) Some Committee members thought the ICC should defer to the standards, i.e. NFPA/UL, process, and 4) There was conflicting data supporting the proposal. I will address all 4 concerns.

1) Existing Alarms

This new language makes it clear that it is only meant to apply to new alarms installed to comply with this code.

2) Limit of New Technology

This language will allow for new technology while not allowing technology, old or new, that relies solely on ionization technology to detect fires. Ion technology has been repeatedly shown to have 2 flaws (often fatal flaws): 1) poor response to smoldering smoke and 2) excessive nuisance alarms, leading to excessive disablement. Either flaw would justify this proposal.

3) Deference to Standards Process

The ICC is a group that represents code officials. The "standards groups" are theoretically consensus groups. In reality the code officials and AHJ's are almost always a minority on these Committees. Here is a quote from Hyman Rickover, "Father of the Nuclear Navy" to Congress in 1970.

"The typical industry-controlled code or standard is formulated by a committee elected or appointed by a technical society or similar group. Many of the committee members are drawn from the manufacturers to whom the code is to be applied. Others are drawn from engineering consulting firms and various Government organizations. However, since near unanimous agreement in the committee must generally be obtained to set requirements or to change them, the code represents a minimum level of requirements that is acceptable to industry. … In a subtle way, the use of industry codes or standards tends to create a false sense of security. Described by code committees and by the language of many codes themselves as safety rules, they tend to inhibit those legally responsible for protecting the public from taking the necessary action to safeguard health and well being. Many states and municipalities have incorporated these codes into their laws, thus, in effect delegating to code committees their own responsibility for protecting the public."

By deferring to the "standards process" the ICC would be *"delegating their own responsibility for protecting the public*" to the industry. The ICC has not delegated their own opinion to the National Association of Home Builders etc. on the sprinkler issue but it has essentially done this in regards to smoke detectors. I would request that the ICC judge my proposal on its own merits and not defer to the "value judgments" of groups who may not represent the public interest. When "neutral" committees, e.g. Vermont Legislature, and Massachusetts Fire and Building Code Boards, reviewed my proposals, to restrict the use ionization technology, they were adopted. (Maine recently adopted language mandating photoelectric alarms within 20 feet of a kitchens or bath. This copied language that I authored for the Massachusetts Building Code in 1998.)

4) Conflicting Data in Supporting Material

I found this comment confusing. I am not aware of any conflicting data that was submitted with the reason statement and none was pointed out at the Hearing or in the "Committee Reason." The failure to point a specific "conflict" makes it impossible for me to challenge this assertion but I will try.

There may exist some studies that show the ionization to be effective however, as I have pointed out in papers that I have written, which have been submitted to the ICC these studies have one of the following characteristics: 1) they utilized older ion technology that was set to a higher sensitivity, they utilized non-synthetics furniture, which produces a type of smoke to which the ion is more sensitive, 3) they used fires that were either flaming or smoldered for only a short period of time , or 4) they never produced untenable conditions. The studies that I referenced have the following things in common which make them relevant to my proposal: 1) used technology similar to today's, 2) used synthetic furniture, 3) allowed fires to develop to untenable conditions, and 4) smoldered material for over 30 minutes. **In every case the researcher obtained results which indicated that the ionization alarm failed in many smoldering tests.** In addition to the studies that I have previously submitted I will add another.

http://smokealarm.nist.gov/pdf_files/Smoke%20Detector_Supplementary%20Qs%20&%20As_091107.pdf

In response to questions that I had submitted NIST published this document. At the bottom of page 2 the following information can be obtained.

	Available safe Egress Time (s) Average +/- 1 Standard Deviation	
	Photoelectric Alarms	Ionization Alarms
Smoldering	2136 +/- 1011	276 +/- 331
Flaming*	129 +/- 74	177 +/- 69
Cooking	739 +/- 148	796 +/- 241

These "flaming" have been characterized by some researchers as "ultra-fast" fires. Most flaming fires have a more moderate growth rate, e.g. cooking fires.

I would like to point out the following:

The only scenario that is producing "negative" escape times is the smoldering scenario with ionization alarms.
In the smoldering scenarios the photoelectric is on average 30 minutes faster than the ionization
In the most common flaming scenario, i.e. the cooking scenario, the ionization is on average 60 seconds faster than the photoelectric, however the photoelectric is still providing over 8 minutes of ASET so the extra 60 seconds is meaningless.
Even in the "ultra-fast" flaming fires the photoelectric is on average providing over 2 minutes warning.

If the Committee, once again rejects my proposal I would request that they identify the studies which indicate that the ionization is adequate for smoldering fires involving synthetic material. In my opinion this is probably the most common non-arson fatal scenario that occurs in the US while occupants are sleeping.

Some argue that if I am correct then why do the statistics indicate that ionization smoke alarms have been so effective. A close analysis of the available data will show that the statistics support my position.

According to the NFPA, (Ahrens 2009) having a smoke alarm reduce your chances of dying in a fire by about 50%. However, this reduction is only obtained if one includes "confined fires." (According to the USFA confined fires are rarely dangerous.) If one only looks at unconfined fires the following results are obtained. (Anyone with access to this report can do the same analysis.)

	Risk with working alarms	**Risk without working alarms**	**% Reduction**
All Fire & All Homes	1040/1764 = 0.589	1780/1537 = 1.158	(1.158-0.589)/1.158 = 49% reduction
Unconfined Fires & All Homes	1030/842 = 1.223	1780/1052 = 1.692	(1.692-1.223)/1.692 = 28% Reduction
Unconfined Fires in Apartments	240/190 = 1.263	200/166 = 1.20	(1.20-1.263)/1.20 = 5% Increase

- Risk, according to the NFPA, is defined as (# Fatalities / 100 Fires)

So smoke alarms, i.e. ionization smoke alarms are not nearly as effective as we are led to believe. The reduction in risk is only 28%. This is particularly troubling since some of the reduction in risk is probably due to socio-economic factors, e.g. poverty. In apartments, where the occupant has to usually exit through the living room they provide no statistical advantage. In fact there is a 5% increase in risk. I do not mean to state that ionization smoke alarms are not better than having no smoke alarm. I do mean to state that if smoke alarms are to achieve the life saving potential that people expect and deserve, we cannot allow ionization smoke alarms to be allowed to meet the code.

Public Comment 2:

Marcelo M. Hirschler, GBH International, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

907.2.11 (IBC [F] 907.2.11) Single and multiple-station smoke alarms. *Listed* single- and multiple-station ~~photoelectric~~ smoke alarms complying with UL 217 shall be installed in accordance with Sections 907.2.11.1 through 907.2.11.4 and NFPA 72. <u>New installations of smoke alarms shall not rely solely on ionization technology to detect a fire.</u>

Commenter's Reason: The technical committee was concerned about two issues: (a) that the original proposal would require the replacement of existing detectors and (b) that the proposal would not permit the use of combination detectors. The revised language addresses this by stating that it is only <u>new installations</u> of detectors that need to be of the photoelectric type and that combination detectors are also permitted.

The technical rationale for needing photoelectric detectors has been well covered in the reasons for the original proposal.

Final Action: AS AM AMPC____ D

F112-09/10, Part II
IRC R314.1

<u>Proposed Change as Submitted</u>

Proponents: Joseph Fleming, Deputy Chief, Boston Fire Department, representing The Boston, MA Fire Department; Sean DeCrane, Cleveland Fire Department representing the Cleveland, OH Fire Department and the International Association of Fire Fighters

PART II – IRC BUILDING/ENERGY

Revise as follows:

R314.1 Smoke detection and notification. All smoke alarms <u>installed to meet the requirements of this code shall be the photoelectric type and</u> shall be listed in accordance with UL 217 and installed in accordance with the provisions of this code and the household fire warning equipment provisions of NFPA 72.

Reason: (**Fleming**) According to the United States Fire Administration (<u>http://www.usfa.dhs.gov/downloads/pdf/tfrs/v5i1.pdf</u>) 37% of fire fatalities occur with operational smoke alarms and another 21% occur with disabled alarms. The use of photoelectric alarms, as opposed to alarms using ionization technology could reduce both by ½. This would reduce fire deaths in the U.S. by approximately 25% which translates into over 750 lives saved each year. The following information supports this estimated benefit.

1. There are some fires were smoke alarms/detectors cannot provide a benefit: arson fires in egress paths, victims intimate with flaming fires, explosions, etc. In addition, it is unlikely that smoke alarms/detectors provide the critical warning to occupants who are awake. As a consequence, when discussing smoke alarms, we should focus our attention on the types of fires where the smoke alarm can provide a crucial benefit to occupants not on all the types of fires that occur. The vast majority of fires where a smoke alarm/detector can help occupants are smoldering fires started when the victim is asleep.

> *Smoke detectors should be able to save at least 60% and possibly 75% of sleeping victims, but only 13% of victims who were awake.* (McGuire, J., Ruscoe, B., The Value of a Fire Detectors in the Home, Fire Study No. 9, National Research Council of Canada, Division of Building Research, Ottawa, Ont., Canada, December, 1962.)
> *"Delayed discovery, typically associated with fires that occur at night when everyone is asleep, also tends to be a characteristic of the smoldering fire caused by discarded smoking material. These smoldering fires are the leading causes of US fire fatalities and detectors are ideally designed to deal with them.* ("A Decade of Detectors", Fire Journal 09/85, John Hall - NFPA.)

2. In flaming fires the ionization alarm/detector is faster than the photoelectric by 30-50 seconds. This extra time is virtually irrelevant to alert occupants. For example, in the recent smoke alarm testing involving flaming cooking fires (<u>http://smokealarm.nist.gov/pdf_files/SmokeDetectors_Q&As_Feb2008.pdf</u>), which is the most common type of flaming fire, although the photo was 30-50 seconds slower than the ionization it still provided on average over 10 minutes warning. It has often been said that in a fire "seconds count." However it is hard to imagine a scenario were the extra seconds provided by the ionization in the most common type of flaming fires makes a difference for life safety, when the photoelectric is already providing on average over 10 minutes of Available Safe Egress Time. As a consequence, although photoelectric alarms/detectors respond later in flaming fires this is a quantitative as opposed to a qualitative advantage. Here are some quotes from researchers.

> *The advantage of ionization smoke detectors during flaming fires is only about a 15-20 second earlier warning. This margin will only be decisive for the loss of human life in extraordinary circumstances. In general the difference between the alarm times for the optical and the ionization detectors are reduced when the detection is made from an adjacent room. (*Meland, Oysten, and Lonuik, Lars, "Detection of Smoke - Full Scale Tests with Flaming and Smouldering Fires, "Fire Safety Science," - Proceedings of the Third International Symposium, July, 1991,)
> *Under the conditions of ignition from flames, the ionization chamber type detector exhibited a greater sensitivity to the smoke produced than the photoelectric system. However, the rate of generation of smoke was so great that the extra time given by*

*the ionization chamber as a result may be of little practical use. (*R., (Riley, K., and Rogers, S., "A Study of the Operation and Effectiveness of Fire Detectors Installed in the Bedrooms and Corridors of Residential Institutions", Fire Research Station, Fire Research Current Paper 26/78, Borehamwood, England, April 1978.)

3. In smoldering fires the photoelectric is faster than the ionization by 30 minutes or more. This extra time is critical for sleeping occupants. If the ionization was consistently providing adequate warning, it would not matter that it was slower than the photoelectric. Unfortunately it doesn't. According to NIST's testimony to the Boston City Council), *"ionization alarms may not always alarm even when a room is filled with smoke from a smoldering fire."* In addition, according to data collected by NIST Report during smoldering fires the ionization smoke alarm often provided less than 1-2 minutes of Available Safe Egress Time. (1-2 minutes is the minimum time needed for sleeping occupants to escape.) In fact the ionization, in many cases, was providing negative available safe egress time. (http://smokealarm.nist.gov/pdf_files/StatementfortheRecordWG1finalsmokealarmstatement.pdf

This finding has been noted by many other researchers.

*Ionization chamber type detectors, in the room of origin and the corridor, did not, in the smoldering fire tests, provide adequate warning that the escape route was impassable or that conditions in the room were potentially hazardous to life. (*R., Riley, K., and Rogers, etc.)

"This test will show that most photoelectric detectors, operated by battery will detect smoke at about 1.5-3% smoke, which is good. The test will show that the photoelectric detectors operated by household current will activate between 2 and 4 %, which is still good. But, the test also will show that many ionization detectors will not activate until the smoke obscuration reaches 10-20 and sometimes 25%. … Therefore, because of the present state of the art in detecting smoke, the Subcommittee on Smoke Detectors can take no other course but to recommend the installation of photoelectric detectors." ("Residential Smoke Alarm Report - Prepared by Special Automatic Detection Committee of the International Association of Fire Chiefs," The International Fire Chief, September 1980.)

The tests i.e. the CALCHIEFS Tests, being commented upon in the previous quote were conducted by the Los Angeles Fire Dept. They concluded that photoelectrics were the preferred smoke alarm for all hallways and bedrooms. ("An Evaluation of Fire Detectors for Residential Placement," Los Angeles City Fire Dept., Fire Prevention Bureau – Research Unit, August 1981.)

"Photoelectric detectors sighted in the hallway are more effective for detecting smoldering smoke than ionization detectors, providing adequate escape time for most conditions of size and location of the smoke sources. Ionization detectors sited in the hallway generally provide inadequate escape times unless smoke movement into the hallway is slowed down by narrow door openings, causing a slower loss of visibility, or unless they are sited close to the smoke source." (P.F. Johnson and S. K. Brown, "Smoke Detection of Smoldering Fires in a Typical Melbourne Dwelling," *Fire Technology,* Vol. 22, No. 4, 1986, pp. 295-340.)

"The ionization detectors detected smoke from a smoldering fire much later than optical (photoelectric) detectors. When the particular conditions during the fire development are taken into consideration there are reasons to indicate that this detection principle would not provide adequate safety during this type of fire". (Meland, Oysten, and Lonuik, Lars, "Detection of Smoke - Full Scale Tests with Flaming and Smouldering Fires, "Fire Safety Science," - Proceedings of the Third International Symposium, July, 1991, pp. 975-984.)

4. In addition to being inadequate at providing adequate warning in smoldering fires, several researchers have identified that the ionization smoke alarm is far more susceptible to disablement due to nuisance alarms than is the photoelectric. Here are some quotes from the recent NIST Smoke Alarm Report. http://smokealarm.nist.gov/

Additionally a separate study of nuisance alarm sources was conducted because this was identified as an important issue in a prior study by the U.S. Consumer Product Safety Commission. It was observed that ionization alarms had a propensity to alarm when exposed to nuisance aerosols produced in the early stages of some cooking activities, prior to noticeable smoke production. This phenomenon could be particularly vexing to homeowners who experience such nuisance alarms. … While one third of the smoke detectors did not work on the initial test, half of these were made operational by restoring power. Homeowners interviewed revealed that most of these were intentionally disconnected due to nuisance alarms, mostly from cooking.

For the Toasting Scenario the ionization located near the kitchen responded in about 130-150 seconds. The photoelectric responded in 225-300. In fact according to NIST, *"Photoelectric alarm thresholds were met only after item started to char and produce visible smoke."* So although both responded, it is much more likely that the ionization will repeatedly respond to most normal toasting and be more likely to be disabled..

Here are some recent quotes by other researchers on nuisance alarms.

*"Homes with ionization alarms had more than 8 times the rate of false alarms as those with photoelectric. In small rural residences, photoelectric smoke alarms have lower rates of false alarms and disconnections." (*Perkins, M., "Ionization and photoelectric smoke alarms in rural Alaskan homes," Western Journal of Medicine, 2000;173:89-92 (Contact: Alaska Injury Prevention Center, Anchorage, AK.))

*"We favor photoelectric detectors to reduce rates of nuisance alarms from cooking and to provide optimal protection from cigarette related fires." (*Kuklinski, D., Berger, L., Weaver, J., "Smoke detector Nuisance Alarms: A Field Study in a Native American Community," NFPA Journal; Sept/Oct. 1995.)

*"On direct observation at first follow-up, ionization study alarms were more likely to be non-functional, 20% ionization vs. 5% photoelectric, with the most common reason being a disconnected or absent battery." (*Mueller, B., et al, "Randomized controlled trial of ionization and photoelectric smoke alarm functionality," Injury Prevention, 2008; 14:80-86.)

Even smoke alarm manufacturers are aware of the benefits of photoelectric technology. (They just do a very poor job of communicating this to consumers.)

*"The optical smoke alarm therefore is less likely to react to the results of cooking and this makes it far more suitable for installation near kitchens or in confined spaces such as bed sits. The slight price differential between the two types of alarms can be balanced out by the elimination of false alarms being triggered by nearby kitchens and bathrooms." "*Domestic smoke alarms – a guide for specifiers," Bendall, D. (BFK Brands Europe), Fire Prevention 281 July/August 1995.

"Never install ionization smoke alarms in areas where cooking fumes, open fires and products of combustion are present. Where these conditions occur and a smoke alarm must be installed, a photoelectric alarm is the best option." http://www.kidde.com.au/utcfs/kid/How+Smoke+Alarms+Work.html

5. Combination alarms/detectors have the potential to provide the quickest response to both smoldering and flaming fires but due to the excessive nuisance alarms from the ionization part of the alarm/detector, they should not be allowed near kitchens and bathrooms. In addition, the minor advantage that ionization or combination have over photoelectric in flaming fires is marginal and probably not critical.

   To quote a study (Mueller et al) cited earlier, *"An alarm containing both technologies is more expensive; it may also be more likely rendered non-functional if either technology causes frequent nuisance alarms. Our results suggest that installing photoelectric alarms on main floors of homes similar to those in our study may increase the proportion of functioning alarms and therefore provided longer term protection,"*

   Other items to consider:

   I am not aware of any "wireless alarms" that come as combination (photo/ion).

   Both ion and photo are sold with 10 year batteries. Are Combination (ion/photo)?

   Combination CO/Smoke come with CO/Ion or CO/Photo. Is there a Combo Smoke Alarm/CO?

   Why require dual in sprinkled occupancies when, according to the USFA, the only type of fire that can kill someone is a smoldering fire? "*Even though fire sprinklers are effective life safety devices you still need smoke alarms. Some fires can begin as smoldering fires that produce smoke and gases but don't generate enough heat to activate the sprinklers. Smoke alarms are needed to provide warning for these situations."* (http://www.usfa.dhs.gov/citizens/all_citizens/home_fire_prev/manufactured/sprinklers-mh.shtm*)*

6. I would like to mention that based on this research the Australasian Fire Authorities Council has recommended the use of photoelectric smoke alarms as opposed to ionization or combination.

   http://www.afac.com.au/__data/assets/pdf_file/0020/3674/AFACSmokeAlarmposition1June2006.pdf

7. Precedents for this action.

   a. Since 1998 the Massachusetts State Building Code has mandated photoelectric smoke alarm within 20 feet of a kitchen or bathroom due to the propensity of ionization smoke alarms to experience nuisance alarms.
   b. Since 2002 **NFPA 72 (the National Fire Alarm Code)** has only allowed ionization smoke alarms near kitchens if they were equipped with a silence button. The NFPA 72 committee has finally recognized the advantage that photoelectric smoke alarms have in regards to nuisance alarms. However I take exception to their assumption that a "hush button" neutralizes the ionizations propensity for nuisance alarms. No study has shown these to be effective at reducing disablement of ionization alarms. http://www.nfpa.org/assets/files/PDF/ROP/72-A2009-ROC.pdf (Page 72-249)
   c. **New Vermont Law** – Photoelectric-only type of smoke alarms are required to be installed in the vicinity of any bedrooms and on each level of a dwelling, for all new dwellings and dwellings that are sold or transferred, beginning January 1, 2009. http://www.dps.state.vt.us/fire/heating/photoelectric.html
   d. **Massachusetts has voted to Change the State Fire Code** so that as of January 1, 2010, smoke alarms with only ionization technology will not be allowed to meet the code. http://www.realtown.com/massachusettsrealestate/blog/massachusetts-smoke-detector-laws-changing
   e. **The 7th Edition of the Massachusetts State Building Code** was updated so that as of January 1, 2008 smoke alarms with only ionization technology will not be allowed to meet the code. http://www.ludlow.ma.us/building/permit_applications/life-safety-systems-app.pdf

Bibliography – In addition to references cited above, the following will be provided to the committee.

2. Fleming, J., *"Photoelectric vs. Ionization Detectors - A Review of the Literature, Revisited,"* (NFPRF Fire Suppression and Detection Research Symposium, Orlando, FL, 01/05. This presentation included analyses of: 1) 30 years of smoke detector studies, 2) the National Institute of Standards Smoke Detector Project, 3) statistic regarding the effectiveness of smoke detectors, ands 4) the effectiveness of Underwriter's Labs Smoke Detector Approval Standard, UL217.)
3. Fleming, J., *"Smoke Detectors and the Investigation of Fatal Fires,"* Published in May 2000 issue of "Fire & Arson Investigator", the official magazine of International Association of Arson Investigators. (Also published on Interfire.org, an Arson Resource Website – posted 02/01.)

