CTC evaluation of the IFC modification:

The mechanical smoke venting system is not an emergency system for "defend-in-place" strategy;
Smoke venting is a post fire fighting operation, not involving life safety of occupants or fire fighters;
It is unlikely there would be a need to intentionally cut power during fire fighting operations in a sprinklered building;
Other systems that are considered critical are not required to have standby power: the fire pump for the sprinklers, and general lighting needed for fire fighting operations;
Supporting one-hour power conductors by an unrated building structure presents a conflict with general fire protection philosophy.

CTC public comment: The mechanical smoke exhaust system is not an emergency smoke control system. A smoke control system is an active system designed to be used during fire conditions. The smoke exhaust system proposed by CTC is intended to be a post-fire system for use by the fire-service. As such, it need not be provided with emergency power. The finish rating originally proposed for 30 minutes is adequate since we are dealing with fully sprinklered buildings and is reasonably accomplished in buildings of all construction types. As a rule of thumb, membranes of one hour fire resistance rated assemblies will provide a 30 minute finish rating. CTC believes that this provides a reasonable level of protection for the circuits and that it should be acceptable to route the conductors within the cavities of one hour assemblies.

This public comment retains the committee modification to reference the 2007 edition of NFPA 204 as the standard is published because the 2010 edition will not be available by the 2010 May Final Action Hearings.

Public Comment 3:

Gregory R. Keith, Professional heuristic Development, representing The Boeing Company, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

910.2.1 (IBC [F] 910.2.1) Group F-1 or S-1. A mechanical smoke removal system shall be installed in buildings or portions thereof used as a Group F-1 or S-1 occupancy exceeding 50,000 square feet.

Exception: Group S-1 aircraft repair hangars.

(Portions of proposal not shown remain unchanged)

Commenter's Reason: The purpose of Item F144-09/10 was to update the provisions that mandate roof vents in industrial and storage buildings. The code change requires that a manually-operated mechanical smoke removal system be provided for large industrial and storage buildings protected by a sprinkler system in lieu of the requirements for roof vents and draft curtains. Formerly, smoke and heat vents were not required in Group S-1 aircraft repair hangars due to an exception to Section 910.2.1. This exception was based on the fact that aircraft hangars are designed in accordance with the provisions of NFPA 409. IBC or IFC fire protection features should not be overlaid on that comprehensive standard.

This public comment for approval as modified reinstates the status quo for aircraft repair hangars. Inasmuch as aircraft repair hangars were exempt from smoke and heat vent requirements, it stands to reason that they should also be exempt from the provisions that replaced them. As was previously the case, NFPA 409 provisions should be allowed to stand on their own merit for these highly specialized buildings. The absence of loss history would indicate that current provisions are very adequate and additional fire protection features are not necessary and are unjustified.

Public Comment 4:

Tracey D. Bellamy, Telgian Corporation, representing self, requests Disapproval.

Commenter's Reason: The provisions of the proposal contain substantial design criteria changes that have not been supported by any technical data. The proposed criteria for design of mechanical exhaust systems using 4 air changes per hour is indicated in the original substantiation as being a reasonable value; however, no technical support is provided other than an indication that it is an average value between 2 and 6 air changes per hour. This change is premature at this time as efforts to develop a consensus design criteria for mechanical exhaust systems in a sprinklered building has not been completed. The far reaching impact of such criteria without sound technical justification is not acceptable.

Final Action: AS AM AMPC____ D

F146-09/10

910.5 (New) [IBC ([F] 910.5 (New)], Chapter 47

Proposed Changes as Submitted

Proponent: Justin H. Beal, representing the City of Fresno, CA, Fire Department

1. Add new text as follows:

<u>**910.5 (IBC [F] 910.5) Maintenance.** Smoke and heat vents and mechanical smoke exhaust systems shall be maintained in an operative condition in accordance with NFPA 204. Fusible links shall be promptly replaced whenever fused, damaged or painted. Smoke and heat vents and mechanical smoke exhaust systems shall not be modified.</u>

2. Add new standard to Chapter 47 as follows:

NFPA
<u>204-2007</u> <u>Standard for Smoke and Heat Venting</u>

Reason: The maintenance of heat and smoke vents and mechanical smoke exhaust systems is not clearly addressed within the model International Fire Code. Installation and design criteria for smoke and heat vents can be found in I.F.C. section 910.3.1 (U.L. 793), however, maintenance provisions for these systems should be included within section 910 to provide clarity for the end user of the code. This proposal incorporates National Fire Protection Association Standard 204, Standard for Smoke and Heat Venting, 2007 edition, as the referenced standard for the maintenance of smoke and heat vents and mechanical smoke exhaust systems.

Routine inspection, testing and maintenance of these devices is essential for several reasons: These devices are typically only found in the largest commercial structures, and within these structures, the amount of fire loading is usually very high, to include high piled combustible storage.

Ensuring that these devices are inspected, tested and maintained in proper working order by the building owner (as specified in the new referenced standard) will have several positive effects for firefighter safety. These benefits include: easy identification of the location of the fire within the structure, the release of excess heat within the structure decreasing fire severity, increased visibility for firefighters within the structure, and the reduction of toxic products of combustion within the structure.

Additionally, the maintenance of these devices will have a mitigating effect on damage to the structure and/or its contents should a fire occur. These include: decreased likelihood of structural failure from heat retained within the structure and reduced damage to the structure and stored materials from smoke.

Finally, these devices are considered “fire protection systems” as noted in the I.F.C. section 902.1, and as such, a provision requiring specified inspection, testing and maintenance intervals via a referenced standard should be included within the body of the code.

The language of this section has been developed to follow (and is substantially similar to, and consistent with) the format found within the International Fire Code, Section 703.2.

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: Review of proposed new standard NFPA 204-2007 indicated that, in the opinion of ICC Staff, the standard did comply with ICC standards criteria.

ICCFILENAME: BEAL-F1-910.5.DOC

<u>Public Hearing Results</u>

Note: The following analysis was not in the Code Change monograph but was published on the ICC website at http://www.iccsafe.org/cs/codes/Documents/2009-10cycle/ProposedChanges/Standards-Analysis.pdf

Analysis: Review of proposed new standard NFPA 204-2007 indicated that, in the opinion of ICC Staff, the standard did comply with ICC standards criteria. Note that section 3.6.3.1 of CP28-05 requires that the standard be completed and readily available prior to Final Action Consideration. The final action of this proposal will occur May 14-23, 2010.

Committee Action: **Approved as Modified**

Modify proposal as follows:

NFPA

204-~~2007~~<u>2010</u> Standard for Smoke and Heat Venting

(Portions of the proposal not shown remain unchanged.)

Committee Reason: The committee approved the proposal as it provides the necessary maintenance requirement for smoke and heat vents that the code currently lacks. The modification simply revises the standard edition of NFPA 204 to the 2010 edition.

Assembly Action: **None**

<u>Individual Consideration Agenda</u>

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment:

Justin Beal representing the City of Fresno, CA, Fire Department and Marcelo M. Hirschler, GBH International, request Approval as Modified by this Public Comment.

Further modify the proposal as follows:

NFPA

204-~~2010~~ 2007 Standard for Smoke and Heat Venting

(Portions of the proposal not shown remain unchanged.)

Commenter's Reason (Beal): I am the original proponent of this code change proposal. During the code development hearings held in October 2009, a floor modification to this proposal was made and approved by the committee. The modification to the proposal consisted of changing the referenced standard to the 2010 edition of National Fire Protection Association Standard 204 – Standard for Smoke and Heat Venting (NFPA 204), from the 2007 edition of the same document. At the time of the code development hearings, it was generally thought that the 2010 edition of the standard would be readily available before the final action hearings, as those hearings had tentatively been scheduled for October 2010. Based upon the facts known at the time, this modification was acceptable.

However, as the final action hearing schedule has been revised, it has become apparent that the 2010 edition of NFPA 204 will not be readily available before the final action hearings as required by I.C.C. policy.

To ensure this proposal is included in the upcoming edition of the International Fire Code, it must be modified back to its original configuration to specify the 2007 edition of NFPA 204 as the referenced standard for the code section.

Commenter's Reason (Hirschler): The public comment simply revises the edition of the standard to 2007 as the 2010 edition will not be available prior to the final action hearings in Dallas. The ICC Code Development Policy Section 3.6.3.1 of CP28-05 requires that the standard be completed and readily available prior to Final Action Consideration.

Final Action: AS AM AMPC____ D

F147-09/10
912.4 (IBC [F] 912.4)

Proposed Change as Submitted

Proponent: Joshua D. Smith, New York State Department of State, Office of Fire Prevention and Control

Revise as follows:

912.4 ~~Signs~~ Markings. A metal sign with raised letters at least 1 inch (25 mm) in size shall be mounted on all fire department connections ~~serving automatic sprinklers, standpipes or fire pump connections~~ to indicate their function. The caps of fire department connections shall also be color-coded to indicate their function. ~~Such signs shall read: AUTOMATIC SPRINKLERS or STANDPIPES or TEST CONNECTION or a combination thereof as applicable.~~ Where the fire department connection does not serve the entire building, a sign shall be provided indicating the portions of the building served. The signs and the caps shall be marked as follows:

1. For a connection serving only a standpipe the sign shall read STANDPIPE and the cap shall be colored red.
2. For a connection serving a combination automatic sprinkler and standpipe system the sign shall read COMBINATION STANDPIPE AND SPRINKLER and the cap shall be colored yellow. If the automatic sprinkler system only covers a portion of the building the sign shall also indicate where the protected areas are located in the building.
3. For a connection serving an automatic sprinkler system only the sign shall read SPRINKLER or AUTOMATIC SPRINKLER and the cap shall be colored green. If the automatic system only covers a portion of the building the sign shall also indicate where the protected areas are located in the building.
4. For a connection serving a systems other than an automatic sprinkler system the sign shall read NON-AUTOMATIC SPRINKLER and the cap shall be colored silver.
5. Test connections shall have signs that read TEST CONNECTION and the caps shall be colored black.

Reason: There are often signs installed for fire department connections that are often a single color, such as chrome or brass signs, that are not easily read from the point where a fire apparatus will be able to first see the connection. The color coding of the caps will make identifying the function of the fire department connection more easily discernable from a greater distance for fire apparatus fire fighters.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: SMITHJ-F1-912.4.DOC

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee disapproved the proposal as there are already so many labels involved with the building and often times the caps on fire department connections go missing. Additionally, colors often cannot be seen at night. Other comments addressed the fact that the methodology of labeling may vary from jurisdiction to jurisdiction.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Joshua D. Smith, New York State Dept. of State – Office of Fire Prevention and Control, requests Approval as Submitted.

Commenter's Reason: The committee stated several reasons for disapproving this proposal to which I would like to answer.

The first comment being that there are already many marking systems in place. The 2009 fire coder does make mandatory the use if signs to indicate the type of system being fed by the fire department connection as well as an additional sign for indicating areas that are protected when a system does not provide full building protection. In my experience in fire fighting and inspections it is often these signs are all one color, often the signs are chrome or brass to match the connections. Unless the responder is at the connection it is often difficult to determine what the FDC is feeding. The color coding provides an often faster means of determining what the FDC feeds.

The committee further stated that FDC caps often go missing. NFPA 25 states that the FDC plugs or caps are to remain in place and be undamaged. Even if a cap does go missing as part of keeping the system compliant the missing caps have to be replaced.

The committee also stated that colors cannot be seen at night. Neither can the signs that are already required. The only way to solve this would be to require the area the FDC is located be lighted on a continuous basis whether or not the caps are colored.

The committee further stated that coding systems may vary from jurisdiction to jurisdiction. The more common use of mutual aid agreements between jurisdictions, and the push to standardize equipment and terminology for NIMS compliance would be of benefit from a standardized color coding system. With this in mind, no matter where a fire department or personnel may be from when they have to respond to a call when covering another jurisdiction's response area the markings of a FDC will all mean the same and the mutual aid departments can still operate efficiently.

Final Action: AS AM AMPC____ D

F152-09/10
1206.2, 1206.2.1 (New), 1206.3, 1206.4

Proposed Change as Submitted

Proponent: David W. Dawson, R. R. Street & Co. Inc.

1. Revise as follows:

1206.2 ~~Type~~ <u>Class</u> I solvents. The maximum quantity of ~~Type I~~ <u>Class I</u> solvents permitted at any work station shall be 1 gallon (4 L). ~~Class I solvents shall be stored in approved safety cans or in sealed DOTn-approved metal shipping containers of not more than 1-gallon (4 L) capacity. Dispensing shall be from approved safety cans.~~ <u>Spotting or pre-spotting shall be permitted to be conducted with Class I solvents where they are stored in and dispensed from approved safety cans or in sealed DOT-approved shipping containers of not more than 1 gallon (4 L) capacity</u>.

2. Add new text as follows:

<u>**1206.2.1 Spotting and pre-spotting.** Spotting and pre-spotting shall be permitted to be conducted with Class I solvents where dispensed from plastic containers of not more than 1 pint (0.5 L) capacity.</u>

3. Revise as follows:

1206.3 ~~Type~~ <u>Class</u> II and III solvents. Scouring, brushing, and spotting and pretreating shall be <u>permitted to be</u> conducted with Class II or III solvents. The maximum quantity of ~~Type~~ <u>Class</u> II or III solvents permitted at any work station shall be 1 gallon (4 L). In other than Group H-2 occupancy, the aggregate quantities of solvents shall not exceed the maximum allowable quantity per control area for use-open system.

1206.4 Type IV systems. Flammable and combustible liquids used for spotting operations shall be stored in approved safety cans or in sealed DOT~~n~~-approved ~~metal~~ shipping containers of not more than 1 gallon (4 L) in capacity. ~~Dispensing shall be from approved safety cans.~~ Aggregate amounts shall not exceed 10 gallons (38 L).

Reason: The purpose of the change is to revise outdated material. The proposed wording is intended to recognize the wide use of DOT-approved plastic containers to ship and store chemicals used in dry cleaning plants, including spotting chemicals. Use of these containers is permitted by OSHA for the storage of flammable and combustible liquids under conditions described in OSHA Directive STD 01-05-014. Equivalent changes have been made to NFPA 32.

Bibliography: 29 CFR 1910.106 Flammable and combustible liquids; OSHA Directive STD-01-05-014; NFPA 32.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: DAWSON-F2-1206.2.DOC

<u>Public Hearing Results</u>

Committee Action: **Approved as Submitted**

Committee Reason: The committee agreed with and approved the proposal based on the proponent's reason statement. The revised requirements will be less restrictive that those required by the OSHA directive listed in the bibliography, which requires fire detection at such work stations.

Assembly Action: **None**

<u>Individual Consideration Agenda</u>

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Bob Eugene representing Underwriters Laboratories Inc, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

1206.2 Class I solvents. The maximum quantity of Class I solvents permitted at any work station shall be 1 gallon (4 L). Spotting or pre-spotting shall be permitted to be conducted with Class I solvents where they are stored in and dispensed from approved safety cans or in sealed DOT-approved <u>metal</u> shipping containers of not more than 1 gallon (4 L) capacity.

(Portions of the proposal not shown remain unchanged.)

Commenter's Reason: NFPA 32 clearly requires approved safety cans or DOT-approved metal shipping containers of not more than 1-gallon capacity for spotting or pre-spotting of Class I solvents.

NFPA 32-2007: 5.1.2 Spotting or prespotting shall be permitted to be conducted with Class I solvents if they are stored in and applied from sealed DOT-approved metal shipping containers of not more than 3.8 L (1 gal) capacity or approved safety cans.

Final Action: AS AM AMPC____ D

F153-09/10
1208.2

<u>Proposed Change as Submitted</u>

Proponent: David W. Dawson, R. R. Street & Co. Inc., representing Textile Care Allied Trades Association (TCATA) and Drycleaning and Laundry Institute (DLI).

Revise as follows:

1208.2 Automatic sprinkler system. An automatic sprinkler system shall be installed in accordance with Section 903.3.1.1 throughout dry cleaning plants containing Type II, Type III-A or Type III-B dry cleaning systems.

Exceptions:

1. An automatic sprinkler system shall not be required in Type III-A dry cleaning plants where the aggregate quantity of Class III-A solvent in dry cleaning machines and storage does not exceed 330 gal (1250 L) and dry cleaning machines are equipped with a feature that will accomplish any one of the following:
   - 1.1. Prevent oxygen concentrations from reaching 8 percent or more by volume.
   - 1.2. Keep the temperature of the solvent at least 30ºF (16.7ºC) below the flash point.
   - 1.3. Maintain the solvent vapor concentration at a level lower than 25 percent of the lower explosive limit (LEL).
   - 1.4. Utilize equipment approved for use in Class I, Division 2 hazardous locations in accordance with NFPA 70.
   - 1.5. Utilize an integrated automatic fire-extinguishing system complying with Section 4.6 of NFPA 32.
2. An automatic sprinkler system shall not be required in Type III-B dry cleaning plants where the aggregate quantity of Class III-B solvent in dry cleaning machines and storage does not exceed 3300 gal (12,490 L).

Reason: The purpose of this proposed code change is to eliminate the overly restrictive requirements for automatic sprinkler systems in dry cleaning facilities using modern dry cleaning equipment. Modern Type IIIA dry cleaning machines have intrinsic safety features that prevent fires from starting within the dry cleaning machine. It is preferable to prevent fires from starting in the first place, rather than extinguishing ones that have already started. NFPA 32 already allows these safety features to be used in lieu of automatic sprinkler systems.

Bibliography: NFPA 32

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: The action on this proposal should be consistent with the action on Code Change F154-09/10.

Public Hearing Results

Committee Action: Approved as Submitted

Committee Reason: The committee agreed with the proponent's reason statement and preferred this proposal over F154-09/10, which its proponent offered to withdraw in favor of this proposal. It was felt that new dry cleaning equipment addresses the safety hazards adequately. Also, stating the exceptions in the code text is preferable to requiring the inspector to carry the referenced standard into the field as code change F154-09/10 would do. It was also noted that California and several other states have banned perchlorethylene which requires that operators purchase new equipment and the committee felt that adding a sprinkler requirement on top of that capital expense would be a hardship.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Abraham B. Cho requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

1208.2 Automatic sprinkler system. An automatic sprinkler system shall be installed in accordance with Section 903.3.1.1 throughout dry cleaning plants containing Type II, Type III-A or Type III-B dry cleaning systems.

Exceptions:

1. An automatic sprinkler system shall not be required in Type III-A dry cleaning plants where the aggregate quantity of Class III-A solvent in dry cleaning machines and storage does not exceed 330 gal (1250 L) and employing dry cleaning machines listed by an approved testing agency, provided it is equipped with a feature that will accomplish any one of ~~the following~~ items 1.1 through 1.5 and each of items 1.6 through 1.8 :
   - 1.1. Prevent oxygen concentrations from reaching 8 percent or more by volume.
   - 1.2. Keep the temperature of the solvent at least 30ºF (16.7ºC) below the flash point.
   - 1.3. Maintain the solvent vapor concentration at a level lower than 25 percent of the lower explosive limit (LEL).
   - 1.4. Features that limit solvent vapor concentration at or below 60 percent of the LEL where automatic instrumentation with safety interlocks is provided in accordance with NFPA 69,
   - 1.5. Utilize equipment approved for use in Class I, Division 2 hazardous locations in accordance with NFPA 70.
   - 1.6. Utilize an integrated automatic fire-extinguishing system complying with Section 4.6 of NFPA 32.
   - 1.7. Utilize two sprinklers overhead using a domestic water line that releases water directly onto the outside of the dry cleaning machine.

1.8. Utilize a computer controlled maintenance and record keeping system to perform periodical maintenance, that also controls the dry cleaning machine to shut down.

2. An automatic sprinkler system shall not be required in Type III-B dry cleaning plants where the aggregate quantity of Class III-B solvent in dry cleaning machines and storage does not exceed 3300 gal (12,490 L).

Commenter's Reason: The purpose of this proposed code change is to eliminate the overly restrictive requirements for automatic sprinkler systems in dry cleaning facilities using modern dry cleaning equipment. Modern Type IIIA dry cleaning machines have intrinsic safety features that prevent and respond to fires within and surrounding the dry cleaning machine. It is preferable to prevent fires from starting in the first place, rather than extinguishing ones that have already started. NFPA 32 2007 Edition already allows some of these safety features to be used in lieu of automatic sprinkler systems.

(1)This proposal is missing 1.4 of the exception paragraph from NFPA 2007 edition. (2)There are two kinds of fire protection systems. One kind is fire prevention system that has features 1.1 thru 1.5 and 1.8 . The other system is a fire responding system as stated above in 1.6 and 1.7.

In order to have fire protection from inside and outside of a dry cleaning machine, the dry cleaning machine must be equipped with 1.6, thru 1.8 and any one of the following between 1.1 thru 1.5.

Bibliography: NFPA 32 2007 Edition

Public Comment 2:

Joe Pierce (Chairman), Dallas Fire Department, representing Joint Fire Service Review Committee, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

1208.2 Automatic sprinkler system. An automatic sprinkler system shall be installed in accordance with Section 903.3.1.1 throughout dry cleaning plants containing Type II, Type III-A or Type III-B dry cleaning systems.

Exceptions:

1. An automatic sprinkler system shall not be required in Type III-A dry cleaning plants where the aggregate quantity of Class III-A solvent in dry cleaning machines and storage does not exceed 330 gal (1250 L) and dry cleaning machines are equipped with a feature that will accomplish any one of the following:
   1.1. Prevent oxygen concentrations from reaching 8 percent or more by volume.
   1.2. Keep the temperature of the solvent at least 30ºF (16.7ºC) below the flash point.
   1.3. Maintain the solvent vapor concentration at a level lower than 25 percent of the lower explosive limit (LEL).
   1.4. Utilize equipment approved for use in Class I, Division 2 hazardous locations in accordance with NFPA 70.
   1.5. Utilize an integrated dry chemical, clean agent or water mist automatic fire extinguishing system ~~complying with Section 4.6 of NFPA 32~~ designed in accordance with Chapter 9.
2. An automatic sprinkler system shall not be required in Type III-B dry cleaning plants where the aggregate quantity of Class III-B solvent in dry cleaning machines and storage does not exceed 3300 gal (12,490 L).

Commenter's Reason: This proposal was Approved as Submitted at the Code Development Hearing. The purpose of this Public Comment is to clarify the types of extinguishing systems which will provide compliance with Exception Item 1.5.

The original code change referenced NFPA 32 Section 4.6 in Item 1.5. Since the requirements in Item 1.5 are substituting a fixed extinguishing for the building sprinkler system, it is preferable to identify the acceptable types of fire extinguishing systems. The reference to NFPA is replaced with a list of the specific types of automatic fire extinguishing systems allowed by NFPA 32 Section 4.6.

This Public Comment specifies that the extinguishing system must be either a dry-chemical system, a clean agent system, or a water mist system in order to be substituted for the fire sprinkler system. Chapter 9 provides design and installation criteria and references the correct NFPA standard for each type of extinguishing system.

Final Action: AS AM AMPC____ D

F155-09/10
1501.1, 1501.2; IBC [F] 416

Proposed Change as Submitted

Proponent: Tom Lariviere, Chairman - Joint Fire Service Review Committee

1. Revise IFC as follows:

1501.1 Scope. This chapter shall apply to locations or areas where any of the following activities are conducted:

1. The application of ~~flammable or combustible paint, varnish, lacquer, stain, fiberglass resins or other flammable or combustible liquid applied~~ flammable finishes to articles or materials by means of spray apparatus ~~in continuous or intermittent processes~~.

2. ~~Dip-tank operations in which articles or materials are passed through contents of tanks, vats or containers of flammable or combustible liquids, including coating, finishing, treatment and similar processes.~~ The application of flammable finishes by dipping or immersing articles or materials into the contents of tanks, vats or containers of flammable or combustible liquids for coating, finishing, treatment or similar processes.
3. The application of flammable finishes by applying combustible powders to articles or materials utilizing ~~when applied by~~ powder spray guns, electrostatic powder spray guns, fluidized beds or electrostatic fluidized beds.
4. Floor surfacing or finishing operations using Class I or II liquids in areas exceeding 350 square feet (32.5 m^2).
5. The application of flammable finishes consisting of dual-component coatings or Class I or II liquids when applied by brush or roller in quantities exceeding 1 gallon (4 L).
6. ~~Spraying and dipping operations.~~

1502.1 Definitions. The following words and terms shall, for the purposes of this chapter and as used elsewhere in this code, have the meanings shown herein.