Reason: (DeCrane) I do not want to get into me too testimony, even during the reason statement, and my colleague Joseph Fleming from the Boston Fire Department has written an extensive Reason Statement. This will make it difficult to go in depth referencing various reports as Chief Fleming has provided the technical substantiation for this code change.

As a representative of the International Association of Fire Fighters (IAFF), I represent the professional fire fighters of North America. At the IAFF's most recent convention, the Union representatives of over 280,000 professional fire fighters across the United States and Canada, with representatives from the United Kingdom, Australia and New Zealand, voted unanimously to support he requirement of photoelectric smoke detectors.

The representatives, of those who respond to difficult fire scenes involving thousands of fatalities, have determined it is time to move forward with the requirement of photoelectric smoke detectors. Countless times our members have responded to residential fires and removed victims who had disabled their detectors due to nuisance alarms. Tragically many of these families forgot to replace the batteries or reinstall the hard wire detector when they were finished cooking. Unfortunately in many incidents these occupants, or a loved one, ended up paying the ultimate price for their forgetfulness, or some may argue, the lack of the detector industry addressing the problem.

On behalf of the nation's professional fire fighters we request your support for this code change.

Cost Impact: (**Fleming)** The code change proposal will not increase construction costs in any meaningful manner. The cost difference between ionization and photoelectric is minimal, particularly when one considers the benefit.

Cost Impact: (DeCrane) The code change proposal will minimally increase construction costs.

ICCFILENAME: FLEMING-DECRANE-F1-907.2.11

Public Hearing Results

PART II- IRC B/E
Committee Action: Disapproved

Committee Reason: The proposed language would only permit the photoelectric type. This change would exclude other types and would limit future technology.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Joseph Fleming, Deputy Chief, Boston Fire Department, representing The Boston, MA Fire Department, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:
R314.1 Smoke detection and notification. All smoke alarms ~~installed to meet the requirements of this code shall be~~ ~~the photoelectric type and~~ shall be listed in accordance with UL 217 and installed in accordance with the provisions of this code and the household fire warning equipment provisions of NFPA 72. New installations of smoke alarms shall not rely solely on ionization technology to detect a fire.

Any smoke alarm newly installed within 20 feet of a kitchen or bathroom cannot include ionization technology even if used in combination with other detection technology

Commenter's Reason: See F112-09/10, Part I

Public Comment 2:

Marcelo M. Hirschler, GBH International, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R314.1 Smoke detection and notification. All smoke alarms ~~installed to meet the requirements of this code shall be~~ ~~the photoelectric type and~~ shall be listed in accordance with UL 217 and installed in accordance with the provisions of this code and the household fire warning equipment provisions of NFPA 72. New installations of smoke alarms shall not rely solely on ionization technology to detect a fire.

Commenter's Reason: See F112-09/10, Part I

Final Action: AS AM AMPC____ D

F113-09/10
907.2.11.2 (IBC [F] 907.2.11.2)

Proposed Change as Submitted

Proponent: Rick Sheets, Fire Committee Chair, Brinks Home Security, representing National Burglar and Fire Alarm Association

Revise as follows:

907.2.11.2 (IBC [F] 907.2.11.1) Groups R-2, R-3, R-4 and I-1. Single- or multiple-station smoke alarms shall be installed and maintained in Groups R-2, R-3, R-4 and I-1 regardless of *occupant load* at all of the following locations:

1. On the ceiling or wall outside of each separate sleeping area in the immediate vicinity of bedrooms.
2. In each room used for sleeping purposes.

~~**Exception:** Single- or multiple-station smoke alarms in Group I-1 shall not be required where smoke detectors are provided in the sleeping rooms as part of an automatic smoke detection system.~~

3. In each *story* within *a dwelling unit,* including basements but not including crawl spaces and uninhabitable *attics.* In *dwellings* or *dwelling units* with split levels and without an intervening door between the adjacent levels, a smoke alarm <u>or smoke detector</u> installed on the upper level shall suffice for the adjacent lower level provided that the lower level is less than one full *story* below the upper level.

   <u>**Exception:** Single- or multiple-station smoke alarms in Groups R-2, R-3, R-4, and I-1 shall not be required where smoke detectors are part of an automatic smoke detection system and installed in all the locations required by Section 907.2.11.2.</u>

Reason: There is no logical reason that these other groups (R-2, R-3, R-4) should be discouraged from installing superior fire alarm and detection systems. Professional protection using system-type smoke detection, with all its associated technological features, should be allowed for all similar occupancies, not just I-1. Chapter one of this code at 104.09 states that equal or superior alternate methods are allowed.

Cost Impact: The code change proposal will not increase the cost of construction. (No increase is required, but the change allows for optional protection at additional costs.)

ICCFILENAME: SHEETS-F7-907.2.11.2.DOC

<u>Public Hearing Results</u>

Committee Action: **Disapproved**

Committee Reason: The proposal was disapproved with concern that connection to the main fire alarm occupant notification system may create many unnecessary alarms throughout the building. These unnecessary alarms would result in occupants not reacting appropriately in a situation where evacuation is necessary.

Assembly Action: **-None**

<u>Individual Consideration Agenda</u>

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Rick Sheets, SET National Burglar and Fire Alarm Association, requests Approval as Submitted.

Commenter's Reason: Stating that unnecessary alarms would be created by using system smoke detectors insinuates that a poor design of the smoke detection system was installed. These devices can also be programmed to only sound in the detector and annunciate a constantly attended location without sounding the entire building alarm.

Final Action: AS AM AMPC____ D

F116-09/10, Part I
907.2.12 (New) [IBC [F] 907.2.12 (New)], 4603.8 (New)

<u>Proposed Change as Submitted</u>

Proponent: David Fredrick Scarelli representing DBA-Sentry Signal Company

PART I – IFC

Add new text as follows:

<u>**907.2.12 (IBC [F] 907.2.12) Line type heat detection.** A line type heat detection system that activates at 475°F (246°C) shall be installed in Group R Occupancies in accordance with Sections 907.2.12.1 through 907.2.12.2, NFPA 72, NFPA 70 and manufacturer's instructions.</u>

<u>**907.2.12.1 (IBC [F] 907.2.12.1) Location.** A line type heat detection shall be installed in the following locations:</u>

1. Above all NM-B Cable
2. Above all electrical boxes
3. Above or near all raceways.

907.2.12.2 (IBC [F] 907.2.12.2) Interconnection. The line type heat detection system shall be interconnected with the smoke alarms required by Section 907.2.11 in such a manner that when the line type heat detection activates such detection shall activate the smoke alarms in all sleeping units and dwelling units.

4603.8 Line type heat detection. A line type heat detection that activates at 475° F (246°C) shall be installed in existing Group R Occupancies in accordance with Sections 4603.8.1 through 4603.8.2, NFPA 72, NFPA 70 and manufacturer's instructions.

4603.8.1 Location. Line type heat detection shall be installed in the following locations:

1. Above all exposed NM-B Cable
2. Above all electrical boxes
3. Above or near all raceways.

4603.8.2 Interconnection. The line type heat detection system shall be interconnected with the smoke alarms required by Section 907.2.11 in such a manner that when the line type heat detection activates such detection shall activate the smoke alarms in all sleeping and dwelling units.

Reason: According to death certificate data, 25% of fire and flame deaths in 2002 were due to smoke inhalation alone, 26% due to burns and 21% to a combination of burns and smoke inhalation. There were 517,000 structural, 3,140 civilian deaths and 17,730 civilian induries. *(page 37).

ESCAPING – all seemed savable …; SLEEPING – 1/3 estimated as savable; RESCUING OR FIREFIGHTING – ¾ estimated savable … **Reanalysis of who can be saved.** (see additional data attached)

Deterioration of electrical wiring caused by time or the environment is a predominant cause of ignition. *+ (pg. 24)

Fires in electrical distribution systems contribute significantly to the U.S. fire problem, accounting for a consistent portion of the problem year after year. *+ (page 69)

In 2006 an estimated 71,360 injuries involving electrical distribution or lighting equipment were reported to hospital emergency rooms. +

Electrical distributions and lighting equipment dwelling fires are the only type of home fires that have been shown to increase in frequency with increasing dwelling age. *+

The majority of 2002-2005 non-confined home structure fires involving electrical distribution or lighting equipment began with the ignition of products and materials often found in structural areas, including wire or cable insulation (30%), structural members or framing (12%), insulation within the structural area (5%). Pg 6#

Three-fourths (75%) of deaths in 2002-2005 home fires involving electrical distribution or lighting equipment involved victims who were outside the area of origin when the fire began. (pg 6#)

Branch circuit wiring (51%) accounted for half of the 2002-2005 non-confined home structure fires involving wiring. (pg 54 #)

Half (52%) of 2002-2005 non-confined home structure fires involving wiring began in fire areas of origin that are all concealed or exterior spaces. (pg 55 #)

The majority (57%) of 2002-2005 non-confined home structure fires involving overcurrent protection devices began with ignition wire or cable insulation. (pg 89#)

SUMMARY: Electrical distribution equipment is a highly significant contributor to the high number of civilian deaths and civilian injuries resulting year after year in home fires. Many lives can be saved and injuries prevented if earlier warning can be sounded.

CONCLUSION: The line type open switch activated by heat and/or fire is designed by earliest warning to prevent death by asphyxiation and burning.

(6b) Circuitry short circuits and overloads trip the circuit breakers when the breaker rating is reached. Lower leakage causes hot spots along the line and eventually causes fires that could be detected long before they could become autocatalytic. The line type open switch is designed to detect this hazard long before life is endangered.

ICCFILENAME: SCARELLI F1-907.2.12.DOC

Public Hearing Results

PART I- IFC
Committee Action: **Disapproved**

Committee Reason: The committee disapproved the proposal as the requirements seemed difficult to enforce and unnecessary. More specifically, the hazards that the proponent is concerned with are already addressed with the reference to the National Electrical Code.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

David F. Scarelli representing Sentry Signal Company, requests Approval as Submitted.

Commenter's Reason: The line type heat sensor should not be any more difficult to enforce than any other Fire Code. It is a life saving factor at the point and time of origin. The NEC does not cover the wall and ceiling enclosures with a heat sensing device. The wood destructively distillates inflammable gasses. When the gasses coalesce with air it becomes an inflammable mixture. Only a spark is required to burst the dwelling into flames capturing and possibly asphyxiating the occupants.

The NEC covers the living sections of a dwelling with heat and smoke sensors. It covers circuit overload with arc-fault circuit –interrupters. None of these systems quickly intercept lightning strikes, grass fires (fires from outside the structure), chimney faults, etc. The line type heat sensor (Line type open switch which closes when heat activated or contact by flame.

NOTE: The NEC strives to minimize fires while the Line Type Heat Sensor- (Line Type Open Switch)- strives to minimize deaths and injuries. Future technical innovations will continue to minimize both.

ICCFILENAME: SCARELLI F1-907.2.12.DOC

Public Hearing Results

PART II- IRC B/E
Committee Action: **Disapproved**

Committee Reason: The electrical portion of the code already provides for protection with the arc-fault circuit-interrupter. There was no documentation provided that a product exists that will provide activation at 475°F.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

David F. Scarelli representing Sentry Signal Company, requests Approval as Submitted.

Commenter's Reason: The arc-fault circuit-interrupter distinguishes the difference between electronic wave patterns of naturally occurring sparks produced by light switches turning on/off and household appliances. When sparking of unknown origin is sensed the circuit is interrupted.

WOOD DOES NOT BURN!! It destructively distillates!!! A fault which does not spark, produces a combustible gas. When the gas mixes with oxygen it becomes inflammable. It travels throughout the walls and ceiling/floor spaces. When it is sparked it ignites explosively trapping the occupants that it surrounds. The line type heat sensor is the only available product that can be strung within the wall and ceiling/floor cavities which can detect hot spots and flame at their place of origin and sound the alarm to alert unsuspecting possible victims to avoid them of horrid death or injury.

The arc-fault circuit-interrupter will reduce detectable fire instances while the line type heat sensor will protect life both human and animal.

The NEC protects against the occurrence of fire while the line type heat sensor protects against loss of life and injury due to the fire itself.

Together, both the NEC and the line type heat sensor through technological innovations will more closely close the gap between death/injuries caused by fires by reducing the conditions which cause them and providing early warning alarms where they were not avoided.

Under-writers Laboratories lists three manufacturers that produce a line type heat sensor which are activated at 475F.

The line type heat sensor in question here was tested and approved May 19, 1999 in their LAB 417 ENG 8475096244. File S7229 Vol. 1 App. B was issued 5-14-99. It is documented at 455-485F.

Smoke Detector and Arc Fault Circuit Interrupter Requirements and Frequently Asked Questions (Washington, North Carolina) http://www.ci.washington.nc.us/planning/planning_smokedetector.aspx

NEMA AFCISafety.org – What is an AFCI (Q&A) http://www.afcisafety.org/qa.html

Final Action: AS AM AMPC____ D

F120-09/10, Part I
907.2.13.1.2 (IBC [F] 907.2.13.1.2)

Proposed Change as Submitted

Proponent: Dave Frable, U.S. General Services Administration

PART I – IFC

Revise as follows:

907.2.13.1.2 (IBC [F] 907.2.13.1.2) Duct smoke detection. Duct smoke detectors complying with Section 907.3.1 shall be located as follows:

1. In the main supply air duct of each air-handling system having a design capacity greater than 2,000 cubic feet per minute (cfm) (0.94 m^3/s), downstream of any filters.
2. ~~1.~~ 2. In the main return ~~air and exhaust air plenum~~ of each air-~~conditioning~~ handling system having a design capacity greater than ~~2,000~~ 15,000 cubic feet per minute (cfm) ~~(0.94 m^3/s)~~(7.1 m^3/s). Such detectors shall be located in a serviceable area downstream of the last duct inlet.
3. In the supply air system where multiple air-handling systems share common or supply return air ducts or plenums with a combined design capacity greater than 2,000 cfm (0.9 m^3/s),
4. At each story in return air systems having a design capacity greater than 15,000 cfm (7.1 m^3/s), where return air risers serve two or more stories.
5. ~~2.~~ 5. At each connection to a vertical duct or riser serving two or more stories from a return air duct or plenum of an air-conditioning system with a design capacity of greater than 15,000 cfm (7.1 m^3/s). In Group R-1 and R-2 occupancies a listed smoke detector is allowed to be used in each return air riser carrying not more than 5,000 cfm (2.4 m^3/s) and serving not more than 10 air inlet openings.

   Exception: Smoke detectors are not required in the return air system where all portions of the building served by the air distribution system are protected by area smoke detectors connected to a fire alarm system in accordance with the *International Fire Code*.

Reason: The intent of this proposal is to improve the level of detection of smoke within air handling units cost effectively and to correlate smoke detector requirements in air handling systems in the IBC, IFC and IMC with the requirements currently found in NFPA 90A, *Standard for the Installation of Air-Conditioning and Ventilating Systems*.

During the 2006/2007 ICC Code Development Hearings in Orlando, both the Fire Code Committee and Mechanical Code Committee recommended approval of two similar code change proposals (F113-06/07 – Part 1& Part 2). However, at the Final Action Hearings of the ICC in May 2007, the ICC membership voted to overturn both the Fire Code Committee and the Mechanical Code Committee's recommendations and disapproved the subject code change proposals. At the hearings, no new information or technical substantiation was brought forth to substantiate overturning the two Code Committee's recommendations for approval. It should be emphasized that the main issue of contention by the opponents of this code change proposal at both the Code Committee and Final Action Hearings was that this issue had been debated many times before in the ICC Code Development Process. However, that is untrue. During the 2009 Code Hearings in Minneapolis, the only mention of this occurring was in the Commonwealth of Virginia's Mechanical Code over 10 years ago.

The technical substantiation to revise the location of smoke detectors from the return air side to the supply air side is valid; and will improve the level of detection of smoke within air-handling units. Opponents may argue that return air detectors will detect fires in a building much quicker than detectors located on the supply air side, but return air detectors are **not** a substitute for area detectors. If there is a desire for early detection of smoke, area smoke detectors should be installed. However, we contend that the detector serving the supply air detector will operate as desired once the smoke concentration levels in the supply air exceeds the alarm threshold so occupants should not be at risk should the return air fan continues to run prior to the supply air fan shutting down. In addition, return air detectors will not be able to detect smoke from a fire on the supply side of air handling units due to fan belts, motors or combustible filters so their respective fan will shut off appropriately. A smoke detector located on the supply side can also detect smoke from an exterior fire that gets pulled into the fresh air intake for the air handling system. Thus, a smoke detector located on the supply side will serve the purpose of protecting building occupants from smoke produced by air handling unit fire or smoke ingress via the fresh air intake for the air handling unit. Therefore overall detection is improved.

Correlating the IFC, IBC and IMC with NFPA 90A is also important as many jurisdictions adopt both the IFC/IMC and NFPA 90A. Accredited health care organizations are required by law to comply with NFPA 90A. Not having the subject requirements in the IBC in concert with NFPA 90A results in the unnecessary installation of smoke detectors in both the return and supply air systems. This code change proposal aims to maintain detection in air handling systems, not remove it. There should be no increase in installation costs as this code change proposal merely shifts the location of devices from the return air side to the supply air side, where air handling units are greater than 2000 cfm. In fact, changing the requirement as proposed will reduce the cost in jurisdictions that must comply with the IFC/IMC and NFPA 90A (i.e., leaving the requirements as currently stated in both the IFC and IMC already results in unnecessary additional costs).

Specific code changes are as follows:

PART I:
(New) IFC 907.2.13.1.2, paragraph 1
Over the past few years, the U.S. General Services Administration has had a number of fire incidences that did not activate the building fire alarm system because there were no smoke detectors installed in the main supply air duct of the air-handling system downstream of any filter.

Conversely, GSA has no incidence of a return air duct smoke detector activating as a result of detecting smoke in the return air handling system. Installing duct smoke detectors in the supply air system would ensure that a fire within the supply air filters, in the air handling motors or originating outside near air intakes can be discovered before it spreads. Establishing a 2,000 cfm threshold for installing detectors in supply air fans appears to be an industry standard.

(New) 907.2.13.1.2, paragraphs 2 & 3 (Note: the intent is for 907.2.13.1.2 to be have similar language as 606.2.2 and 606.2.3 so the codes are coordinated). The current requirement for installing duct smoke detectors in return air systems exceeding 2,000 cfm is overly restrictive. The 15,000 cfm threshold for return air systems appears to be an industry standard, as this capacity was used in the legacy codes and is currently used by NFPA 90A. The term “air conditioning system” has been replaced with “air handling system to more accurately reflect the type of system used in buildings today.

(Deleted text) Per the commentary for Section 606.1, requiring duct smoke detectors in exhaust air plenums does not provide any protection for the fan or the building occupants, since smoke is being exhausted out of the building. In addition, return air smoke detection is not supposed to be used as a means for detecting smoke in buildings.

(New) IFC 907.2.13.1.2, paragraph 4 is material extracted from IMC existing 606.2.3 (changed to 606.2.4). This is an editorial change to coordinate the two codes.

(Revision) 907.2.13.1.2 Paragraph No. 5 (formally Paragraph No. 2) – The purpose of this code change is to correlate this paragraph with the changes above. The code language contained in the IBC does not have a capacity threshold for return air ducts/plenum with connections to more than two stories and, therefore, all return duct/plenum system that connects more than two floors would require duct mounted smoke detectors at the connection to the riser regardless of the size of the system. This would be onerous to smaller buildings that have multi-story returns. In addition, no other code (either the legacy codes or NFPA 90A require duct smoke detectors in multi-story return air systems unless they exceed 15,000 cfm. This change also would correlate the capacity requirements currently specified in NFPA 90A - 2007 edition (NFPA 90A – 6.4.2).

(New) Exception to IFC 907.2.13.1.2 (2) through (5) is material extracted from the IMC existing exception to 606.2.1 (changed to 606.2.2) that eliminates the need for duct smoke detectors in return air systems when the entire building is protected by area smoke detectors.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: FRABLE-F1-907.2.13.1.2.DOC

Public Hearing Results

PART I- IFC
Committee Action: Approved as Modified

Modify the proposal as follows:

907.2.13.1.2 (IBC [F] 907.2.13.1.2) Duct smoke detection. Duct smoke detectors complying with Section 907.3.1 shall be located as follows:

1. In the main supply air duct of each air-handling system having a design capacity greater than 2,000 cubic feet per minute (cfm) (0.94 m^3/s), downstream of any filters.
2. In the main return of each air handling system having a design capacity greater than 15,000 cubic feet per minute (cfm)(7.1 m^3/s). Such detectors shall be located in a serviceable area downstream of the last duct inlet.
3. In the supply air system where multiple air-handling systems share common or supply return air ducts or plenums with a combined design capacity greater than 2,000 cfm (0.9 m^3/s),
4. At each story in return air systems having a design capacity greater than 15,000 cfm (7.1 m^3/s), where return air risers serve two or more stories.
5. At each connection to a vertical duct or riser serving two or more stories from a return air duct or plenum of an air-~~conditioning~~ <u>handling</u> system with a design capacity of greater than 15,000 cfm (7.1 m^3/s). In Group R-1 and R-2 occupancies a listed smoke detector is allowed to be used in each return air riser carrying not more than 5,000 cfm (2.4 m^3/s) and serving not more than 10 air inlet openings.

   Exception: Smoke detectors are not required in the return air system where all portions of the building served by the air distribution system are protected by area smoke detectors connected to a fire alarm system in accordance with the *International Fire Code*.

Committee Reason: The proposal was approved as it correlates with NFPA 90A and provides the detection on the supply side where it is most effective. The modification was simply to change the terminology from "air-conditioning" to "air handling" to be consistent with the intent and the wording throughout the proposed revisions.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Richard Grace representing VPMIA/VBCOA, requests Disapproval.

Commenter's Reason: The purpose of this code section is to protect the people in the structure and to allow time for evacuation during a fire. The purpose is not to protect the equipment. If the detection takes place in the supply duct, the air being tested will have been filtered by the unit filters and diluted with the outside air introduced through the return, which will jeopardize the effectiveness of the smoke detector. The proponent indicated that area smoke detectors were the primary protection for the occupants, however they do not shut down the air distribution equipment, allowing any smoke developed to be distributed throughout the structure while people are trying to evacuate.

This proposed change has been submitted many times in the past, and has been defeated every time except this time. The difference between then and now is that only the IFC committee heard testimony for both parts. A lot of people in the mechanical community, including myself, was not even aware that this change to the IMC was being presented. In the past, the ICC membership having vested interest in the IMC was included in this discussion by being presented with either Part I or Part II of the proposed change. Not this time.

The intent of installing a smoke detector in an air handling unit is simple, prevent the passage of smoke from one space to another. By installing this smoke detector in the return air portion of the air handling unit, upstream of any filters, exhaust air connections, outdoor air connections, or decontamination equipment, the smoke detector has a chance of doing what it is supposed to do. By installing the smoke detector as outlined in these proposed changes (Parts I and II), this will allow smoke that is being drawn into the return air system from one space to become diluted by filters, outdoor air, and decontamination equipment (not to mention that some is actually going to be exhausted to the exterior) prior to reaching the smoke detector and shutting down the air handling unit. This will allow smoke to be transferred from one space to another, effectively rendering a smoke detector operation ineffective.

Final Action: AS AM AMPC____ D

F120-09/10, Part II
IMC 606.2.1 (New), 606.2.2

<u>Proposed Change as Submitted</u>

Proponent: Dave Frable, U.S. General Services Administration

PART II – IMC

Revise as follows:

606.2 Where required. Smoke detectors shall be installed where indicated in Sections 606.2.1 through ~~606.2.3~~ <u>606.2.4</u>.

> **Exception:** Smoke detectors shall not be required where air distribution systems are incapable of spreading smoke beyond the enclosing walls, floors and ceilings of the room or space in which the smoke is generated.

<u>**606.2.1 Supply air systems.** Smoke detectors shall be installed in supply air systems with a design capacity greater than 2,000 cubic feet per minute (cfm) (0.94 m^3/s), in the supply air duct or plenum downstream of any filters</u>.

~~606.2.1~~ <u>606.2.2</u> Return air systems. Smoke detectors shall be installed in return air systems with a design capacity greater than ~~2,000~~ <u>15,000</u> cfm (~~0.9~~ <u>7.1</u>m^3/s), in the return air duct or plenum upstream of any filters, exhaust air connections, outdoor air connections, or decontamination equipment and appliances.

> **Exception:** Smoke detectors are not required in the return air system where all portions of the building served by the air distribution system are protected by area smoke detectors connected to a fire alarm system in accordance with the *International Fire Code*. The area smoke detection system shall comply with Section 606.4.

~~606.2.2~~ <u>606.2.3</u> Common supply and return air systems. Where multiple air-handling systems share common supply or return air ducts or plenums with a combined design capacity greater than 2,000 cfm (0.9 m^3/s), the <u>supply</u> ~~return~~ air system shall be provided with smoke detectors in accordance with Section 606.2.1.

> ~~**Exception:** Individual smoke detectors shall not be required for each fan-powered terminal unit, provided that such units do not have an individual design capacity greater than 2,000 cfm (0.9 m^3/s) and will be shut down by activation of one of the following:~~
>
> ~~1. Smoke detectors required by Sections 606.2.1 and 606.2.3.~~
> ~~2. An approved area smoke detector system located in the return air plenum serving such units.~~
> ~~3. An area smoke detector system as prescribed in the exception to Section 606.2.1~~.

In all cases, the smoke detectors shall comply with Sections 606.4 and 606.4.1.

Reason: The intent of this proposal is to improve the level of detection of smoke within air handling units cost effectively and to correlate smoke detector requirements in air handling systems in the IBC, IFC and IMC with the requirements currently found in NFPA 90A, *Standard for the Installation of Air-Conditioning and Ventilating Systems*.

During the 2006/2007 ICC Code Development Hearings in Orlando, both the Fire Code Committee and Mechanical Code Committee recommended approval of two similar code change proposals (F113-06/07 – Part 1& Part 2). However, at the Final Action Hearings of the ICC in May 2007, the ICC membership voted to overturn both the Fire Code Committee and the Mechanical Code Committee's recommendations and disapproved the subject code change proposals. At the hearings, no new information or technical substantiation was brought forth to substantiate overturning the two Code Committee's recommendations for approval. It should be emphasized that the main issue of contention by the opponents of this code change proposal at both the Code Committee and Final Action Hearings was that this issue had been debated many times before in the ICC Code Development Process. However, that is untrue. During the 2009 Code Hearings in Minneapolis, the only mention of this occurring was in the Commonwealth of Virginia's Mechanical Code over 10 years ago.

The technical substantiation to revise the location of smoke detectors from the return air side to the supply air side is valid; and will improve the level of detection of smoke within air-handling units. Opponents may argue that return air detectors will detect fires in a building much quicker than detectors located on the supply air side, but return air detectors are **not** a substitute for area detectors. If there is a desire for early detection of smoke, area smoke detectors should be installed. However, we contend that the detector serving the supply air detector will operate as desired once the smoke concentration levels in the supply air exceeds the alarm threshold so occupants should not be at risk should the return air fan continues to run prior to the supply air fan shutting down. In addition, return air detectors will not be able to detect smoke from a fire on the supply side of air handling units due to fan belts, motors or combustible filters so their respective fan will shut off appropriately. A smoke detector located on the supply side can also detect smoke from an exterior fire that gets pulled into the fresh air intake for the air handling system. Thus, a smoke detector located on the supply side will serve the purpose of protecting building occupants from smoke produced by air handling unit fire or smoke ingress via the fresh air intake for the air handling unit. Therefore overall detection is improved.

Correlating the IFC, IBC and IMC with NFPA 90A is also important as many jurisdictions adopt both the IFC/IMC and NFPA 90A. Accredited health care organizations are required by law to comply with NFPA 90A. Not having the subject requirements in the IBC in concert with NFPA 90A results in the unnecessary installation of smoke detectors in both the return and supply air systems. This code change proposal aims to maintain detection in air handling systems, not remove it. There should be no increase in installation costs as this code change proposal merely shifts the location of devices from the return air side to the supply air side, where air handling units are greater than 2000 cfm. In fact, changing the requirement as proposed will reduce the cost in jurisdictions that must comply with the IFC/IMC and NFPA 90A (i.e., leaving the requirements as currently stated in both the IFC and IMC already results in unnecessary additional costs).

Specific code changes are as follows:

PART II:
(Revision) 606.2. This is an editorial change to coordinate the two codes.

(New) IMC 606.2.1

Over the past few years, the U.S. General Services Administration has had a number of fire incidences that did not activate the building fire alarm system because there were no smoke detectors installed in the main supply air duct of the air-handling system downstream of any filter. Conversely, GSA has no incidence of a return air duct smoke detector activating as a result of detecting smoke in the return air handling system. Installing duct smoke detectors in the supply air system would ensure that a fire within the supply air filters, in the air handling motors or originating outside near air intakes can be discovered before it spreads. Establishing a 2,000 cfm threshold for installing detectors in supply air fans appears to be an industry standard.

(Revision/New) 606.2.1 and 606.2.2 (changed to 606.2.2 and 606.2.3, respectively) (Note: the intent is for 907.2.13.1.2 paragraphs 2 & 3 to have similar language as 606.2.2 and 606.2.3 so the codes are coordinated). The current requirement for installing duct smoke detectors in return air systems exceeding 2,000 cfm is overly restrictive. The 15,000 cfm threshold for return air systems appears to be an industry standard, as this capacity was used in the legacy codes and is currently used by NFPA 90A. The term "air conditioning system" has been replaced with "air handling system to more accurately reflect the type of system used in buildings today.

(Deletion) Exception to IMC 606.2.2 (changed to IMC 606.2.3):

The 2,000 cfm requirement has been applied to the supply air side. Therefore the Exception needs to be deleted given the proposed new return air threshold will be increased from 2,000 cfm to 15,000 cfm.

(Revision) IMC 606.2.3 (changed to IMC 606.2.4) editorial as a new section was inserted. Existing text unchanged.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: FRABLE-F1-907.2.13.1.2.DOC

Public Hearing Results

PART II- IMC

Committee Action: **Approved as Submitted**

Committee Reason: This proposal was approved to be consistent with the action taken on Part I of this proposal.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Richard Grace representing VPMIA/VBCOA, requests Disapproval.

Commenter's Reason: See F120-09/10, Part I.

Final Action: AS AM AMPC____ D

F121-09/10
907.4, 907.4.1 (New) [IBC [F] 907.3, [F] 907.3.1 (New)]

Proposed Change as Submitted

Proponent: Rick Sheets, Fire Committee Chair, Brinks Home Security, representing National Burglar and Fire Alarm Association

Revise as follows:

907.4 (IBC [F] 907.3) Fire safety functions. Automatic fire detectors utilized for the purpose of performing fire safety functions shall be connected to the building's fire alarm control unit where a fire alarm system is required by Section 907.2. Detectors shall, upon actuation, perform the intended function and activate the alarm notification appliances or activate a visible and audible supervisory signal at *a constantly attended location.*

907.4.1 (IBC [F] 907.3.1) Power source. In buildings not equipped with a fire alarm system, the automatic fire detector shall be powered by normal electrical service and, upon actuation, perform the intended function. The detectors shall be located in accordance with NFPA 72.

> **Exception:** Elevator recall and supervisory service detectors shall be connected to a dedicated function fire alarm control unit that shall be designated as "Elevator Recall Control & Supervisory Unit".

Reason: Including this exception means-monitoring the integrity of the initiating device circuits cannot be omitted. In the past, smoke alarms and heat detectors were directly wired in the elevator equipment without providing the required monitoring for integrity of the circuit wiring, allowing elevators to be used during a fire. The requirement for the use of a fire alarm control unit for elevator recall is also a requirement of NFPA 72, (found in Section 6.16.3 in the 2007 edition), and should be added here for conformity as well as safety.

Cost Impact: The code change proposal will not increase the cost of construction since compliance with NFPA 72 is already required by this code and elevator codes.

ICCFILENAME: SHEETS-F12-907.4.1.DOC

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The proposal was disapproved as the exception has limited applicability and the code format of the exception was inappropriate. More specifically, the exception as written is actually a requirement which would be cause for confusion.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Rick Sheets, SET National Burglar and Fire Alarm Association, Approval as Modified by this Public Comment.

Modify proposal as follows:

[F] **907.4 Fire safety functions.** Automatic fire detectors utilized for the purpose of performing fire safety functions shall be connected to the building's fire alarm control unit where a fire alarm system is required by Section 907.2. Detectors shall, upon actuation, perform the intended function and activate the alarm notification appliances or activate a visible and audible supervisory signal at *a constantly attended location.*

~~**907.4.1 (IBC [F] 907.3.1) Power source.**~~ In buildings not equipped with a fire alarm system, the automatic fire detectors shall be ~~powered by normal electrical service and, upon actuation, perform the intended function~~. ~~The detectors shall be~~ located and installed in accordance with NFPA 72.

> ~~**Exception:** Elevator recall and supervisory service detectors shall be connected to a dedicated function fire alarm control unit that shall be designated as "Elevator Recall Control & Supervisory Unit".~~

Commenter's Reason: To ensure monitoring of integrity of wiring the fire safety function system should be required to be installed per NFPA 72, 2007 Section 6.16.3.

Final Action: AS AM AMPC____ D

F122-09/10
907.5.1 (IBC [F] 907.4.1)

Proposed Change as Submitted

Proponent: Thomas P. Hammerberg, Automatic Fire Alarm Association, Inc

Revise as follows:

907.5.1 (IBC [F] 907.4.1) Protection of fire alarm control unit. In areas that are not continuously occupied, a single smoke detector shall be provided at the location of each fire alarm control unit, notification appliance circuit power extenders and supervising station transmitting equipment.

Exception~~s~~:

~~1.~~ Where ambient conditions prohibit installation of smoke detector, a *heat detector* shall be permitted.
~~2. The smoke detector shall not be required where the building is equipped throughout with an *automatic sprinkler system* in accordance with Section 903.3.1.1 or 903.3.1.2.~~

Reason: This exception was added to this requirement during the last code cycle so the language would be consistent with NFPA 72. This exception was deleted in the 2010 edition of NFPA 72, so needs to be deleted here for consistency.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: HAMMERBERG-F2-907.5.1.DOC

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The committee approved the proposal to delete the exception because it was felt that if the exception remains, early notification and alarm would be jeopardized since sprinklers react slower than smoke detectors.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Dave Frable representing U.S. General Services Administration, requests Disapproval.

Commenter's Reason: We are in opposition of deleting Exception 2 which permits and recognizes that a building protected throughout by an automatic sprinkler systems, installed in accordance with the requirements in NFPA 13 provides an acceptable alterative to installing a smoke detector at the location of each fire alarm control unit, each notification appliance circuit power extender, and supervising station transmitting equipment within a building. It should be noted that this issue has been debated by the NFPA 72 Technical Committee over numerous code development cycles in NFPA 72 and involves much more than eliminating or installing 1 smoke detector directly over one fire alarm control unit.

We are in opposition for the following reasons:

1. The basis of Exception 2 was that the installation of a smoke detector over the subject equipment only offered limited value in terms of detecting all threats to a fire alarm system from a fire and that fire growth would be limited in a fully sprinklered building. It should be noted that the installation of a smoke detector within the vicinity of this equipment is not required to meet the spacing requirements for smoke detection in NFPA 72.
2. We strongly believe that the protection of each control unit, each notification appliance circuit power extender and supervising station transmitting equipment is a determination that should be made by the designer based on risk.
3. The proponent of this code change has not demonstrated that the installation of a smoke detector at the location of each fire alarm control unit, notification appliance circuit power extender, and supervising station transmitting equipment within a building protected throughout by an

automatic sprinkler system will improve the overall reliability and performance of the system based on the smoke detectors not meeting the spacing requirements in NFPA 72.

4. The proponents assumption that a smoke detector not meeting the spacing requirements in NFPA 72; installed at the location of each fire alarm control unit, notification appliance circuit power extender, and supervising station transmitting equipment in all conditions will protect the operation of the fire alarm system in a fire scenario is illogical and to delete the subject sprinkler exception is unreasonable since no evidence has been brought forth by the proponents that fire alarm system failures are occurring at an alarming rate due to a fires in buildings protected by an automatic sprinkler system without the subject smoke detector installed. In addition, no recent evidence has been brought forth by the proponents that the installation of the smoke detector of the fire alarm system protected the operation of the system in a fire scenario.
5. Proponents also stated in their testimony that an activated sprinkler could spray water on fire alarm control equipment, thus disabling the equipment. This should be a concern regardless of whether or not a smoke detector is installed above the control equipment. Sprinklers can also be activated by physical damage, and locating fire alarm control equipment in the direct spray pattern should probably be avoided in all conditions.
6. Proponents also noted that NFPA 13, Section 8.15.10.3 permits sprinklers to be omitted from certain electrical rooms, and thus there would be no sprinkler protection should a fire alarm control panel be installed in such a room. The “certain electrical rooms” permitted to have sprinklers omitted must comply with 4 conditions per NFPA 13: (1) the room is dedicated to electrical equipment only, (2) only dry-type electrical equipment is used, (3) equipment is installed in a 2 hour fire rated enclosure including protection for penetrations, and (4) no combustible storage is permitted in the room. When this is taken in context, it indicates that the room has limited combustible loading, and is protected from fire outside the room by a two hour enclosure. Rather than have this scenario be a source of concern regarding the protection of fire alarm control equipment, this sounds like an ideal application with 2 hour protection from fire outside the room, and no storage of combustibles permitted in the room. This scenario certainly isn’t justification to remove exception no. 2. In addition, in all new high-rise construction, the building is required to be protected throughout by an automatic sprinkler system and the fire alarm control units are required to be installed in a fire command center that is separated from the remainder of the building by not less than a 1-hour fire barrier. Once again, this scenario certainly isn’t justification to remove exception No. 2 and require the installation of unjustified smoke detection.

We also disagree with the proponent that this code change will not increase the cost of construction as the proponent has stated in his reason statement. We believe not only will this code change increase the cost of initial construction but will also increase the cost of maintenance over the life of the building.

Final Action: AS AM AMPC____ D

F128-09/10
907.6.2.3.4 (IBC [F] 907.5.2.3.4)

Proposed Change as Submitted

Proponent: Gene Boecker, Code Consultants, Inc.

Revise as follows:

907.6.2.3.4 (IBC [F] 907.5.2.3.4) Group R-2. In Group R-2 occupancies required by Section 907 to have a fire alarm system, all dwelling units and sleeping units shall be provided with the ~~capability~~ <u>capacity at the fire alarm control unit</u> to support visible alarm notification appliances in accordance with ICC A117.1.

Reason: The section indicates that all dwelling units shall be provided with the capability to support visible alarm notification appliances in accordance with ICC/ANSI A117.1. The code requires that all dwelling units be provided with the capability to support visible notification appliances, which allows for misinterpretation. The added text clarifies the intent for the dwelling units being capable of supporting visible notification appliances and provides a means of enforcing the intent of the code.

The cost of construction may or may not be increased depending on what is currently being used as the “norm” for meeting this provision. Therefore, the comment below is stating the position with regards to increase in cost. It is just as likely, however, that the cost will be reduced if there are more restrictive interpretations being used to meet the requirement.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: BOECKER-F5-907.6.2.3.4.DOC

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: Although the committee agreed that clarification of this section was necessary the proposal was disapproved with the primary concerns being that the revisions may conflict with ICC/ANSI A117.1 and would not clarify the intent of the section for visible alarm notification.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Lawrence G. Perry, AIA, representing Building Owners and Managers Association (BOMA) International, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

907.6.2.3.4 (IBC [F] 907.5.2.3.4) Group R-2. In Group R-2 occupancies required by Section 907 to have a fire alarm system, all dwelling units and sleeping units shall be provided with the capability to support visible alarm notification appliances in accordance with ICC A117.1. <u>Such capability shall be permitted to include the potential for future interconnection of the building fire alarm system with the unit smoke alarms, replacement of audible appliances with combination audible/visible appliances, or future extension of the existing wiring from the unit smoke alarm locations to required locations for visible appliances.</u>

Commenter's Reason: This public comment seeks to better address the original intent of the 'capability' requirement for visible alarms in dwelling and sleeping units. As originally crafted by the A117 Committee, the intent was as follows:

1. It was assumed that the unit would be provided with hard-wired, interconnected smoke alarms.
2. It was assumed that the either the building fire alarm system would have an audible appliance within the unit (to satisfy audibility requirements); if not, at a minimum, the building fire alarm system would have wiring extended into the unit to a point where it could, in the future, be 'tapped' for use for visible signals within the unit.
3. It was assumed that, if visible appliances were needed within the unit in the future, that the fire alarm wiring could be interconnected with the smoke alarm wiring through a relay. The A117 Committee submitted a change to NFPA 72 to specifically permit this interconnection; this change was approved. It has since been expanded on to allow system interconnections, provided they meet protocols specified in NFPA 72.
4. It was assumed that providing visible alarm coverage in the unit would require replacement of audible-only appliances with combination audible/visible appliances, or additional wiring would be added from the audible appliance to the appropriate location of a newly-installed visible appliance.
5. There apparently are widely varying interpretations of the current IBC and A117 text. In some cases, all units are being required to be pre-wired for visible appliances, which was not the intent of the A117 Committee.

Final Action: AS AM AMPC____ D

F132-09/10, Part II
IRC R315, R202, Chapter 44

NOTE: PART I WAS WITHDRAWN BY PROPONENT. PART I IS REPRODUCED ONLY FOR INFORMATIONAL PURPOSES FOLLOWING ALL OF PART II.