FLAMMABLE FINISHES. ~~Material coatings~~ Coatings to articles or materials in which the material being applied is a flammable liquid, combustible liquid, combustible powder, fiberglass resin or flammable or combustible gel coating.

2. Revise IBC as follows:

SECTION 416
SPRAY APPLICATION OF FLAMMABLE FINISHES

[F] 416.1 General. The provisions of this section shall apply to the construction, installation and use of buildings and structures, or parts thereof, for the spraying of flammable ~~paints, varnishes and lacquers~~ finishes ~~or other flammable materials or mixtures or compounds used for painting, varnishing, staining or similar purposes~~. Such construction and equipment shall comply with the International Fire Code.

[F] 416.2 Spray rooms. *(No change to current text.)*

[F] 416.2.1 Surfaces. *(No change to current text.)*

[F] 416.2.2 Ventilation. Mechanical ventilation and interlocks with the spraying operation shall be in accordance with the International Fire Code.

[F] 416.3 Spraying spaces. *(No change to current text.)*

[F] 416.3.1 Surfaces. *(No change to current text.)*
[F] 416.4 Spray booths. *(No change to current text.)*

[F] 416.5 Fire protection. An automatic fire-extinguishing system shall be provided in all spray~~, dip and immersing spaces and storage~~ rooms and shall be installed in accordance with Chapter 9.

Reason: Item 1 – IFC: The revisions in this section are intended to clarify the application of Chapter 15. There is no change in application of this Chapter or the requirements therein.

First, the Scope is revised using the defined term of "flammable finishes".
1. Item #1 covers spray operations
2. Item #2 covers dipping operations
3. Item #3 covers electrostatic and fluidized beds
4. Item #4 specifies the limitation of Class I or II liquids when conducting floor surfacing
5. Item #5 covers dual-component coatings
6. Item #6 is deleted since it is covered in Items #1 and #2.

Second, the definition of "flammable finishes" is revised to include the coatings that are already regulated in Chapter 15.

These revisions are essentially editorial changes that will add clarity in the application of Chapter 15.

Item 2 – IBC: This proposal is designed to correlate the requirements for spray operations found in the IBC and the IFC.
Section 416 is revised to specify spray application of materials. This is consistent with the wording in Section 416.1 which limits the application of these requirements to spray operations.
Section 416.1 is revised to provide consistency with the scope in IFC Section 1501.1. This revision will include all of the operations that would be regulated within a spray room or spray booth.
Section 416.2.2 is added to reference the IFC which contains requirements for ventilation velocities and for interlocking the ventilation system with the spraying apparatus.
Section 416.5 is revised to be consistent with IFC Section 1505.4. A fire extinguishing system is not required for all dipping operations. For example, when using dip tanks of less than 150 gallons, a fire extinguishing system is an optional method of protection.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: LARIVIERE-F17-1501.1-G2-IBC416.DOC

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee had concerns about combustible finishes being deleted and disagreed with the blanket removal of dipping operations from IBC Section 416.5 since the IFC does require fire protection for some dipping operations.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Joe Pierce (Chairman), Dallas Fire Department, representing Joint Fire Service Review Committee, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

1501.1 Scope. This chapter shall apply to locations or areas where any of the following activities are conducted:

1. The application of *flammable finishes* to articles or materials by means of spray apparatus.
2. The application of a *flammable finishes* by dipping or immersing articles or materials into the contents of tanks, vats or containers of flammable or combustible liquids for coating, finishing, treatment or similar processes.
3. The application of *flammable finishes* by applying combustible powders to articles or materials utilizing powder spray guns, electrostatic powder spray guns, fluidized beds or electrostatic fluidized beds.
4. Floor surfacing or finishing operations using Class I or II liquids in areas exceeding 350 square feet (32.5 m^2).
5. The application of *flammable finishes* consisting of <u>organic peroxides,</u> dual-component coatings or Class I or II liquids when applied by brush or roller in quantities exceeding 1 gallon (4 L).

1502.1 Definitions. The following words and terms shall, for the purposes of this chapter and as used elsewhere in this code, have the meanings shown herein.

(Portions of the proposal not shown, remain unchanged.)

FLAMMABLE FINISHES. Coatings to articles or materials in which the material being applied is a flammable liquid, combustible liquid, combustible powder, fiberglass resin, <u>organic peroxide,</u> or flammable or combustible gel coating.

Commenter's Reason: This proposal was Disapproved at the Code Change Hearing because it needed clarification in the proposed text for both the IFC and IBC. The original item has been split into two Public Comments; one addressing the IBC and the other addresses the IFC. This Public Comment is intended to only address the revisions to the IFC. The revisions in this section are intended to clarify the application of IFC Chapter 15. There is no change in the requirements of this Chapter or the requirements therein.

The Scope has been revised by replacing the defined term of "flammable finishes" for the laundry list of processes the can be considered application of flammable finishes. This simple reference to flammable finishes, rather than the list, reduces the chance of leaving out a possible operation that should be regulated by this Chapter but not included in the list.

The arrangement of processes in 1501.1 is as follows:
Item 1 – spraying operations
Item 2 – dipping operations
Item 3 – electrostatic and fluidized beds
Item 4 – floor surfacing and floor refinishing
Item 5 – dual-component coatings and organic peroxides

Organic peroxides has been added to Item 5. Use of organic peroxides is already regulated in Section 1508 and now it will included in the scope of the Chapter.

Also, the definition of "flammable finishes" is revised to include the organic peroxide materials which are used as a flammable finish and are regulated in Chapter 15 as a flammable finish.

Public Comment 2:

Joe Pierce (Chairman), Dallas Fire Department, representing Joint Fire Service Review Committee, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

[F] SECTION 416 ~~SPRAY~~ APPLICATION OF FLAMMABLE FINISHES

416.1 General. The provisions of this section shall apply to the construction, installation and use of buildings and structures, or parts thereof, for the ~~spraying~~ <u>application</u> of flammable finishes. Such construction and equipment shall comply with the *International Fire Code*.

416.2 Spray rooms. *(No change to text)*

416.2.1 Surfaces. *(No change to text)*

416.2.2 Ventilation. Mechanical ventilation and interlocks with the spraying operation shall be in accordance with the *International ~~Fire~~ <u>Mechanical</u> Code*.

416.3 Spraying spaces. *(No change to text)*

416.3.1 Surfaces. *(No change to text)*

416.4 Spray booths. *(No change to text)*

416.5 Fire protection. An *automatic fire-extinguishing system* shall be provided in all spray<u>, dip and immersing spaces and storage</u> rooms and shall be installed in accordance with Chapter 9.

(Portions of the proposal not shown, remain unchanged.)

Commenter's Reason: This proposal was Disapproved at the Code Change Hearing because it needed clarification in the proposed text for both the IFC and IBC. The original item has been split into two Public Comments; one addressing the IBC and the other addresses the IFC. This Public Comment is intended to only address the revisions to the IBC. The revisions in this section are intended to clarify the application of IBC Section 416.

Section 416.1 is revised to cover the "application of flammable finishes" rather than just the spray operations of flammable finishes. Spray application is not the only method of applying flammable finishes. This revision will allow all of those other methods to be covered in this section.

Section 416.2.2 is revised to reference the IMC which contains requirements for ventilation velocities and for interlocking the ventilation system with the spraying apparatus.

Section 416.5 is revised by reverting back to the original text currently in the 2009 IBC. This wording includes dipping and immersing operations, and storage rooms where fire protection systems are required. Since the scope of Section 416 is revised to cover methods of application other than just spraying, it is appropriate to leave the reference to these other operations in this section.

Final Action: AS AM AMPC____ D

F156-09/10
1504.6.1.2.1

<u>Proposed Change as Submitted</u>

Proponent: Geoff Raifsnider, Global Finishing Solutions, representing self

Revise as follows:

1504.6.1.2.1 Interlocks. The spraying apparatus, drying apparatus and ventilating system for the spray booth or spray room shall be equipped with interlocks arranged to:

1. Prevent operation of the spraying apparatus while drying operations are in progress.
2. <u>Prevent operation of the drying appratus until a timed purge of spray vapors from the spray booth or spray room is complete. This purge time shall be based upon introducing at least 4 standard cubic feet of fresh air per cubic foot of spray booth or spray room volume.</u> ~~Purge spray vapors from the spray booth or spray room for a period of not less than 3 minutes before the drying apparatus is rendered operable.~~
3. Have the ventilating system maintain a safe atmosphere within the spray booth or spray room during the drying process and automatically shut off drying apparatus in the event of a failure of the ventilating system.
4. Shut off the drying apparatus automatically if the air temperature within the booth exceeds 200°F (93°C).

Reason: Although "not less than" implies that the value could be more, the current language does not state how the value is calculated. The proposed language clarifies how to calculate the purge time and bases it upon the amount of fresh air introduced. This proposal also eliminates the 3 minute minimum. There are applications where the delay in proceeding to curing can affect the quality of the product finish. In these applications the heating apparatus is often the same industrial heater that maintains the temperature during painting and the apparatus is outside the spray area and not subject to exposure to overspray. It should be acceptable to have a design where the purge time is a function of air flow.

Cost Impact: Any additional cost would be justified based upon the importance of the reduced purge time to achieve the quality of the product. This additional cost may be offset by the reduction in operating cost.

ICCFILENAME: RAIFSNIDER-F2-1504.6.1.2.1.DOC

Public Hearing Results

Committee Action: Disapproved

Committee Reason: The committee did not feel that it had adequate information to properly evaluate the proposal and that there was inadequate justification provided. It was unclear as to how the 4 scf per cubic foot of booth volume was determined. The current time-out interlock is straight forward and easy to inspect while the volume-based interlock would be difficult to inspect.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Geoff Raifsnider, Global Finishing Solutions, representing self, requests Approval as Submitted.

Commenter's Reason: Original proposal was rejected for lack of "adequate information to properly evaluate the proposal and that there was inadequate justification provided". The following comments are intended to serve as the additional information and justification requested during the code development hearings:

- A purge interval is a function of the spray booth size (cubic feet) and the ventilation rate (cubic feet per minute). Both of these values are documented and measurable for a given spray booth.
- The original proposal is based upon the language in NFPA 86 Standard for Ovens and Furnaces 2007 Edition. The idea is to replace the air in the booth at least four times (4 ft^3 of air/ft^3 of booth) to ensure that the concentration at the end of the purge interval is less than 25% of the lower flammable limit.
- To verify that the purge time is sufficient to meet the code, multiply the volume of the booth by four (4) and divide by the exhaust flow rate. An example would be a spray booth that measures 10 ft wide x 10 ft high x 14 ft long (volume = 1,400 ft3). If this booth was designed for 100 feet per minute downdraft the exhaust flow rate would be 14,000 ft3/min (10 ft x 14 ft x 100 fpm). To calculate the minimum purge time you would multiply 1400 ft3 by four (4) and divide by 14,000 ft3/min. The resulting minimum purge time would be 0.4 minutes (1400x4/14000=0.4).
- To address the comments that the proposed changes would be difficult to inspect. The IFC (1506.1.2) currently requires compliance with Chapter 21 when utilizing drying in a spray booth. Section 2107.2 states that a nameplate shall be provided that, among other information, indicates the required purge time (2107.2(3)). The code official can initially verify that the purge timer is set to this value. If there is cause to doubt this information the calculations mentioned can be performed to verify the minimum purge time.
- There are many paint finishing operations, typically in the automotive refinish industry, that are negatively affected by the delay between painting and curing at an elevated temperature. By allowing the proposed changes, the spray booth designer can take into account the importance the purge interval may have on the process. By designing for the correct air flow, both a safe environment for energizing the drying apparatus and a minimum time between spray and cure can be achieved.

Final Action: AS AM AMPC____ D

F157-09/10
1504.7.3

Proposed Change as Submitted

Proponent: Geoff Raifsnider, Global Finishing Solutions, representing self

Revise as follows:

1504.7.3 Air velocity. Ventilation systems shall be designed, installed and maintained to be capable of confining and removing overspray and vapors. The vapor concentration in the exhaust air stream shall be less than 25 percent of the lower flammable limit. ~~such that the average air velocity over the open face of the booth, or booth cross section in the direction of airflow during spraying operations, shall not be less than 100 feet per minute (0.51 m/s).~~

Reason: This proposal eliminates the 100 fpm minimum air velocity. The proposed language removes the specific value while still stating the required performance. There are many types of booths and rooms in which the 100 fpm value would be detrimental to the quality of the product and is well in excess of the minimum dilution air needed to keep the space and exhaust below 25% of the LFL. This extra air also increases the operating costs. The air velocities for a specific spray booth or spray room should be specific to the individual design that accomplishes the desired performance (ie. 25% LFL or containment of overspray at openings). Chapter 13.75 of Industrial Ventilation – A Manual of Recommended Practice 26th Edition Published by ACGIH, lists many air velocity ranges for various painting operations, some above and some below 100 fpm. This publication could be included in the standard as reference material.

Cost Impact: The code change proposal would decrease the construction and operating costs.

ICCFILENAME: RAIFSNIDER-F1-1504.7.3.DOC

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee did not feel that it had adequate information to properly evaluate the proposal and that there was inadequate justification provided. The current stated air velocity is straight forward and easy to measure, whereas determining 25% of the LFL would require expensive equipment and it is unclear as to who would be responsible to provide such equipment.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Geoff Raifsnider, Global Finishing Solutions, representing self, requests Approval as Submitted.

Commenter's Reason: Original proposal was rejected for lack of "adequate information to properly evaluate the proposal and that there was inadequate justification provided". The following comments are intended to serve as the additional information and justification requested during the code development hearings:

Comments

- The original proposal is based upon language in NFPA 33 Standard for Spray Application Using Flammable or Combustible Materials 2007 Edition.
- The intent of the original proposal was to establish a performance requirement. The desired consequences of ventilation in an open spray booth are to confine the overspray to the booth and to ensure that the concentration level does not reach the flammability limit. To assign a fixed value to all spray booth configuration may not provide for a safe and efficient piece of equipment.
- Confinement by velocity is unnecessary in a totally enclosed spray booth.
- Concentration levels can be calculated based upon the material feed rate and quantity of the spray guns and the exhaust flow rate.
- It was not the intent of the proposal to add requirements for equipment to monitor the concentration of flammable vapors in the booth or booth exhaust. With regards to ventilating spray areas, rooms, and booths, NFPA 33 and the IFC already have similar language stating that the concentration of flammable materials in the exhaust system must be kept below 25 percent of the lower flammable limit (LFL).[1, 2]
- The minimum velocity in a paint spray booth could be calculated based upon the requirement to keep the exhaust below 25 of the LFL. However, there are additional performance requirements that may increase this value. NFPA 33 describes the objective of the ventilation system as being capable of confining and removing flammable and combustible materials without prescribing a minimum value of air flow or velocity.[1] It becomes the responsibility of the equipment manufacturer to adequately design the ventilation system to achieve the stated objective based upon conditions such as the type of enclosure and paint application devices.
- Chapter 13.75 of Industrial Ventilation – A Manual of Recommended Practice 26th Edition Published by ACGIH, lists many air velocity ranges for various painting operations, some above and some below 100 fpm. This publication could be included in the standard as reference material. Some examples from this reference are:
  - Large Paint Booth, Cross Draft, Walk-in, Airless Electrostatic or HVLP Spray = 60 cfm/sq ft
  - Open Face Booth, Over 4 sq ft, Airless Electrostatic or HVLP Spray = 100 cfm/sq ft
  - Vehicle Paint Booth, Cross Draft, W x H >150 sq ft = 50 cfm/sq ft

References

1 Chapter 7.2, NFPA 33, Standard for Spray Application Using Flammable or Combustible Materials 2007 Edition
"Each spray area shall be provided with mechanical ventilation that is capable of confining and removing vapors and mists to a safe location and is capable of confining and controlling combustible residues, dusts, and deposits. The concentration of the vapors and mists in the exhaust stream of the ventilation system shall not exceed 25 percent of the lower flammable limit."

2 Chapter 510.3, 2009 International Mechanical Code® 2009 Edition
"The design and operation of the exhaust system shall be such that flammable contaminants are diluted in noncontaminated air to maintain concentrations in the exhaust flow below 25 percent of the contaminant's lower flammability limit."

Final Action: AS AM AMPC____ D

F163-09/10

1803.16 (New), 1802.1, 3704.1.2, 3704.1.3

Proposed Change as Submitted

Proponent: Ron Fuhrhop, Praxair, Inc.

1. Add new text as follows:

1803.16 Sub-atmospheric Gas Systems (SAGS) Type 1 and Type 2. The storage and use of Sub-atmospheric Gas Systems (SAGS) shall be in accordance with Sections 1803.16.1 through 1803.16.1.3.
1803.16.1 General. Sub-atmospheric Gas Systems (SAGS) gas source packages shall meet all of the requirements for compressed gases and gases except as provided for in 1803.16.1.1 through 1803.16.1.3.

1803.16.1.1 Incompatible gases. Sub-atmospheric Gas Systems (SAGS) gas source packages with a water volume of 2.64 gallons (10 L) or less containing incompatible gases shall be permitted to occupy the same gas cabinet or exhausted enclosure.

1803.16.1.2 Ventilation. For Sub-atmospheric Gas Systems (SAGS), gas source packages, ventilation in gas cabinets and exhausted enclosures shall be sufficient to maintain vapors below 25 percent of LFL and below the IDLH concentration.

1803.16.1.3 Overpressure protection. The gas distribution system to which Sub-atmospheric Gas Systems (SAGS) are connected shall be equipped with an approved method of protection against components exceeding their pressure rating in the event of a failure in a SAGS.

1802.1 Definitions. The following words and terms shall, for the purposes of this chapter and as used elsewhere in this code, have the meanings shown herein.

SUB-ATMOSPHERIC GAS SYSTEM (SAGS) Type 1. A gas source package that stores and delivers gas at sub-atmospheric pressure and includes a container (e.g., gas cylinder and outlet valve) that stores and delivers gas at a pressure of less than 14.7 psia at a package temperature of less than 110^{o} F.

SUB-ATMOSPHERIC GAS SYSTEM (SAGS) Type 2. A gas source package that stores compressed gas and delivers gas sub-atmospherically and includes a container (e.g., gas cylinder and outlet valve) that stores gas at a pressure greater than 14.7 psia and delivers gas at a pressure of less than 14.7 psia at a package temperature of less than 110^{o} F.

2. Revise as follows:

3704.1.2 Gas cabinets. Gas cabinets containing highly toxic or toxic *compressed gases* shall comply with Section 2703.8.6 and the following requirements:

1. The average ventilation velocity at the face of gas cabinet access ports or windows shall not be less than 200 feet per minute (1.02 m/s) with a minimum of 150 feet per minute (0.76 m/s) at any point of the access port or window.
2. Gas cabinets shall be connected to an exhaust system.
3. Gas cabinets shall not be used as the sole means of exhaust for any room or area.
4. The maximum number of cylinders located in a single gas cabinet shall not exceed three, except that cabinets containing cylinders not over 1 pound (0.454 kg) net contents are allowed to contain up to 100 cylinders.
5. Gas cabinets required by Section 3704.2 or 3704.3 shall be equipped with an *approved automatic sprinkler system* in accordance with Section 903.3.1.1. Alternative fire-extinguishing systems shall not be used.

   Exception: Sub-atmospheric Gas Systems (SAGS) Type 1 and Type 2 shall be in accordance with Section 1803.16.1.2

3704.1.3 Exhausted enclosures. 3704.1.3 Exhausted enclosures. Exhausted enclosures containing highly toxic or toxic *compressed gases* shall comply with Section 2703.8.5 and the following requirements:

1. The average ventilation velocity at the face of the enclosure shall not be less than 200 feet per minute (1.02 m/s) with a minimum of 150 feet per minute (0.76 m/s).
2. Exhausted enclosures shall be connected to an exhaust system.
3. Exhausted enclosures shall not be used as the sole means of exhaust for any room or area.

4. Exhausted enclosures required by Section 3704.2 or 3704.3 shall be equipped with an *approved automatic sprinkler system* in accordance with Section 903.3.1.1. Alternative fire-extinguishing systems shall not be used.

   Exception: Sub-atmospheric Gas Systems (SAGS) Type 1 and Type 2 shall be in accordance with Section 1803.16.1.2.

Reason: This code change proposal adds definitions and requirements to address the technology of sub-atmospheric gas systems (SAGS), which are not currently found in the code. This new language is proposed for Chapter 18, since SAGS's are exclusively used in Semiconductor Fabs.

A primary goal of SAGS is to improve safety by reducing the risk of a gas release. The risk is reduced, because SAGS only deliver gas when a vacuum is applied to the cylinder connection. In a SAGS, the cylinder valve can be opened, but no gas is released until the pressure downstream of the outlet connection is below atmospheric pressure. This is in contrast to a typical gas cylinder, which releases gas when the cylinder valve is opened. The semiconductor industry has used SAGS successfully for ten years.

1802.1: The proposed definitions are similar to the definitions in the 2009 Edition of NFPA 318, Standard for the Protection of Semiconductor Fabrication Facilities. However, one change was made (110 ^{o} F is referenced instead of NTP). To meet the SAGS definition in NFPA 318, the pressure in a SAGS container must be sub-atmospheric at or below NTP, which is a temperature of 70 ^{o} F. SAGS used in semiconductor tools are located in exhausted enclosures with internal temperatures of 86^o F to 104^o F (above 70^o F). SAGS stored outside may reach temperatures of 110^o F (above 70^o F). So, to meet this proposed definition for SAGS, the container pressure should be sub-atmospheric at temperatures up to 110^o F. If NTP is used as a reference, some Type 1 SAGS could go "above" atmospheric pressure under these normal storage and use conditions.

1803.16.1: All SAGS shall meet the requirements for gases and compressed gases set forth throughout the IFC & IBC, with the specific exceptions allowed in the new SAGS section. Treating SAGS as compressed gases or gases maintains risk-mitigating controls that are well-established in safety and fire protection standards.

1803.16.1.1: This section will allow the placement of SAGS containers with incompatible gases in the same exhausted enclosure, such as containers of arsine and boron trifluoride. IFC Section 1804.3.3 requires the separation of these containers. This separation does not reflect current industry practice and is not necessary with the enhanced safety provided by SAGS. It should be noted, this exception is limited to small cylinders of 10 L of water volume or less. This limits the quantity of material and covers current semiconductor tool applications where SAGS are used.

1803.16.1.2: Ventilation is still required for SAGS. Potential releases from SAGS are very small. For this reason lower ventilation rates are acceptable. The performance standard (maintain vapors below 25 percent of LFL and below IDLH) was used instead of velocity or other prescribed values.

1803.16.1.3: Overpressure protection is standard practice for piping systems. Since SAGS delivery piping systems normally operate in a vacuum, this requirement was added to clarify that overpressure condition could result from potential failure scenarios. There are several methods used today to address this issue. It is also a performance based requirement.

3704.1.2 and 3704.1.3: These additions eliminate a conflict in Chapter 37 that would be created by adopting the new language of 1803.16.1.2. They refer the code user back to Chapter 18 to determine exhaust requirements for SAGS.

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: The action on this proposal should be consistent with the action on Code Change F164-09/10.

ICCFILENAME: FUHRHOP -F1-1802.1.DOC

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee preferred code change F164-09/10 over this proposal to avoid conflicting requirements with NFPA 318.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Ron Fuhrhop representing Praxair Inc, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

1803.16 Sub-atmospheric Gas Systems (SAGS) ~~Type 1 and Type 2~~. The storage and use of Sub-atmospheric Gas Systems (SAGS) shall be in accordance with Sections 1803.16.1 and 1803.16.1.1 ~~through 1803.16.1.3~~.

1803.16.1 General. Sub-atmospheric Gas Systems (SAGS) gas source packages shall meet all of the requirements for compressed gases and gases except as provided for in 1803.16.1.1 ~~through 1803.16.1.3~~.

~~**1803.16.1.1 Incompatible gases.** Sub-atmospheric Gas Systems (SAGS) gas source packages with a water volume of 2.64 gallons (10 L) or less containing incompatible gases shall be permitted to occupy the same gas cabinet or exhausted enclosure.~~

1803.16.1.~~2~~.1 Ventilation. For Sub-atmospheric Gas Systems (SAGS), gas source packages, ventilation in gas cabinets and exhausted enclosures shall be sufficient to maintain vapors below 25 percent of LFL and below the IDLH concentration.

~~**1803.16.1.3 Overpressure protection.** The gas distribution system to which Sub-atmospheric Gas Systems (SAGS) are connected shall be equipped with an approved method of protection against components exceeding their pressure rating in the event of a failure in a SAGS.~~

1802.1 Definitions. The following words and terms shall, for the purposes of this chapter and as used elsewhere in this code, have the meanings shown herein.

<u>**SUB-ATMOSPHERIC GAS SYSTEM (SAGS)** Sub-atmospheric Gas Storage and Delivery System. A system that includes a gas container (e.g., gas cylinder or authorized DOT gas receptacle) which under normal operation allows for gas flow from a container only when the container valve outlet is exposed to a pressure of less than one atmosphere pressure (760 Torr).</u>

~~**SUB-ATMOSPHERIC GAS SYSTEM (SAGS) Type 1.** Sub-atmospheric Gas Storage and Delivery System. A gas source package that stores and delivers gas at sub-atmospheric pressure and includes a container (e.g., gas cylinder and outlet valve) that stores and delivers gas at a pressure of less than 14.7 psia at a package temperature of less than 110°F.~~

~~**SUB-ATMOSPHERIC GAS SYSTEM (SAGS) Type 2.** Sub-atmospheric Gas Delivery System. A gas source package that stores compressed gas and delivers gas sub-atmospherically and includes a container (e.g., gas cylinder and outlet valve) that stores gas at a pressure greater than 14.7 psia and delivers gas at a pressure of less than 14.7 psia at a package temperature of less than 110°F.~~

3704.1.2 Gas cabinets. Gas cabinets containing highly toxic or toxic *compressed gases* shall comply with Section 2703.8.6 and the following requirements:

1. The average ventilation velocity at the face of gas cabinet access ports or windows shall not be less than 200 feet per minute (1.02 m/s) with a minimum of 150 feet per minute (0.76 m/s) at any point of the access port or window.

   <u>**Exception:** Sub-atmospheric Gas Systems (SAGS) shall be in accordance with Section 1803.16.1.1.</u>

2. Gas cabinets shall be connected to an exhaust system.
3. Gas cabinets shall not be used as the sole means of exhaust for any room or area.
4. The maximum number of cylinders located in a single gas cabinet shall not exceed three, except that cabinets containing cylinders not over 1 pound (0.454 kg) net contents are allowed to contain up to 100 cylinders.
5. Gas cabinets required by Section 3704.2 or 3704.3 shall be equipped with an *approved automatic sprinkler system* in accordance with Section 903.3.1.1. Alternative fire-extinguishing systems shall not be used.

   ~~**Exception:** Sub-atmospheric Gas Systems (SAGS) Type 1 and Type 2 shall be in accordance with Section 1803.16.1.2~~

3704.1.3 Exhausted enclosures. Exhausted enclosures containing highly toxic or toxic *compressed gases* shall comply with Section 2703.8.5 and the following requirements:

1. The average ventilation velocity at the face of the enclosure shall not be less than 200 feet per minute (1.02 m/s) with a minimum of 150 feet per minute (0.76 m/s).

   <u>**Exception:** Sub-atmospheric Gas Systems (SAGS) shall be in accordance with Section 1803.16.1.1.</u>

2. Exhausted enclosures shall be connected to an exhaust system.
3. Exhausted enclosures shall not be used as the sole means of exhaust for any room or area.
4. Exhausted enclosures required by Section 3704.2 or 3704.3 shall be equipped with an *approved automatic sprinkler system* in accordance with Section 903.3.1.1. Alternative fire-extinguishing systems shall not be used.

   ~~**Exception:** Sub-atmospheric Gas Systems (SAGS) Type 1 and Type 2 shall be in accordance with Section 1803.16.1.2.~~

Commenter's Reason: The following reason was prepared by William Winslow. Sub-atmospheric gas systems (SAGS) are used primarily in the semiconductor industry. As such, the issues regarding SAGS are not well understood by some fire protection officers (FPO). After a number of code development cycles where SAGS proposals were discussed and disapproved, the Fire Code Committee voted to wash its hands of the issue by disapproving Item 163 and adopting Item 164. Item 164 references NFPA 318, Standard for the Protection of Semiconductor Facilities, for the regulation of SAGS. Many jurisdictions and organizations routinely involved with the semiconductor industry and the use of SAGS, including the California Fire Chiefs Association (Cal Chiefs), don't agree with the Committee's action. Adoption of NFPA 318 eliminates safety controls required for the prudent use of toxic and highly toxic gases in SAGS containers, including automatic shutoff valves, gas treatment systems and incompatible gases in the same enclosure. On the other hand, approving Item 163, as modified by this public comment, will maintain all of the existing safety controls, with the exception of allowing a small reduction in exhaust ventilation. I have worked for and regulated the semiconductor industry for many years. I agree with the Cal Chiefs that the best course of action is to approve Item 163, as modified by this public comment, and disapprove Item 164. This will keep the technical safety issues regarding the use of SAGS in the hands of FPOs, where they belong. William Winslow CIH, CFI, CMI, previous member of the Fire Code Committee and past National Codes Director for the Washington State Association of Fire Marshals.

Cost Impact: The code change proposal may reduce the cost of construction and operation.

Final Action: AS AM AMPC____ D

F164-09/10
1803.16 (New), Chapter 47

Proposed Change as Submitted

Proponent: James McManus, ATMI, Inc.

1. **Add new text as follows:**

1803.16 Sub-atmospheric pressure gas systems. Sub-atmospheric pressure gas systems (SAGS) shall be in accordance with NFPA 318.

2. Add new standard to Chapter 47 as follows:

NFPA
318—09 Standard for the Protection of Semiconductor Fabrication Facilities

Reason: Sub-atmospheric pressure gas systems (SAGS) are the preferred method for storing and delivering the toxic and corrosive dopant gases used in ion implantation processes worldwide. Other uses include solar and electronics. SAGS operate by either removing pressure [Type 1] or internally controlling gas pressure [Type 2]. Both require a vacuum [sub-atmospheric condition, < 14.7 psia] before flow from a cylinder will occur. SAGS significantly reduce the risk associated with Hazardous Production Materials because they mitigate the likelihood and magnitude of a gas release and their use is becoming more common. As such, provisions regulating SAGS should be included in the code.

NFPA 318 already defines and addresses these systems so there is no reason to reinvent provisions for these systems. This proposal recommends that provisions for SAGS be adopted by reference as shown. It is the intent of this code change to adopt only the provisions relating to SAGS within NFPA 318. Those sections are: Section 3.3.28.5 for the definition, and Section 8.6.2 addressing uses and controls. It is not the intent of this proposal to adopt NFPA 318 in total. The charging statement of this proposal clearly indicates that only SAGS be in accordance with NFPA 318.

The definition and controls for use of SAGS are the work-product of a lengthy public debate and consensus building effort undertaken by knowledgeable ESH and risk management professionals. The NFPA 318 Technical Committee approved the language unanimously and it was adopted by a substantial majority at the NFPA annual meeting in June 2008.

Using the NFPA definition in section 3.3.28.5 incorporates language that most accurately defines SAGS and avoids possible conflicts that may be inadvertently introduced with alternative language.

Systems fitting this description include:
Sub-atmospheric Gas System. [Type 1/SAGS] A gas source container where the contents are at sub-atmospheric pressure [<14.7 psia] at NTP* [21ºC and 1 atmosphere]. Type 1/SAGS are not compressed gases.

Vacuum Initiated Gas Cylinder. [Type 2/SAGS] A compressed gas cylinder, modified internally using pressure and flow components to limit and control delivery pressure to sub-atmospheric pressure operation [<14.7 psia]. Today such systems are *designed to fail* in a closed [no-flow] position.

Section 8.6.2 contains requirements consistent with the risk reduction afforded by the SAGS technology. Local jurisdictions may, at their discretion, further modify the uses and controls based on existing ordinances or practice, or exceptions to the provisions could be added to this proposal.

Recognizing SAGS in the code helps officials and users ensure uniform application and understanding of this important risk reduction technology.

*NTP—see 2702.1

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: A review of the standard(s) proposed for inclusion in the code, NFPA 318—09, for compliance with ICC criteria for referenced standards given in Section 3.6 of Council Policy #CP 28 will be posted on the ICC website on or before September 24, 2009. The action on this proposal should be consistent with the action on Code Change F163-09/10.

ICCFILENAME: MCMANUS-F1-1803.16.DOC

Public Hearing Results

Note: The following analysis was not in the Code Change monograph but was published on the ICC website at http://www.iccsafe.org/cs/codes/Documents/2009-10cycle/ProposedChanges/Standards-Analysis.pdf :

Analysis: Review of the proposed new standard NFPA 318-09 indicated that, in the opinion of ICC staff, the standard did comply with ICC standards criteria.

Committee Action: Approved as Submitted

Committee Reason: The committee preferred this proposal over F163-09/10 because it is more comprehensive in its approach to the subject matter by referencing a nationally recognized standard that SAGS facilities will be required (by insurers) to comply with anyway. Also, F163-09/10 would only regulate ventilation whereas NFPA 318 regulates the entire concept of SAGS.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Ron Fuhrhop representing Praxair Inc, requests Disapproval.

Commenter's Reason: Recommend disapproval of F164 and approval of Item 163, as modified by the public comment. See Reason statement in F163 comment.

Final Action: AS AM AMPC____ D

F166-09/10

1805.2.3.4

Proposed Change as Submitted

Proponent: Patrick A. McLaughlin, McLaughlin & Associates, representing The Semiconductor Industry Association

Revise as follows:

1805.2.3.4 Pyrophoric liquids and Class 3 water-reactive liquids. Pyrophoric liquids and Class 3 water-reactive liquids in containers greater than 0.5-gallon (2 L) but not exceeding 5.3-gallon (20 L) capacity shall be allowed at workstations when located inside cabinets and the following conditions are met:

1. Maximum amount per cabinet: The maximum amount per cabinet shall be limited to 5.3 gallons (20L).
2. Cabinet construction: Cabinets shall be constructed in accordance with the following:
   - 2.1. Cabinets shall be constructed of not less than 0.097-inch (2.5 mm) (12 gage) steel.
   - 2.2. Cabinets shall be permitted to have self-closing limited access ports or noncombustible windows that provide access to equipment controls.
   - 2.3. Cabinets shall be provided with self- or manual-closing doors. Manual-closing doors shall be equipped with a door switch that will initiate local audible and visual alarms when the door is in the open position.
3. Cabinet exhaust ventilation system: An exhaust ventilation system shall be provided for cabinets and shall comply with the following:
   - 3.1. The system shall be designed to operate at a negative pressure in relation to the surrounding area.
   - 3.2. The system shall be equipped with ~~a pressure monitor and a flow switch alarm monitored~~ <u>monitoring equipment to ensure exhaust flow and alarmed</u> at the on-site *emergency control station*.
4. Cabinet spill containment: Spill containment shall be provided in each cabinet, with the spill containment capable of holding the contents of the aggregate amount of liquids in containers in each cabinet.
5. Valves: Valves in supply piping between the product containers in the cabinet and the workstation served by the containers shall fail in the closed position upon power failure, loss of exhaust ventilation and upon actuation of the fire control system.
6. Fire detection system: Each cabinet shall be equipped with an automatic fire detection system complying with the following conditions:
   - 6.1. Automatic detection system: UV/IR, highsensitivity smoke detection (HSSD) or other *approved d*etection systems shall be provided inside each cabinet.
   - 6.2. Automatic shutoff: Activation of the detection system shall automatically close the shutoff valves at the source on the liquid supply.
   - 6.3. Alarms and signals: Activation of the detection system shall initiate a local alarm within the *fabrication area* and transmit a signal to the *emergency control station*. The alarms and signals shall be both visual and audible.

Reason: Several commercially available bulk liquid pyrophoric cabinets are designed to meet the requirements of the IFC Chapter 18 section 1805.2.3.5 Pyrophoric Liquids and Class 3 water-reactive liquids. Typical pyrophoric cabinets are designed with nitrogen gas (N_2) fire protection systems to meet the requirements for pyrophoric liquids as outlined in Chapter 18 Table 1805.2.2 note d "Allowed only in workstations that are internally protected with an approved automatic fire-extinguishing or fire protection system complying with Chapter 9 and compatible with the reactivity of the materials in use at the workstation." In order for an N_2 fire suppression system to be effective it must displace the O_2 within the cabinet. In order to displace O_2 within the cabinet and still maintain at a negative exhaust pressure within the cabinet in relation to the surrounding area, these cabinets must be airtight. Airtight indicates that these cabinets will operate under static only, when exhaust is applied, however, there will be no exhaust flow because there is no mechanism for make-up air into the cabinet. Design criteria are currently specified for liquid pyrophoric cabinets on site to meet O_2 levels below 1% within 60 seconds during discharge of the N_2 fire suppression system, which again requires these cabinets to be airtight. The current exhaust flow within these cabinets with the doors closed is effectively zero and to low for commercially available exhaust flow meters to detect. Cabinet exhaust is monitored with an exhaust pressure switch to detect available exhaust static. Some facilities currently monitor cabinet exhaust static within cabinets with a Neo-Dyn pressure switch (part#142P80CC3443) or a Dwyer (part#1910-1) and alarm for exhaust static below 1" w.c. The installation of a flow switch in addition to the pressure switch is redundant to the pressure switch. The installation of a flow switch is also ineffective due to the zero exhaust flow condition based on the cabinet design. Therefore requirements for exhaust flow monitoring are being changed to a performance requirement.

Cost Impact: The code change proposal will not increase the cost of construction.

Public Hearing Results

Committee Action: Approved as Submitted

Committee Reason: The committee agreed with the proponent's reason statement and felt that the proposal provides a needed update to current performance-based technology.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Patrick A. McLaughlin, McLaughlin & Associates, representing The Semiconductor Industry Association, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

1805.2.3.4 Pyrophric liquids and Class 3 Water-reactive liquids. Pyrophoric liquids and …

1. through 2.3. (No change)
3. Cabinets exhaust ventilation system: An exhaust ventilation system shall be provided for cabinets and shall comply with the following:
   3.1. The system shall be designed to operate at a negative pressure in relation to the surrounding area.
   3.2. The system shall be equipped with monitoring equipment to ensure that required exhaust flow or static pressure is provided and that low flow or static pressure conditions send an alarm~~ed~~ ~~at~~ to the on-site emergency control station.
4. through 6.3. (No change)

Commenter's Reason: To clarify that exhaust static will be monitored if there is no exhaust flow. That was the intent of the original proposal. SIA was made aware of the potential confusion at the Code Development Hearings and committed to correct it.

Public Comment 2

Joe Pierce (Chairman), Dallas Fire Department representing Joint Fire Service Review Committee, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

1805.2.3.4 Pyrophoric liquids and Class 3 water-reactive liquids. Pyrophoric liquids and Class 3 water-reactive liquids in containers greater than 0.5-gallon (2 L) but not exceeding 5.3-gallon (20 L) capacity shall be allowed at workstations when located inside cabinets and the following conditions are met:

1. through 2.3. *(No change)*
3. Cabinet exhaust ventilation system: An exhaust ventilation system shall be provided for cabinets and shall comply with the following:
   3.1. The system shall be designed to operate at a negative pressure in relation to the surrounding area.
   3.2. The system shall be equipped with monitoring equipment to ensure that required exhaust flow or static pressure is provided. ~~and~~
   3.3. Low flow or static pressure conditions shall send an alarm~~ed~~ ~~at~~ to the on-site emergency control station. The alarm shall be both visual and audible.
4. through 6.3 (No change)

Commenter's Reason: This Public Comment revises Item 3 to clarify and separate the issues of monitoring and the resultant alarms associated with exhaust monitoring.

Item 3.2 is revised to clarify that exhaust static will be monitored when there is no exhaust flow. That was the intent of the original proposal and this proposal states it clearly.

Item 3.3 addresses the action when there is low flow or failure of the exhaust system. The requirement that the alarm must be audible and visual is also included. Currently, Item 6.3 requires an audible and visual alarm for the fire detection system. The failure of the exhaust ventilation system on a cabinet containing pyrophoric materials deserves the same level of notification. Therefore, the language from Item 6.3 is duplicated in Item 3.3 to require audible and visual alarms when the exhaust ventilation system fails.

Final Action: AS AM AMPC____ D

F173-09/10
2206.8.1, 2206.8.2 (New), 2202.1

Proposed Change as Submitted

Proponent: Ken Boyce, Underwriters Laboratories, representing Doug Horne, Clean Vehicle Education Foundation; Wendy Clark, National renewable Energy Laboratory

1. Revise as follows:

2206.8.1 Approval of equipment. Dispensers, hoses, nozzles, breakaway fittings, swivels, flexible connectors or dispenser emergency shutoff valves, vapor recovery systems, leak detection devices and pumps used in alcohol blended fuel-dispensing systems shall be listed or approved for the specific purpose.

2. Add new text as follows:

2206.8.2 Material compatibility. Tanks and fluid handling components that contact alcohol blended fuels shall be fabricated from corrosion resistant materials that mitigate galvanic action and resist corrosion from internal and external sources. Dissimilar metallic parts that promote galvanic action shall not be joined.

(Renumber subsequent sections)

3. Revise definition as follows:

2202.1 Definitions. The following words and terms shall, for the purposes of this chapter and as used elsewhere in this code, have the meanings shown herein.

ALCOHOL BLENDED FUELS. Alcohol blended fuels, including those containing nominally 85-percent ethanol 15-percent unleaded gasoline (E85), are flammable liquids consisting of ethanol or other alcohols blended greater than ~~15~~10-percent by volume.

Reason: This proposal updates E85 and other alcohol blended fuel dispensing requirements. Specifically, the proposal:
1. Revises the definition of alcohol blended fuels that was introduced into the 2006 IFC. The proposed revision clarifies that these are fuels containing between 10 and 85% ethanol by volume. Presently, gasoline blends containing up to 10% ethanol (also known as "gasohol") are permitted to be dispensed into conventional (non-flex fuel) vehicles, although there the possibility in the near-term that blends containing more that 10% ethanol may be permitted for conventional vehicles. Clarifying the limit from 15 to 10% is necessary and will help the IFC address potential near-term deployment of fuels with more ethanol.
2, Adds leak detection devices to the types of equipment specifically requiring approval for use with alcohol blended fuels. Practical experience has shown that leak detection equipment needs to be compatible for use with alcohol blended fuels or it may not be able to perform its intended function.
3. Adds a new section 2606.8.2 with requirements covering the compatibility of the fuel containment systems materials with the alcohol blended fuels. The wording for this section is similar to wording currently in Section 3403.6.5, which addresses external corrosion, not internal corrosion. Alcohols are polar compounds that exhibit increased moisture absorption, water solubility, polar solvency and solution conductivity relative to gasoline, and can cause increased corrosion.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: BOYCE-F1-2206.8.1.DOC

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The committee agreed with the proponent's reason statement and felt that the code change better accommodates alcohol-blended fuels.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Richard S Kraus representing American Petroleum Institute (API) and Jeffrey Shapiro, International Code Consultants representing Steel Tank Institute, request Approval as Modified by this Public Comment.

Modify the proposal as follows:

~~**2206.8.2 Material compatibility.** Tanks and fluid handling components that contact alcohol blended fuels shall be fabricated from corrosion resistant materials that mitigate galvanic action and resist corrosion from internal and external sources. Dissimilar metallic parts that promote galvanic action shall not be joined.~~

(Portions of the proposal not shown remain unchanged.)

Commenter's Reason (KRAUS): This comment is to delete a new added section 2606.8.2. The proposed requirements would severely restrict the use if existing tanks and piping. There have been no reported serious problems due to the supposedly incompatibility of the fuel containment systems materials with alcohol blended fuels.

(1) The wording for this section is similar to the wording proposed in F202-09/10 which was DISAPPROVED by the Committee because "this proposal would limit the use of all aboveground and underground, inside and outdoor steel tanks or require them to be lined, including retroactivity".

The change would require the exclusive use of gold or gold lined tanks and components as gold is the ONLY metal that resists galvanic corrosion. Additionally, although the IFC Committee stated the action denying F202 was not in conflict with the action taken in F173, it obviously has now created a potential conflict in code requirements.

(2) The proponent stated that this change would increase the cost of construction. This is more than true. Requiring gold or other inert material and/or requiring lined tanks and components or other approved means of galvanic action mitigation (such as cathodic protection systems) particularly if applied retroactively, and replacing or retrofitting all existing tanks, piping and associated equipment is COST PROHIBITIVE.

Proponent also stated that this change is similar to wording in 3403.6.5. However 3603.6.5 only covers piping for which EXTERNAL corrosion protection has always been required. This proposal would require INTERNAL corrosion protection (gold plated or linings) and extends coverage to ALL tanks, piping, dispensers, hoses, pumps, connectors, nozzles and any other fluid handling equipment and devices NOT just to piping. .

(3) A Task Group assigned to study a similar issue at the last NFPA 30 Committee meeting in December 2010, reached the following conclusions supporting the position that galvanic act ion with blended fuels is not a substantive problem:

(a) The Steel tank Institute reported they could not recollect any piece of equipment that could not be subject to galvanic corrosion or cracking, whether it be steel, plastic, or elastomeric, (only gold is not afflicted). Therefore, if the new Section 2206.8.2 remains in the code, all existing tanks, equipment and appurtenances handling blended fuels would have to be replaced and all new items would have to be gold or lined with . .

(b) IFC already requires inspection, monitoring and maintenance of tanks and appurtenances and NFPA 30 has similar requirements in Sections 21.8, 22.17, and 23.17. These requirements assure corrosion is monitored and controlled. Additionally, EPA has strict requirements for monitoring leakage (and to take subsequent corrective action). These requirements have been effective to date in controlling corrosion related leakage.

(c) There is a lack of known failures with existing E85 tanks. The only cracking of steel tanks systems where alcohol content exceeds 10% is with denatured ethanol (approximately 97% ethanol) in large terminal tank facilities and loading racks. API has a document 939 (D and E) that discusses this phenomenon. It is not occurring in shop-fabricated tanks, or with E85 storage tanks in the existing marketplace, or at ethanol producers facilities, or in transport barges with steel tanks, or in railroad transport containers. So it has been a very isolated event, and certainly not worthy of an annual inspection on all tank systems and all tank equipment.

(4) NFPA 30 23.3.4, 23.3.4.1 and 23.3.4.2 (2008) which covers protection of tanks and piping, allows the AHJ to waive requirements where engineering evaluations have evidenced that corrosion does not occur. Information is available from industry studies, surveys and testing conducted by the API (American Petroleum Institute), STI (Steel Tank Institute) and other industry associations to assist AHJs in their determination. These all indicate that corrosion in tanks and piping containing alcohol based fuels is minimal.

(5) Section 2206.8.1 already requires equipment to be listed or approved. UL has a listing for dispensers using E85 fuels. AHJ approval can be similar to that initiated by the State of Illinois Fire Marshal, as follows (in part):

"The agency will only permit the distribution of a blended fuel in those tanks and piping that have been certified by the manufacturer or registered professional engineer as compatible with the blended fuel that will be stored"

"In lieu of such certification from the manufacturer or registered professional engineer, the OSFM will permit a blended fuel to be stored in steel tanks, single wall and double wall fiberglass tanks manufactured after 1991, or any tank that has been certified by a registered professional engineer as compatible with the blended fuel".