Proposed Change as Submitted

Proponent: Roger Evans, Park City Municipal Corporation, representing Utah Chapter of ICC

PART II – IRC BUILDING/ENERGY

1. Revise as follows:

R315.1. <u>**Carbon monoxide alarms, carbon monoxide detectors or combination smoke/carbon monoxide devices.** Carbon monoxide alarms, carbon monoxide detectors and combination smoke/carbon monoxide devices described in sections R315.1.1 through R315.1.4 shall be installed and maintained in accordance with the provisions of this code, NFPA 72 and NFPA 720.</u> ~~**Carbon monoxide alarms.** In new construction, dwelling units within which fuel-fired appliances are installed or have attached garages shall be provided with an approved carbon monoxide alarm installed outside of each separate sleeping area in the immediate vicinity of the bedroom(s).~~

<u>**R315.1.1 Carbon monoxide alarms.** Single- or multiple-station carbon monoxide alarms shall be listed and labeled in accordance with ANSI/UL 2034.</u>

<u>**R315.1.2 Carbon monoxide detectors.** Carbon monoxide detectors shall be listed and labeled in accordance with ANSI/UL 2075.</u>

R315.1.3 Combination smoke/carbon monoxide alarms. Combination smoke/carbon monoxide alarms shall be listed and labeled in accordance with ANSI/UL 217 and ANSI/UL 2034

R315.1.4 Combination smoke/carbon monoxide detectors. Combination smoke/carbon monoxide detectors shall be listed and labeled in accordance with ANSI/UL 268 and ANSI/UL 2075.

R315.2 Where Required in New Construction. **In new construction within which fuel burning appliances exist or which have attached garages, carbon monoxide alarms, carbon monoxide detectors, combination smoke/carbon monoxide alarms or combination smoke/carbon monoxide detectors shall be installed in the following locations:**

1. Outside each separate dwelling unit sleeping area in the immediate vicinity of the bedrooms.
2. On every level of a dwelling unit, including basements

~~**R315.2**~~ **R315.3 Where required in existing dwellings.** Where work requiring a permit occurs in existing dwellings that have attached garages or in existing dwellings within which fuel-fired appliances exist, carbon monoxide alarms/detectors shall be provided in accordance with Sections R315.1 and R315.2.

~~**R315.3 Alarm Requirements** Single station carbon monoxide alarms shall be listed as complying with UL 2034 and shall be installed in accordance with this code and the manufacturer's installation instructions.~~

R315.4 Carbon monoxide alarm signal requirements. Where more than one listed carbon monoxide alarm, or combination smoke/carbon monoxide is required to be installed within a dwelling unit they shall be interconnected in such a manner that the activation of one carbon monoxide alarm shall activate all of the carbon monoxide alarms in the dwelling unit and the activation of a carbon monoxide detector or combination smoke/carbon monoxide detector shall activate the carbon monoxide audible notification devices throughout the individual dwelling unit. The required carbon monoxide alarm signal shall be clearly audible in all sleeping rooms, having a sound level of at least 15 db above average ambient sound level or 5 db above the maximum sound level, or a sound level at least 75 db at the pillow.

R315.5 Power source. Required single- or multiple-station carbon monoxide alarms, carbon monoxide detectors, combination smoke/carbon monoxide alarms or combination smoke/carbon monoxide detectors shall receive their power by one of the following means:

1. Listed carbon monoxide alarms shall be battery-powered, plug-in with battery backup, or receive their primary power from the building wiring when such wiring is served from a commercial source with secondary power backup and without a disconnecting switch other than those required for overcurrent protection.Listed carbon monoxide alarms that are battery-powered or plug-in with battery backup shall not be permitted in new construction.
2. Listed carbon monoxide detectors shall receive their power from the approved control panel. The approved control panel shall receive its primary power from the building wiring when such wiring is served from a commercial source and the primary power source shall not include a disconnecting switch other than those required for overcurrent protection. The control panel shall be equipped with rechargeable batteries for secondary power backup.
3. Listed low-power radio frequency (wireless) detectors shall be permitted to be battery powered when the battery is electrically supervised and shall be capable of sending an alarm signal to the approved control panel for a minimum of 7 days after sending the initial battery depletion signal.

2. Add new definition to Section R202 as follows:

CARBON MONOXIDE.

Single-Station Carbon Monoxide Alarm. A device intended for the purpose of detecting carbon monoxide gas and alerting occupants by a distinct and audible signal comprising of an assembly that incorporates a sensor, control components and an alarm notification appliance in a single unit operated from a power source either located in the unit or obtained at the point of installation.

Multiple-Station Carbon Monoxide Alarm. A carbon monoxide alarm capable of being interconnected to one or more additional carbon monoxide alarms so that the actuation of one causes the appropriate alarm signal to be annunciated in all interconnected alarms.

Carbon Monoxide Detector. A device intended to be connected to an approved carbon monoxide detection system for the purpose of detecting carbon monoxide gas and alerting occupants by a distinct and audible signal.
Carbon Monoxide Detection System. A system of devices that consists of a control panel and circuits arranged to monitor and annunciate the status of carbon monoxide detectors and to initiate the appropriate response to those signals.

Combination Smoke/Carbon Monoxide Device. A device that combines a carbon monoxide alarm or carbon monoxide detector with smoke sensing technology; provided that the combined device is listed by a nationally recognized testing laboratory (NRTL) to the applicable ANSI/ UL Standards for both smoke detection and carbon monoxide detection. Such combined alarm units or detection systems shall emit an audible alarm in a manner that clearly differentiates between the two hazards as specified in the appropriate NFPA and ANSI/UL Standard.

3. Add new standards to Chapter 44 as follows:

NFPA
720-2009 Standard for the Installation of Carbon Monoxide (CO) Detection and Warning Equipment 2009 Edition

UL
2075-2004 First Edition of the Standard for Gas and vapor Detectors and Sensors, with revisions through September 28, 2007

Reason (Part II): The purpose for this code change is to improve the life safety of citizens by reducing the incidence of carbon monoxide (CO) poisoning in dwellings and to revise the language in the 2009 edition of the IRC so it is consistent with nationally recognized industry consensus standards.

The CO provisions in the 2009 edition of the IRC did not include the reliable, proven and tested technologies of system-connected CO detectors even though they meet nationally recognized industry consensus standards

1. ANSI/UL 2075, *Gas and Vapor Detectors and Sensors*
2. ANSI/NFPA 720, *Standard for the Installation of Carbon Monoxide (CO) Detection and Warning Equipment*

The performance and reliability of system-connected CO detectors have shown to be extremely high if they are listed and maintained to ANSI/UL 2075 and installed in accordance with NFPA 720. System-connected CO detectors designed to be part of a carbon monoxide detection system are required to be connected to an approved panel. The panel is required to be equipped with rechargeable batteries that keep the carbon monoxide detection system operating during a power outage and will communicate the power loss condition to the supervising station. When the primary power is restored, the control panel will fully recharge the standby batteries. An added feature of a carbon monoxide detection system is that the interconnecting wiring to system-connected CO detectors are supervised such that a wiring fault results in a trouble signal at the premises and the supervising station.

The installation provisions in the 2009 edition of the IRC seem inconsistent with NFPA 720 when two or more CO alarms are installed within a dwelling unit. Section 9.6.5 of NFPA 720 requires that when two or more carbon monoxide alarms are to be installed that they are interconnected.. The rationale for this requirement is if a CO device is activated in the basement the occupants on the second floor on the opposite end of the home is unable to hear the audible alarm if the devices are not interconnected.

The 2009 edition of the IRC requires CO alarms outside each separate dwelling unit sleeping area in the immediate vicinity of the bedrooms. However, NFPA 720 requires CO devices to be installed on every level of a dwelling unit, including basements as well as outside each separate dwelling unit sleeping area in the immediate vicinity of the bedrooms.

Cost Impact (Part II): It is estimated that the proposed code modification will have a minimal cost impact on the construction of one- and two- family dwellings and townhouses. The proposed new requirements will not require addition CO detection devices to be installed; however the proposed changes will require additional wiring. While there are many variables that affect the cost of construction, most new dwelling construction is anticipated no more than two stories in height and will require wiring between no more than three CO detection devices: one per floor and one in the basement.

Analysis (Part II): A review of the standard(s) proposed for inclusion in the code, NFPA 720-2009, for compliance with ICC criteria for referenced standards given in Section 3.6 of Council Policy #CP 28 will be posted on the ICC website on or before September 24, 2009.

UL 2075 is already referenced in the IFC but not currently in the IBC. If the code change is approved, UL 2075 would be added to Chapter 35 of the IBC as a referenced standard.

ICCFILENAME: EVANSR-F1-908.DOC

Public Hearing Results

PART II- IRC B/E

Note: The following analysis was not in the Code Change monograph but was published on the ICC website at http://www.iccsafe.org/cs/codes/Documents/2009-10cycle/ProposedChanges/Standards-Analysis.pdf :

Analysis: Review of the proposed new standards NFPA 720-2009 and UL 2075-2004 indicated that, in the opinion of ICC staff, the standards did comply with ICC standards criteria. Standard UL 2075 is already referenced in the IFC but not currently in the IRC. If the code change is approved, UL 2075 would be added to Chapter 44 of the IRC as a referenced standard.

Committee Action: **Disapproved**

Committee Reason: Based upon the proponent's request for disapproval. The proponent will rework this and bring it back to the Final Action.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Roger R. Evans, Park City Municipal Corporation, representing Utah Chapter of ICC, requests Approval as Modified by this Public Comment.

Replace the proposal with the following:

Add new text as follows:

R315.2 Carbon monoxide detection systems. Carbon monoxide detection systems, that include carbon monoxide detectors and audible notification appliances, installed and maintained in accordance with this section for carbon monoxide alarms and NFPA 720 shall be permitted. The carbon monoxide detectors shall be listed as complying with UL 2075. Where a household carbon monoxide detection system is installed it shall become a permanent fixture of the occupancy, owned by the homeowner and shall be monitored by an approved supervising station.

Exception: Where carbon monoxide alarms are installed meeting the requirements of Section R315.1 compliance with Section 315.2 is not required.

Add standards to Chapter 44 as follows:

NFPA 720-2009 Standard for the Installation of Carbon Monoxide (C0) Detection and Warning Equipment 2009 Edition

UL 2075-2004 First Edition of the Standard for Gas and vapor Detectors and Sensors, with revisions through September 28, 2007.

Commenter's Reason: The purpose of the original proposal was to permit carbon monoxide detection systems that include carbon monoxide detectors and audible notification appliance to be installed. During the Code Development Hearings the proponent realized the original proposal needed to be reworked and asked the committee to disapprove so that a public comment could be submitted for the Final Action Hearing. Therefore this public comment provides a straightforward solution of permitting carbon monoxide detection systems and carbon monoxide detectors to be installed. Furthermore, the requirement for the household carbon monoxide detection system to be owned by the homeowner and to be monitored by an approved supervising station mirrors the household fire alarm system requirements that were added to Section 314.2 of the 2009 edition of the IRC.

Final Action: AS AM AMPC____ D

NOTE: PART I REPRODUCED FOR INFORMATIONAL PURPOSES ONLY – SEE ABOVE

F132-09/10, Part I
908 (New) [IBC [F] 908(New)], 902 (IBC [F] 902), Chapter 47 (IBC Chapter 35)

PART I – IFC

1. Add new text as follows:

SECTION 908 (IBC SECTION [F] 908)
CARBON MONOXIDE ALARMS AND
CARBON MONOXIDE DETECTION SYSTEMS

908.1 General. This section covers the application, installation, performance and maintenance of carbon monoxide alarms and carbon monoxide detection systems in new buildings and structures.

908.1.1 Carbon monoxide alarms, carbon monoxide detectors and combination smoke/carbon monoxide devices. Carbon monoxide alarms, carbon monoxide detectors and combination smoke/carbon monoxide alarms and combination smoke/carbon monoxide detectors described in sections 908.1.2 through 908.1.5 shall be installed and maintained in accordance with the provisions of this code, NFPA 72 and NFPA 720.
908.1.2 Carbon monoxide alarms. Single- or multiple-station carbon monoxide alarms shall be listed and labeled in accordance with ANSI/UL 2034.

908.1.3 Carbon monoxide detectors. Carbon monoxide detectors shall be listed and labeled in accordance with ANSI/UL 2075.

908.1.4 Combination smoke/carbon monoxide alarms. Combination smoke/carbon monoxide alarms shall be listed and labeled in accordance with ANSI/UL 217 and ANSI/UL 2034

908.1.5 Combination smoke/carbon monoxide detectors. Combination smoke/carbon monoxide detectors shall be listed and labeled in accordance with ANSI/UL 268 and ANSI/UL 2075

908.2 Power Source. Required single- or multiple-station carbon monoxide alarms, carbon monoxide detectors, combination smoke/carbon monoxide alarms or combination smoke/carbon monoxide detectors shall receive their power by one of the following means:

1. Listed carbon monoxide alarms shall receive their primary power from the building wiring when such wiring is served from a commercial source with secondary power backup and without a disconnecting switch other than those required for overcurrent protection. Listed carbon monoxide alarms that are battery-powered or plug-in with battery backup shall not be permitted in new construction.
2. Listed carbon monoxide detectors shall receive their power from the approved control panel. The approved control panel shall receive its primary power from the building wiring when such wiring is served from a commercial source and the primary power source shall not include a disconnecting switch other than those required for overcurrent protection. The control panel shall be equipped with rechargeable batteries for secondary power backup.
3. Listed low-power radio frequency (wireless) detectors shall be permitted to be battery powered when the battery is electrically supervised and shall be capable of sending an alarm signal to the approved control panel for a minimum of 7 days after sending the initial battery depletion signal.

908.2.1 Interconnection. Where more than one listed carbon monoxide alarm, or, combination smoke/carbon monoxide alarm is required to be installed within a dwelling unit they shall be interconnected in such a manner that the activation of one carbon monoxide alarm shall activate all of the carbon monoxide alarms in the dwelling unit and the activation of a carbon monoxide detector or combination smoke/carbon monoxide detector shall activate the carbon monoxide audible notification devices throughout the individual dwelling unit. The required carbon monoxide alarm signal shall be clearly audible in all sleeping rooms, having a sound level of at least 15 db above average ambient sound level or 5 db above the maximum sound level, or a sound level at least 75 db at the pillow.

> **Exception:** Carbon monoxide alarms, carbon monoxide detectors, combination smoke/carbon monoxide alarms or combination smoke/carbon monoxide detectors installed in existing construction shall not be required to cause all carbon monoxide alarms to sound.

908.2.2 Acceptance testing. When the installation of carbon monoxide alarms, carbon monoxide detectors, combination smoke/carbon monoxide alarms or combination smoke/carbon monoxide detectors is complete, each alarm or detector and interconnecting wiring shall be tested in accordance with NFPA 72 and NFPA 720.

908.2.3 Where required. Listed single- or multiple-station carbon monoxide alarms, carbon monoxide detectors, combination smoke/carbon monoxide alarms or combination smoke/carbon monoxide detectors shall be installed in locations described in sections 908.2.4 through 908.2.5.

908.2.4 Group R-1. Group R-1 occupancies located in a buildings that contain fuel burning appliances or which have attached garages, listed multiple-station carbon monoxide alarms, carbon monoxide detectors, combination smoke/carbon monoxide alarms or combination smoke/carbon monoxide detectors shall be installed in the following locations:

1. On the ceiling or wall of the same room as permanently installed fuel burning appliances in accordance with manufacturers published instructions
2. Centrally located on every habitable level, in every HVAC zone of the building

   Exception: Carbon monoxide alarms or carbon monoxide detectors shall not be required in sleeping units unless the sleeping unit contains a fuel-burning appliance.

The required carbon monoxide alarms or carbon monoxide detectors shall be annunciated at a constantly attended location

908.2.5 Groups R-2, R-3 and R-4. Group R-2, R-3 and R-4 occupancies located in buildings that contain fuel burning appliances or which have attached garages, listed multiple-station carbon monoxide alarms, carbon monoxide detectors, combination smoke/carbon monoxide alarms or combination smoke/carbon monoxide detectors shall be installed in the following:

1. Outside each separate dwelling unit sleeping area in the immediate vicinity of the bedrooms
2. On every level of a dwelling unit, including basements and in every HVAC zone of the building
3. On the ceiling or wall of the same room as permanently installed fuel burning appliances in accordance with manufacturers published instructions.

   Exception: Carbon monoxide alarms or carbon monoxide detectors shall not be required in sleeping units unless the sleeping unit contains a fuel-burning appliance.

The required carbon monoxide alarms or carbon monoxide detectors shall be annunciated at a constantly attended location

2. Add new definitions as follows:

902.1(IBC [F] 902.1) Definitions. The following words and terms shall, for the purposes of this chapter and as used elsewhere in this code, have the meanings shown herein.

CARBON MONOXIDE.

Single-Station Carbon Monoxide Alarm. A device intended for the purpose of detecting carbon monoxide gas and alerting occupants by a distinct and audible signal comprising of an assembly that incorporates a sensor, control components and an alarm notification appliance in a single unit operated from a power source either located in the unit or obtained at the point of installation.

Multiple-Station Carbon Monoxide Alarm. A carbon monoxide alarm capable of being interconnected to one or more additional carbon monoxide alarms so that the actuation of one causes the appropriate alarm signal to be annunciated in all interconnected alarms.

Carbon Monoxide Detector. A device intended to be connected to an approved carbon monoxide detection system for the purpose of detecting carbon monoxide gas and alerting occupants by a distinct and audible signal.

Carbon Monoxide Detection System. A system of devices that consists of a control panel and circuits arranged to monitor and annunciate the status of carbon monoxide detectors and to initiate the appropriate response to those signals.

Combination Smoke/Carbon Monoxide Device. A device that combines a carbon monoxide alarm or carbon monoxide detector with smoke sensing technology; provided that the combined device is listed by a nationally recognized testing laboratory (NRTL) to the applicable ANSI/ UL Standards for both smoke detection and carbon monoxide detection. Such combined alarm units or detection systems shall emit an audible alarm in a manner that clearly differentiates between the two hazards as specified in the appropriate NFPA and ANSI/UL Standard.

3. Add new standards to Chapter 47 (IBC Chapter 35) as follows:

NFPA

720-2009	Standard for the Installation of Carbon Monoxide (CO) Detection and Warning Equipment 2009 Edition

UL

2034-2008	Standard for Single and Multiple Station Carbon Monoxide Alarms, with Revisions through February 20, 2009
2075-2004	Standard for Gas and vapor Detectors and Sensors, with revisions through September 28, 2007

Reason (Part I): The purpose for this code change is to protect people sleeping in commercial Group R occupancies such as hotels, motels, adult & child day care, apartments and dormitories from serious injury or possibly death from unintentional non-fire related carbon monoxide (CO) exposure by mandating the installation of carbon monoxide detection devices. The Centers for Disease Control and Prevention (CDC) reports that an estimated 15,000 emergency department visits and 500 unintentional deaths in the United States each year for the six year period 1999-2004. These carbon monoxide incidents were a contributing factor for 20 states enacting laws to require the installation of carbon monoxide detection devices. Of the 20 states that have adopted requirements for carbon monoxide detection, ten require the installation of carbon monoxide detectors in commercial Group R occupancies. In the absence of a national installation standard for commercial Group R occupancies each jurisdiction developed its own regulations with varying installation requirements.

We recommend that the International Fire Code develop the necessary installation requirements for CO detection devices in commercial Group R.

Cost Impact (Part I): It is estimated that the proposed code modification will have a minimal cost impact on the construction of Group R occupancies. For example in R-1 occupancies a CO alarm or detector will be installed by fuel burning appliance(s) and in each HVAC zone. In other R occupancies cost will be minimal as installation requirements are outside of each sleeping area and on each floor.

Analysis (Part I): UL 2034 is already referenced in the IRC but not currently in the IFC or IBC. If the code change is approved, UL 2034 would be added to Chapter 47 of the IFC and Chapter 35 of the IBC as a referenced standard.

UL 2075 is already referenced in the IFC but not currently in the IBC. If the code change is approved, UL 2075 would be added to Chapter 35 of the IBC as a referenced standard.

PART I- IFC **Withdrawn by Proponent**

F133-09/10

908.7 (New) [IBC [F] 908.7 (New)], 4606.1 (New), Chapter 47 (IBC Chapter 35)

Proposed Change as Submitted

Proponent: Robert J Davidson, Code Consultant/Alan Shuman, President, representing the National Association of State Fire Marshals (NASFM)

1. Add new text as follows:

908.7 (IBC [F] 908.7) Carbon monoxide alarms. Group I or R occupancies located in a building containing a fuel-burning appliance or a building which has an attached garage shall be provided with single station carbon monoxide alarms. The carbon monoxide alarms shall be listed as complying with UL 2034 and be installed and maintained in accordance with NFPA 720 and the manufacturer's instructions. An open parking garage, as defined in the *International Building Code*, shall not be deemed to be an attached garage.

> **Exception:** Sleeping units or dwelling units which do not themselves contain a fuel-burning appliance or have an attached garage, but which are located in a building with a fuel-burning appliance or an attached garage, need not be provided with single station carbon monoxide alarms provided that:
>
> 1. The ~~s~~sleeping unit or dwelling unit is located more than one story above or below any story which contains a fuel-burning appliance or an attached garage;

2. The sleeping unit or dwelling unit is not connected by duct work or ventilation shafts to any room containing a fuel-burning appliance or to an attached garage; and
3. The building is provided with a common area carbon monoxide alarm system.

4606.1 Carbon monoxide alarms. Existing Group I or R occupancies located in a building containing a fuel-burning appliance or a building which has an attached garage shall be provided with single station carbon monoxide alarms. The carbon monoxide alarms shall be listed as complying with UL 2034 and be installed and maintained in accordance with NFPA 720 and the manufacturer's instructions. An open parking garage, as defined in the *International Building Code*, shall not be deemed to be an attached garage.