"The associated piping must be steel, fiberglass piping manufactured after 1991 or piping that was certified by a registered professional engineer as compatible with the blended fuel."

"In lieu of such certification from the manufacturer or registered professional engineer as to the compatibility of the material, the OSFM will permit the use of such ancillary equipment provided the equipment is inspected on a yearly basis by a licensed contractor."

"The owner/operator must also maintain at the facility location maintenance and inspection documentation from the licensed contractor that the ancillary equipment has been inspected and in good operating condition for use with the blended fuel being distributed"

(6) The proposed change is totally unnecessary. The majority of service stations are independently owned (or leased) and owners and operators are responsible for tanks, piping, dispensers, hoses, nozzles and appurtenances. This totally unnecessary proposed change would place a tremendous burden on these small business men and women as there is no way that they could comply (gold plated or lined equipment, indeed) and remain in business. The adherence of these responsible service station owners and operators to existing fire code, regulatory and industry requirements to monitor, inspect and maintain equipment and to control and mitigate any leakage has been commendable over the past years.

Commenter's Reason (SHAPIRO): Material compatibility is not an issue that should be dealt with uniquely in Chapter 22. The general requirements for material compatibility to prevent excessive corrosion are contained in Section 3403.6.5, where they apply to all piping systems.

As written, the proposed Section 2206.8.2 suggests that a tank in contact with an alcohol blended fuel must be fabricated from corrosion resistant materials, which essentially eliminates the permissible use of steel tanks for these fuels unless they are lined to prevent fluid contact with the tank shell. In addition, the text considered in Baltimore also prohibits steel tanks because they are subject to corrosion from external sources. Such corrosion can be (and is routinely) limited and controlled by cathodic protection and other methods, but these other methods are not recognized or permitted by the proposed text (note that the IFC addresses corrosion protection methods for all tanks in 3404.2.7.9, so there is no need for unique treatment in Chapter 22).

In discussion with the proponent, I was told that the main concern is preventing excessive corrosion that may occur when dissimilar metals are joined in the presence of a conductive liquid. This is certainly a valid issue for the code to deal with, but the code already addresses it in Section 3403.6.5, which regulates fuel dispensing systems along with all other flammable liquid piping.

Public Comment 2:

Jeffrey Shapiro, International Code Consultants representing Steel Tank Institute, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

ALCOHOL BLENDED FUELS. ~~Alcohol blended fuels, including those containing nominally 85-percent ethanol 15-percent unleaded gasoline (E85), are f~~ Flammable liquids consisting of 10-percent or greater, by volume, ethanol or other alcohols blended with gasoline ~~greater than 10-percent by volume~~.

(Portions of the proposal not shown remain unchanged.)

Commenter' s Reason: This comment is provided as an editorial rewrite of the definition, which is not in proper definition format as it was approved in Baltimore (or for that matter, in the 2009 code). There is no intent to change the technical provisions from what was approved in Baltimore. The current reference to E85 (85-percent alcohol and 15 percent gasoline) in the definition has been deleted because it is unneeded and potentially confusing. The definition states that any alcohol-gasoline mixture with 10-percent or more alcohol is an “alcohol blended fuel.” With E85 being 85-percent alcohol (well above the 10-percent threshold), it makes no sense to specifically name E85 in the definition versus other ethanol blends, such as E15.

Final Action: AS AM AMPC____ D

F175-09/10

2209.2.2, Table 2209.2.2 (New), Chapter 47

Proposed Change as Submitted

Proponent: Julie Cairns, CSA America, Inc., representing CSA America Automotive Technical Committee

1. Revise as follows:

2209.2.2 Listed equipment. Hoses, hose connections, compressors, hydrogen generators, dispensers, detection systems and electrical equipment used for hydrogen shall be *listed* for use with hydrogen in accordance with the applicable standard in Table 2209.2.2. Hydrogen motor fueling connections shall be *listed* and *labeled* for use with hydrogen.

TABLE 2209.2.2
HYDROGEN HANDLING COMPONENT STANDARDS

HYDROGEN HANDLING COMPONENT	STANDARD
Compressed Hydrogen Dispensers	CSA America HGV 4.1
Hoses and Hose Assemblies for Gaseous Hydrogen Vehicles and Dispensing Systems	CSA America HGV 4.2
Breakaway Devices for Hoses Used in Compressed Hydrogen Vehicle Fueling Stations	CSA America HGV 4.4
Priority and Sequencing Equipment for Gaseous Hydrogen Dispensing Systems	CSA America HGV 4.5
Manually Operated Valves Used in Gaseous Hydrogen Vehicle Fueling Stations	CSA America HGV 4.6
Standard for Automatic Pressure Operated Valves for Use in Gaseous Hydrogen	CSA America HGV 4.7

Vehicle Fueling Stations	
Hydrogen Gas Vehicle Fueling Station Compressor	CSA America HGV 4.8
Fittings for Compressed Hydrogen Gas and Hydrogen Rich Gas Mixtures	CSA America HGV 4.10

2. Add new standards to Chapter 47 as follows:

CSA America, Inc.
8501 E. Pleasant Valley Rd.
Cleveland, OH 44131

HGV 4.1 Compressed Hydrogen Dispensers
HGV 4.2 Hoses and Hose Assemblies for Gaseous Hydrogen Vehicles and Dispensing Systems
HGV 4.4 Breakaway Devices for Hoses Used in Compressed Hydrogen Vehicle Fueling Stations
HGV 4.5 Priority and Sequencing Equipment for Gaseous Hydrogen Dispensing Systems
HGV 4.6 Manually Operated Valves Used in Gaseous Hydrogen Vehicle Fueling Stations
HGV 4.7 Standard for Automatic Pressure Operated Valves for Use in Gaseous Hydrogen Vehicle Fueling Stations
HGV 4.8 Hydrogen Gas Vehicle Fueling Station Compressor
HGV 4.10 Fittings for Compressed Hydrogen Gas and Hydrogen Rich Gas Mixtures

Reason: The proposal is to reference CSA America documents used by industry for certification of the dispenser and related equipment.

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: A review of the standard(s) proposed for inclusion in the code, CSA HGV 4.1, 4.2, 4.4, 4.5, 4.6, 4.7, 4.8 and 4.10, for compliance with ICC criteria for referenced standards given in Section 3.6 of Council Policy #CP 28 will be posted on the ICC website on or before September 24, 2009.

ICCFILENAME: CAIRNS-F1-2209.2.2

Public Hearing Results

Note: The following analysis was not in the Code Change monograph but was published on the ICC website at http://www.iccsafe.org/cs/codes/Documents/2009-10cycle/ProposedChanges/Standards-Analysis.pdf :

Analysis: Drafts of the proposed CSA HGV 4 standards were not submitted for review.

Committee Action: Disapproved

Committee Reason: The documents proposed as referenced standards are still in draft form and were not submitted to staff or the committee for review.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment:

Robert W. Boyd, The Linde Group, representing the Hydrogen Industry Panel on Codes; Julie Cairns, CSA America, Inc, representing CSA America, Automotive Technical Committee; and Larry Fluer, Fluer, Inc. and Pat McLaughlin, McLaughlin & Associates, representing the Compressed Gas Association, request Approval as Modified by this Public Comment.

Modify the proposal as follows:

2209.2.2 Listed or approved equipment. Hoses, hose connections, compressors, hydrogen generators, dispensers, detection systems and electrical equipment used for hydrogen shall be *listed* or approved for use with hydrogen ~~in accordance with the applicable standard in Table 2209.2.2.~~ Hydrogen motor fueling connections shall be *listed* and *labeled* or approved for use with hydrogen.

~~TABLE 2209.2.2~~
~~HYDROGEN HANDLING COMPONENT STANDARDS~~

~~HYDROGEN HANDLING COMPONENT~~	~~STANDARD~~
~~Compressed Hydrogen Dispensers~~	~~CSA America HGV 4.1~~

~~Hoses and Hose Assemblies for Gaseous Hydrogen Vehicles and Dispensing Systems~~	~~CSA America HGV 4.2~~
~~Breakaway Devices for Hoses Used in Compressed Hydrogen Vehicle Fueling Stations~~	~~CSA America HGV 4.4~~
~~Priority and Sequencing Equipment for Gaseous Hydrogen Dispensing Systems~~	~~CSA America HGV 4.5~~
~~Manually Operated Valves Used in Gaseous Hydrogen Vehicle Fueling Stations~~	~~CSA America HGV 4.6~~
~~Standard for Automatic Pressure Operated Valves for Use in Gaseous Hydrogen Vehicle Fueling Stations~~	~~CSA America HGV 4.7~~
~~Hydrogen Gas Vehicle Fueling Station Compressor~~	~~CSA America HGV 4.8~~
~~Fittings for Compressed Hydrogen Gas and Hydrogen Rich Gas Mixtures~~	~~CSA America HGV 4.10~~

~~CSA America, Inc.~~
~~8501 E. Pleasant Valley Rd.~~
~~Cleveland, OH 44131~~

~~HGV 4.1 Compressed Hydrogen Dispensers~~
~~HGV 4.2 Hoses and Hose Assemblies for Gaseous Hydrogen Vehicles and Dispensing Systems~~
~~HGV 4.4 Breakaway Devices for Hoses Used in Compressed Hydrogen Vehicle Fueling Stations~~
~~HGV 4.5 Priority and Sequencing Equipment for Gaseous Hydrogen Dispensing Systems~~
~~HGV 4.6 Manually Operated Valves Used in Gaseous Hydrogen Vehicle Fueling Stations~~
~~HGV 4.7 Standard for Automatic Pressure Operated Valves for Use in Gaseous Hydrogen Vehicle Fueling Stations~~
~~HGV 4.8 Hydrogen Gas Vehicle Fueling Station Compressor~~
~~HGV 4.10 Fittings for Compressed Hydrogen Gas and Hydrogen Rich Gas Mixtures~~

Commenter's Reason (BOYD/CAIRNS): Equipment used for hydrogen may not always be listed or listed and labeled given the evolving nature of hydrogen technologies. An alternate provision that the equipment be approved provides the fire code official with a means to regulate hydrogen equipment installations and is consistent with section 2703.2.3 which provides that equipment and machinery associated with the use of hazardous materials be listed or approved. The original proposal attempted to provide both the code official and industry tools to use for the installation of hydrogen motor fuel facilities, however, the standards listed have not completed the consensus process. This public comment will allow code officials and industry to apply the standards once they have completed the process by inserting the words "or approved" to match existing language for other hazardous material activities.

The original proponent of F175, Julie Cairns of CSA International, is in support of this public comment. In addition, HIPOC has been in contact with CGA who submitted an identical public comment. We are in support of this change and wish to reflect that CGA, CSA, and HIPOC all support this public comment.

Commenter's Reason (FLUER/McLAUGHLIN): The proposed new CSA standards are not yet standards so they were removed from the proposal. Currently there are no listing standards for many of the items included in the list of equipment which may be utilized in this application, including, compressors, generators and dispensers. On the other hand, motor fueling connections are listed. This modification resolves the lack of listing standards by adding "or approved", and thus will accomplish the submitter's intent by allowing the local authority to approve the equipment using CSA America, Inc. HGVs or other approved standards when they are ultimately published.

Final Action: AS AM AMPC____ D

F179-09/10
2301.5 (New), 2302 (New), 2303.2, 2303.6, 2308.2.1, Chapter 47

Proposed Change as Submitted

Proponent: Jimbo Schifiliti, Fire Safety Consultants, Inc., representing self

1. Add new text as follows:

2301.5 Pallets. All pallets shall be wooden as defined by this Chapter or shall be *listed* and *labeled* in accordance with UL 2335 or FM 4996

SECTION 2302
DEFINITIONS

2302.1 Definitions. The following words and terms shall, for the purposes of this chapter and as used elsewhere in this code, have the meanings shown herein.

WOODEN PALLET. A wooden pallet is defined as a 42 in. x 42 in., 2-way entry Stringer Pallet constructed from hardwood as described in ASME MH1.

2. Revise as follows:

2303.2 Class I commodities. Class I commodities are essentially noncombustible products ~~on wooden or nonexpanded polyethylene solid deck~~ <u>with or without pallets</u> , in ordinary corrugated cartons with or without single-thickness dividers, or in ordinary paper wrappings with or without pallets. Class I commodities are allowed to contain a limited amount of Group A plastics in accordance with Section 2303.7.4. Examples of Class I commodities include, but are not limited to, the following:

Alcoholic beverages not exceeding 20-percent alcohol
Appliances noncombustible, electrical
Cement in bags
Ceramics
Dairy products in nonwax-coated containers (excluding bottles)
Dry insecticides
Foods in noncombustible containers
Fresh fruits and vegetables in nonplastic trays or containers
Frozen foods
Glass
Glycol in metal cans
Gypsum board
Inert materials, bagged
Insulation, noncombustible
Noncombustible liquids in plastic containers having less than a 5-gallon (19 L) capacity
Noncombustible metal products

2303.6 High-hazard commodities. High-hazard commodities are high-hazard products presenting special fire hazards beyond those of Class I, II, III or IV. Group A plastics not otherwise classified are included in this class. Examples of high-hazard commodities include, but are not limited to, the following:

Aerosol, Level 3 (see Chapter 28)
Alcoholic beverages, exceeding 80-percent alcohol, in bottles or cartons
Commodities of any class in plastic containers in carousel storage
Flammable solids (except solid combustible metals)
Glycol in combustible containers (50 percent or greater)
Lacquers, which dry by solvent evaporation, in metal cans or cartons
Lubricating or hydraulic fluid in plastic containers
Mattresses, foam rubber or foam plastics
~~Pallets and flats which are idle combustible~~
Paper, asphalt, rolled, horizontal storage
Paper, asphalt, rolled, vertical storage
Paper and pulp, rolled, in vertical storage which is unbanded or not protected with an *approved* wrap
Pillows, foam rubber and foam plastics
Pyroxylin
Rubber tires
Vegetable oil and butter in plastic containers

2308.2.1 Plastic ~~pallets and~~ shelves. Storage on ~~plastic pallets or~~ plastic shelves shall be protected by *approved* specially engineered *fire protection systems*.

> ~~**Exception:** Plastic pallets listed and labeled in accordance with UL 2335 shall be treated as wood pallets for determining required sprinkler protection~~.

3. Add new standards to Chapter 47 as follows:

<u>ANSI/FM 4996-2007</u>	<u>American National Standard for Classification of Idle Plastic Pallets as Equivalent to Wood Pallets</u>
<u>ASME MH1-2005</u>	<u>Pallets, Slip Sheets, and Other Bases for Unit Loads</u>

Reason: Over the years the types of pallets utilized in day to day commerce has changed. When the density requirements relative to the impact pallets have on commodity classification and as idle pallet storage the standard wooden pallet was the hardwood, stringer type. Today a wooden pallet may be a 9-block, 4-way, softwood type or other variations including “one-way” pallets of a mixture of wood and composites. Some pallets are plastic, some are a combination of plastic and wood products.

NFPA 13 has undergone revisions over the last several cycles to increase density requirements based upon test data for the newer wood pallets. In addition, NFPA 13 added definitions as follows:

> “3.10.12 Wood Pallet. A wood pallet is defined as a pallet constructed entirely of wood with metal fasteners.”
>
> “3.10.13 Plastic Pallet. A plastic pallet is defined as a pallet having any portion of its construction consisting of a plastic material.”

The new definitions serve as a partial solution in that the pallet is either wood or plastic, and if classified as plastic verification of whether or not it is a listed and labeled plastic pallet can be made.

But the changes in NFPA 13 do not address the entire problem. Though the more recent additions of NFPA 13 have had increases made to density requirements to handle the challenge of some of the newer wood pallet types or new construction projects, those densities do not cover all of the newer types of materials in use in pallets and do not address the fact that the pallets are in use in facilities built under early editions of NFPA 13 and as a result do not have the needed water flow densities.

We have an additional problem in Chapter 23. Whereas NFPA 13 addresses the impact of pallets at “5.6.2 Pallet Types”, (which may require a one or two class commodity increase or specific laboratory testing), and at “12.12 Protection of Idle Pallets” regardless or storage method, (solid pile versus rack storage), the IFC only addresses the issue in relation to rack storage and by classifying “*Pallets and flats which are idle combustible*” as a High-hazard commodities.

> “2308.2.1 Plastic pallets and shelves. Storage on plastic pallets or plastic shelves shall be protected by approved specially engineered fire protection systems.
>
> Exception: Plastic pallets listed and labeled in accordance with UL 2335 shall be treated as wood pallets for determining required sprinkler protection”

This presents the real possibility that a building designed under the IFC did not have the correct commodity class for determining sprinkler density assigned unless the designer, plan reviewer and/or field inspector was aware of this issue and applied NFPA 13 to this topic even though classification is covered by the IFC.

In a practical sense, we cannot expect every existing building containing pallets with a fire suppression system installed prior to the 2002 edition of NFPA 13 to have the systems retroactively reassessed by a design professional and upgraded to handle the increased sprinkler demands of a violating product introduced after the building was constructed. It is easier and more cost effective to address the offending product, i.e., the unlisted or labeled pallet.

This proposal addresses the issue by requiring all pallets other than the hardwood, stringer type to be listed and labeled in accordance with the existing UL or FM standards. There is already one wood pallet provider that had their “yellow pine, 9-block” pallet tested for listed under the standards documenting that it can be done. In fact, it was some of those tests that identified the need to make changes to NFPA 13.

By requiring all pallets to be listed or labeled it will ensure that the pallets present can be handled by the existing suppression systems including those designed under the IFC where the required commodity class increase may have been missed and provide the code official with an effective tool to apply during maintenance inspections by spot checking for labels. It will also serve the building owner/operator by making it easy for him/her to verify that the pallets entering their facility do not place it at risk from a damaging fire.

Cost Impact: The code change will not increase the cost of construction.

Analysis: A review of the standard(s) proposed for inclusion in the code, ANSI/FM 4996-2007 and ASME MH1-2005, for compliance with ICC criteria for referenced standards given in Section 3.6 of Council Policy #CP 28 will be posted on the ICC website on or before September 24, 2009.

ICCFILENAME: SCHIFILITI-F1-2301.5.DOC

Public Hearing Results

Note: The following analysis was not in the Code Change monograph but was published on the ICC website at http://www.iccsafe.org/cs/codes/Documents/2009-10cycle/ProposedChanges/Standards-Analysis.pdf :

Analysis: Review of the proposed new standard FM 4996-07 indicated that, in the opinion of ICC staff, the standard did not comply with ICC standards criteria, Section 3.6.2.1. ASME MH1-2005 was not submitted for review.

Committee Action: Disapproved

Committee Reason: The committee disapproved the proposal as it would severely limit the types of pallets allowed. A more generic approach was preferred versus allowing wood pallets in all cases but limiting other types of pallet through a testing procedure. In addition, the standard FM 4996 was noted by staff as not complying with the CP28 and ASME MH1 was not provided for review. This proposal would also remove idle pallets from the high hazard category which created concern for some committee members.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Bruce Torrey, representing Intelligent Global Pooling Systems, requests Approval as Modified by this Public Comment.

Replace the proposal as follows:

Add new definition to Section 2302.1 as follows:

WOODEN PALLET. A nominal 42 x 42 x 5 inch (1.07 x1.07 x 0.13 m) 2-way hardwood pallet.

Revise as follows:

2308.2.1 ~~Plastic~~ Pallets and shelves. Storage on combustible non-wooden ~~plastic~~ pallets or plastic shelves shall be protected by approved specially engineered fire protection systems .

> **Exception:** ~~Plastic~~ Pallets listed and labeled in accordance with UL 2335 shall be treated as wooden pallets for determining required sprinkler protection.

Commenter's Reason: The 42 x 42 x 5 inch (1.07 x 1.07 x 0.13 m) 2-way hardwood pallet has and continues to be the standard test pallet used as the baseline pallet for virtually all Sprinkler and Commodity Classification testing [1]. Standard test commodities used for sprinkler and commodity fire testing/research are also configured to fit the 42 x 42 inch wood pallet footprint [2]. Since sprinkler design and commodity classification fire tests are based on the fire input of this particular pallet it is by default the baseline pallet; in the same manner that test commodities have been standardized. Changes in pallet material compositions, dimensions, and geometries beyond this standard "conventional pallet" can, and often do, introduce variables that change the standard fire exposure baseline for commodity and sprinkler testing, causing test failures [3]. Sprinkler design and protection based on the conventional 42 x 42 –inch 2-way pallet must take into account the variability in fire exposures by the use of untested pallets.

The use of the term "non-wood" provides definition for code application regarding untested plastic, and the growing number of hybrid pallets on the market. The term "combustible" differentiates between metal (steel/aluminum) pallets and combustible ones.

Final Action: AS AM AMPC____ D

F180-09/10
2302.1

Proposed Change as Submitted

Proponent: Ron Clements, Chesterfield County Virginia Building Inspection Department, representing self

Revise as follows:

2302.1 Definitions. The following words and terms shall, for the purposes of this chapter and as used elsewhere in this code, have the meanings shown herein.

HIGH-PILED STORAGE AREA. An area within a building which is designed, intended, proposed or actually used for high-piled combustible storage. The area of aisles is not included in the determination of the size of the high-piled storage area.

Reason: There is some ambiguity regarding if the area of aisles within high piled storage areas is to be included in the high-piled storage area value used by this chapter per this definition. Section 2306.9.1.1 bases some required aisle widths on the high-piled storage area. If the aisle widths area required to be included in the high piled storage area by definition, then it would be mathematically impossible to calculate the high-piled storage area because you cannot determine the aisle widths needed to calculate the aisle areas without the high-piled storage area. Additionally it does not make sense to include large aisles widths of 20', 30' or more between storage racks as part of the storage area. Clearly the intent is to measure the actual area of floor that is covered by the stored commodity.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: CLEMENTS-F1-2302.DOC

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The proposal was disapproved as it was felt that aisles are an integral part of the fire protection in a warehouse and should not be excluded in the definition.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Ron Clements, Chesterfield County Virginia Building Inspection Department, representing self, requests Approval as Submitted.

Commenter's Reason: The Committee Reason was **"**The proposal was disapproved as it was felt that aisles are an integral part of the fire protection in a warehouse and should not be excluded in the definition." Clearly that reason does not address the issue raised by my original reason statement. Yes the aisles are part of the overall design but Section 2306.9.1.1 bases some required aisle widths on the high-piled storage area. If the aisle widths area required to be included in the high piled storage area by definition, then it would be mathematically impossible to calculate the high-piled storage area because you cannot determine the aisle widths needed to calculate the aisle areas without the high-piled storage area. The committee reasoning also did not address the issue of large spaces between aisles as discussed in the original reason statement.

Final Action: AS AM AMPC____ D

F183-09/10
2308.2.1, Chapter 47

Proposed Change as Submitted

Proponent: Jesse J. Beitel, Hughes Associates, Inc., representing FM Approvals

1. Revise as follows:

2308.2.1 Plastic pallets and shelves. Storage on plastic pallets or plastic shelves shall be protected by approved specially engineered fire protection systems.

> **Exception:** Plastic pallets listed and labeled in accordance with UL 2335 <u>or ANSI/FM 4996</u> shall be treated as wood pallets for determining required sprinkler protection.

2. Add new standard to Chapter 47 as follows:

FM
<u>ANSI/FM 4996-2007</u> <u>American National Standard for Classification of Idle Plastic Pallets as Equivalent to Wood Pallets</u>

Reason: The purpose of this code change is to include reference to ANSI/FM 4996 as an alternate to UL 2335 in the International Fire Code. ANSI/FM 4996 is an ANSI approved standard.

The inclusion of this alternate test method would provide the authority having jurisdiction with the flexibility to accept listed and labeled products evaluated in accordance with either UL 2335 or ANSI/FM 4996. This will also assist pallet manufacturers by providing two sources of listings and also not require pallet manufacturers currently listed with FM to have to retest and co-list with another laboratory/agency.

Both standards are similar in that they require full-scale fire tests and they address the issue of appropriate sprinkler protection for plastic pallets.

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: A review of the standard proposed for inclusion in the code, ANSI/FM 4996-2007, for compliance with ICC criteria for referenced standards given in Section 3.6 of Council Policy #CP 28 will be posted on the ICC website on or before September 24, 2009.

ICCFILENAME: BEITEL-F1-2308.2.1.DOC

Public Hearing Results

Note: The following analysis was not in the Code Change monograph but was published on the ICC website at <u>http://www.iccsafe.org/cs/codes/Documents/2009-10cycle/ProposedChanges/Standards-Analysis.pdf</u> :

Analysis: Review of the proposed new standard FM 4996-07 indicated that, in the opinion of ICC staff, the standard did not comply with ICC standards criteria, Section 3.6.2.1.

Committee Action: **Disapproved**

Committee Reason: The proposal was disapproved based both upon the action on code change F179-09/10 and also per the proponents request. Additionally, the standard was noted by staff as not complying with ICC CP28.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Jesse J. Beitel, Hughes Associates, Inc., representing FM Approvals, requests Approval as Modified.

Modify the proposal as follows:

ANSI/FM 4996-<u>2010</u> ~~2007~~ American National Standard for Classification of Idle Plastic Pallets as Equivalent to Wood Pallets

(Portions of the proposal not shown remain unchanged)

Commenter's Reason: Since the submitted edition of ANSI/FM Standard 4996 did not meet the ICC Standard's criteria, this proposal was disapproved. It is anticipated that the ANSI/FM 4996, 2010 edition will be revised in early April, 2010 and be published and be available for review prior to the Final action hearings.

The standard will be provided for review as soon as possible.

Analysis: Note that section 3.6.3.1 of CP28-05 requires that the standard be completed and readily available prior to Final Action Consideration. The final action of this proposal will occur May 14-23, 2010.

Public Comment 2:

Bruce Torrey representing Intelligent Global Pooling Systems, requests Disapproval.

Commenter's Reason: The recognition of ANSI/FM 4996 as an alternate test protocol to ANSI/UL 2335 is not appropriate. Industry testing has demonstrated that plastic pallets can, and often do, influence commodity classification by one, two or more classes [1]. NFPA 13 also recognizes the importance of commodity class testing by penalizing plastic pallets in commodity classification unless testing is performed on the commodity unit, Chapter 5 of NFPA 13. The ANSI/FM 4996 test protocol does not evaluate the influence of plastic pallets on commodities. As stated in section 1,1 Purpose, of ANSI/FM 4996, "This standard states test requirements for fire hazard classification of idle plastic pallets as equivalent to wood pallets." More specifically this standard evaluates the fire performance of idle plastic pallets in racks; which is addressed in Chapter 12, section 12.12.2.3.1 of NFPA 13 [2], "When specific test data and a product listing are available, the data shall take precedence in determining the required protection of idle plastic pallets stored in racks."

The title and purpose statement within FM 4996 states the limitation of the standard to the assessment of idle plastic pallets [3]. ANSI/UL 2335 however, addresses both commodity classification jump potential as well as idle stacked plastic pallets for proper sprinkler protection [4]. ICC Policy, Section 3.6.2.2 also states - The standard shall be appropriate for the subject covered. ANSI/FM 4996 only assesses the idle rack storage of plastic pallets and should not be referenced as an equivalent to UL 2335.

[2] National Fire Protection Association, NFPA 13 – 2007, Section 12.12.2.3, "Idle plastic pallets shall be stored only in racks where protected in accordance with the requirements of Table 12.12.2.1.", Section 12.12.2.3.1 states, "When specific test data and a product listing are available, the data shall take precedence in determining the required protection of idle plastic pallets stored in racks".

[3] American National Standard for Classification of Idle Plastic Pallets as Equivalent to Wood Pallets, ANSI/FM Approvals 4996, 2007, pg 1, 1.1, Purpose: "This standard states test requirements for fire hazard classification of idle plastic pallets as equivalent to wood pallets." http://www.fmglobal.com/assets/pdf/fmapprovals/4996ansi.pdf

[4] UL 2335 Fire Tests of Storage Pallets, ANSI/UL 2335, 2004, pg. 5 Scope: "This standard measures the fire performance of pallets in idle palletized and rack storage arrangements."

Final Action: AS AM AMPC____ D

F184-09/10
2308.3.1 (New)

Proposed Change as Submitted

Proponent: Amber Anderson/Stuart Tom, Cosumnes CSD Fire Department, representing California Fire Chief's Association

Add new text as follows:

2308.3.1 Flue space protection. Where required by the fire code official, flue spaces required by Table 2308.3, in single, double or multiple row rack storage installations shall be equipped with approved devices to protect the required flue spaces. Such devices shall not be removed or modified.

Reason: This proposal authorizes the enforcing agency to require devices, when appropriate, to maintain the required flue spaces in rack storage systems found in IFC Section 2308 and IFC Table 2308.3. It is not the intent of this proposal to require such devices in each instance, but rather when the business practice has established a history of poor flue space maintenance.

Approved devices to protect required flue spaces may be any of the following: brackets, cables or other elements that are securely fastened to the load bearing columns of racks, which control the depth or width to which a product, pallet or similar material can be stored in the rack system thereby preventing obstruction of the required flue space.

Once approved devices are installed, most business owner confusion regarding flue space requirements are removed. Other benefits include; property loss reduction through quick activation of the fire protection system; improved penetration of extinguishing agent through the rack system to the seat of the fire; faster activation of smoke and heat vent systems, improved employee safety, public safety and firefighter safety.

Cost Impact: The code change proposal will increase the cost of construction

ICCFILENAME: ANDERSON-TOM-F1-2308.3.1.DOC

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The proposal was approved as it provides a necessary tool to address an ongoing problem of maintaining flue spaces in a rack configuration in high-piled storage applications.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Tracey D. Bellamy, Telgian Corporation, representing self, requests Disapproval.

Commenter's Reason: Without the existence of a specific directive as to appropriate measures upon which approval can be based or consensus design application for such devices, the section is subject to substantial misapplication. This could potentially give rise to other unintended material handling issues or misguided installations.

Final Action: AS AM AMPC____ D

F186-09/10

Table 2703.1.1(1) [IBC [F] Table 307.1(1)]; 3302.1 (IBC [F]307.2)

Proposed Change as Submitted

Proponent: Glenn A. Dean, Virginia State Fire Marshal's Office

Revise as follows:

TABLE 2703.1.1(1) [IBC TABLE [F] 307.1(1)]
MAXIMUM ALLOWABLE QUANTITY PER CONTROL AREA OF HAZARDOUS MATERIALS POSING A PHYSICAL HAZARD[a,j,n,p]

MATERIAL	CLASS	GROUP WHEN THE MAXIMUM ALLOWABLE QUANTITY IS EXCEEDED	STORAGE[b]			USE-CLOSED SYSTEM[b]			USE-OPEN SYSTEMS	
			SOLID POUNDS (CUBIC FEET)	LIQUID GALLONS (POUNDS)	GAS (CUBIC FEET AT NTP)	SOLID POUNDS (CUBIC FEET)	LIQUID GALLONS (POUNDS)	GAS (CUBIC FEET AT NTP)	SOLID POUNDS (CUBIC FEET)	LIQUID GALLONS (POUNDS)
~~Consumer fireworks (Class C, Common)~~	~~1.4G~~	~~H-3~~	~~125[d,e,l]~~	~~N/A~~	~~N/A~~	~~N/A~~	~~N/A~~	~~N/A~~	~~N/A~~	~~N/A~~

(Portions of table and notes not shown remain unchanged)

3302.1 (IBC [F]307.2) Definitions. The following words and terms shall, for the purposes of this chapter and as used elsewhere in this code, have the meanings shown herein.

FIREWORKS, 1.4G. (Formerly known as Class C, Common Fireworks.) Small fireworks devices containing restricted amounts of pyrotechnic composition designed primarily to produce visible or audible effects by combustion or deflagration that complies~~. Such 1.4G fireworks which comply~~ with the construction, chemical composition and labeling regulations of the DOTn for Fireworks, UN 0336, and the U.S. Consumer Product Safety Commission as set forth in CPSC 16 CFR: Parts 1500 and 1507~~, are not explosive materials for the purpose of this code~~.

(Portions of definition of "Fireworks" not shown remain unchanged)

Reason: The intent of this change is to revert to language stating consumer fireworks are explosive in nature.

The IFC definition language denoting that consumer fireworks would not be considered "explosive materials for the purpose of this code" originated through IFC code change F97-99. The proponent at the time stated the change was to "revise the definitions for consumer fireworks and display to be more closely aligned with the definitions contained in the 1997 IFCI Uniform Fire Code including 1999 Accumulative Supplement and the 1999 BOCA National Fire Prevention Code.“

In looking back for the UFC and BOCA fire codes that were referenced in the F97-99 change to the IFC, code change B3-97 introduced language through the BOCA building code claiming consumer fireworks are not explosive materials and did not provide any technical substantiation to support the claim. I would accept the proponent was making the claim as a means to justify reclassifying the storage and/or sale of consumer fireworks from an H-1 to an H-3 building. For that, I would agree somewhat with the proponent in saying that it “appears reasonable” given the comparison for other H-3 commodities but that is not the issue in this proposed change.

The next BOCA cycle saw the introduction of F18-98 changing the definition of consumer fireworks, 1.4G as “not explosive materials for the purpose of this code”. The committee hearing the change at the time denied the proposal with a conference action to amend. Subsequently the proponent brought the issue back in the form of an amendment. But here again, a technical substantiation was not provided.

This same F18-98 change, as amended, carved out consumer fireworks from BOCA’s MAQ table to “correlate with code change B3-97 to the 1996 BOCA National Building Code” to be shown as a Group H-3 building instead of a Group H-1. The proponent also stated that it was to “correlate definitions used in the BOCA National Fire Prevention Code and Building Code with terminology used in the new DOTn/UN classifications and regulations and NFPA standards.” That may be true to a point and it’s that point that gets to the heart of the reason behind this proposed change, which is, DOTn 49 CFR Parts 100-178, U.S Consumer Products Safety Commission as set forth in CPSC 16 CFR, UN 0336, NFPA standards 495, 1123, 1124, and 1126 **do not** contain language saying consumer fireworks are not explosive, at least not that I found. I went so far as to check pamphlets published by the Institute of Makers of Explosives; the U.S. Department of Justice, Bureau of Alcohol, Tobacco, Firearms and Explosives, AFT Publication 5400.7; the American Pyrotechnics Association Standard 87-1, and found nothing in that respect. In fact, everything found labels fireworks as “explosive” without distinction for 1.4G “consumer fireworks” versus a 1.4G professional pyrotechnic device such as the “gerb” that was used and ignited The Station nightclub fire in Rhode Island.

It is the accumulative results of B3-97 and F18-98 that lent itself to the reference in IFC code change F97-99 supporting statement.

That portion of the proposed definition change to include “deflagration” is a resurrection of a previously used descriptor and is to more accurately reflect the functioning of some consumer fireworks. While a sparkler or fountain may operate through combustion, simple combustion does not necessarily mean enough force will be produced quickly enough for the device to function in a desired manner. If the pyrotechnic material does not deflagrate, the flaming balls of roman candles may not launch; aerial devices may not have enough expelling force to obtain the needed altitude.

The change to Table 2703.1.1(1) is a change to reflect that consumer fireworks are indeed properly classified as an Explosive 1.4G and it’s not necessary to have a separate line with identical threshold values, including all footnotes, to determine at what point a building would be classified as a Group H-3. It’s redundant within the same table. In reality, at the model code level, other than the deletion of language saying consumer fireworks are not explosive, the net effect of this change will be zero to what is taking place in the world of consumer fireworks manufacturing, storage, sale and use.

At the time of this submission I have not located copies of the UFC code changes referenced above but I suspect the supporting statements closely resembled those submitted to BOCA.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: DEAN-F1-TABLE 2703.1.1(1).DOC

Public Hearing Results

Committee Action: Approved as Modified

Modify the proposal as follows:

3302.1 Definitions. The following words and terms shall, for the purposes of this chapter and as used elsewhere in this code, have the meanings shown herein.

EXPLOSIVE. A chemical compound, mixture or device, the primary or common purpose of which is to function by explosion. The term includes, but is not limited to, dynamite, black powder, pellet powder, initiating explosives, detonators, safety fuses, squibs, detonating cord, igniter cord, igniters and display fireworks, 1.3G (Class B, Special).

~~The term “Explosive” includes any material determined to be within the scope of USC Title 18: Chapter 40 and also includes any material classified as an explosive other than consumer fireworks, 1.4G (Class C, Common) by the hazardous materials regulations of DOTn 49 CFR Parts 100-185.~~

(Portions of the proposed code change not shown remain unchanged.)

Committee Reason: The committee agreed with the proponent's reason statement and felt that the proposal removes an unnecessary redundancy in the table. The modification completes the code change since the 2009 edition was not available when the proponent prepared the code change and also removes potential conflict between the fireworks and explosives definitions.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Rick Thornberry, PE, The Code Consortium, Inc. representing American Pyrotechnics Association (APA), requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

TABLE 2703.1.1(1) [IBC TABLE [F] 307.1(1)]
MAXIMUM ALLOWABLE QUANTITY PER CONTROL AREA OF HAZARDOUS MATERIALS POSING A PHYSICAL HAZARD[a,j,n,p]

MATERIAL	CLASS	GROUP WHEN THE MAXIMUM ALLOWABLE QUANTITY IS EXCEEDED	STORAGE[b]			USE-CLOSED SYSTEM[b]			USE-OPEN SYSTEMS	
			SOLID POUNDS (CUBIC FEET)	LIQUID GALLONS (POUNDS)	GAS (CUBIC FEET AT NTP)	SOLID POUNDS (CUBIC FEET)	LIQUID GALLONS (POUNDS)	GAS (CUBIC FEET AT NTP)	SOLID POUNDS (CUBIC FEET)	LIQUID GALLONS (POUNDS)
Consumer fireworks	1.4G	H-3	125[d,e,f]	N/A	N/A	N/A	N/A	N/A	N/A	N/A

(Portions of table and notes not shown remain unchanged)

3302.1 (IBC [F]307.2) Definitions. The following words and terms shall, for the purposes of this chapter and as used elsewhere in this code, have the meanings shown herein.

EXPLOSIVE. A chemical compound, mixture or device, the primary or common purpose of which is to function by explosion. The term includes, but is not limited to, dynamite, black powder, pellet powder, initiating explosives, detonators, safety fuses, squibs, detonating cord, igniter cord, igniters and display fireworks, 1.3G ~~(Class B, Special)~~.

The term "Explosive" includes any material determined to be within the scope of USC Title 18: Chapter 40 and also includes any material classified as an explosive other than consumer fireworks, 1.4G (Class C, Common) by the hazardous materials regulations of DOTn 49 CFR Parts 100 – 185.

FIREWORKS, 1.4G. ~~(Formerly known as Class C, Common Fireworks.)~~ Small fireworks devices containing restricted amounts of pyrotechnic composition designed primarily to produce visible or audible effects by combustion ~~or deflagration that complies~~. Such 1.4G fireworks which comply with the construction, chemical composition and labeling regulations of the DOTn for Fireworks, UN 0336 as set forth in DOTn 49 CFR: Part 172, and the U.S. Consumer Product Safety Commission as set forth in CPSC 16 CFR: Parts 1500 and 1507, are not explosive materials for the purpose of this code.

(Portions of the definition of "Fireworks" not shown remain unchanged)

Commenter's Reason: This Public Comment basically reinstates the current definitions for "Explosive" and "Fireworks, 1.4G" with some additional revisions to further clarify them to make them more consistent with the DOTn regulations for them.

This Public Comment also reinstates the entry in Table 2703.1.1(1) for Consumer Fireworks, 1.4G based on it being a defined term that is distinctive from Explosives, 1.4G by its definition.

It should also be noted that a very significant, unintended consequence will result if Code Change F186-09/10 is approved as modified by the Committee without further modification by this Public Comment regarding the definition for "Explosive" because of the deletion of the second paragraph of the definition which currently includes materials within the scope of USC Title 18: Chapter 40, as well as materials classified as an explosive by the Hazardous Materials Regulations of DOTn 49 CFR: Parts 100 – 185. The inclusion of that paragraph within the definition for "Explosive" is also consistent with the definition for "Explosive Material" found in Section 3.3.98 of the 2009 NFPA 1 Fire Code including the Annex Note A.3.3.98, as well as with the definition for "Explosive" in Section 3.3.18 of NFPA 495 Explosive Materials Code (2006) including the Annex Note A.3.3.18. This paragraph is important to complete the definition for "Explosive" to be consistent with federal regulations.

This Public Comment also further revises the current definition for "Fireworks, 1.4G" to include a reference to DOTn 49 CFR: Part 172 which makes the definition consistent with the definition currently contained in NFPA 1124, Code for the Manufacture, Transportation, Storage, and Retail Sales of Fireworks and Pyrotechnic Articles (2006), as well as with the definition for "Consumer Fireworks" in the Bureau of Alcohol, Tobacco, Firearms and Explosives (BATF) Federal Explosives Law and Regulations, ATF Publication 5400.7 (November 2007). Contrary to the proponent's Reason Statement, the current definition for "Fireworks, 1.4G" is totally consistent with the definitions in NFPA 1123 and NFPA 1124. And as noted previously, although not mentioned in the submitter's statement, the definition is also totally consistent with that contained in the NFPA 1 Fire Code (2009) including the Annex Note. The definition in NFPA 1123 is extracted from NFPA 1124 and the Annex Note to that definition in Section A.3.3.15.1 includes the following: "Consumer fireworks contain limited quantities of pyrotechnic composition per unit and do not pose a mass explosion hazard where stored. Therefore, they are not required to be stored in a magazine." The Annex Note to the definition for "Consumer Fireworks" in NFPA 1124-2006 in Section A.3.3.30.1 states: "Consumer fireworks… are not considered to be explosive materials for the purposes of this code." Similarly, the Annex Note to the definition for "Consumer Fireworks" in the NFPA 1 Fire Code (2009) Section A.3.3.115.1 contains the same statement. Also, the Annex Note to the definition for "Explosive Material" in the NFPA 1 Fire Code Section A.3.3.98 contains the following statement: "The term explosive includes any material determined to be within the scope of Title 18, United States Code, Chapter 40, and also includes any material classified as an explosive, other than consumer fireworks, 1.4G, by the Hazardous Materials Regulations of the U.S. Department of Transportation in 49 CFR."

The proponent's Reason Statement also states that the following regulations, standards and codes do not contain language saying that consumer fireworks are not explosive:

DOTn 49 CFR: Parts 100 – 178
US CPSC 16 CFR, UN0336

NFPA 495 Explosives Materials Code (2006)
NFPA 1123 Code for Fireworks Display (2010)
NFPA 1126 Standard for the Use of Pyrotechnics Before a Proximate Audience (2006)

The following discusses why that is or is not the case.

The regulations in DOTn 49 CFR: Parts 100 – 178 establish the UN classification scheme for explosives as the basis of the DOTn regulations for the transportation of explosives in the United States. In that classification scheme consumer fireworks in the U.S. are classified as fireworks, 1.4G (UN0336) for the purposes of regulating these devices in transportation. The International Fire Code (IFC) has also utilized the UN classification scheme for explosives for regulating explosives in other uses and applications, as well as in transportation. Because of this, it was necessary to adapt the classification scheme for consumer fireworks, 1.4G for regulating those devices in other than transportation since they are truly not explosive within the context of the IFC requirements for explosives. Even the BATF exempts consumer fireworks from their Federal Explosives Law and Regulations (2007) which establish requirements for explosives. The BATF Federal Explosives Law and Regulations define consumer fireworks as follows: "Any small firework device designed to produce visible effects by combustion and which must comply with the construction, chemical composition, and labeling regulations of the U.S. Consumer Products Safety Commission, as set forth in Title 16, Code of Federal Regulations, Parts 1500 and 1507. Some small devices designed to produce audible effects are included, such as whistling devices, ground devices containing 50 mg or less of explosive materials, and aerial devices containing 130 mg or less of explosive materials. Consumer fireworks are classified as fireworks UN0336 and UN0337 by the U.S. Department of Transportation at 49 CFR 172.101. This term does not include fused setpieces containing components which together exceed 50 mg of salute powder."

The US CPC 16 CFR, UN0336 contains the regulations for the construction, chemical composition, and labeling of consumer fireworks (UN0336) which establish the basis for regulating consumer fireworks in the U.S. Therefore, those regulations are not concerned with the need to indicate that consumer fireworks are not considered explosives. They simply establish the criteria for what makes a pyrotechnic device a consumer fireworks regulated by the CPSC which are the only types of consumer fireworks allowed to be sold for use by consumers in the U.S.

NFPA 495 Explosive Materials Code (2006) does not contain such a statement since the application of that code does not apply to consumer fireworks. In fact, Section 1.3.4 states: "This code shall not apply to pyrotechnics such as flares, fuses, and railway torpedoes. It also shall not apply to fireworks and pyrotechnic special effects as defined in NFPA 1123, Code for Fireworks Display; NFPA 1124, Code for the Manufacture, Transportation, Storage, and Retail Sales of Pyrotechnic Articles; and NFPA 1126 Standard for the Use of Pyrotechnics Before a Proximate Audience."

Similarly, the scope of NFPA 1123 Code for Fireworks Display (2010) in Section 1.1.2 states: "This code shall not apply to the following: (3) Use of consumer fireworks by the public." The same is true for NFPA 1126 Standard for the Use of Pyrotechnics Before a Proximate Audience (2006) which states in Section 1.38: "This standard shall not apply to the use of consumer fireworks by the general public."

In conclusion, it becomes readily apparent when the proper research is conducted in a thorough manner of all of the applicable codes, standards, and regulations for consumer fireworks, 1.4G that approving this code change as modified by the Committee would make the IFC inconsistent with all the previously noted regulations, standards, and codes. However, approving this code change as modified by the Committee as further modified by this Public Comment will maintain the IFC consistent with those regulations, standards, and codes regarding consumer fireworks, 1.4G. Therefore, we urge the Class A voting members to vote for Approval as Modified by this Public Comment to obtain the necessary two-thirds majority vote to approve this Public Comment.

Public Comment 2:

Rick Thornberry, PE, The Code Consortium, Inc. representing American Pyrotechnics Association (APA), requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

IBC [F] TABLE 414.5.1
EXPLOSION CONTROL REQUIREMENTS[a]

MATERIAL	CLASS	EXPLOSION CONTROL METHODS: Barricade construction	EXPLOSION CONTROL METHODS: Explosion (deflagration) venting or explosion (deflagration) prevention systems[b]
HAZARD CATEGORY			
Combustible dusts[c]	–	Not Required	Required
Cryogenic flammables	–	Not Required	Required
Explosives	Division 1.1 Division 1.2 Division 1.3 Division 1.4[h] Division 1.5 Division 1.6	Required Required Not Required Not Required Required Required	Not Required Not Required Required Required Not Required Not Required
Flammable gas	Gaseous Liquefied	Not Required Not Required	Required Required
Flammable liquid	IA[d] IB[e]	Not Required Not Required	Required Required
Organic peroxides	U I	Required Required	Not Permitted Not Permitted
Oxidizer liquids and solids	4	Required	Not Permitted
Pyrophoric gas	–	Not Required	Required
Unstable (reactive)	4 3 Detonable 3 Nondetonable	Required Required Not Required	Not Permitted Not Permitted Required
Water-reactive liquids and solids	3	Not Required	Required

	2[g]	Not Required	Required
SPECIAL USES			
Acetylene generator rooms	–	Not Required	Required
Grain processing	–	Not Required	Required
Liquefied petroleum gas-distribution facilities	–	Not Required	Required
Where explosion hazards exist[f]	Detonation Deflagration	Required Not Required	Not Permitted Required

a. See Section 414.1.3.
b. See the International Fire Code.
c. As generated during manufacturing or processing. See definitions of "Combustible dust" in Chapter 3.
d. Storage or use.
e. In open use or dispensing.
f. Rooms containing dispensing and use of hazardous materials when an explosive environment can occur because of the characteristics or nature of the hazardous materials or as a result of the dispensing or use process.
g. A method of explosion control shall be provided when Class 2 water-reactive materials can form potentially explosive mixtures.
h. This table shall not apply to consumer fireworks, 1.4G.