Exception: Sleeping units or dwelling units which do not themselves contain a fuel-burning appliance or have an attached garage, but which are located in a building with a fuel-burning appliance or an attached garage, need not be provided with single station carbon monoxide alarms provided that:

1. The sleeping units or dwelling unit is located more than one story above or below any story which contains a fuel-burning appliance or an attached garage;
2. The sleeping units or dwelling unit is not connected by duct work or ventilation shafts to any room containing a fuel-burning appliance or to an attached garage; and
3. The building is provided with a common area carbon monoxide alarm system.

2. Add new standards to Chapter 47 (IBC Chapter 35) as follows:

NFPA
720-2005 Standard for the Installation of Carbon Monoxide (CO) Warning Equipment in Dwelling Units

UL
2034-2008 Standard for Single and Multiple Station Carbon Monoxide Alarms

Reason: At the final action hearings for the last code change cycle held in Minnesota the voting membership present voted overwhelmingly to add requirements for the installation of carbon monoxide alarms for dwelling units built in compliance with the International Residential Code (IRC). The threat of poisoning from exposure to carbon monoxide is not limited to dwellings regulated by the IRC, it includes other institutional and residential occupancies. This proposal is intended to provide correlation with the position the membership took on this issue and add language to the IBC/IFC requiring the installation of carbon monoxide alarms in institutional and residential group occupancies.

According to the Journal of the American Medical Association (JAMA), carbon monoxide is the leading cause of accidental poisoning deaths in America with approximately 2,100 deaths per year. http://jama.ama-assn.org/cgi/search?fulltext=Carbon+Monoxide Over 15,000 people seek medical attention due to carbon monoxide exposure each year. http://www.ul.com/newsroom/newsrel/nr012609a.html

The industry has addressed the issue of reliability by updating the requirements of the UL 2034 standard. http://www.iccsafe.org/cs/cc/ctc/CO/CO_UL2034History.pdf Underwriters Laboratories instituted a Carbon Monoxide Field Study in 1994 and completed the study in March of 2004. The report on the study includes the following summary:

> *"Throughout the first phase of this study, the CO alarms have performed in an effective manor. During the September 2002 tests we recorded our first false positive at 70ppm CO (94 minutes into the test, post 1998 alarm). Also during the September 2002 tests we recorded our first no response sample (pre1998 alarm). During the September 2003 we recorded a significant late response sample (pre1998 alarm). These samples have been returned and analyzed by the manufacturer and/or the UL Field Report Group has opened an investigation. Other samples in the survey of the same, or similar, models are continuing to perform as expected.*
>
> *On one occasion, a field study CO sample alarmed in an employee's home after their furnace was serviced. It was confirmed that there was a high level of CO present in their home. The problem was corrected and the alarm continues to function properly during follow-up sensitivity tests. On another occasion, a field sample was activated when the damper on a fireplace closed prematurely. The damper was opened, the house vented, and the alarm returned to its normal standby condition.*
>
> *Throughout the entire survey program we have experienced a few units providing early/delayed signals during the sensitivity tests, but all of these CO alarms would provide effective signaling protection to the users should there be a fatal concentration of CO.*
>
> *Of the few CO alarms that did not meet the UL2034 test points, most of them alarmed early and it was determined with the Stability Test results that these samples would most likely not false alarm in the field.*
>
> *It is important to note that providing effective signaling protection does not necessarily mean complying with the finite test points of UL2034. All the alarms would have sounded while a person can react and follow the recommended procedures during an alarm signal.*
>
> *The data shows that these CO alarms are providing the necessary signaling protection."*
>
> http://www.iccsafe.org/cs/cc/ctc/CO/CO_UL_AlarmSurvey.doc

All carbon monoxide detectors available today meet the updated requirements of the UL standard which eliminated the false positive indications that occurred when carbon monoxide detectors were first brought to market in the 1990's. The State of New Jersey has had regulations mandating the installation of carbon monoxide alarms in all new and existing residential occupancies since 1992. The state implemented a reporting program at that time to identify reliability and false positive indication problems and there have been no problems identified in over 10 years.

Carbon monoxide poisonings leading to injury or death is well documented and the only way to protect the occupants from this odorless and tasteless product of combustion, known as the "Silent Killer" is through the installation of detectors complying with today's standards.

Cost Impact: The code change proposal will increase the cost of construction.

Analysis: A review of the standards proposed for inclusion in the code, NFPA 720-2005 and UL 2034-2008, for compliance with ICC criteria for referenced standards given in Section 3.6 of Council Policy #CP 28 will be posted on the ICC website on or before September 24, 2009.

ICCFILENAME: DAVIDSON-SHUMAN-F14-908.7.DOC

Public Hearing Results

Committee Action: Approved as Modified

Note: The following analysis was not in the Code Change monograph but was published on the ICC website at http://www.iccsafe.org/cs/codes/Documents/2009-10cycle/ProposedChanges/Standards-Analysis.pdf

Analysis: Review of proposed new standards NFPA 720-2009 and UL 2034-2008 indicated that, in the opinion of ICC Staff, the standards did comply with ICC standards criteria.

Modify proposal as follows:

908.7 (IBC [F] 908.7) Carbon monoxide alarms. Group I or R occupancies located in a building containing a fuel-burning appliance or a building which has an attached garage shall be provided with single station carbon monoxide alarms. The carbon monoxide alarms shall be listed as complying with UL 2034 and be installed and maintained in accordance with NFPA 720 and the manufacturer's instructions. An open parking garage, as defined in the *International Building Code*, <u>or enclosed parking garage ventilated in accordance with Section 404 of the *International Mechanical Code*</u> shall not be deemed to be an attached garage.

> **Exception:** Sleeping units or dwelling units which do not themselves contain a fuel-burning appliance or have an attached garage, but which are located in a building with a fuel-burning appliance or an attached garage, need not be provided with single station carbon monoxide alarms provided that:
>
> 1. The sleeping unit or dwelling unit is located more than one story above or below any story which contains a fuel-burning appliance or an attached garage;
> 2. The sleeping unit or dwelling unit is not connected by duct work or ventilation shafts to any room containing a fuel-burning appliance or to an attached garage; and
> 3. The building is provided with a common area carbon monoxide alarm system.

<u>**908.7.1 Carbon monoxide detection systems.** Carbon monoxide detection systems, that include carbon monoxide detectors and audible notification appliances, installed and maintained in accordance with this section for carbon monoxide alarms and NFPA 720 shall be permitted. The carbon monoxide detectors shall be listed as complying with UL 2075.</u>

4606.1 Carbon monoxide alarms. Existing Group I or R occupancies located in a building containing a fuel-burning appliance or a building which has an attached garage shall be provided with single station carbon monoxide alarms. The carbon monoxide alarms shall be listed as complying with UL 2034 and be installed and maintained in accordance with NFPA 720 and the manufacturer's instructions. An open parking garage, as defined in the *International Building Code*, <u>or enclosed parking garage ventilated in accordance with Section 404 of the *International Mechanical Code*</u> shall not be deemed to be an attached garage.

> **Exception:** Sleeping units or dwelling units which do not themselves contain a fuel-burning appliance or have an attached garage, but which are located in a building with a fuel-burning appliance or an attached garage, need not be provided with single station carbon monoxide alarms provided that:
>
> 1. The sleeping units or dwelling unit is located more than one story above or below any story which contains a fuel-burning appliance or an attached garage;
> 2. The sleeping units or dwelling unit is not connected by duct work or ventilation shafts to any room containing a fuel-burning appliance or to an attached garage; and
> 3. The building is provided with a common area carbon monoxide alarm system.

(Portions of the proposal not shown remain unchanged.)

Committee Reason: The committee approved the proposal adding CO detectors to the code since having provisions within the IBC and IFC is a better approach than what has been occurring on a state level through the legislative process. This also makes the IBC and IFC consistent with the IRC. The first modification clarifies that ventilated enclosed parking garages were not intended to be considered as an attached garage for the purposes of enforcing this section. The second modification includes the use of CO detectors and associated systems in accordance with UL 2075. Such detectors are allowed by NFPA 720 and the committee felt it was appropriate to recognize both CO alarms and detectors.

Assembly Action: None

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Ron Nickson representing National Multi Housing Council, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

908.7 (IBC [F] 908.7) Carbon monoxide alarms. Group I or R occupancies located in a building containing a fuel-burning appliance or a building which has an attached garage <u>with a communicating opening</u> shall be provided with single station carbon monoxide alarms <u>outside of each separate dwelling unit sleeping area in the immediate vicinity of the bedrooms and on every occupiable level of a dwelling unit</u>. The carbon monoxide alarms shall be listed as complying with UL 2034 and be installed and maintained in accordance with NFPA 720 and the manufacturer's instructions. An open parking garage, as defined in the *International Building Code*, or enclosed parking garage ventilated in accordance with Section 404 of the *International Mechanical Code* shall not be deemed to be an attached garage.

Exception: Sleeping units or dwelling units which do not themselves contain a fuel-burning appliance or have an attached garage, but which are located in a building with a fuel-burning appliance or an attached garage, need not be provided with single station carbon monoxide alarms provided that:

1. The sleeping unit or dwelling unit is located more than one story above or below any story which contains a fuel-burning appliance or an attached garage;
2. The sleeping unit or dwelling unit is not connected by duct work or ventilation shafts to any room containing a fuel-burning appliance or to an attached garage; and
3. ~~The building is provided with a common area carbon monoxide alarm system the room with the fuel burning~~ A carbon monoxide detector is installed in the room containing the fuel burning appliance.

908.7.1 Carbon monoxide detection systems. Carbon monoxide detection systems, that include carbon monoxide detectors and audible notification appliances, installed and maintained in accordance with this section for carbon monoxide alarms and NFPA 720 shall be permitted. The carbon monoxide detectors shall be listed as complying with UL 2075.

4606.1 Carbon monoxide alarms. Existing Group I or R occupancies located in a building containing a fuel burning appliance or a building which has an attached garage with a communicating opening shall be provided with single station carbon monoxide alarms outside of each separate dwelling unit sleeping area in the immediate vicinity of the bedrooms and on every occupiable level of a dwelling unit . The carbon monoxide alarms shall be listed as complying with UL 2034 and be installed and maintained in accordance with NFPA 720 and the manufacturer's instructions. An open parking garage, as defined in the *International Building Code*, or enclosed parking garage ventilated in accordance with Section 404 of the *International Mechanical Code* shall not be deemed to be an attached garage.

Exception: Sleeping units or dwelling units which do not themselves contain a fuel-burning appliance or have an attached garage, but which are located in a building with a fuel-burning appliance or an attached garage, need not be provided with single station carbon monoxide alarms provided that:

1. The sleeping units or dwelling unit is located more than one story above or below any story which contains a fuel-burning appliance or an attached garage;
2. The sleeping units or dwelling unit is not connected by duct work or ventilation shafts to any room containing a fuel-burning appliance or to an attached garage; and
3. ~~The building is provided with a common area carbon monoxide alarm system the room with the fuel burning~~ A carbon monoxide detector is installed in the room containing the fuel burning appliance.

(Portions of the proposal not shown remain unchanged.)

Commenter's Reason: The modification to F133 cleans up the language approved during the code development hearings as to when carbon monoxide detection is required in Group I and R occupancies. The change modifies the requirement to requirement carbon monoxide detectors only when the attached garage has an opening that communicates with the dwelling unit and second clarifies the location when the carbon monoxide detectors are installed. The change to item 3 of the exception removes the requirement for a carbon monoxide alarm system and requires only that a carbon monoxide detector be installed in the room containing a fuel burning appliance. This type of installation would provide warning of any problem with the heating system, without the excessive cost burden associated with a complete carbon monoxide alarm system.

This change as modified has been submitted as a public comment to PM-23-09/10 which was approved by the code development establishing requirements for carbon monoxide in the IPMC and IEBC. If the modifications as proposed above and the modifications as proposed by NMHC to PM23-09/10 are approved by the membership the codes will be aligned with the same requirements thus eliminating the problem that the requirements for new construction differ from those in the IPMC and IEBC that are enforced after the building is completed.

F134-09/10
909.2 (IBC [F] 909.2), 909.10.2.1 (IBC [F] 909.10.2.1)

Proposed Change as Submitted

Proponent: Tony Crimi, A.C. Consulting Solutions Inc., representing International Firestop Council

Revise as follows:

909.2 (IBC [F] 909.2) General design requirements. Buildings, structures or parts thereof required by this code to have a smoke control system or systems, or a stair pressurization system shall have such systems designed in accordance with the applicable requirements of Section 909 and the generally accepted and well-established principles of engineering relevant to the design. The construction documents shall include sufficient information and detail to adequately describe the elements of the design necessary for the proper implementation of the smoke control systems. These documents shall be accompanied by sufficient information and analysis to demonstrate compliance with these provisions.

909.20.6.1 Ventilation systems. Smokeproof enclosure <u>and pressurized stairway</u> ventilation systems shall be independent of other building ventilation systems. The equipment, control wiring, power wiring and ductwork shall comply with one of the following:

1. Equipment, control wiring, power wiring and ductwork shall be located exterior to the building and directly connected to the smokeproof enclosure <u>or pressurized stairway</u> or connected to the smokeproof enclosure <u>or pressurized stairway</u> by ductwork enclosed by not less than 2-hour *fire barriers* constructed in accordance with <u>Section 707</u> or *horizontal assemblies* constructed in accordance with <u>Section 712</u>, or both.
2. Equipment, control wiring, power wiring and ductwork shall be located within the smokeproof enclosure <u>or pressurized stairway</u> with intake or exhaust directly from and to the outside or through ductwork enclosed by not less than 2-hour *fire barriers* constructed in accordance with <u>Section 707</u> or *horizontal assemblies* constructed in accordance with <u>Section 712</u>, or both.
3. Equipment, control wiring, power wiring and ductwork shall be located within the building if separated from the remainder of the building, including other mechanical equipment, by not less than 2-hour *fire barriers* constructed in accordance with <u>Section 707</u> or *horizontal assemblies* constructed in accordance with <u>Section 712</u>, or both.

Exceptions:

1. Control wiring and power wiring utilizing a 2-hour rated cable or cable system.
2. Where encased with not less than 2 inches (51 mm) of concrete.
3. <u>Ductwork shall be permitted to be protected using an approved alternative fire-resistive duct assembly that is a *listed* and *labeled* specifically for such purpose.</u>

Reason: This proposal would require Stair pressurization ducts installed for the purposes of stairwell pressurization to be enclosed within a shaft or protected by an equivalent tested and listed assembly or system evaluated for the purpose. Smoke control systems have been required in nearly two thirds of the United States for over a decade. High-rise buildings constructed to the requirements of International Building Code, but without any specific measures to control smoke migration, are all the more vulnerable to property damage and occupants' loss of life.

The purpose of a closed pressurization system is to provide fresh air directly to stairwells or egress areas. This design air pressures need to be sufficient to maintain closed doors while preventing smoke from entering the egress path. Several incidents in North America during the past 40 years have demonstrated that serious fires can occur in modern high-rise buildings, that these fires can generate tremendous quantities of smoke, and that smoke can spread rapidly throughout these buildings. Most notable were the 1970 One New York Plaza fire, the1973 Hyatt Regency O'Hare Hotel fire, the 1980 MGM Grand Hotel in Las Vegas, a 1981 fire in North York Ontario at the Inn on the Park Hotel, the 1983 First Canadian Place in Toronto, Ontario, One Meridian Plaza, Philadelphia, Pennsylvania and the First Interstate Bank in Los Angeles, California in the 1990's, and the 2001 World Trade Center.

There is a large body of available research that indicates the need for smoke control is more pressing in tall buildings that in any other type of construction. Pressurization results in airflows of high velocity in the gaps around closed doors and construction cracks, thereby preventing smoke from flowing back into the pressurized space through these openings. Pressurized stairwells are provided with the goal of maintaining a tenable environment within the escape routes in the event of a building fire. While the option to use stairwell pressurization exists, the IBC does not require stairwell pressurization in high-rise buildings, and only requires smoke control in underground buildings, atriums, and covered mall buildings. Section 403.13 of the 2009 IBC requires smokeproof exit enclosures for high-rise buildings in every required stairway serving floors more than 75 feet (22.86 m) above the ground. Section 909.20.5 merely permits sprinklered Buildings to use stairwell pressurization as an alternate to the smokeproof enclosures. When employed, ducts used for Stair pressurization to provide uncontaminated air within required interior exit stairwells or areas of egress need to be protected from the effect of fire, or constructed as fire resistant systems.

Particularly in the case of tall buildings, the predominant factors that cause smoke movement in tall buildings are stack effects, the affect of external wind forces, and forced air movement within the building. Smoke removal and venting practices are complicated by stack effects, which will tend to favor natural air movement vertically through the building as a result of differences in temperature and densities between the inside and outside air. [1]

Options such as the use of natural ventilation are only available where openings in exterior stairwells can be accommodated. Even then, a number of problems have been identified with this approach. Firstly, the required volume of fresh air is high. Secondly, natural supply and exhaust through vents may be subject to adverse exterior wind conditions, and even when functioning satisfactorily, would generally require vents located on different exterior walls. Thirdly, the performance of natural vents is influenced by building stack effects, which may be particularly significant on the upper or lowermost stories for tall buildings. This effect can range from either strong inflow or strong outflow from all natural vents on a given storey.[2]

The IBC needs to provide more effective means to prevent smoke from entering critical exit stairwells in high-rise buildings. Properly designed stairwell pressurization prevents smoke from flowing back into the pressurized exit stairwells and smokeproof enclosures. The goal of this proposal is maintaining a tenable environment within the escape routes in the event of a building fire.

Cost Impact: The code change proposal will not increase the cost of construction

ICCFILENAME: CRIMI-F1-909.2.DOC

Public Hearing Results

Committee Action: Disapproved

Committee Reason: The committee disapproved the proposal for a couple reasons. First, it was felt that the proposed exception is best dealt with as an alternative method in accordance with Chapter 1. The second reason was concern with the inconsistency with terminology related to pressurized systems. Finally there was concern that there are other pressurization methods such as elevator pressurization that should be correlated with this section.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Tony Crimi, A.C. Consulting Solutions Inc., representing International Firestop Council, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

909.2 (IBC [F] 909.2) General design requirements. Buildings, structures or parts thereof required by this code to have a smoke control system or systems, or a stair pressurization system shall have such systems designed in accordance with the applicable requirements of Section 909 and the generally accepted and well-established principles of engineering relevant to the design. The construction documents shall include sufficient information and detail to adequately describe the elements of the design necessary for the proper implementation of the smoke control systems. These documents shall be accompanied by sufficient information and analysis to demonstrate compliance with these provisions.

IBC 909.20.6.1 Ventilation systems. <u>The ventilation system for </u>smokeproof enclosure<u>s</u> and pressurized stairway<u>s</u> ~~ventilation systems~~ shall be independent of other building ventilation systems. The equipment, control wiring, power wiring and ductwork shall comply with one of the following:

1. Equipment, control wiring, power wiring and ductwork shall be located exterior to the building and directly connected to the smokeproof enclosure or pressurized stairway or connected to the smokeproof enclosure or pressurized stairway by ductwork enclosed by not less than 2-hour *fire barriers* constructed in accordance with Section 708 or *horizontal assemblies* constructed in accordance with Section 712, or both.
2. Equipment, control wiring, power wiring and ductwork shall be located within the smokeproof enclosure or pressurized stairway with intake or exhaust directly from and to the outside or through ductwork enclosed by not less than 2-hour *fire barriers* constructed in accordance with Section 708 or *horizontal assemblies* constructed in accordance with Section 712, or both.
3. Equipment, control wiring, power wiring and ductwork shall be located within the building if separated from the remainder of the building, including other mechanical equipment, by not less than 2-hour *fire barriers* constructed in accordance with Section 708 or *horizontal assemblies* constructed in accordance with Section 712, or both.