IBC [F] 415.3.1 Group H occupancy minimum fire separation distance. Regardless of any other provisions, buildings containing Group H occupancies shall be set back to the minimum fire separation distance as set forth in Items 1 through 4 below. Distances shall be measured from the walls enclosing the occupancy to lot lines, including those on a public way. Distances to assumed lot lines established for the purpose of determining exterior wall and opening protection are not to be used to establish the minimum fire separation distance for buildings on sites where explosives are manufactured or used when separation is provided in accordance with the quantity distance tables specified for explosive materials in the International Fire Code.

1. Group H-1. Not less than 75 feet (22 860 mm) and not less than required by the International Fire Code.

   Exceptions:

   1. Fireworks manufacturing buildings separated in accordance with NFPA 1124.
   2. Buildings containing the following materials when separated in accordance with Table 415.3.1:
      2.1. Organic peroxides, unclassified detonable.
      2.2. Unstable reactive materials, Class 4.
      2.3. Unstable reactive materials, Class 3.
      2.4. Detonable pyrophoric materials.

2. Group H-2. Not less than 30 feet (9144 mm) where the area of the occupancy exceeds 1,000 square feet (93 m^2) and it is not required to be located in a detached building.
3. Groups H-2 and H-3. Not less than 50 feet (15 240 mm) where a detached building is required (See Table 415.3.2).
4. Groups H-2 and H-3. Occupancies containing materials with explosive characteristics shall be separated as required by the International Fire Code. Where separations are not specified, the distances required shall not be less than the distances required by Table 415.3.1.

   Exception: Consumer fireworks, 1.4G.

IBC [F] TABLE 415.3.2
DETACHED BUILDING REQUIRED

A DETACHED BUILDING IS REQUIRED WHEN THE QUANTITY OF MATERIAL EXCEEDS THAT LISTED HEREIN			
Material	**Class**	**Solids and Liquids (tons)[a, b]**	**Gases (cubic feet)[a, b]**
Explosives	Division 1.1 Division 1.2 Division 1.3 Division 1.4 Division 1.4[c] Division 1.5 Division 1.6	Maximum Allowable Quantity Maximum Allowable Quantity Maximum Allowable Quantity Maximum Allowable Quantity 1 Maximum Allowable Quantity Maximum Allowable Quantity	Not Applicable
Oxidizers	Class 4	Maximum Allowable Quantity	Maximum Allowable Quantity
Unstable (reactives) detonable	Class 3 or 4	Maximum Allowable Quantity	Maximum Allowable Quantity
Oxidizer, liquids and solids	Class 3 Class 2	1,200 2,000	Not Applicable Not Applicable
Organic peroxides	Detonable Class I Class II Class III	Maximum Allowable Quantity Maximum Allowable Quantity 25 50	Not Applicable Not Applicable Not Applicable Not Applicable
Unstable (reactives) nondetonable	Class 3 Class 2	1 25	2,000 10,000
Water reactives	Class 3 Class 2	1 25	Not Applicable Not Applicable
Pyrophoric gases	Not Applicable	Not Applicable	2,000

For SI: 1 ton = 906 kg, 1 cubic foot = 0.02832 m^3, 1 pound = 0.454 kg.
a. For materials that are detonable, the distance to other buildings or lot lines shall be as specified in Table 415.3.1 based on trinitrotoluene (TNT) equivalence of the material. For materials classified as explosives, see Chapter 33 the International Fire Code. For all other materials, the distance shall be as indicated in Section 415.3.1.
b. "Maximum Allowable Quantity" means the maximum allowable quantity per control area set forth in Table 307.7(1).
c. Limited to Division 1.4 materials and articles, including articles packaged for shipment, that are not regulated as an explosive under Bureau of Alcohol, Tobacco and Firearms (BATF) regulations or unpackaged articles used in process operations that do not propagate a detonation or

deflagration between articles, providing the net explosive weight of individual articles does not exceed 1 pound. <u>This table shall not apply to consumer fireworks, 1.4G.</u>

(Portions of proposal not shown, remain unchanged.)

Commenter's Reason: This Public Comment proposes revisions to several sections of the International Building Code (IBC) that will end up regulating consumer fireworks, 1.4G if this Code Change F186-06/10 as modified by the Committee is approved. That is because consumer fireworks, 1.4G will be considered to be an explosive by the International Fire Code (IFC) due to the revisions made to the definitions for "Explosive" and "Fireworks, 1.4G" by Code Change F186-09/10. We have conducted an extensive evaluation and analysis of the requirements in the IBC and the IFC regulating explosives to determine those sections that would subsequently apply to consumer fireworks, 1.4G based on approval as modified of this Code Change. The result is that the following tables and section would be applicable to consumer fireworks, 1.4G, although they are not currently:

[F] Table 414.5.1 Explosion Control Requirements
[F] 415.3.1 Group H Occupancy Minimum Fire Separation Distance
[F] Table 415.3.2 Detached Building Required

The proponent's Reason Statement contains the following: "In reality, at the model code level, other than the deletion of language saying consumer fireworks are not explosive, the net effect of this change will be zero to what is taking place in the world of consumer fireworks manufacturing, storage, sales and use." In other words, the proponent is indicating that his code change should not change the application of the requirements of the IBC and the IFC for explosives regarding consumer fireworks, 1.4G. So we are proposing revisions to the above noted section and tables to implement that intent as follows.

We have proposed to add a new Footnote h to Table 414.5.1 to indicate that the entry for Explosives, Division 1.4 does not apply to consumer fireworks, 1.4G for explosion control requirements.

We have also proposed a revision to Item 4 of Section [F] 415.3.1 to add an Exception for consumer fireworks, 1.4G. This is necessary since this item specifies that Group H-3 occupancies (which consumer fireworks, 1.4G are classified as) are required to be separated in accordance with the IFC, but where those separations are not specified, the distances shall not be less than those distances required by Table 415.3.1 Minimum Separation Distances for Buildings Containing Explosive Materials. In reviewing the separation requirements in Chapter 33 of the IFC, consumer fireworks, 1.4G have been exempt from Table 3301.8.1(3) Application of Separation Distance (Q-D) Tables – Division 1.4 Explosives by Footnote d and Table 3304.5.2(3) Table of Distances (Q-D) For Buildings Containing Explosives – Division 1.4 by Footnote c. Therefore, the Exception we are proposing to Item 4 of Section 415.3.1 is needed so that the separation distances in Table 415.3.1 Minimum Separation Distances for Buildings Containing Explosive Materials are not applied to consumer fireworks, 1.4G.

And, finally, we have proposed a revision to Footnote c to Table 415.3.2 to indicate that the Table does not apply to consumer fireworks, 1.4G similar to the exemptions indicated above to the Tables in Chapter 33 of the IFC. In fact, Footnote c with the proposed revision is identical to Footnote c to Table 3304.5.2(3).

In conclusion, if the Class A voting members approve Code Change F186-09/10 as modified by the International Fire Code Committee, then the members should also vote to approve this Public Comment to further modify that Code Change to implement the intent of the original Code Change not to change the application of the explosive materials requirements of the IBC and IFC to consumer fireworks, 1.4G by simply changing the definition for "Explosive" and "Fireworks, 1.4G."

Final Action: AS AM AMPC____ D

F190-09/10
2703.8.3.2 (IBC [F] 414.2.2); 2702.1 (IBC [F] 307.2)

<u>Proposed Change as Submitted</u>

Proponent: Sarah A. Rice, CBO, representing self

Revise as follows:

2703.8.3.2 (IBC [F] 414.2.2) Percentage of maximum allowable quantities. The percentage of maximum allowable quantities of hazardous materials per *control area* allowed at each floor level within a building hall be in accordance with Table 2703.8.3.2. <u>Where the quantity of hazardous material stored in the building is equal to or less than the maximum allowable quantity per control area in Tables 2703.1.1(1) and 2703.1.1(2), the entire building shall be considered a single control area and the maximum allowable quantity of hazardous material shall be permitted to be located anywhere in the building subject to the per-floor limitations of Table 2703.8.3.2.</u>

2702.1 (IBC [F] 307.2) Definitions. The following words and terms shall, for the purposes of this chapter, Chapters 28 through 44 and as used elsewhere in this code, have the meanings shown herein.

CONTROL AREA. <u>A space or</u> spaces within a building where quantities of hazardous materials not exceeding the maximum allowable quantities per control area are stored, dispensed, used or handled. <u>A control area may be an entire building or a portion of a building.</u> See also the definition of "Outdoor control area."

Reason: The intent of this proposal is to codify IFC Committee Interpretations #51-07 and #52-07. Interpretation #51-07 states that "When the quantity of hazardous material stored in the building is equal to or less than the maximum allowable quantity per control area in Tables 2703.1.1(1) and 2703.1.1(2), the entire building would be considered the control area. When the entire building is the control area, the maximum allowable quantity of material may be located anywhere in the building subject to the per-floor limitations of Table 2703.8.3.2." Interpretation #52-07 states that "When the quantity of hazardous material being stored in each control area is equal to or less than the maximum allowable quantity per control area in Tables 2703.1.1(1) and 2703.1.1(2), the maximum allowable quantity of material per control area may be located anywhere within a multi-story control area, subject to the per-floor limitations of Table 2703.8.3.2."

This proposal revises Section 2703.8.3.2 to clarify that the provisions of Table 2703.8.3.2 are applicable to a multi-story building that is a single control area. The control area definition is also being revised to clarify that an entire building of any height or area can, in fact, be considered a control area

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: RICE-G5-414~RENAMED-F1-2703.8.2

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee felt that the proposal, while consistent with the issued committee interpretations, does not clarify the code because the interpretations themselves are a problem. The code has always allowed multi-story control areas. The committee did feel, however, that the proposed revision to the definition of Control Area had merit and should be pursued in a public comment.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Sarah A. Rice, CBO, The Preview Group, representing self, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

2703.8.3.2 (IBC [F] 414.2.2) Percentage of maximum allowable quantities. The percentage of maximum allowable quantities of hazardous materials per *control area* allowed at each floor level within a building hall be in accordance with Table 2703.8.3.2. ~~Where the quantity of hazardous material stored in the building is equal to or less than the maximum allowable quantity per control area in Tables 2703.1.1(1) and 2703.1.1(2), the entire building shall be considered a single control area and the maximum allowable quantity of hazardous material shall be permitted to be located anywhere in the building subject to the per-floor limitations of Table 2703.8.3.2.~~

2702.1 (IBC [F] 307.2) Definitions. The following words and terms shall, for the purposes of this chapter, Chapters 28 through 44 and as used elsewhere in this code, have the meanings shown herein.

CONTROL AREA. A space or spaces within a building where quantities of hazardous materials not exceeding the maximum allowable quantities per control area are stored, dispensed, used or handled. A control area may be an entire building or a portion of a building. See also the definition of "Outdoor control area."

Commenters Reason: The code change has been modified to reflect the comments received during the public hearings in Baltimore. The committee confirmed that there is NOT a consensus regarding the distribution of hazardous materials within a single control area, that language has been removed. The code change not only seeks to act on the committees' recommendation to modify the definition of "control area" by making it clear that a single building (regardless of the number of stories in the building) can be considered and regulated as a one (1) control area.

Final Action: AS AM AMPC____ D

F196-09/10

3301.1, 3301.1.3.1 (New), 3302.1, Chapter 47; IBC [F] 307.2, IBC Chapter 35

Proposed Change as Submitted

Proponent: Rick Thornberry, PE, The Code Consortium, Inc., representing: American Pyrotechnics Association (APA)

1. Revise the IFC as follows:

3301.1 Scope. The provisions of this chapter shall govern the possession, manufacture, storage, handling, sale and use of explosives, explosive materials, fireworks and small arms ammunition.

Exceptions:

1. The Armed Forces of the United States, Coast Guard or National Guard.
2. Explosives in forms prescribed by the official United States Pharmacopoeia.
3. The possession, storage and use of small arms ammunition when packaged in accordance with DOTn packaging requirements.
4. The possession, storage and use of not more than 1 pound (0.454 kg) of commercially manufactured sporting black powder, 20 pounds (9 kg) of smokeless powder and 10,000 small arms primers for hand loading of small arms ammunition for personal consumption.
5. The use of explosive materials by federal, state and local regulatory, law enforcement and fire agencies acting in their official capacities.
6. Special industrial explosive devices which in the aggregate contain less than 50 pounds (23 kg) of explosive materials.
7. The possession, storage and use of blank industrial power load cartridges when packaged in accordance with DOTn packaging regulations.
8. Transportation in accordance with DOTn 49 CFR Part 100-185.
9. Items preempted by federal regulations.
10. Novelties.

3302.1 Definitions. The following words and terms shall, for the purposes of this chapter and as used elsewhere in this code, have the meanings shown herein.

EXPLOSIVE. A chemical compound, mixture or device, the primary or common purpose of which is to function by explosion. The term includes, but is not limited to, dynamite, black powder, pellet powder, initiating explosives, detonators, safety fuses, squibs, detonating cord, igniter cord, igniters and display fireworks, 1.3G (Class B, Special).

The term “Explosive” includes any material determined to be within the scope of USC Title 18: Chapter 40 and also includes any material classified as an explosive other than consumer fireworks, 1.4G (Class C, Common) and novelties, 1.4G by hazardous materials regulations of DOTn 49 CFR Parts 100-185.

2. Add new text to the IFC as follows:

3301.1.3.1 Novelties, 1.4G. Novelties, 1.4G shall be regulated as fireworks, 1.4G for the purpose of this code.

3302.1 Definitions. The following words and terms shall, for the purposes of this chapter and as used elsewhere in this code, have the meanings shown herein.

NOVELTIES. Small pyrotechnic devices not requiring DOTn approval and containing small amounts of pyrotechnic or explosive composition designed to produce limited visible or audible effects and not classified as consumer fireworks, 1.4G or novelties, 1.4G. Such novelties which comply with the labeling regulations of the US Consumer Product Safety Commission as set forth in CPSC 16 CFR: Parts 1500 and 1507 are not explosive materials for the purpose of this code.

NOVELTIES, 1.4G. Small pyrotechnic devices approved by DOTn and containing small amounts of pyrotechnic or explosive composition designed to produce limited visible or audible effects and not classified as consumer fireworks, 1.4G. Such 1.4G novelties which comply with the construction, chemical composition, and labeling regulations of American Pyrotechnics Association Standard 87-1 and the US Consumer Products Safety Commission as set forth in CPSC 16 CFR: Parts 1500 and 1507 are not explosive materials for the purpose of this code.

3. Revise the IBC as follows:

IBC [F] 307.2 Definitions. The following words and terms shall, for the purposes of this section and as used elsewhere in this code, have the meanings shown herein.

EXPLOSIVE. A chemical compound, mixture or device, the primary or common purpose of which is to function by explosion. The term includes, but is not limited to, dynamite, black powder, pellet powder, initiating explosives, detonators, safety fuses, squibs, detonating cord, igniter cord, igniters and display fireworks, 1.3G (Class B, Special).

The term “Explosive” includes any material determined to be within the scope of USC Title 18: Chapter 40 and also includes any material classified as an explosive other than consumer fireworks, 1.4G (Class C, Common) and novelties, 1.4G by hazardous materials regulations of DOTn 49 CFR Parts 100-185.

4. Add new text to the IBC as follows:

IBC [F] 307.2 Definitions. The following words and terms shall, for the purposes of this section and as used elsewhere in this code, have the meanings shown herein.

NOVELTIES, 1.4G. Small pyrotechnic devices approved by DOTn and containing small amounts of pyrotechnic or explosive composition designed to produce limited visible or audible effects and not classified as consumer fireworks, 1.4G. Such 1.4G novelties which comply with the construction, chemical composition, and labeling regulations of American Pyrotechnics Association Standard 87-1 and the US Consumer Products Safety Commission as set forth in CPSC 16 CFR: Parts 1500 and 1507 are not explosive materials and shall be regulated as fireworks, 1.4G for the purpose of this code.

5. Add new referenced standard to IFC Chapter 47 and IBC Chapter 35 as follows:

APA
American Pyrotechnics Association
Post Office Box 30438
Bethesda, MD 20824

87-1 (2001)	Standard for Construction and Approval for Transportation of Fireworks, Novelties, and Theatrical Pyrotechnics

Reason: Items 1 and 2: The purpose of this proposed code change is to close a loophole in the current requirements in Chapter 33 that regulate consumer fireworks, 1.4G. There is another class of similar fireworks items with a lesser hazard that are classified as novelties, 1.4G. These items, in general, have less pyrotechnic and/or explosive composition than consumer fireworks, 1.4G so they are less of a fire and life safety hazard. However, they are still regulated by the DOTn and are also required to meet the labeling requirements of the CPSC for consumer fireworks, 1.4G. This information can be found in Section C.3.2 Novelty of American Pyrotechnics Association APA Standard 87-1 which is being proposed as a referenced standard. APA Standard 87-1 is titled “Standard for Construction and Approval for Transportation of Fireworks, Novelties, and Theatrical Pyrotechnics.” APA Standard 87-1 comprises Annex C of NFPA 1124-2006, Code for the Manufacture, Transportation, Storage, and Retail Sales of Fireworks and Pyrotechnics Articles. It is also referenced by the DOTn in Title 49, CFR, 171-180 and by the CPSC in Title 16, CFR, 1000 to End. It is available from both the federal government and the APA.

This code change proposal also clarifies that novelties which are not classed as novelties, 1.4G because they do not require DOTn approval and they are not regulated as explosives by the DOTn are exempt from the requirements of Chapter 33. However, they are still required to comply with the labeling regulations of the US Consumer Products Safety Commission as set forth in CPSC 16, CFR: Parts 1500 and 1507.

New definitions have also been provided for “Novelties” and “Novelties, 1.4G” in order to help implement this code change proposal.

The proposed new definition for “Novelties” is necessary so the term can be referenced in this code change proposal in order to specifically exempt “novelties” from the requirements of Chapter 33. This will make the International Fire Code consistent with the DOTn regulations which do not require approval of novelties meeting the specific requirements of Section C.3.2 of APA Standard 87-1. In fact, such novelties are not regulated by the DOTn as explosives, although they are still required to comply with CPSC labeling requirements for consumer fireworks. Such “novelties” contain very small amounts of pyrotechnic and/or explosive compositions which for transportation purposes are not considered to be a fire or explosion hazard in their manufactured form.

The proposed new definition for “Novelties, 1.4G” is based on the definition contained in Section C.2.12 Novelty of the American Pyrotechnics Association APA Standard 87-1.

Items 3 and 4: The purpose of this proposed code change is to close a loophole in the current requirements that regulate consumer fireworks, 1.4G. There is another class of similar fireworks items with a lesser hazard that are classified as novelties, 1.4G. These items, in general, have less pyrotechnic and/or explosive composition than consumer fireworks, 1.4G so they are less of a fire and life safety hazard. However, they are still regulated by the DOTn and are also required to meet the labeling requirements of the CPSC for consumer fireworks, 1.4G.

A new definition has also been provided for “Novelties, 1.4G” in order to help implement this code change proposal. This proposed new definition for “Novelties, 1.4G” is based on the definition contained in Section C.2.12 Novelty of the American Pyrotechnics Association APA Standard 87-1, Standard for Construction and Approval for Transportation of Fireworks, Novelties, and Theatrical Pyrotechnics which is being proposed as a referenced standard. APA Standard 87-1 comprises Annex C of NFPA 1124-2006, Code for the Manufacture, Transportation, Storage, and Retail Sales of Fireworks and Pyrotechnics Articles. It is also referenced by the DOTn in Title 49, CFR, 171-180 and by the CPSC in Title 16, CFR, 1000 to End. It is available from both the federal government and the APA. Additional information can also be found in Section C.3.2 Novelty of APA Standard 87-1.

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: A review of the standard(s) proposed for inclusion in the code, APA 87-1 (2001), for compliance with ICC criteria for referenced standards given in Section 3.6 of Council Policy #CP 28 will be posted on the ICC website on or before September 24, 2009.

ICCFILENAME: THORNBERRY-F1-3301 COMBINED W-G3-307.2

Public Hearing Results

Note: The following analysis was not in the Code Change monograph but was published on the ICC website at http://www.iccsafe.org/cs/codes/Documents/2009-10cycle/ProposedChanges/Standards-Analysis.pdf :

Analysis: Review of the proposed new standard APA 87-1 (2001) indicated that, in the opinion of ICC staff, the standard did not comply with ICC standards criteria, Sections 3.6.2.1, 3.6.2.11 and 3.6.3.2.

Committee Action: Disapproved

Committee Reason: The committee felt that the proposal is inconsistent with the action taken on code change F186-09/10 and that a modification suggested by the proponent to resolve that inconsistency was more confusing than helpful. Also, the proposed referenced standard does not comply with ICC CP-28, Section 3.6 and was also found to be unclear and confusing by some committee members.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Rick Thornberry, PE , The Code Consortium Inc, representing American Pyrotechnics Association (APA), requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

3301.1 Scope. The provisions of this chapter shall govern the possession, manufacture, storage, handling, sale and use of explosives, explosive materials, fireworks and small arms ammunition.

Exceptions:

1 through 9 *(No change to text)*
~~10. Novelties.~~

3301.1.3.1 Novelties, 1.4G. Novelties, 1.4G shall be regulated as consumer fireworks, 1.4G for the purpose of this code

3302.1 Definitions. The following words and terms shall, for the purposes of this chapter and as used elsewhere in this code, have the meanings shown herein.

EXPLOSIVE. A chemical compound, mixture or device, the primary or common purpose of which is to function by explosion. The term includes, but is not limited to, dynamite, black powder, pellet powder, initiating explosives, detonators, safety fuses, squibs, detonating cord, igniter cord, igniters and display fireworks, 1.3G (Class B, Special).

The term "Explosive" includes any material determined to be within the scope of USC Title 18: Chapter 40 and also includes any material classified as an explosive other than consumer fireworks, 1.4G (Class C, Common) ~~and novelties, 1.4G~~ by hazardous materials regulations of DOTn 49 CFR Parts 100-185.

~~**NOVELTIES.** Small pyrotechnic devices not requiring DOTn approval and containing small amounts of pyrotechnic or explosive composition designed to produce limited visible or audible effects and not classified as consumer fireworks, 1.4G or novelties, 1.4G. Such novelties which comply with the labeling regulations of the US Consumer Product Safety Commission as set forth in CPSC 16 CFR: Parts 1500 and 1507 are not explosive materials for the purpose of this code.~~

NOVELTIES, 1.4G. Small pyrotechnic devices approved by DOTn and containing small amounts of pyrotechnic or explosive composition designed to produce limited visible or audible effects and not classified as consumer fireworks, 1.4G. Such 1.4G novelties which comply with the construction, chemical composition, and labeling regulations of ~~American Pyrotechnics Association Standard 87-1 and~~ the US Consumer Products Safety Commission as set forth in CPSC 16 CFR: Parts 1500 and 1507 and the standard referenced in DOTn 49 CFR: Part 173.56(j)(1) are not explosive materials for the purpose of this code.

IBC [F] 307.2 Definitions. The following words and terms shall, for the purposes of this section and as used elsewhere in this code, have the meanings shown herein.

EXPLOSIVE. A chemical compound, mixture or device, the primary or common purpose of which is to function by explosion. The term includes, but is not limited to, dynamite, black powder, pellet powder, initiating explosives, detonators, safety fuses, squibs, detonating cord, igniter cord, igniters and display fireworks, 1.3G (Class B, Special).

The term "Explosive" includes any material determined to be within the scope of USC Title 18: Chapter 40 and also includes any material classified as an explosive other than consumer fireworks, 1.4G (Class C, Common) ~~and novelties, 1.4G~~ by hazardous materials regulations of DOTn 49 CFR Parts 100-185.

~~**NOVELTIES, 1.4G.** Small pyrotechnic devices approved by DOTn and containing small amounts of pyrotechnic or explosive composition designed to produce limited visible or audible effects and not classified as consumer fireworks, 1.4G. Such 1.4G novelties which comply with the construction, chemical composition, and labeling regulations of American Pyrotechnics Association Standard 87-1 and the US Consumer Products Safety Commission as set forth in CPSC 16 CFR: Parts 1500 and 1507 are not explosive materials for the purpose of this code.~~

~~American Pyrotechnics Association~~

~~**APA**~~	~~Post Office Box 30438~~ ~~Bethesda, MD 20824~~
~~APA 87-1 (2001)~~	~~Standard for Construction and Approval for Transportation of Fireworks, Novelties, and Theatrical Pyrotechnics~~

Commenter's Reason: This Public Comment contains revisions that respond to the Committee Reason Statement indicating why the International Fire Code Development Committee voted for disapproval of this Code Change Proposal. First, the Committee felt that this Code Change Proposal was inconsistent with the action they took on F186-09/10 for approval as modified. We have addressed that concern by deleting the proposed new definition for "Novelties" in both the International Building Code (IBC) and the International Fire Code (IFC). We have also deleted novelties from the Exceptions to Section 3301.1 Scope of the IFC. And we have deleted the reference to novelties, 1.4G in the second paragraph of the definition for "Explosive." Although the second paragraph was recommended for deletion in Code Change F186-09/10, we have proposed the deletion of the reference to novelties, 1.4G just in case F186-09/10 is disapproved or further revised during the ICC Final Action Hearings.

The Committee also expressed its concern about the reference to the American Pyrotechnics Association Standard 87-1 contained in the proposed new definition for "novelties, 1.4G" since it did not comply with the ICC standards criteria for consensus standards and it was also found to be unclear and confusing by some Committee members. So we deleted the reference to the standard and substituted a reference to DOTn 49 CFR: Part 173.56(J)(1) which provides the necessary reference for the DOTn regulations defining novelties which also include their construction, chemical composition, and labeling regulations.

As a result of the revisions contained in this Public Comment, novelties, 1.4G will be regulated the same as consumer fireworks, 1.4G are currently regulated in both the IBC and the IFC. This will close an unintended loophole in these codes which is currently the result of the DOTn differentiating between novelties, 1.4G and consumer fireworks, 1.4G for the purposes of regulating these devices in transportation. This will make the IBC and the IFC consistent with DOTn regulations for these pyrotechnic devices.

Analysis: The standard referenced by DOTn 49 CFR Part 173.56 (j)(l) in IFC Section 3302.1 in the proposed revision to the definition of Novelties, 1.4G, is American Pyrotechnics Association (APA) Standard 87-1 (2001).

Final Action: AS AM AMPC____ D

F203-09/10
3404.2.7.3.2, 3404.2.9.7.3

Proposed Change as Submitted

Proponent: Steve M. Crothers, Seattle Fire Department, representing Washington State Association of Fire Marshals

Revise as follows:

1. Revise as follows:

3404.2.7.3.2 Vent-line flame arresters and ~~venting devices~~ pressure-vacuum vents. Listed or approved flame arresters or pressure-vacuum (PV) vents that remain closed unless venting under pressure or vacuum conditions shall be installed in normal vents of tanks containing Class IB and IC liquids.

> **Exception:** When determined by the fire code official that the use of such devices can result in damage to the tank.

Vent-line flame arresters and venting devices shall be installed and maintained in accordance with their listings and API 2000. ~~Use of~~ In-line flame arresters in piping systems shall be installed and maintained in accordance with their listing and API 2028. Pressure vacuum vents shall be installed and maintained in accordance with API 2000.

2. Delete without substitution:

~~**3404.2.9.7.3 Flame arresters.** Approved flame arresters or pressure breather valves shall be installed in normal vents.~~

(Renumber subsequent sections)

Reason: The code currently requires that a flame arrester or pressure-vacuum (PV) vent be installed in the normal vent of all protected aboveground tanks containing flammable or combustible liquids but it does not have a similar requirement for other aboveground tanks whose design and construction provides significantly less protection and control than a protected tank. This code change accomplishes several things, it:

1. Correlates the requirement for flame arresters and PV vents so that regardless of the tank type the requirement is the same.
2. Modifies the current provision requiring a flame arrester for all flammable and combustible liquids so that a flame arrester or PV vent is only required for tanks containing Class IB and IC liquids. Because the primary function of a flame arrester is to prevent the unrestricted propagation of flame through flammable gas or vapor mixtures, it is not necessary to install a flame arrester on tanks containing combustible liquids. Additionally, because flame arresters cannot prevent detonation or control flame propagation speeds associated with

a detonation (flame speeds greater than the speed of sound), flame arresters are not effective when installed on tanks containing Class IA liquids. This revision establishes a requirement for a tank vent flame arrester only when there is a sound technical reason to provide one.

3. Provides a much needed correlation between the IFC and NFPA 30, *Code for Flammable and Combustible Liquids*, for establishing when flame arresters are required on tank vents.
4. Adds a new exception that allows omitting the use of a tank vent flame arrester in situations where the properties of the liquid can cause the tank to be damaged by use of the device. Properties of some Class IB and IC liquids such as crystallization, polymerization and corrosion can present obstructions in flame arresters that may justify omitting the device.
5. Clarifies that the existing API reference document (API 2028) addresses in-line flame arresters for piping systems. An end-of-line flame arrester is a flame arrester that is mounted at the end of a pipe (flanged or threaded inlet connection) and vents directly to the atmosphere whereas an in-line flame arrester may be mounted upstream of a pressure/vacuum relief vent, or may be located upstream of a specified maximum length of vent piping to atmosphere. Both are approved devices.
6. Addresses maintenance of flame arresters and pressure vacuum vents. Not only is proper installation of these devices important but their maintenance is critical. A blocked or corroded flame arrester can render the device ineffective and lead to catastrophic results. This code change adds a new requirement to maintain flame arresters and PV devices in accordance with their listings and API 2000.

Cost Impact: Costs will decrease since currently any aboveground tank containing Class I, II or III liquids requires a flame arrestor on the normal vent and this proposal will require flame arrestors only on Class I liquid tanks. There could be some cost increase where maintenance of flame arrestors does not currently occur.

ICCFILENAME: CROTHERS-F2-3404.2.9.7.3.DOC

Public Hearing Results

Committee Action: Approved as Modified

Modify the proposal as follows:

3404.2.7.3.2 Vent-line flame arresters pressure-vacuum vents. Listed or approved flame arresters or pressure-vacuum (PV) vents that remain closed unless venting under pressure or vacuum conditions shall be installed in normal vents of tanks containing Class IB and IC liquids.

Exception: When determined by the fire code official that the use of such devices can result in damage to the tank.

Vent-line flame arresters ~~and venting devices~~ shall be installed ~~and maintained~~ in accordance with their listings ~~and~~ or API 2000 and maintained in accordance with Section 21.8.6 of NFPA 30 or API 2000. ~~Use of~~ In-line flame arresters in piping systems shall be installed and maintained in accordance with their listing ~~and~~ or API 2028. Pressure vacuum vents shall be installed in accordance with Section 21.4.3 of NFPA 30 or API 2000 and maintained in accordance with Section 21.8.6 of NFPA 30 or API 2000.

3404.2.9.7.3 Flame arresters. Approved flame arresters or pressure breather valves shall be installed in normal vents.

Committee Reason: The committee agreed that the proposal provides a needed improvement in the level of protection afforded to aboveground tanks that are not classified as protected aboveground tanks. The modification to Section 3404.2.7.3.2 adds a reference to the appropriate NFPA 30 section as an alternative to API 2000. The modification to reinstate Section 3404.2.9.7.3 maintains the extra measure of protection that has always been afforded to protected aboveground tanks.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Lynne M. Kilpatrick, Seattle Fire Department, representing Washington State Association of Fire Marshal's, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

3404.2.7.3.2 Vent-line flame arresters and pressure-vacuum vents. Listed or approved flame arresters or pressure-vacuum (PV) vents that remain closed unless venting under pressure or vacuum conditions shall be installed in normal vents of tanks containing Class IB and IC liquids.

Exception: When ~~determined by the fire code official that the~~ use of such devices can result in damage to the tank due to the liquid properties, including but not limited to, condensation, crystallization, corrosiveness, freezing, polymerization, or plugging.

Vent-line flame arresters shall be installed in accordance with their listings or API 2000 and maintained in accordance with Section 21.8.6 of NFPA 30 or API 2000. Inline flame arresters in piping systems shall be installed and maintained in accordance with their listing or API 2028. Pressure-vacuum vents shall be installed in accordance with Section 21.4.3 of NFPA 30 or API 2000 and maintained in accordance with Section 21.8.6 of NFPA 30 or API 2000.

~~**3404.2.9.7.3 Flame arresters.** Approved flame arresters or pressure breather valves shall be installed in normal vents.~~

Commenter's Reason: The exception is revised in response to a Committee comment to eliminate the fire code official's responsibility to 'determine' when the tank can be damaged. This revision also adds more information to assist the code user in determining when omitting the device is justified.

The intent of the original code change proposal was to require flame arresters and pressure breather valves on aboveground tanks when the liquid in the tank presented the hazard that the device is intended to control. That was accomplished by the Committee action taken in Section 3404.2.7.3.2, which limits the requirement for flame arresters and pressure breather valves to tanks (UL142-steel aboveground tanks or UL2085-protected aboveground tanks) containing Class IB and IC liquids.

Section 3404.2.9.7 sets forth additional requirements for UL2085 protected aboveground tanks, and if Section 3404.2.9.7.3 is retained, it will require flame arresters or pressure breather valves to be installed on all aboveground protected tanks (UL2085), regardless of the fuel contained, including tanks containing Class II and Class III combustible liquids. Retaining 3404.2.9.7.3 simply adds a control that is not necessary and sets up an unwarranted disparity between the requirements for steel aboveground tanks (UL142) and aboveground protected tanks (UL2085).

This proposed change is consistent with 2008 NFPA 30 Section 21.4.3.9 and its Annex note:

> *"21.4.3.6 Tanks and vessels that store Class IA liquids shall be equipped with venting devices that are closed, except when venting under pressure or vacuum conditions.*
>
> *21.4.3.7 Tanks and pressure vessels that store Class IB and Class IC liquids shall be equipped with venting devices or with listed flame arresters. When used, vent devices shall be closed, except when venting under pressure or vacuum conditions.*
>
> *21.4.3.9* Flame arresters or venting devices required in 21.4.3.6 and 21.4.3.7 shall be permitted to be omitted on tanks that store Class IB or Class IC liquids where conditions are such that their use can, in case of obstruction, result in damage to the tank.*
>
> *Annex Note A.21.4.3.9 Liquid properties that justify omitting such devices include, but are not limited to, condensation, corrosiveness, crystallization, polymerization, freezing, or plugging. When any of these conditions exist, consideration should be given to heating, use of devices that employ special materials of construction, use of liquid seals, or inerting. See NFPA 69, Standard on Explosion Prevention Systems."*

Final Action: AS AM AMPC____ D

F204-09/10
3404.2.7.4

Proposed Change as Submitted

Proponent: Lynne M. Kilpatrick, Fire Department, City of Seattle, WA, representing Washington State Association of Fire Marshals

Revise as follows:

3404.2.7.4 Emergency venting. Stationary, aboveground tanks shall be equipped with additional venting that will relieve excessive internal pressure caused by exposure to fires. Emergency vents for Class I, II and IIIA liquids shall not discharge inside buildings. The venting shall be installed and maintained in accordance with Section 22.7 of NFPA 30.

Exceptions:

1. Tanks larger than 12,000 gallons (45 420 L) in capacity storing Class IIIB liquids which are not within the diked area or the drainage path of Class I or II liquids do not require emergency relief venting.
2. Emergency vents on protected aboveground tanks complying with UL 2085 containing Class II or IIIA liquids are allowed to discharge inside the building.

Reason: UL 2085 protected aboveground tanks are designed and constructed to withstand a two-hour fire test of 2000°F during which no single point temperature may exceed 400°F and the average temperature rise throughout the internal tank can be no greater than 260°F. The largest quantity of Class II or IIIA liquid that can be stored indoors in a UL 2085 tank unprotected by an approved automatic sprinkler system is 660 gallons. Given the stringent testing requirement, and the required sprinkler coverage, activation of the emergency vent is likely only under extreme fire conditions over an extended period of time. Further, NFPA 30 requires that emergency vents placed on vent pipes that extend beyond twelve inches from the tank be reengineered to account for the potential back pressure and ensure activation at the appropriate pressure. It is not unusual to see vent lines extending 30 or 40 feet or more through a building in order to achieve the exterior discharge. Allowing the emergency vent to discharge inside eliminates the need to reengineer the venting and ensures proper sizing and activation of the emergency vent.

Cost Impact: There is a cost savings since emergency vent lines would not be required to extend through buildings to the exterior.

ICCFILENAME: KILPATRICK-F4-3404.2.7.4.DOC

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The committee agreed with the proponent's reason statement that the proposal will provide increased safety for protected aboveground tanks installed indoors and storing Class I liquids.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Rick Thornberry, PE, The Code Consortium Inc, representing ConVault, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

3404.2.7.4 Emergency venting. Stationary, aboveground tanks shall be equipped with additional venting that will relieve excessive internal pressure caused by exposure to fires. Emergency vents for Class I, II, and IIIA liquids shall not discharge inside buildings. The venting shall be installed and maintained in accordance with Section 22.7 of NFPA 30.

Exceptions:

1. Tanks larger than 12,000 gallons (45 420 L) in capacity storing Class IIIB liquids which are not within the diked area or the drainage path of Class I or II liquids do not require emergency relief venting.
2. Emergency vents on protected aboveground tanks complying with UL 2085 containing Class ~~II or~~ IIIA liquids are allowed to discharge inside the building.

Commenter's Reason: The purpose of this Public Comment is to limit the application of the proposed new Exception 2 to Section 3404.2.7.4 Emergency Venting so that it only allows the emergency vent on protected aboveground tanks to discharge inside the building where Class IIIA liquids are stored in the tanks. We believe that such an exception will not unduly compromise the very excellent safety record that protected aboveground tanks have displayed in the field and will maintain the level of fire and life safety intended by such tanks when they were originally developed and incorporated into the requirements of the legacy model fire codes.

We expressed our concerns in public testimony to the International Fire Code Committee during the hearings in Baltimore that we were basically opposed to any exception to the emergency venting requirements for protected aboveground tanks that would reduce the level of safety. But we felt reasonably comfortable if Class IIIA liquids were allowed to be vented inside the building. Our main concern is that Class II liquids have a flash point as low as 100°F and it could be possible to have vapors generated during a significant fire exposure released into the fire area via the emergency vent, even though there are very severe limitations on the temperature rise allowed for the contents of a protected aboveground tank when exposed to a 2-hour flammable liquid pool fire. The original concept of the protected aboveground tank was that it was intended to provide comparable safety to an underground storage tank. Thus, a very conservative approach was taken to the requirements in the fire codes to allow protected aboveground tanks in situations where they had been previously prohibited since only underground tanks were allowed. Therefore, we believe there is a need to continue to be cautious when looking at the possibility of relaxing any of the requirements currently contained in the IFC for protected aboveground tanks.

In conclusion, we would request that the Class A voting members either approve this Public Comment amending Code Change F204-09/10 to eliminate Class II liquids from Exception 2 to Section 3404.2.7.4 or disapprove this code change proposal altogether.

Final Action: AS AM AMPC____ D

F211-09/10
3405.3.6.1, Chapter 47

Proposed Change as Submitted

Proponent: Bob Eugene, Underwriters Laboratories, Inc.

1. Revise as follows:

3405.3.6.1 Cleaning operations. Class IA liquids shall not be used for cleaning. Cleaning with Class IB, IC or II liquids shall be conducted as follows:

1. In a room or building in accordance with Section 3405.3.7; or
2. In a parts cleaner ~~machine~~ listed and labeled in accordance with UL 1204 and approved for the purpose in accordance with Section 3405.3.6.2.

Exception: Materials used in commercial and industrial process-related cleaning operations in accordance with other provisions of this code and not involving facilities maintenance cleaning operations.

2. Add new standard to Chapter 47 as follows:

UL
1204-04 Outline of Investigation for Parts Cleaners

Reason: UL's Subject 1204 Outline of Investigation includes a comprehensive set of construction and performance requirements that are used to evaluate and list parts cleaners. This equipment is reviewed to ensure the use and operation of the equipment provides a safe involvement using the flammable and combustible solvents. Five companies currently have parts cleaners listed.

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: A review of the standard(s) proposed for inclusion in the code, UL 1204-04, for compliance with ICC criteria for referenced standards given in Section 3.6 of Council Policy #CP 28 will be posted on the ICC website on or before September 24, 2009.

Public Hearing Results

Note: The following analysis was not in the Code Change monograph but was published on the ICC website at http://www.iccsafe.org/cs/codes/Documents/2009-10cycle/ProposedChanges/Standards-Analysis.pdf :

Analysis: Review of the proposed new standard UL 1204-04 indicated that, in the opinion of ICC staff, the standard did not comply with ICC standards criteria, Sections 3.6.2.11 and 3.6.3.2.

Committee Action: **Approved as Submitted**

Committee Reason: The committee agreed with the proponent's reason statement and felt that the proposal provided clearer guidance on the standard to which the machines must be listed.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jonathan Humble (Chairman) representing ICC Reference Standards Committee requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

3405.3.6.1 Cleaning operations. Class IA liquids shall not be used for cleaning. Cleaning with Class IB, IC or II liquids shall be conducted as follows:

1. In a room or building in accordance with Section 3405.3.7; or
2. In a parts cleaner listed, ~~and~~ labeled ~~in accordance with UL 1204~~ and approved for the purpose in accordance with Section 3405.3.6.2.

   Exception: Materials used in commercial and industrial process-related cleaning operations in accordance with other provisions of this code and not involving facilities maintenance cleaning operations.

UL
~~1204-04 Outline of Investigation for Parts Cleaners~~

Commenter's Reason: The ICC Reference Standards Committee is a committee that was organized "to support the codes development committees through the review of reference standards for the International Codes." We submit this code challenge to provide an opinion regarding code change.

It is the reference standards committee's view that the proposal currently lacks sufficient information concerning the promulgation process. We would preface this opinion that it is not our view to state that the proposed document is technically deficient or that the proposal does not have technical merit, but rather to state that the document development process and maintenance process do not comply with ICC Council Policy 28, specifically Section 3.6.3, which requires standards be promulgated according to a consensus process.

We therefore propose to have deleted the reference standard and subsequent reference to that standard as part of this proposal to modify the original proposal.

Final Action: AS AM AMPC____ D

F216-09/10
3804.3.1 (New)

Proposed Change as Submitted

Proponent: Tom Lariviere, Chairman, Joint Fire Service Review Committee

Add new text as follows:

3804.3.1 Installation on roof prohibited. The installation of LP-gas containers on the roofs of buildings is prohibited.

(Renumber subsequent sections)

Reason: Currently, Chapter 38 also refers to NFPA 58. NFPA 58 will allow the installation of LP-gas containers on rooftops. This proposal will include a specific restriction which will supersede the provisions in the referenced standard NFPA 58. As a result, propane tank installation will not be permitted on roof tops.

LP-gas is a flammable gas with a vapor density heavier than air. The heavier vapor density means that any leak from a roof mounted propane storage tank will travel down into the occupied spaces of the building where there is a very high probability of fire or explosion due to all the potential ignition sources.

Additionally, a building fire beneath the LP-gas container will impinge upon or heat the tank causing activation of the pressure relief valve. When the pressure relief valve is activated, it will release propane, which still is heavier than air, and the propane will travel downwards toward the fire and increase fire intensity. This could endanger the building or neighboring buildings and exposures.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: LARIVIERE-F20-3804.3.1.DOC

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee felt that the proposal was taking too broad an approach with a total prohibition of LPG containers on roofs and felt that the code should not override the referenced standard, NFPA 58, which allows containers on roofs under certain conditions. The committee suggested that a container size limitation might be useful and also that the proposal should clarify that it would be applicable only to permanent installations and not to DOTn cylinders used in roofing operations.

Assembly Action: **Approved as Submitted**

Individual Consideration Agenda

This code change proposal is on the agenda for individual consideration because the proposal received a successful assembly action and public comments were submitted. Note that the assembly action, Approved as Submitted, will be the initial motion on the floor for consideration when this item is called.

Public Comment 1:

Joe Pierce (Chairman), Dallas Fire Department, representing Joint Fire Service Review Committee, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

3804.3.1 Installation on roof prohibited. ~~The installation of~~ Stationary LP-gas containers shall not be installed on the roofs of buildings ~~is prohibited~~.

(Renumber subsequent sections…)

Commenter's Reason: This code change was Approved as Submitted, but there were some comments at the Code Development Hearing that have resulted in some refinement of the wording. Comments indicated that the wording was too broad, and also that the code could not override the standard.

This Public Comment has been reworded to narrow its application in two ways: 1) it states that is only applies to "stationary" containers, 2) it is clearer now that it applies to "installation". Therefore, it does not apply to the use of LP-gas containers for torch applied roofing, or brazing for example. This restriction only applies to the installation of a stationary container.

The second concern of the Code Development Committee was that this code requirement would be more restrictive than the standard. This concept is commonly done in the I-Codes and in fact Section 102.7 states in part: "Where differences occur between the provisions of this code and the referenced standards, the provisions of this code shall apply." The Assembly body has anticipated differences between the code's provisions and the standard's provisions, and accepts those differences, provided that the code takes precedence over the standard.

In fact the differences between the code and the standard are intentional, as it is with this code change. For example:

Section 903.3.1.1.1 contains a list of areas exempt from fire sprinkler installation; which is not consistent with NFPA 13.
Section 903.3.1.2.1 contains requirements for fire sprinkler installation on balconies and decks; which is not consistent with NFPA 13R.
Section 1208.2 contains requirements for installation of fire sprinklers in Type III-A or Type III-B dry cleaning systems; which is not consistent with NFPA 32.
Section 907.5.2.3 requires manual fire alarm boxes to be red; which is not mentioned in NFPA 72.

This code change intends to disallow the installation of LP-gas containers on rooftops. It is simply a fire safety issue based on physics. Any leak of LP-gas will expose the building because the vapors are heavier than air.

The Public Comment will help ensure that this section is not misinterpreted to include containers used for temporary applications on the roof.

Public Comment 2:

Bruce Swiecicki, representing National Propane Gas Association, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

3804.3.1 Installation on roof prohibited. ~~The installation of~~ LP-gas containers <u>used in stationary installations shall not be located</u> on the roofs of buildings ~~is prohibited~~.

Commenter's Reason: The term "stationary installation" is used in NFPA 58 and defined as follows: "An installation of LP-Gas containers, piping, and equipment for indefinite use at a particular location; an installation not normally expected to change in status, condition, or location." Inserting the word "stationary" will ensure that this section is not misinterpreted to include containers used for temporary applications such as sealing roofing materials or brazing operations.

Final Action: AS AM AMPC____ D

F220-09/10

4603.4.3, 4603.4.4, 4603.4.5 (All New)

<u>Proposed Change as Submitted</u>

Proponents: Robert J Davidson, Code Consultant/Alan Shuman, President, representing the National Association of State Fire Marshals (NASFM)

Add new text as follows:

<u>**4603.4.3 Group F-1.** An automatic sprinkler system shall be provided throughout all buildings containing a Group F-1 occupancy used for the manufacture of upholstered furniture or mattresses.</u>

<u>**4603.4.4 Group M**. An automatic sprinkler system shall be provided throughout all buildings containing a Group M occupancy used for the display and sale of upholstered furniture or mattresses.</u>

<u>**4603.4.5 Group S-1.** An automatic sprinkler system shall be provided throughout all buildings containing a Group S-1 occupancy used for the storage of upholstered furniture or mattresses.</u>

Reason: This proposal adds retroactive requirements to install an automatic sprinkler system in buildings containing F-1, M and S-1 occupancies involving upholstered furniture and mattresses. The purpose is to build upon the change approved last cycle to require mercantile occupancies with any amount of upholstered furniture to be suppressed as requested by the upholstered furniture industry.