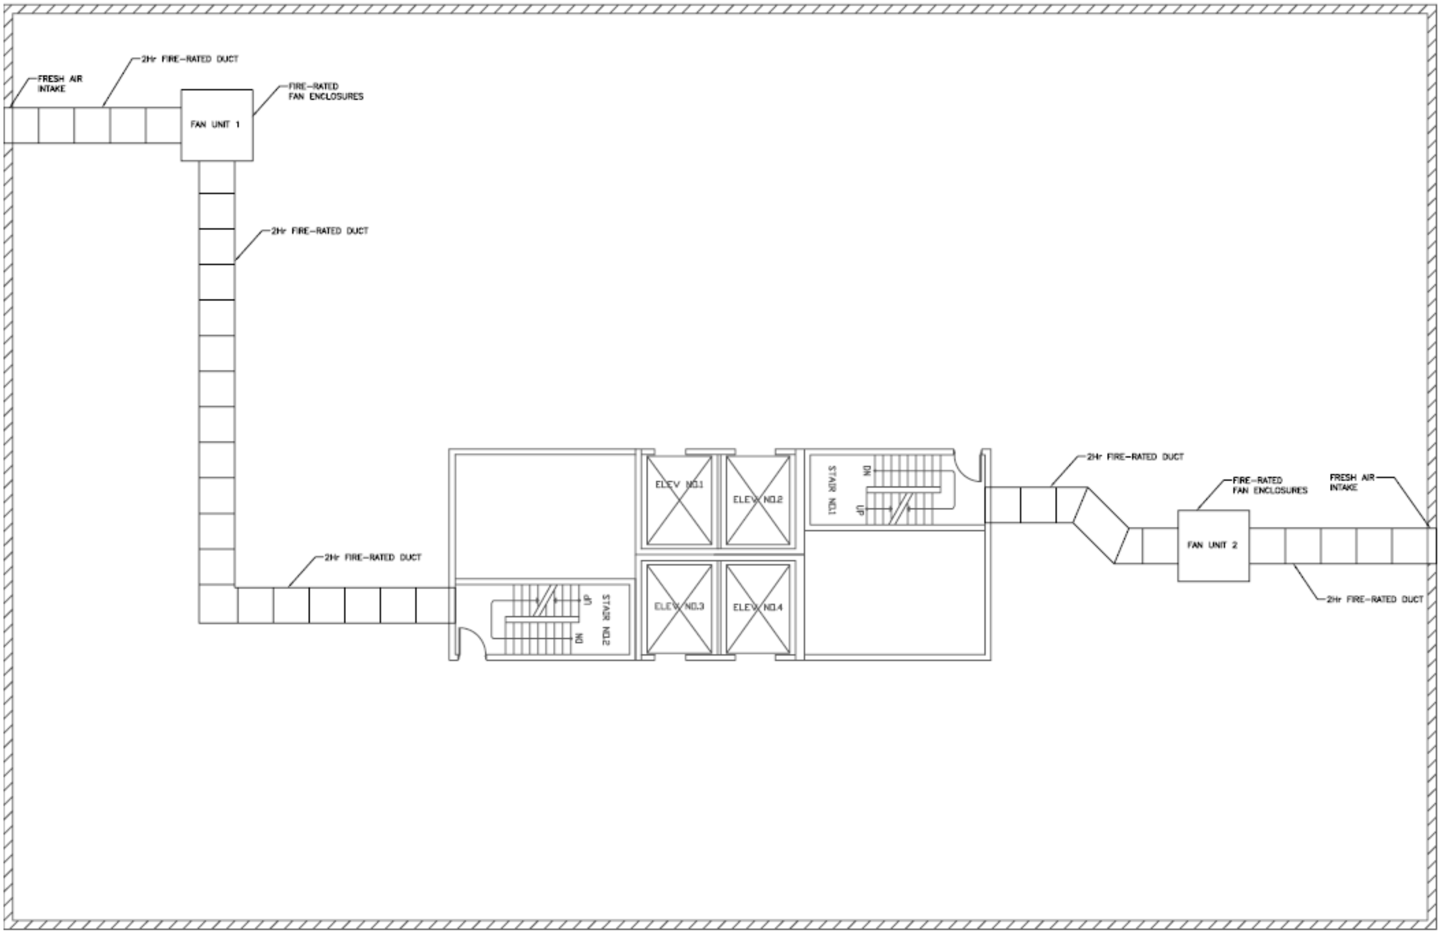
Exceptions:

1. Control wiring and power wiring utilizing a 2-hour rated cable or cable system.
2. Where encased with not less than 2 inches (51 mm) of concrete.
3. Ductwork shall be permitted to be protected using an approved alternative <u>fire resistant</u> ~~fire-resistive~~ duct ~~assembly~~ <u>construction approved by the building official.</u> ~~that is a *listed* and *labeled* specifically for such purpose~~.

Commenter's Reason: The purpose of a closed pressurization system is to provide fresh air directly to stairwells or egress areas. This proposal would require Stair pressurization systems to be designed in accordance with the existing requirements of section 909, and require ducts installed for the purposes of stairwell pressurization to be enclosed within a shaft enclosure or alternate construction approved by the building official, in accordance with the IBC.

Where stair pressurization is used, the design air pressures need to be sufficient to maintain closed doors while preventing smoke from entering the egress path. At the same time, the ducts and fans supplying the pressurized air to the Stairwells need to be protected in order to ensure that they can continue to function in the event of a fire in the remainder of the floor area. This is particularly critical because, even if installed, fire and/or smoke dampers are not closed during a fire emergence in a pressurization duct designed to supply air to the stairwell.

The illustration below shows a typical contemporary floor plate. Stairwells are not typically located on the exterior wall of a building. It is not unlikely that the ducts supply the pressurization will pass through the floor are, and possibly through fire resistance rated separations. The IBC needs to stipulate the design and protection required to ensure reliable operation of these systems during a fire event. Properly designed stairwell pressurization prevents smoke from flowing back into the pressurized exit stairwells and smokeproof enclosures.



TYPICAL FIRE-RATED STAIR
PRESSURIZATION SYSTEM

Final Action: AS AM AMPC____ D

F135-09/10

909.3 (IBC [F] 909.3, IMC [F] 513.3), 909.18.8 (IBC [F] 909.18.8), 909.18.8.1 (IBC [F] 909.18.8.1), 909.18.8.2 (IBC [F] 909.18.8.2), 909.18.8.2.1 (IBC [F] 909.18.8.2.1), 909.18.8.2.2 (IBC [F] 909.18.8.2.2), 909.18.8.2.3 (IBC [F] 909.18.8.2.3); IBC [F] 1704.16, [F] 1704.16.1, [F] 1704.16.2

Proposed Change as Submitted

Proponent: Vickie Lovell, Representing National Energy Management Institute

1. Revise as follows:

909.3 (IBC [F] 909.3, IMC [F] 513.3) Special inspection and test requirements. In addition to the ordinary inspection and test requirements to which buildings, structures and parts thereof are required to undergo, smoke control systems subject to the provisions of Section 909 shall undergo special inspections and tests sufficient to verify the proper commissioning of the smoke control design in its final installed condition. The design submission accompanying the *construction documents* shall clearly detail procedures and methods to be used and the items subject to such inspections and tests. Such commissioning shall be in accordance with generally accepted engineering practice and, where possible, based on published standards for the particular testing involved. The special inspections and tests required by this section shall be conducted under the same terms as in Section 1704 of the International Building Code <u>and Section 909.18 of this code.</u>

909.18.8 (IBC [F] 909.18.8) Special inspections for smoke control. Smoke control systems shall be tested by a special inspector in accordance with the requirements for special inspections in Sections 909.18 through 909.19 and Section 909.20.6.3 of the *International Building Code*.

909.18.8.1 (IBC [F] 909.18.8.1) Scope of testing. Special inspections shall be conducted in accordance with the following:

1. During erection of ductwork and prior to concealment for the purposes of leakage testing and recording of device location.
2. Prior to occupancy and after sufficient completion for the purposes of pressure-difference testing, flow measurements, and detection and control verification.

909.18.8.2 (IBC [F] 909.18.8.2) Qualifications. Special inspection agencies for smoke control shall have expertise in fire protection engineering, mechanical engineering and certification as air balancers, or be certified by a third party accreditation program for air testing, adjusting and air balancing and for inspection of smoke control systems. An approved special inspection agency shall provide all information as necessary for the building official to determine that the agency meets the applicable requirements and shall be qualified to conduct, supervise and evaluate tests and periodic inspections and maintenance.

909.18.8.2.1 (IBC [F] 909.18.8.2.1) Independence. An approved special inspection agency shall be objective, competent and independent from the contractor responsible for the work being inspected. The agency shall also disclose possible conflicts of interest so that objectivity can be confirmed.
909.18.8.2.2 (IBC [F] 909.18.8.2.2) Equipment. An approved special inspection agency shall have adequate equipment to perform required tests. The equipment shall be periodically calibrated.

909.18.8.2.3 (IBC [F] 909.18.8.2.3) Personnel. An approved special inspection agency shall employ experienced personnel educated in conducting, supervising and evaluating tests and inspections.

IBC [F] 1704.16 Special inspection for smoke control. Smoke control systems shall be tested by a special inspector in accordance with Section 909.18.8.

~~**IBC [F] 1704.16.1 Testing scope.** The test scope shall be as follows:~~

1. ~~During erection of ductwork and prior to concealment for the purposes of leakage testing and recording of device location.~~
2. ~~Prior to occupancy and after sufficient completion for the purposes of pressure difference testing, flow measurements and detection and control verification.~~

~~**IBC [F] 1704.16.2 Qualifications**. *Special inspection* agencies for smoke control shall have expertise in fire protection engineering, mechanical engineering and certification as air balancers.~~

Reason: The purpose of this code change is to clarify and centralize the language as it relates to the qualifications of special inspectors and special inspection agencies of smoke control systems. This ties together the IBC, IFC, and IMC with consistent language as it relates to special inspections, testing and maintenance of smoke control systems.
909.3. This is an editorial change which adds the reference of the new language in Sections 909.18.
909.18.8. The addition of the referenced sections clarifies the intent of the code's requirement of special inspections, agencies, and inspectors.
909.18.8.2. through 909.18.8.2.3. This language is derived from Chapter 1703.1.1 of the 2009 IBC.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: LOVELL-F2-909.3

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee disapproved this code change with concern that Section 909.18.8.2.1 did not include the engineer and only referenced the contractor. In addition it would be more appropriate to reference the fire code official versus the building official. Generally there was concern that allowing third party accreditation may lessen the testing requirements. It should be noted that the committee did like that the proposal coordinated the smoke control special inspection requirements between the IBC, IFC and the IMC.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Vickie Lovell, InterCode Incorporated, representing National Energy Management Institute, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

909.3 (IBC [F] 909.3, IMC [F] 513.3) Special inspection and test requirements. In addition to the ordinary inspection and test requirements to which buildings, structures and parts thereof are required to undergo, smoke control systems subject to the provisions of Section 909 shall undergo special inspections and tests sufficient to verify the proper commissioning of the smoke control design in its final installed condition. The design submission accompanying the *construction documents* shall clearly detail procedures and methods to be used and the items subject to such inspections and tests. Such commissioning shall be in accordance with generally accepted engineering practice and, where possible, based on published standards for the particular testing involved. The special inspections and tests required by this section shall be conducted under the same terms as in Section 1704 of the International Building Code and Section 909.18 of this code.

909.18.8 (IBC [F] 909.18.8) Special inspections for smoke control. Smoke control systems shall be tested by a special inspector in accordance with the requirements for special inspections in Sections 909.18 through 909.19 and Section 909.20.6.3 of the *International Building Code*.

909.18.8.1 (IBC [F] 909.18.8.1) Scope of testing. Special inspections shall be conducted in accordance with the following:

1. During erection of ductwork and prior to concealment for the purposes of leakage testing and recording of device location.
2. Prior to occupancy and after sufficient completion for the purposes of pressure-difference testing, flow measurements, and detection and control verification.

909.18.8.2 (IBC [F] 909.18.8.2) Qualifications. Special inspection agencies for smoke control shall have expertise in fire protection engineering, mechanical engineering and certification as air balancers,or be certified by a third party accreditation program for air testing, adjusting and air balancing and for inspection of smoke control systems. An approved special inspection agency shall provide all information as necessary for the ~~building~~ fire code official to determine that the agency meets the applicable requirements and shall be qualified to conduct, supervise and evaluate the annual and semiannual operational test required by 909.20 ~~tests and periodic inspections and maintenance~~.

> **Exception:** Periodic component inspection and maintenance shall be permitted to be performed by facility maintenance personnel, or personnel certified by a third party accreditation program for inspection and maintenance of the components of the system.

909.18.8.2.1 (IBC [F] 909.18.8.2.1) Independence. An approved special inspection agency shall be objective, competent and independent from the contractor responsible for the work being inspected. The agency shall also disclose possible conflicts of interest so that objectivity can be confirmed.

909.18.8.2.2 (IBC [F] 909.18.8.2.2) Equipment. An approved special inspection agency shall have adequate equipment to perform required tests. The equipment shall be periodically calibrated.

909.18.8.2.3 (IBC [F] 909.18.8.2.3) Personnel. An approved special inspection agency shall employ experienced personnel educated in conducting, supervising and evaluating tests and inspections.

IBC [F] 1704.16 Special inspection for smoke control. Smoke control systems shall be tested by a special inspector in accordance with Section 909.18.8.

(Portions of the proposal not shown remain unchanged.)

Commenter's Reason: The International Fire Code specifies in 909.20.1 that a routine inspection and maintenance program and an annual or semi annual operational testing program of the system be initiated immediately after the smoke control system has passed the acceptance tests. The IBC, IMC, IFC all have partial requirements as to who should be qualified to execute this work, which may be divided into two categories of work. One type of inspection is the ongoing system component maintenance which may be required regular inspections per the written schedule for routine maintenance. The other is annual or semiannual operational testing of the entire smoke control system.

This public comment combines the requirements of the IBC, IMC, IFC into one location in the IFC and makes a distinction between maintenance personnel, or otherwise qualified individuals who can perform routine inspections and maintenance and those who have the technical expertise to evaluate the operation and function of the entire smoke control system.

Final Action: AS AM AMPC____ D

F142-09/10
909.20

Proposed Change as Submitted

Proponent: Vickie Lovell, Representing National Energy Management Institute

Add new text as follows:

909.20 Maintenance. Smoke control systems shall be maintained to ensure to a reasonable degree that the system is capable of controlling smoke for the duration required. The maintenance and testing of the smoke control system shall be supervised by personnel who have expertise in fire protection engineering, mechanical engineering and certified as air balancers, or are certified by a third party accreditation program for air testing, adjusting and air balancing and for inspection of smoke control systems. The system shall be maintained in accordance with the manufacturer's instructions and Sections 909.20.1 through 909.20.5.

Reason: The purpose of this addition is to further clarify the requirements of those supervising individuals who test and maintain smoke control systems. Third-party accreditation programs provide individuals with the needed expertise in fire-protection engineering, mechanical engineering, and air adjusting and balancing.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: LOVELL-F3-909.20

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee felt that it would be too restrictive to require the proposed level of qualifications for the maintenance of approved smoke control systems.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Vickie Lovell, InterCode Incorporated, representing National Energy Management Institute, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

909.20 Maintenance. Smoke control systems shall be maintained to ensure to a reasonable degree that the system is capable of controlling smoke for the duration required. The annual and semiannual inspection and operational ~~maintenance and~~ testing of the smoke control system as required by 909.20.4 and 909.20.5 shall be supervised by personnel who have expertise in fire protection engineering, mechanical engineering and certified as air balancers, or are certified by a third party accreditation program for air testing, adjusting and air balancing and for inspection of smoke control systems. The system components shall be maintained in accordance with the manufacturer's instructions and Sections 909.20.1 through 909.20.5.

Commenter's Reason: The purpose of this public comment is to clarify that this requirement for qualified supervisory personnel is intended to fulfill the required annual and semiannual operational testing of the smoke control system. Routine component maintenance and testing may be performed by either a certified third-party or otherwise qualified individuals, such as facility maintenance personnel; however it is not required by this new code section.

Final Action: AS AM AMPC____ D

F144-09/10

910 (IBC [F] 910), 2306, Chapter 47 (IBC Chapter 35)

Proposed Change as Submitted

Proponent: Paul K. Heilstedt, PE, HonAIA, Chair, representing ICC Code Technology Committee (CTC)

1. Revise as follows:

SECTION 910
SMOKE AND HEAT VENTS

910.1 (IBC [F] 910.1) General. Where required by this code ~~or otherwise installed~~, smoke and heat vents and draft curtains or mechanical smoke ~~exhaust~~ removal systems~~, and draft curtains~~ shall conform to the requirements of this section. The provisions of Section 910.3 shall only apply to buildings or portions thereof, which are not protected by an automatic sprinkler system. The provisions of Section 910.4 shall apply to buildings or portions thereof which are protected by an automatic sprinkler system in accordance with Section 903.3.1.1.

~~**Exceptions:**~~

1. ~~Frozen food warehouses used solely for storage of Class I and II commodities where protected by an approved automatic sprinkler system.~~
2. ~~Where areas of buildings are equipped with early suppression fast-response (ESFR) sprinklers, automatic smoke and heat vents shall not be required within these areas.~~

910.2 (IBC [F] 910.2) Where required. Smoke and heat vents and draft curtains or a smoke removal system shall be ~~installed in the roofs of one-story buildings or portions thereof occupied for the uses set forth in Sections 910.2.1 through 910.2.3.~~ provided as required by Sections 910.2.1 through 910.2.3

910.2.1 (IBC [F] 910.2.1) Group F-1 or S-1. ~~Buildings and portions thereof used as~~ A mechanical smoke removal system shall be installed in one story buildings or portions thereof used as a Group F-1 or S-1 occupancy exceeding 50,000 square feet. ~~having more than 50,000 square feet (4645 m^2) in undivided area.~~

~~**Exception:** Group S-1 aircraft repair hangars.~~

910.2.2 (IBC [F] 910.2.2) Nonsprinklered high-piled combustible storage. Smoke and heat vents and draft curtains shall be installed in one story buildings or portions thereof containing high-piled combustible storage ~~stock~~ which is not protected by an automatic sprinkler system ~~or rack storage in any occupancy group~~ in accordance with Section 2306.7.

910.2.3 (IBC [F] 910.2.3) Sprinklered high-piled combustible storage. A mechanical smoke removal system shall be installed in one story buildings or portions thereof containing high-piled combustible storage which is protected by an automatic sprinkler system in accordance with Section 413 and the *International Fire Code*.

910.3 (IBC [F] 910.3) Design and installation. The design and installation of smoke and heat vents and draft curtains in buildings which are not protected by an automatic sprinkler system shall be ~~as specified in Sections 910.3.1 through 910.3.5.2 and Table 910.3.~~ in accordance with NFPA 204 and this section.

~~**TABLE 910.3 (IBC [F] TABLE 910.3)**~~
~~**REQUIREMENTS FOR DRAFT CURTAINS AND SMOKE AND HEAT VENTS[a]**~~
(Delete table and notes in their entirety)

910.3.1 (IBC [F] 910.3.1) Smoke boundary layer. Smoke and heat vents and draft curtain installations shall be designed to maintain the elevation of the smoke boundary layer as defined by NFPA 204 a minimum of 6 feet above the elevation of the means of egress for a period of 20 minutes after effective ignition.

~~**910.3.1 (IBC [F] 910.3.1) Design.**~~ **910.3.2 (IBC [F] 910.3.2) Listing and labeling.** Smoke and heat vents shall be listed and labeled to indicate compliance with UL 793 or FM 4430..

~~**910.3.2 (IBC [F] 910.3.2) Vent operation.** Smoke and heat vents shall be capable of being operated by approved automatic and manual means. Automatic operation of smoke and heat vents shall conform to the provisions of Sections 910.3.2.1 through 910.3.2.3.~~

~~**910.3.2.1 (IBC [F] 910.3.2.1) Gravity-operated drop-out vents.** Automatic smoke and heat vents containing heat-sensitive glazing designed to shrink and drop out of the vent opening when exposed to fire shall fully open within 5 minutes after the vent cavity is exposed to a simulated fire, represented by a time-temperature gradient that reaches an air temperature of 500°F (260°C) within 5 minutes.~~

~~**910.3.2.2 (IBC [F] 910.3.2.2) Sprinklered buildings.** Where installed in buildings provided with an approved automatic sprinkler system, smoke and heat vents shall be designed to operate automatically.~~

~~**910.3.2.3 (IBC [F] 910.3.2.3) Nonsprinklered buildings.** Where installed in buildings not provided with an approved automatic sprinkler system, smoke and heat vents shall operate automatically by actuation of a heat-responsive device rated at between 100°F (38°C) and 220°F (104°C) above ambient.~~

~~**Exception:** Gravity-operated drop-out vents complying with Section 910.3.2.1~~

~~**910.3.3 (IBC [F] 910.3.3) Vent dimensions.** The effective venting area shall not be less than 16 square feet (1.5 m^2) with no dimension less than 4 feet (1219 mm), excluding ribs or gutters having a total width not exceeding 6 inches (152 mm).~~

~~**910.3.4 (IBC [F]**~~ ~~**910.3.4**~~ <u>**910.3.3 (IBC [F] 910.3.3**</u> **Vent locations.** Smoke and heat vents shall be located 20 feet (6096 mm) or more from adjacent lot lines and fire walls and 10 feet (3048 mm) or more from fire barriers. ~~Vents shall be uniformly located within the roof in the areas of the building where the vents are required to be installed by Section 910.2 with consideration given to roof pitch, draft curtain location, sprinkler location and structural members~~.

~~**910.3.5 (IBC [F] 910.3.5)**~~ <u>**910.3.4 (IBC [F] 910.3.4**</u> **Draft curtains.** Where required by ~~Table 910.~~3 <u>NFPA 204</u>, draft curtains shall be installed on the underside of the roof in accordance with this section.

Exception: Where areas of buildings are equipped with ESFR sprinklers, draft curtains shall not be provided within these areas. Draft curtains shall only be provided at the separation between the ESFR sprinklers and the non ESFR sprinklers.

~~**910.3.5.1 (IBC [F]**~~ ~~**910.3.5.1**~~ <u>**910.3.4.1 (IBC [F] 910.3.4.1)**</u> **Construction.** Draft curtains shall be constructed of sheet metal, lath and plaster, gypsum board or other approved materials which provide equivalent performance to resist the passage of smoke. Joints and connections shall be smoke tight.

~~**910.3.5.2 (IBC [F] 910.3.5.2) Location and depth.** The location and minimum depth of draft curtains shall be in accordance with Table 910.3.~~

~~**910.4 (IBC [F] 910.4) Mechanical smoke exhaust.** Where approved by the fire code official, engineered mechanical smoke exhaust shall be an acceptable alternate to smoke and heat vents.~~
<u>**[F] 910.4. Mechanical smoke removal system.** Where required by Sections 910.2.1 and 910.2.3, a mechanical smoke removal system shall be provided in accordance with this section.</u>

<u>**Exception:** Buildings or portions thereof which are protected by ESFR sprinklers.</u>

~~**910.4.1 (IBC [F] 910.4.1) Location.** Exhaust fans shall be uniformly spaced within each draft-curtained area and the maximum distance between fans shall not be greater than 100 feet (30 480 mm).~~

<u>**910.4.1 (IBC [F] 910.4.1) Exhaust fan number and spacing.** A minimum of two exhaust fans shall be provided. The spacing between exhaust inlets shall be a minimum of 40 feet and not exceed 100 feet.</u>

~~**910.4.2 (IBC [F] 910.4.2) Size.** Fans shall have a maximum individual capacity of 30,000 cfm (14.2 m3/s). The aggregate capacity of smoke exhaust fans shall be determined by the equation:~~

~~$C=A\times 300$ **(Equation 9-10)**~~

~~where:~~

~~*C* = Capacity of mechanical ventilation required, in cubic feet per minute (m3/s).~~
~~*A* = Area of roof vents provided in square feet (m2) in accordance with Table 910.3.~~

<u>**910.4.2 (IBC [F] 910.4.2) Exhaust fan construction.** Exhaust fans which are part of the smoke removal system shall be rated for operation at ambient temperatures. Exhaust fan motors shall be located outside of the exhaust air stream.</u>

<u>**910.4.2 (IBC [F] 910.4.3) System design criteria.** The mechanical smoke removal system shall be sized to exhaust the building at a minimum rate of 4 air changes per hour based upon the volume of the building or portion thereof without contents. The capacity of each exhaust fan shall not exceed 30,000 cubic feet per minute. Adequate make-up air shall be available and approved.</u>

~~**910.4.3 (IBC [F] 910.4.3) Operation.** Mechanical smoke exhaust fans shall be automatically activated by the automatic sprinkler system or by heat detectors having operating characteristics equivalent to those described in Section 910.3.2. Individual manual controls of each fan unit shall also be provided.~~

910.4.4 (IBC [F] 910.4.4) Activation. The mechanical smoke removal system shall be activated by manual controls. The mechanical smoke removal system shall not be automatically activated.

910.4.5 (IBC [F] 910.4.5) Manual control location. Manual controls shall be located so as to be accessible to the fire service from the exterior of the building and be protected against interior fire exposure by not less than 1-hour fire barriers constructed in accordance with Section 707 or horizontal assemblies constructed in accordance with Section 712, or both.

~~**[F] 910.4.4 Wiring and control.** Wiring for operation and control of smoke exhaust fans shall be connected ahead of the main disconnect and protected against exposure to temperatures in excess of 1,000°F (538°C) for a period of not less than 15 minutes. Controls shall be located so as to be immediately accessible to the fire service from the exterior of the building and protected against interior fire exposure by not less than 1-hour fire barriers constructed in accordance with Section 706 or horizontal assemblies constructed in accordance with Section 711, or both.~~

910.4.6 (IBC [F] 910.4.6) Wiring and control. Wiring for the operation and control of smoke removal system fans shall be connected ahead of the main disconnect and be protected by materials with a finish rating of 30 minutes.

~~**910.4.5 (IBC [F] 910.4.5) Supply air.** Supply air for exhaust fans shall be provided at or near the floor level and shall be sized to provide a minimum of 50 percent of required exhaust. Openings for supply air shall be uniformly distributed around the periphery of the area served.~~

~~**910.4.6 (IBC [F] 910.4.6) Interlocks.** In combination comfort air-handling/ smoke removal systems or independent comfort air-handling systems, fans shall be controlled to shut down in accordance with the approved smoke control sequence.~~

910.4.7 (IBC [F] 910.4.7) Interlocks. Where building air-handling and smoke removal systems are combined or where independent building air-handling systems are provided, fans shall automatically shut down in accordance with the *International Mechanical Code*. The manual controls provided for the smoke removal system shall have the cability to override the automatic shutdown of fans that are part of the smoke removal system.

TABLE 2306.2
GENERAL FIRE PROTECTION AND LIFE SAFETY REQUIREMENTS

COMMODITY CLASS	**SIZE OF HIGH-PILED STORAGE AREA[a] (square feet) (see Sections 2306.2 and 2306.4)**	**ALL STORAGE AREAS (See Sections 2306, 2307 and 2308)[b]**

(Portions of table not shown remain unchanged)

For SI: 1 foot = 304.8 mm, 1 cubic foot = 0.02832 m^3 , 1 square foot = 0.0929 m^2 .

a. When automatic sprinklers are required for reasons other than those in Chapter 23, the portion of the sprinkler system protecting the high-piled storage area shall be designed and installed in accordance with Sections 2307 and 2308.

b. For aisles, see Section 2306.9.

c. Piles shall be separated by aisles complying with Section 2306.9.

d. For storage in excess of the height indicated, and high hazard storage areas greater than 300, 000 square feet, ~~special fire protection~~ an approved engineering design such as fire protection of structural elements and enhanced fire suppression shall be provided ~~in accordance with Note g when required by the fire code official~~. See also Chapters 28 and 34 for special limitations for aerosols and flammable and combustible liquids, respectively.

e. Section 503 shall apply for fire apparatus access.

f. For storage exceeding 30 feet in height, Option 1 shall be used.

~~g. Special fire protection provisions including, but not limited to, fire protection of exposed steel columns; increased sprinkler density; additional in-rack sprinklers, without associated reductions in ceiling sprinkler density; or additional fire department hose connections shall be provided when required by the fire code official.~~

h. High-piled storage areas shall not exceed 500,000 square feet. A 2-hour fire wall constructed in accordance with the International Building Code shall be used to divide high-piled storage exceeding 500,000 square feet in area.

i. Not required when an automatic fire-extinguishing system is designed and installed to protect the high-piled storage area in accordance with Sections 2307 and 2308.

j. Smoke and heat venting shall not be ~~Not~~ required when storage areas are protected by early suppression fast response (ESFR) sprinkler systems installed in accordance with NFPA 13. Where a standard sprinkler system is installed in these locations, a mechanical smoke removal system shall be provided in accordance with Section 910.4. See Section 2306.7.

2306.7 Smoke and heat ~~removal~~ venting. Where smoke and heat ~~removal~~ venting ~~are~~ is required by Table 2306.2 in buildings not protected by an automatic sprinkler system, smoke and heat vents and draft curtains shall be provided in accordance with Section 910. Smoke and heat venting shall not be required where storage areas are protected by early suppression fast response (ESFR) sprinkler systems installed in accordance with NFPA 13. Where Table 2306.2

requires smoke and heat venting in a building with a standard sprinkler system, a mechanical smoke removal system shall be provided in accordance with Section 910.4. Where draft curtains are required by Table 2306.2, they shall be provided in accordance with Section 910.3.4.

2. Add new standards to Chapter 47 (IBC Chapter 35) as follows:

FM
4430-07 Approval Standard for Heat and Smoke Vents

NFPA
204-2010 Standard for Smoke and Heat Venting

Reason: The ICC Board established the ICC Code Technology Committee (CTC) as the venue to discuss contemporary code issues in a committee setting which provides the necessary time and flexibility to allow for full participation and input by any interested party. The code issues are assigned to the CTC by the ICC Board as "areas of study". Information on the CTC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CTC effort can be downloaded from the following website: http://www.iccsafe.org/cs/cc/ctc/index.html. Since its inception in April/2005, the CTC has held seventeen meetings - all open to the public.

This proposed change is a result of the CTC's investigation of the area of study entitled "Balanced Fire Protection – Roof vents". The scope of the activity is noted as:

Review the current IBC/IFC requirements for smoke/heat vents and draft curtains relative to balanced fire protection**.**

The purpose of this code change is to update the provisions which mandate roof vents in one-story industrial and storage buildings. The code change will delete the specification-oriented provisions for roof vents and draft curtains for unsprinklered buildings and substitute a reference to NFPA 204. The code change will further require that a manually-operated mechanical smoke removal system be provided for large one-story industrial and storage buildings protected by a sprinkler system in lieu of the requirements for roof vents and draft curtains.

The first issue assigned by the ICC Board of Directors to the Code Technology Committee (CTC) in 2005 was the issue of "balanced" fire protection. As part of the CTC's review of the "balanced" fire protection issue, the CTC formed a Study Group to review the issue of whether or not smoke/heat vents were necessary in large buildings protected by a sprinkler system.

After reviewing the available research on the interaction of standard sprinklers and roof vents (NISTIR 6196-1), it was determined that individually-activated automatic roof vents are unlikely to activate automatically in buildings protected by standard spray sprinklers (provided that the sprinkler system is adequate for the hazard protected and is operational). Given this determination, it was concluded that the performance of individually-activated automatic roof vents is essentially the same as manually-operated roof vents in buildings protected by a sprinkler system.

The explanatory information provided in NFPA 204 indicates that the capabilities of roof vents to perform their function are dependent upon the depth of the smoke layer which develops and the temperature differential between the smoke layer and ambient temperature. Given that standard spray sprinklers are highly efficient in reducing ceiling temperatures due to the finely divided water spray produced by these types of sprinklers, the ceiling temperatures produced even in "high challenges" fires are rapidly reduced and, after about 10 minutes of sprinkler discharge, return to near ambient and continue to drop with additional time. Based upon this, it can be concluded that roof vents which are manually opened 10 minutes or more after sprinkler activation will not provide effective venting for the building.

Where the smoke layer temperature differentials are less than 110^{o}C (198^{o}F), NFPA 204 recommends that a powered (mechanical) exhaust system be provided in lieu of providing roof vents. Based upon the recommendations contained in NFPA 204, the provisions for providing roof vents have been deleted and a requirement for a manually-operated mechanical smoke removal system has been substituted.

The proposal requires that the manually-operated mechanical smoke removal system be sized to provide a minimum of 6 air changes per hour. Since the use of roof vents for the purpose of providing venting in sprinklered buildings has been acceptable for over 25 years, the sizing of the mechanical smoke removal system has been determined based upon the venting capabilities of roof vents at a time equal to the typical fire department response time, 10 minutes and beyond. Given that opened roof vents will provide little actual venting capability after the sprinkler system has been discharging water spray for 10 minutes, providing a mechanical smoke removal system which provides a minimum of 4 air changes an hour will be a substantial improvement over the presently acceptable venting capabilities for sprinklered buildings required by the IBC/IFC. The 4 air changes were viewed as a reasonable value when compared against the BOCA National Building Code which required 2 and the Uniform Building Code which required 6.

It should be noted that this code change proposal permits the mechanical smoke removal system to designed to operate at ambient temperatures. The rationale for this provision is that the ceiling temperatures throughout the building will be returned to close to ambient at between 10 and 15 minutes after the first sprinkler activates. Given that the typical response time for fire departments is roughly 10 minutes, and the ceiling temperatures expected after 10 minutes, there is no need to design the mechanical system to withstand temperatures higher than ambient.

In the opinion of the Study Group which has developed this code change proposal, the proposal is a vast improvement over the existing provisions for roof venting presently contained in the IBC/IFC.

It should be noted that simply making a reference to NFPA 204 as a substitute for the present specification-oriented provisions for roof vents/draft curtains contained in the IBC/ IFC is not an option because the current edition of NFPA 204 does not contain specific design provisions for the design of roof vent systems in buildings protected by a standard sprinkler system. Without specific provisions for roof vent system in sprinklered buildings, the requirements for roof vent systems in sprinklered buildings cannot be enforced in a uniform manner in all jurisdictions which utilize the IBC/IFC.

It should also be noted that the NFPA 204 committee is presently working developing provisions which address the design of roof venting systems in sprinklered buildings; however, these provisions have been under development for more than 30 years. It is the Study Group's opinion that the IBC/IFC should not be written based upon the assumption that the NFPA 204 committee will be able to develop provisions for the design of venting systems anytime in the near future.

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: A review of the standard proposed for inclusion in the code, FM 4430-07, for compliance with ICC criteria for referenced standards given in Section 3.6 of Council Policy #CP 28 will be posted on the ICC website on or before September 24, 2009. Review of proposed new standard NFPA 204-2010 indicated that, in the opinion of ICC Staff, the standard did comply with ICC standards criteria.

ICCFILENAME: HEILSTEDT-F1-910.1.DOC

Public Hearing Results

Note: The following analysis was not in the Code Change monograph but was published on the ICC website at http://www.iccsafe.org/cs/codes/Documents/2009-10cycle/ProposedChanges/Standards-Analysis.pdf :

Analysis: Review of proposed new standard NFPA 204-2010 indicated that, in the opinion of ICC Staff, the standard did comply with ICC standards criteria in terms of the availability of a consensus draft for the committee hearing. Note that section 3.6.3.1 of CP28-05 requires that the standard be completed and readily available prior to Final Action Consideration. The final action of this proposal will occur May 14-23, 2010.

Review of the proposed standard FM 4430-07 indicated that in the opinion of ICC Staff the standard did not comply with ICC standards criteria. More specifically the standard did not meet the consensus process of requirement of Section 3.6.3.2 of CP28-05.

Committee Action: Approved as Modified

Modify proposal as follows:

910.2.1 (IBC [F] 910.2.1) Group F-1 or S-1 ~~.~~A mechanical smoke removal system shall be installed in ~~one story~~ buildings or portions thereof used as a Group F-1 or S-1 occupancy exceeding 50,000 square feet.

910.2.3 (IBC [F] 910.2.3) Sprinklered high-piled combustible storage~~.~~ A mechanical smoke removal system shall be installed in ~~one story~~ buildings or portions thereof containing high-piled combustible storage which is protected by an automatic sprinkler system in accordance with Section 413 and the *International Fire Code*.

[F] 910.4. Mechanical smoke removal system. Where required by Sections 910.2.1 and 910.2.3, a mechanical smoke removal system shall be provided in accordance with this section.

Exceptions:

1. Buildings or portions thereof which are protected by ESFR sprinklers.
2. Buildings equipped with smoke and heat vents designed in accordance with NFPA 204, when permitted by NFPA 13.

910.4.6 (IBC [F] 910.4.6) Wiring and control. Wiring for the operation and control of smoke removal system fans ~~shall be connected ahead of the main disconnect~~ provided with power in accordance with Section 909.11 and be protected by materials with a finish rating of ~~30 minutes~~ not less than 1 hour.

2306.7 Smoke and heat venting. Where smoke and heat venting is required by Table 2306.2 in buildings not protected by an automatic sprinkler system, smoke and heat vents and draft curtains shall be provided in accordance with Section 910. Smoke and heat venting shall not be required where storage areas are protected by early suppression fast response (ESFR) sprinkler systems installed in accordance with NFPA 13. Where Table 2306.2 requires smoke and heat venting in a building with a standard sprinkler system, ~~a mechanical~~ smoke removal ~~system~~ shall be provided in accordance with Section 910.4. Where draft curtains are required by Table 2306.2, they shall be provided in accordance with Section 910.3.4.

Revise Table 2306.2 Note j as follows:

j. Smoke and heat venting shall not be required when storage areas are protected by early suppression fast response (ESFR) sprinkler systems installed in accordance with NFPA 13. Where a standard sprinkler system is installed in these locations, ~~a mechanical~~ smoke removal ~~system~~ shall be provided in accordance with Section 910.4. See Section 2306.7.

NFPA

204-~~2010~~ 2007 Standard for Smoke and Heat Venting

(Portions of the proposal not shown remain unchanged)

Committee Reason: The committee approved the proposal with amendments as it was felt that a major revision to this section was necessary. The proposal essentially requires mechanical smoke removal in sprinklered buildings and using smoke and heat vents in unsprinklered buildings. There were four major modifications to this code change. The first removed the phrase “one-story” from sections 910.2.1 and 910.2.3 as mechanical smoke removal does not need to be limited to ‘one story” buildings as smoke and heat venting is limited. The second modification increases the rating of the wiring for the smoke removal system from 30 minutes to 1 hour and also requires standby power and some associated passive protection of such power supplies in accordance with Section 909.11. Members of the committee felt smoke removal systems are critical emergency systems that need additional protection even in buildings where sprinklers are operating. The third modification recognizes some situations that are permitted by NFPA 13 to allow smoke and heat vents in sprinklered buildings. Allowing smoke and heat vents as an option when appropriate was felt to be necessary. This revision adds a new exception to Section 910.4 to allow this in lieu of smoke removal systems. In addition, Section 2306.7 and footnote j to Table 2306.2 makes the reference to smoke removal more general to be inclusive of mechanical smoke removal and smoke and heat vents. The fourth modification changes the referenced edition of NFPA 204 from the 2010 edition to the 2007 edition. The reason for the change of edition years relates to the fact that the 2010 edition is likely not to be available prior to the final action hearings.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Richard Schulte representing Schulte & Associates, requests Approval as Submitted.

Commenter's Reason: The reason for submitting this public comment is that it is Schulte & Associates' opinion that testimony heard in support of the modification to this code change proposal made by William Koffel, Koffel & Associates, was factually in error and, hence, the code changes committee was misled into believing that it is the intent of the 2010 edition of NFPA 13 to consider that the installation of roof vents "***is a viable technology in sprinklered buildings***".

It is also Schulte & Associates' opinion that the code changes committee was further misled by testimony provided by William Koffel that the next edition of NFPA 204 will contain a "methodology" for designing roof vent/draft curtain systems in buildings protected by a sprinkler system.

The text of William Koffel's testimony on the modification to code change proposal F144-09/10 is as follows:

> *"To the modification. As Carl* [Baldassarra] *said, the name of this committee is Code Technology Committee, but their proposal is eliminating a technology that has been used for years without adequate substantiation. So, the nature of our modification is merely in sprinklered buildings to give the option using mechanical system or to use vents as we've used for a number of years.*
>
> *Now, in their supporting statement, they identify several reasons for doing this. In the second to the last paragraph on the first page of their substantiation, they indicate that the differential on the smoke temperatures will be approximately 198°F. I don't see where they came up with that. In fact, Carl stood here earlier and said that the test to determine adequate sprinkler performance is that temperatures do not threaten the structural steel system. That's substantially higher than the temperatures that they just referenced here. And in fact, NFPA 13 encourages the use of high temperature, 286°F sprinklers, in this type of occupancy. So, we clearly could have temperatures in excess of what they've identified. Secondly, they talk about a recommendation of the NFPA 204 committee. I sit on the NFPA smoke management committee responsible for 204. I'm not representing that committee here. I sit on NFPA 13 discharge criteria committee which is responsible for Chapter 12. I'm not representing that committee. But I think this committee needs to know that NFPA 13 now allows vents and draft curtains in buildings protected throughout with a sprinkler system. In fact, they've even gone so far to allow it in a building with ESFR sprinklers, smoke vents that is, if the vents have a certain criteria. That's in Chapter 12 of the 2010 edition of NFPA 13.* ***So the 13 committee recognizes that this is a viable technology in sprinklered buildings.*** [Emphasis added.] *204 has a proposal, or a comment, that is being balloted now that has a new chapter for designing smoke vents in buildings protected with a sprinkler system, so the technology is being addressed by the appropriate NFPA committees. Thank you.*

The issue of whether roof vents should be required in buildings protected by a sprinkler system was first discussed at the Code Technology Committee (CTC) meeting held in Detroit in late September 2005. The CTC voted to form a study group on the issue of roof vents as part of the CTC's study of the "balanced fire protection" issue at its meeting in Kansas City in October 2006. The study group began its work in January 2007 and it quickly became apparent (in my opinion) that the representatives of the Smoke Vent Task Group, Dr. Craig Beyler and Rick Thornberry, intended to delay the work of the study group for as long as possible.

At the CTC meeting held in Cincinnati in June 2007, the CTC voted to hold a debate over the issue of the use of roof vents in buildings protected by a sprinkler system in order to "break the logjam" created by Messrs. Thornberry and Beyler. Each side in the debate was given 30 minutes to make a presentation to the CTC. The debate before the CTC took place in Baltimore in late May 2008. Given the lack of time available for discussion at the meeting in Baltimore, the debate was repeated at the next CTC meeting held in Chicago in November 2008.

Speaking for the Smoke Vent Task Group, Dr. Craig Beyler, Hughes Associates, Inc. (HAI), presented HAI's research on the concept of the automatic "ganged" operation of roof vents (60 seconds after sprinkler system water flow is detected) to the CTC. This research relied on a fire modeling study of the interaction between sprinklers and roof vents. The "validation" of the fire model used in HAI's research was challenged and it was eventually determined that the use of the fire model, the Fire Dynamics Simulator (FDS), was not "validated" for the purpose the model was utilized by HAI. In a Smoke Vent Task Group teleconference held on March 24, 2009, the SVTG characterized HAI's fire modeling study as "***worthless***" and both of the SVTG's representatives to the CTC Roof Vent Study Group appear to have been dismissed by the Smoke Vent Task Group some time during 2009.