The recognized hazard by a fuel load consisting of upholstered furniture and mattresses has been as identified as requiring sprinkler protection in newly constructed buildings that would also be required to meet all other current requirements of the International Series of Codes. Most, if not all existing buildings do not meet the current requirements of the International Series of Codes. A building that existed prior to the current editions of the International Series Codes most likely has less protective features and the existence of the fuel load presented by upholstered furniture and mattress would then create a greater hazard and an increased need for automatic fire suppression.

Cost Impact: The code change proposal will increase the cost of existing occupancies containing these hazards.

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee felt that the proposal would create a financial hardship in these difficult economic times for existing businesses, especially small retailers, and would affect all occupancies in mixed-use buildings that house these types of businesses. The proposal should also be correlated with the action taken on code change F69-09/10 which established a threshold for these occupancies when new to prevent a more restrictive requirement for existing buildings.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Marcelo M. Hirschler (GBH International), requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

4603.4.3 Group F-1. An automatic sprinkler system shall be provided throughout all buildings containing a Group F-1 occupancy used for the manufacture of upholstered furniture or mattresses if the Group F-1 fire area exceeds 12,000 square feet (1,115 m^2), and the area that is used for the manufacture of upholstered furniture or mattresses exceeds 2,500 square feet (232 m^2).

4603.4.4 Group M. An automatic sprinkler system shall be provided throughout all buildings containing a Group M occupancy used for the display and sale of upholstered furniture or mattresses if the Group M fire area exceeds 12,000 square feet (1,115 m^2), and the area that is used for the display and sale of upholstered furniture or mattresses exceeds 2,500 square feet (232 m^2).

4603.4.5 Group S-1. An automatic sprinkler system shall be provided throughout all buildings containing a Group S-1 occupancy used for the storage of upholstered furniture or mattresses if the Group S-1 fire area exceeds 12,000 square feet (1,115 m^2), and the area that is used for the storage of upholstered furniture or mattresses exceeds 2,500 square feet (232 m^2).

Commenter's Reason: The technical committee was concerned that the proposal was not coordinated with the results of code change F69-09/10, which was approved. The revised code change language addresses that. The committee was also concerned that the proposal would have caused an undue burden on very small retailers and the revised language excludes them.

The language approved in code change F69 is as follows:

903.2.4 (IBC [F] 903.2.4) Group F-1. An automatic sprinkler system shall be provided throughout all buildings containing a Group F-1 occupancy where one of the following conditions exists:
1. Where a Group F-1 fire area exceeds 12,000 square feet (1115 m^2);
2. Where a Group F-1 fire area is located more than three stories above grade plane; or
3. Where the combined area of all Group F-1 fire areas on all floors, including any mezzanines, exceeds 24,000 square feet (2230 m^2).
4. Where a Group F-1 occupancy that is used for the manufacture of upholstered furniture or mattresses exceeds 2,500 square feet (232 m^2).
.
903.2.7 (IBC [F] 903.2.7) Group M. An automatic sprinkler system shall be provided throughout buildings containing a Group M occupancy where one of the following conditions exists:
1. Where a Group M fire area exceeds 12,000 square feet (1115 m^2);
2. Where a Group M fire area is located more than three stories above grade plane; or
3. Where the combined area of all Group M fire areas on all floors, including any mezzanines, exceeds 24,000 square feet (2230 m^2). ; or
4. Where a Group M occupancy that is used for the display and sale of upholstered furniture or mattresses exceeds 5,000 square feet (464 m^2).

903.2.9 (IBC [F] 903.2.9) Group S-1. An automatic sprinkler system shall be provided throughout all buildings containing a Group S-1 occupancy where one of the following conditions exists:
1. A Group S-1 fire area exceeds 12,000 square feet (1115 m^2);
2. A Group S-1 fire area is located more than three stories above grade plane; or
3. The combined area of all Group S-1 fire areas on all floors, including any mezzanines, exceeds 24,000 square feet (2230 m^2).
4. A Group S-1 fire area used for the storage of commercial trucks or buses where the fire area exceeds 5,000 square feet (464 m^2).
5. A Group S-1 occupancy that is used for the storage of upholstered furniture or mattresses exceeds 2,500 square feet (232 m^2).

Final Action: AS AM AMPC____ D

F224-09/10
4603.6.7

Proposed Change as Submitted

Proponent: Gene Boecker, Code Consultants, Inc.

Revise as follows:

4603.6.7 Group R-4. ~~An automatic or~~ A manual fire alarm system that activates an occupant notification system in accordance with Section 907.6 shall be installed in existing Group R-2 residential care/assisted living facilities in accordance with Section ~~907.2.10~~ 907.2.10.1.

Exceptions:

1. Where there are interconnected smoke alarms meeting the requirements of Section 907.2.11 and there is at least one manual fire alarm box per floor arranged to continuously sound the smoke alarms.
2. Other manually activated, continuously sounding alarms *approved* by the *fire code official*.

Reason: During the prior code change cycle the effort was made to clear up the confusion between whether the required system must be a manual or automatic fire alarm system. Consistently, the code changes noted that the required retrofit system must be a manual one. However, in a few instances the clarification was not addressed in a code change.

This proposal is an effort to finish up the clean-up which began with the prior code change cycles in rewriting the requirements for fire alarms in existing buildings.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: BOECKER-F11-4603.6.7.DOC

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee felt that removing the requirement for automatic systems would be inappropriate. It was also noted that the title of the section indicates that it is applicable to Group R-4 but the text indicates Group R-2.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Joe Pierce (Chairman), Dallas Fire Department, representing Joint Fire Service Review Committee, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

4603.6.7 Group R-4. A manual fire alarm system that activates an occupant notification system in accordance with Section 907.6 shall be installed in existing Group ~~R-2~~ R-4 residential care/assisted living facilities in accordance with Section 907.2.10.1.

Exceptions:

1. Where there are interconnected smoke alarms meeting the requirements of Section 907.2.11 and there is at least one manual fire alarm box per floor arranged to continuously sound the smoke alarms.
2. Other manually activated, continuously sounding alarms *approved* by the *fire code official*.

Commenter's Reason: This proposal was Disapproved at the Code Development Hearing because of the confusion as to whether it applied to Group R-4 (as in the section title), or to Group R-2 (as in the text). This Public Comment clarifies that this code section applies to existing Group R-4 residential care/assisted living facilities.

During the prior code change cycle the effort was made to clear up the confusion between whether the required system must be a manual or automatic fire alarm system. Consistently, the code changes noted that the required retrofit system must be a manual one. However, in a few instances the clarification was not addressed in a code change.

This proposal is an effort to finish up the clean-up which began with the prior code change cycles in rewriting the requirements for fire alarms in existing buildings.

Analysis: Current Section 4603.6.7 reads "Group R-4" in both the title and the text.

Final Action: AS AM AMPC____ D

F225-09/10

4603.7.1

Proposed Change as Submitted

Proponent: Jeffrey M. Shapiro, PE, International Code Consultants, representing National Multi Housing Council

Revise as follows:

4603.7.1 Where required. Existing Group R occupancies and *dwellings* not classified as Group R occupancies, which are not already provided with single-station smoke alarms complying with requirements of the code that governed at the time of construction, shall be provided with single-station smoke alarms~~. Installation shall be~~ in accordance with Section 907.2.11, except as provided in Sections 4603.7.2 and 4603.7.3.

Reason: This proposal is intended as a clarification to assist in proper application of the existing text. The key phrase that determines exactly what is required in existing Group R occupancies is "Existing Group R occupancies…not already provided with single station smoke alarms..." Although this statement appears fairly straightforward in its intended application, it is occasionally misinterpreted, perhaps because the IFC Commentary on this issue is even more misleading than the code itself. To some, the text suggests that anytime smoke alarms are not already installed throughout a Group R occupancy, located as required for new construction in accordance with Section 907.2.10, additional alarms must be installed to protect any areas, such as bedrooms, that would require protection in new construction. However, I can state with great certainty that this was never the intended application of the code.

The IFC text originated in the UFC in 1995, and it was carried directly into the IFC during the drafting process. Thereby, the intent of this section was established by the original UFC provision. The provision in question resulted from a code change proposal submitted by the Minnesota State Fire Chiefs Association in 1995 (Proposal #21, 1007-95-1). The proposal was initially disapproved by the UFC Code Development Committee, but was approved at the final action hearing after initial objections were addressed by a public comment.

Part 4 of the public comment was further revised by a floor motion at the hearing, which was when the text "not already provided with single station smoke detectors" was added to the code. This text replaced other proposed text "…in accordance with the building code under which the building was constructed. Buildings that were not constructed under the requirements of a building code shall meet the minimum requirements of Section 1007.2.9.2," which needed to be changed because it didn't require buildings that were constructed under an old building code, prior to when smoke alarms were first required, to be retrofitted. By adding "not already provided with single station smoke detectors," the intent was to retain a "grandfather" clause for existing buildings that were previously provided with smoke alarms, while adding a requirement to retrofit buildings that were not.

When the IFC was developed, it was drafted using a combination of NFPA 1 Fire Prevention Code, NFPA 101 Life Safety Code and the UFC. Documentation from the drafting committee's work on the retroactive smoke alarm section show that the committee was given a choice of accepting either the NFPA 101 provisions (Sections 19-3.4 through 19.3.4.4.2) or the UFC provisions (Sections 1007.2.9.2 through 1007.2.9.2.4) for apartments. With respect to smoke alarms in sleeping rooms, the choice made no difference because neither code required smoke alarms to be retrofitted in these areas. In fact, NFPA 101 quite clearly maintains that approach today in Section 31.3.4.5.1.

In the end, the IFC adopted the UFC text, which included the "Existing Group R occupancies not already provided with single station smoke alarms..." text that remains today. Lacking any code change that would have revised the intended application of Section 4603.7.1, I am confident that the original intent of the code, to grandfather existing buildings that had smoke alarms installed prior to adoption of the IFC, remains the proper application of the code today. Accordingly, this proposal should be approved to remove the existing ambiguity.

Cost Impact: The code change proposal will not increase the cost of construction

ICCFILENAME: SHAPIRO-F1-4603.7.1.DOC

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee felt that the proposal would allow for the avoidance altogether of installing smoke alarms for buildings originally built under a code that did not require them. For buildings that were not built under any construction code, this becomes a property maintenance issue that does not belong in the IFC. The proposed language could also be in conflict with state legislations that require retroactive smoke alarm installations.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Joe Pierce (Chairman), Dallas Fire Department, representing Joint Fire Service Review Committee and Jeffrey Shapiro, representing the National Multi Housing Council, request Approval as Modified by this Public Comment.

Replace the proposal as follows:

4603.7.1 Where required. Existing Group R occupancies and *dwellings* not classified as Group R occupancies~~, not already provided with single-station smoke alarms,~~ shall be provided with single-station smoke alarms~~. Installation shall be~~ in accordance with Section 907.2.11, except as provided in Sections 4603.7.2 and 4603.7.3.

<u>**Exceptions:**</u>

1. <u>Where the code that was in effect at the time of construction required smoke alarms and smoke alarms complying with those requirements are already provided.</u>
2. <u>Where smoke alarms have been installed in occupancies and dwellings that were not required to have them at the time of construction, additional smoke alarms shall not be required provided that the existing smoke alarms comply with requirements that were in effect at the time of installation.</u>
3. <u>Where smoke detectors connected to a fire alarm system have been installed as a substitute for smoke alarms.</u>

Commenter's Reason: This proposal was Disapproved at the Code Development Hearing because the Committee felt that it did not satisfactorily address structures that were built under a code that did not require smoke alarms. This Public Comment revises the wording and adds exceptions with the simple intent of clarifying how the code is intended to apply.

The text of this public comment restructures the requirement into a base provision with exceptions. The base provision mandates smoke alarm installation in all existing Group R and other dwellings. Then, three exceptions are provided to address possible scenarios where smoke alarms have already been installed into an R occupancy but do not meet the current code requirements, recognizing that the intent of the existing code requirement was to permit existing smoke alarms to continue if they meet the code that was in effect at the time they were made.

Exception 1 indicates that smoke alarms which have been installed and maintained in accordance with the applicable code at the time of construction can continue.

Exception 2 indicates that smoke alarms, which were not required by the code at the time of construction, but were later installed, can continue when they meet the requirements of the applicable code at the time of installation.

Exception 3 indicates that smoke detectors connected to a fire alarm system may be used in lieu of smoke alarms.

In summary, the target of this code section has always been placing smoke alarms into Group R occupancies and dwellings that do not have ANY smoke alarms. This section was not intended to require compliance with the current smoke alarm requirements if the building already has smoke alarms that meet requirements that were applicable when they were installed. The focus is not to have the owner replace or revise their smoke alarms any time the code requirements for new construction change.

Final Action: AS AM AMPC____ D

F226-09/10
4603.8 (New)

Proposed Change as Submitted

Proponent: A. Hal Key, P.E., Fire Department, Mesa, AZ

Add new text as follows:

<u>**4603.8 Existing fire alarm systems.** When an existing fire alarm system becomes unserviceable due to non-availability of components or parts, that system shall be replaced in accordance with Section 907.2.</u>

Reason: When a fire alarm system becomes unserviceable due to the age of the equipment, the entire system must be replaced to maintain the system in operation. In most cases, the type of system (addressable vs. analog) changes and these systems need to be installed to the latest edition of the adopted code. Where an existing system has not yet been upgraded to the latest ADA requirements, the owners of these systems are already required to upgrade the system annunciation.

Cost Impact: The code change proposal will increase the cost of maintaining the system.

ICCFILENAME: KEY-F2-4603.8.DOC

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee felt that replacement of an entire unserviceable system may not always be necessary but would be required by this proposal which could create a hardship for building owners.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Joe Pierce (Chairman), Dallas Fire Department, representing Joint Fire Service Review Committee, requests Approval as Modified by this Public Comment.

Replace the proposal as follows:

~~4603.8~~ 907.9.2 ~~Existing~~ Unserviceable fire alarm systems. When ~~an existing~~ a fire alarm system, or a portion of a fire alarm system, becomes unserviceable due to nonavailability of components or parts, that system, or portion thereof, shall be made serviceable or replaced ~~in accordance with Section 907.2~~.

(Renumber subsequent sections

Commenter's Reason: This proposal was Disapproved at the Code Development Hearing because the Committee felt that it was not clear on what specific items needed to be replaced.

There are times when a Fire Alarm Control Panel needs to be replaced because parts are no longer available, but the existing wiring throughout the building is intact and usable. In this case, the FACP would be replaced and the remainder of the system would remain. This will allow systems to be maintained in a working manner without complete removal and replacement of the entire fire alarm system.

The reference to Section 907.2 is deleted to eliminate the potential confusion that this requirement necessitates replacing the entire system, and needed to comply with current regulations. The intent of this section is to replace the components necessary to maintain the fire alarm system in an operational condition.

Additionally, this section is placed into Section 907.9 which deals with maintenance. Even though this section deals with existing buildings, it is more specific to maintenance of fire alarm systems which are regulated in Section 907. Therefore, Section 907.9.2 is a more appropriate location for this item, rather than Chapter 46.

Final Action: AS AM AMPC____ D

F229-09/10
Chapter 46, 102.1

Proposed Change as Submitted

Proponent: Lawrence G. Perry, AIA, representing Building Owners and Managers Association (BOMA) International

1. Revise by relocating Chapter 46 in its entirety as follows:

~~CHAPTER 46~~ APPENDIX K
CONSTRUCTION REQUIREMENTS FOR EXISTING BUILDINGS

2. Revise as follows:

102.1 Construction and design provisions. The construction and design provisions of this code shall apply to:

1. Structures, facilities and conditions arising after the adoption of this code.
2. Existing structures, facilities and conditions not legally in existence at the time of adoption of this code.
3. ~~Existing structures, facilities and conditions when required in Chapter 46.~~

~~4.~~ 3. Existing structures, facilities and conditions which, in the opinion of the *fire code official*, constitute a distinct hazard to life or property.

Reason: Many jurisdictions that adopt a model fire code lack the authority to retroactively mandate construction upgrades to existing buildings without some specific 'triggering' event. Additionally, as written, the triggering language in Chapter 46 is vague, and would lead to a lack of consistency in enforcement. Section 4601.4 states "Where a building is found to be in noncompliance, the fire code official shall duly notify the owner of the building." What is the mechanism for the fire code official to 'find' the building in noncompliance? Without some specific mechanism in the code, this will lead to arbitrary application of these retroactive requirements.

By relocating Chapter 46 to an appendix Chapter, those jurisdictions that have the authority, the mechanism, and the desire to require assessment and retrofit of existing buildings will have a framework on which they can build a comprehensive package. By removing the Chapter from the body of the code, the majority of jurisdictions, who are either unauthorized or unable to assess every existing building and mandate every possible retrofit outlined in the chapter, will not need to amend these provisions out of the code, or ignore
the potential impact that the breadth of this Chapter would have on some older existing buildings. Note that even with the deletion of this Chapter from the body of the code, the fire code official still has the authority to mandate that 'distinct hazards to life and property' be mitigated.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: PERRY-F1-CHAP46.DOC

Public Hearing Results

Committee Action: Disapproved

Committee Reason: The committee felt that Chapter 46 should remain intact within the body of the code. Moving it to an appendix would require removal of the many "pointer" sections within the code that now direct the user to Chapter 46 because the code style does not allow directing the user to optional appendices since they are not part of the code. The committee also expressed its desire that Chapter 46, which is new to the 2009 edition of the IFC, be allowed to develop some use history before being substantially changed. The committee also observed that jurisdictions that adopt the code always have the authority to make amendments to it in their adopting ordinance and can just as easily amend out Chapter 46 if so desired.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Lawrence G. Perry, AIA, representing Building Owners and Managers Association (BOMA) International, requesting Approval as Modified by this Public Comment.

Modify the proposal as follows:

APPENDIX K
CONSTRUCTION REQUIREMENTS FOR EXISTING BUILDINGS

102.1 Construction and design provisions. The construction and design provisions of this code shall apply to:

1. Structures, facilities and conditions arising after the adoption of this code.
2. Existing structures, facilities and conditions not legally in existence at the time of adoption of this code.
3. Existing structures, facilities and conditions which, in the opinion of the *fire code official*, constitute a distinct hazard to life or property.

607.1 Emergency operation. ~~Existing elevators with a travel distance of 25 feet (7620 mm) or more shall comply with the requirements in Chapter 46.~~ New elevators shall be provided with Phase I emergency recall operation and Phase II emergency in-car operation in accordance with ASME A17.1.

704.1 Enclosure. ~~Interior vertical shafts, including but not limited to *stairways*, elevator hoistways, service and utility shafts, that connect two or more stories of a building shall be enclosed or protected as required in Chapter 46.~~ New floor openings in existing buildings shall comply with the *International Building Code*.

~~**903.6 Existing buildings.** The provisions of this section are intended to provide a reasonable degree of safety in existing structures not complying with the minimum requirements of the *International Building Code* by requiring installation of an automatic fire-extinguishing system.~~

~~**903.6.1 Pyroxylin plastics.** All structures occupied for the manufacture or storage of articles of cellulose nitrate (pyroxylin) plastic shall be equipped with an *approved* automatic fire-extinguishing system where required in Chapter 46.~~

~~**903.6.2 Group I-2.** An *automatic sprinkler system* shall be provided throughout Group I-2 *fire areas* where required in Chapter 46.~~

~~**905.11 Existing buildings.** Where required in Chapter 46, existing structures shall be equipped with standpipes installed in accordance with Section 905.~~

~~**907.3 Where required in existing buildings and structures.** An *approved* fire alarm system shall be installed in existing buildings and structures where required in Chapter 46.~~

2506.1 Required access. New tire storage yards shall be provided with fire apparatus access roads in accordance with Section 503 and Section 2506.2. ~~Existing tire storage yards shall be provided with fire apparatus access roads where required in Chapter 46.~~

Commenter's Reason: This code change should be Approved as Modified for the following reasons:
1. There is likely not a single jurisdiction that uses the *International Fire Code* that retroactively applies all of the requirements of Chapter 46 to all existing buildings in the jurisdiction.
2. Selective application of portions of Chapter 46, or application only to certain buildings in a jurisdiction, exposes the jurisdiction to accusations of applying the code in an arbitrary and capricious manner.
3. One of the opponents of this change testified in Baltimore, Chapter 46 'sets a baseline for discussion' about existing buildings. Code requirements should not be 'baselines for discussion'.
4. If the intent of the IFC is that every existing building in a jurisdiction be brought up to the 'baseline' of Chapter 46, the provisions of Chapter 46 need to be clearly spelled out as to when they must be satisfied.
5. This comment proposes to delete the handful of 'pointers' to chapter 46 that are scattered in other parts of the IFC, which were pointed out during testimony in Baltimore. Deleting these 'pointers' would have no effect on jurisdictions that choose to adopt Chapter 46.

Final Action: AS AM AMPC____ D

F235-09/10

Appendix K (New)

Proposed Change as Submitted

Proponent: Michael Jacoby, Seven Valleys, PA, representing self

Add new text as follows:

APPENDIX K
EMERGENCY COMMUNICATION SYSTEMS
(HAZARDOUS SUBSTANCE)

The provisions contained in this appendix are not mandatory unless specifically referenced in the adopting ordinance.

SECTION K101
GENERAL

K101.1 Scope. This appendix contains provisions that are available for adoption by governments, communities or tribes who will have an opportunity to use the National Fire Protection Association's (NFPA) NFPA 72 codes that just added three new chapters at the same time made a name change to the National Fire Alarm and Signaling Codes that also includes the requirements for mass notification systems that can be found in a new chapter called Emergency Communication System (ECS) in NFPA 72-2010.

By adopting the provisions within this appendix it will give governments, communities or tribes etc. who already adopted the International Code Council (ICC) Codes, the ability to enhance their emergency communication by bringing these two major code organizations together to ensure that NFPA 72/National Fire Alarm and Signaling Codes, Emergency Communication Systems (ECS) such as in one-way, two-way and mass notification systems etc. are being designed and later installed per code as desired.

These requirements/codes/specifications could then be used in such applications as for college campuses, schools, and stadiums, community centers to include even local community warning/notification systems etc. when these emergency communication systems are being upgraded or initially installed thus providing early warning messages before, during or after manmade disasters/situations/events, natural disasters such as hurricanes, tornadoes, snowstorms, blizzards, flooding, massive fires while giving instructions to the public in times of crisis etc.

This appendix will also address system upgrades or the initial requirements for fixed sites/facilities with hazardous substances.

K101.2 Emergency communication system requirements. Fire alarm system upgrades to the new National Fire Alarm and Signaling Codes can be applied to such sites that meet the requirements set forth in ICC IFC Section

2701.5.1 and 2701.5.2 or for those sites that already meet the following criteria with the focus being on outside emergency communication that is commonly known as mass notification now known as emergency communications systems while other parts of the National Fire Alarm and Signaling Codes can also be applied.

Guidelines:

1. Sites containing hazardous substances subject to **Pub.L. 109-295** that is commonly referred to by the public as the Department of Homeland Security's Chemical Facility Anti-Terrorism Standards (CFATS).
2. Sites containing hazardous substances with a federal recognized classification of **SARA Title III**, Superfund Amendments and Reauthorization Act (SARA) Title III of SARA ("SARA Title III") that is part of the Emergency Planning and Community Right-To-Know Act (EPCRA) requiring a Risk Management Plan (RMP) as part of a site's emergency response also known by the International Fire Code (IFC) as sites/facilities having a Hazardous Materials Management Plan (HMMP) sometimes referred to by federal or state governments as a Crisis Response Plan, Hazardous Material Emergency Plan or Hazardous Material Off-Site Response Plan.
3. Emergency Communication System Upgrade clarification: A site's risk analysis, being the basis of site's emergency communication design will be done by others unless the fire code official is qualified, and the future site designs of an IFC H classification site/facility/structure has a potential of reaching a DHS/CFATS, SARA Title III classification or will meet ICC IFC Section 2701.5.1 and or 2701.5.2 and the requirements when applicable for the new National Fire Alarm and Signaling