(**Source:** Minutes of the Smoke Vent Task Group Conference Call-Tuesday, March 24, 2009; 2009 AAMA 72nd Annual Conference, February 22-25, 2009-Revised as of May 11, 2009. See the notes at the end of this comment for the exact text indicating that the research work done by Hughes Associates, Inc. is "***worthless***".)

Based upon direction by the CTC provided at its November, 2008 meeting, the Roof Vent Study Group developed what became code change F144-09/10. The CTC's direction to the Study Group was that the code change proposal should reference NFPA 204.

Given that the latest edition of NFPA 204, the 2007 edition, does not contain any mandatory provisions for the design of roof vent/draft curtain systems in buildings protected by a sprinkler system, the Study Group developed a code change proposal which references NFPA 204 for the design of roof vent/draft curtain systems in buildings which are not protected by a sprinkler system and requires a manually-activated mechanical smoke removal system for buildings protected by a sprinkler system. Providing a mechanical smoke removal system is in accordance with the provisions contained in NFPA 204 which state that a mechanical smoke removal system should be considered, rather than roof vents, where the differential between the (**average**) temperature of the smoke layer and ambient temperature is less than 100^{o}C (198^{o}F).

The code change proposal developed by the Roof Vent Study Group/CTC contains no provisions for the use of roof vent systems in buildings protected by a sprinkler system. **Over the course of the three years in which the Roof Vent Study Group has been in existence, neither the Smoke Vent Task Group, the consultants retained by the SVTG or other interested parties submitted any documentation or testing which demonstrated that roof vent systems in buildings protected by a sprinkler system actually "work".**

In 1997/1998, a research study of the interaction between sprinklers and roof vents funded by the National Fire Protection Research Foundation (NFPRF) and conducted at Underwriters Laboratories (UL) determined that it was unlikely that thermally-activated automatic roof vents would open if the temperature rating of the activating device was the same (or greater than the) temperature rating of the sprinklers. More specifically, **Test P-2** in a series of five large-scale fire tests which were conducted as part of this research demonstrated that even if the ignition point of the fire was directly beneath an automatic roof vent, a vent may fail to open due to the activation of sprinklers in the vicinity of the vent. (The final report on this research can be found in a document referred to as **NISTIR 6196-1** dated September 1998. The title of this report is "Sprinkler, Smoke & Heat Vent, Draft Curtain Interaction-Large Scale Experiment and Model Development". The authors of this report were Kevin B. McGrattan, Anthony Hamins and David Stroup of NIST. The summary and discussion of Test P-2 begins on page 42 of this report.)

In response to the published report on the UL/NFPRF research, the chairman of the Smoke Vent Task Group, Paul Simony, issued a memorandum in early September 1999 which made a commitment to fund additional research into the interaction of sprinklers and roof vents. After 10-1/2 years, the research announced in September 1999 has yet to begin.

In the Summer 2006 issue of the AAMA newsletter, AAMAnet.work, the Smoke Vent Task Group announced that a contract had been awarded to Hughes Associates, Inc. to conduct fire modeling "***to concretely demonstrate the value of S&HV*** [smoke and heat vents] ***in terms of property protection, occupant safety, firefighter safety, and firefighter effectiveness***". The findings of this research were released in a report titled

"*Analysis of the Performance of Ganged Operation of Smoke and Heat Vents with Sprinklers and Draft Curtains*" dated February 18, 2008, however, the "validation" of the fire model, the Fire Dynamics Simulator (FDS), for the purposes utilized in the research was challenged (by Schulte & Associates and others) and Hughes Associates, Inc. was unable to demonstrate that the FDS has been "validated" for the purposes which the FDS was used. Hence, Hughes Associates, Inc.'s client, the Smoke Vent Task Group has characterized the fire modeling study which was to *"concretely demonstrate the value of S&HV*" as "***worthless***".

(**Source:** Minutes of the Smoke Vent Task Group Conference Call-Tuesday, March 24, 2009; 2009 AAMA 72nd Annual Conference, February 22-25, 2009-Revised as of May 11, 2009. See the notes at the end of this comment for the exact text indicating that the research work conducted by Hughes Associates, Inc. is "***worthless***".)

In a meeting of the CTC Balanced Fire Protection Study Group held at the Orange County Fire Authority (OCFA) in January 2007, Rick Thornberry, representing the Smoke Vent Task Group, announced that the SVTG would conduct testing of the concept of the "ganged" operation of roof vents in an aircraft hangar scheduled for demolition located on the Marine Corps Base in Orange County, California in conjunction with the OCFA. Later in 2007, Rick Thornberry announced that the planned research had been cancelled because of a lack of agreement regarding the use of the aircraft hangar with the United States Navy and that there were no other plans to conduct further research due to the problem of finding a suitable building and compliance with air pollution regulations.

In summary, in the 11-1/2 years since the findings of the UL/NFPRF study were published, the manufacturers of roof vents have made three commitments to conduct additional studies and research on the interaction of roof vents and sprinklers, but have not honored any of these commitments. (One of those commitments did result in "***worthless***" research, however.) In other words, the 1998 finding that the operation of sprinklers interferes with the openings of roof vents remains uncontested by any additional research. Further, Dr. Craig Beyler, formerly a representative for the Smoke Vent Task Group, has stated on a number of occasions since September 1998 that the number of thermally-activated roof vents which will open automatically in a fire in a building protected by a sprinkler system will be either 0 or 1 (if the sprinkler system effectively controls the fire).

Recently, the NFPA 13 committee has addressed the issue of the installation of roof vents in buildings protected by a sprinkler system. The original proposal considered by the NFPA 13 subcommittee published in the ROP document dated **October 20, 2007** reads as follows:

"**12.1.1** *Roof Vents and Draft Curtains. Roof vents and draft curtains shall* ***not*** *be used in conjunction with the sprinkler protection criteria for storage in this standard.*

This original 2007 proposal was amended to its final form for inclusion in the 2010 edition of NFPA 13. The substantiation for the provisions addressing roof vents included in the 2010 edition of NFPA 13 reads as follows:

"**Substantiation:** *The intent of the standard is that roof vents and draft curtains should* ***not*** *be used in conjunction with storage protection. Previous language was unenforceable.*"

In addition to the above, an "Explanation of Negative" comment submitted on the proposal which addresses the use of roof vent systems in buildings protected by a sprinkler system reads as follows:

MULTER, T.: *The following original proposal on ROP documents dated 10/20/2007 should be accepted as proposed but with a change to the annex statement. . . .*

A.12.1.1 *The design parameters in NFPA 13 were developed based upon the absence of roof vents or draft curtains. (See Annex C.6) Fire tests for sprinklers specifically listed for storage applications are tested without vents or draft curtains. References to control mode sprinklers in other building standards pertain to standard spray sprinklers that were not specifically tested by the laboratories for storage applications. With the advent of K-11.2 and larger sprinklers for storage applications and now Specific Application Control Mode sprinklers (being revised to CMSA), we need to realize that ESFRs are not the only storage sprinklers and that* ***the use of smoke vents and draft curtains can be detrimental to all sprinklers that are specifically tested for storage applications.*** *FM Global's recommended storage protection designs are based upon vents not being provided and that the use of automatic vents may increase the sprinkler water demand.*"

(**Source:** [NFPA] 13-325 Log #CP43 AUT-SSD Final Action: Accept; **Submitter:** *Technical Committee on Sprinkler System Discharge Criteria*)

Given all of the information above, it would be difficult to conclude anything but that William Koffel's statement that ***"this is a viable technology in sprinklered buildings"*** in his testimony at the code development hearings in Baltimore was misinformation. Given the fact that William Koffel is (and was) a member of the NFPA 13 sub-committee which developed the NFPA 13 provisions addressing roof vents and that he cast ballots on these proposals, it is also not too difficult to conclude that William Koffel's statement was intentional disinformation. (It should be noted that an ethics complaint against William Koffel based upon his testimony in the code development hearings in Baltimore was filed with the ICC in January, 2010.)

Regarding William Koffel's statements that "***204 has a proposal, or a comment, that is being balloted now that has a new chapter for designing smoke vents in buildings protected with a sprinkler system, so the technology is being addressed by the appropriate NFPA committees"***, two special expert members of the NFPA Smoke Management Committee submitted the following comments regarding the proposed "methodology" for utilizing roof vents/draft curtains in buildings protected by a sprinkler system:

DILLON, M.: *The document* ***prematurely and improperly*** *requires and relies upon unproven methods of calculation for the effectiveness of smoke and heat vents in the presence of automatic water-based sprinkler protection systems.* ***It also relies on calculations of questionable accuracy to determine activation times for the vents and the sprinklers.***

WOLIN, S.: *While the proposal would substantially increase the amount of text in Chapter 11, I do not believe that the proposed revisions provide any significant guidance on the use of smoke and heat vents in sprinklered buildings that would not otherwise be addressed in the performance analysis that is already required*. . . .

(Source: [NFPA] 204-1 Log #5, Report on Comments, June 2010.)

While the comments above made by Messrs. Dillon and Wolin were published after William Koffel's testimony, these comments are essentially the same comments made 6 months prior to the code development hearings in Baltimore by Messrs. Kenneth Isman, representing the National Fire Sprinkler Association (NFSA), and Richard Schulte, Schulte & Associates.

The following are excerpts from comments made by Messrs. Isman and Schulte in the spring of 2009:

ISMAN, K.: *We have seen extremely knowledgeable and experienced users of FDS be completely incapable of correctly predicting the number of sprinklers that would open and the opening time of these sprinklers in dry-pipe systems prior to arrival of water. If experienced users of FDS can't predict the situation correctly with no water flowing, how can we rely on data generated after water flow has arrived?*

Even if Dr. Beyler is capable of making sufficient adjustments to the FDS program to correctly predict sprinkler response times and locations, we have concerns about the average user of FDS being able to make this technological leap. According to the proposed section 11.3.2, the FDS model (or something equivalent) needs to be used to make section 11.2 work. ***We question whether the state-of-the-art in fire protection is ready for this step.***

SCHULTE, R.: *The capabilities of the Fire Dynamics Simulator to accurately predict the activation times of multiple sprinklers and the number of sprinklers which will activate is certainly questionable at best. At this point in time, it appears that the only "expert" who contends that these capabilities of the FDS have been "totally" validated (validation without any limitations) is Dr. Craig Beyler of Hughes Associates. To my knowledge, no other researcher or user of the FDS, including other employees of Hughes Associates, such as Dr. Jason Floyd, have come forward to support Dr. Beyler's assertions regarding the validation of these capabilities of the Fire Dynamics Simulator since late May, 2008 (when the question regarding validation of the FDS for the purpose used in the research first surfaced).*

With respect to the issue of validation of the FDS to accurately predict the activation times of multiple sprinklers and the number of sprinkler activations, Dr. Kevin McGrattan of the Building and Fire Research Laboratories (BFRL) at NIST responded to questions regarding the validation of the FDS for these purposes on the FDS Bulletin Board on February 17, 2009 as follows:

". . . . *there is* ***no consensus*** *metric in fire protection engineering by which a model is considered validated or not for a particular application. . . .All large scale fire experiments have a considerable amount of uncertainty in the reported heat release rate, environmental conditions, sprinkler characteristics (like droplet size, RTI, etc), and various other parameters that are input into the fire model. Because of the complexity of the experiments and simulations of fires in large warehouse type facilities, especially those involving multiple sprinkler activations, we do not have a good way (yet) of quantifying the experimental uncertainty. It might be as hard to do that as to predict the experimental results themselves. . . .****But I hope you understand that I simply cannot make a blanket statement like "FDS is validated for predicting multiple sprinkler activations.***"

(**Source:** [NFPA] 204-6 Log #1; Report on Comments A2010)

Given that William Koffel is a member of the NFPA Smoke Management Committee and is listed on the roster of committee members as representing the Smoke Vent Task Group, there can be little doubt that William Koffel reviewed the comments by Messrs. Isman and Schulte. Hence, it seems reasonable to assume that William Koffel is and was aware that the "methodology" for utilizing roof vent systems in building protected by a sprinkler system was considered to be questionable at the time of his testimony in the code development hearings. Once again, the above demonstrates that William Koffel's testimony was at best misinformation and, more than likely, intentional disinformation.

Subsequent to the code development hearings held in Baltimore, William Koffel has now been named as the representative of the Smoke Vent Task Group for purposes of participation in the ICC code development process. In the latest two teleconferences, one held on January 22, 2010 and another held on February 2, 2010, William Koffel no longer asserts that roof vents "work" in buildings protected by a sprinkler system, however, William Koffel has asserted that manually-activated roof vents can be used as a source of make-up air for exhaust fans provided and deployed by the fire service and that manually-activated roof vents are equivalent to the manually-activated smoke removal system proposed in code change proposal F144-09/10. (It should be noted that William Koffel has yet to concede that roof vents do **not** "work" in buildings protected by a sprinkler system, at least in the two teleconferences addressed above.)

Are manually-operated roof vents really the equivalent of a manually-activated smoke removal system? In order to open manually-activated roof vents, it is necessary for fire fighters to go onto the roof and individually open each roof vent and, since cold smoke does not rise, fire fighters must also deploy portable exhaust fans at the floor of the building (or attempt positive pressure ventilation). A manually-activated mechanical smoke removal system is activated by a switch located in an approved location and does not require that fire fighters go onto the roof or deploy portable exhaust fans. Obviously, from the standpoint of fire fighter safety, the level of safety provided by a manually-activated mechanical system far exceeds that provided by manually-operated roof vents. Given this, William Koffel's assertion that these two systems provide an e-quivalent level of fire fighter safety is obviously in error.

The public comment submitted by the ICC Code Technology Committee (CTC) will address other modifications approved to code change proposal F144-09/10. The public comment submitted by the CTC will provide the rationale and justification for providing 30 minute finish rating protection for the wiring for the mechanical smoke removal system and for not including a requirement for standby power. Hence, this comment will not address these issues.

The modifications to code change F144-09/10 approved by the code changes committee do not improve the original proposal and, in my opinion, the committee's decision to allow the use of roof vents was based upon hearing the misinformation included in William Koffel's testimony in the code development hearing. Given this, it is requested that code change proposal F144 be approved "as submitted".

The probability that code change F144 being approved as "as submitted" is essentially nil. Given this, I would like to urge that the membership give consideration to the "as further modified" proposal submitted by the ICC Code Technology Committee. While I find any provisions which permits manually-activated roof vents to be provided, and to be considered to be equivalent to the manually-activated mechanical smoke removal system proposed, to be objectionable, the CTC's "as further amended" proposal is at least a first step in recognizing that roof vents do not perform as claimed by the vent manufacturers and their highly-paid consultants/lobbyists.

If the manufacturers of roof vents want to claim that their product does indeed "work" in buildings protected by a sprinkler system, then the further testing and research that was promised by the manufacturers 11-1/2 years ago should be conducted. The membership should not continue to "fall prey" to promises of imminent testing and research made time and again by a trade association with a long history of making false commitments to conducting further testing and research. It is time for the ICC membership to demand to see the research and testing from the vent manufacturers' trade association that conclusively demonstrates that roof vents will make "cold and wet smoke" defy the laws of physics and actually rise.

For more than 30 years now, the vent manufacturers have claimed that roof vents cause "cold and wet smoke" to defy the laws of physics and many in the fire service have fallen for this ruse. The "**laws of physics**" are referred to as laws because they have been proven over and over again to be true. The vent manufacturers cannot point to a single test or study that demonstrates that their product causes "cold and wet smoke" to rise. Why do so many in the fire service continue to believe the manufacturers claims without any evidence?

A vote for "as submitted" will force the manufacturers of vents to either do the testing and research to prove their claims or to stop making unsubstantiated claims. A vote for "as further modified" as proposed by the CTC will also do the same, but in a less forceful manner. Adopting this public comment or the CTC's public comment is far more preferable than the present code provisions or the original CTC proposal as modified by the code changes committee.

Notes: Excerpt from AAMA Smoke Vent Task Group (SVTG) Teleconference Minutes-March 24, 2009:

> "*. . . .The concern remains that if C. Beyler is not willing to support the $100K SVTG Modeling Study, then the study is **worthless**. The members questioned why no other groups, organizations, or Fire Protection Engineers have come forward to defend the FDS program, particularly, Kevin McGratten* [McGrattan]*, from NIST, who wrote the original version of FDS, and has been intimately involved in it since its development. B.Sampson will contact K. McGratten* [McGrattan] *to obtain his thoughts on this.*"

Public Comment 2:

Paul K. Heilstedt, PE, HonAIA, Chair, representing ICC Code Technology Committee (CTC), requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

910.2.1 (IBC [F] 910.2.1) Group F-1 or S-1 -A mechanical smoke removal system shall be installed in buildings or portions thereof used as a Group F-1 or S-1 occupancy exceeding 50,000 square feet <u>in undivided area.</u>

[F] 910.4. Mechanical smoke removal system. Where required by Sections 910.2.1 and 910.2.3, a mechanical smoke removal system shall be provided in accordance with this section.

Exception<u>s</u>:

1. Buildings or portions thereof which are protected by ESFR sprinklers.
2. Buildings equipped with smoke and heat vents ~~designed in accordance with NFPA 204, when permitted by NFPA 13.~~ <u>where approved by the code official. Where installed in buildings provided with an approved automatic sprinkler system, the operation of smoke and heat vents shall be in accordance with NFPA 13.</u>

910.4.6 (IBC [F] 910.4.6) Wiring and control. Wiring for the operation and control of smoke removal system fans shall be <u>connected ahead of the main disconnect</u> <u>installed in an approved location.</u> ~~provided with power in accordance with Section 909.11~~ and be protected by materials with a finish rating of <u>30 minutes</u> ~~not less than 1 hour~~.

(Portions of proposal not shown remain unchanged)

Commenter's Reason: The CTC studied available information and conducted numerous public meetings on this subject through a study group representing various interests, including building officials, fire officials, manufacturers, architects, engineers and consultants. The intent of the original proposal was to provide reasonable smoke removal provisions for post-fire fighting considerations. The IFC committee, via the modifications that were approved in Baltimore, has taken the original proposal in a direction for which the CTC is in significant disagreement. In effect, the modification took the proposal in a direction not intended by the original code change. This was evidenced by testimony at the hearings themselves where the CTC representative spoke against the modifications. Further, upon confusion of the committee action for "As Modified"; the CTC representative made a floor motion for "As Submitted" as the modified change is not consistent with the intent of the original proposal. The following is a discussion of the modifications approved by the IFC committee and how this public comment intends to direct the code change more closely back to the original intent.

Section 910.2.1:
IFC Modification: The IFC committee modification extends the application of the present smoke venting requirements from being limited to one-story buildings to buildings of any story height.

CTC's evaluation of the IFC modification:

The modification lacks technical substantiation;
This is a post fire fighting operation, not involving life safety;

CTC Public comment: As a post fire fighting system, CTC has not proposed to revise the requirements back to one story buildings. If the system is necessary and works for a single story, it will work for buildings having multiple stories. The public comment proposes to clarify that the 50,000 square feet area is a contiguous area and not the entire area of the building.

Section 910.4:
IFC Modification: The IFC committee modification allows the continued use of smoke and heat vents in sprinklered buildings.

CTC evaluation of the IFC modification:

After studying this issue for 2-1/2 years, the CTC concluded that there is no technical basis for vents in sprinklered buildings and proposed to remove the requirement;
Mechanical systems should be required for sprinklered buildings because any smoke removal must deal with cool smoke; reference is made to NFPA 204 for unsprinklered buildings only;
A review of the rationale included in the recent change to NFPA 13 includes recognition by the NFPA 13 technical committee that vents are mandated by other regulations, e.g., the IBC, and the standard actually includes precautionary measures for the use of vents in sprinklered buildings;
NFPA 204 -2010; CTC's original code change proposed a reference to the 2010 edition of NFPA 2010 which is not yet complete:

- o The draft of NFPA 204 – 2010 does not provide design criteria for vents in a sprinklered building; the draft of NFPA 204 includes vague guidance formerly included in the Annex of the standard;
- o The draft of NFPA 204 - 2010 does not include a design goal for the system (unlike the the criteria for mechanical systems), nor one which can be evaluated by an AHJ.

NFPA 204 – 2007: The modification by the IFC committee changed the referenced edition of NFPA 204 to the 2007 edition because this edition was complete and the 2010 edition (which may not be published until 2011) will not be available by the May/2010 Final Action Hearings:

- The 2007 edition of the standard includes only an Annex which is not part of the standard for smoke and heat vent design.

CTC public comment: Due to a lack of comprehensive design criteria in the 2007 edition of NFPA 204, the decision to allow smoke and heat vents needs to rest with the code official in terms of an assessment of the building in question. The added text to Exception 2 is taken from current section 910.3.2 which stipulates that the vents must be operational in accordance with NFPA 13.

Section 910.4.6:
IFC Modification: The IFC committee modification requires standby-power and one-hour rated electrical service to the ventilation equipment.
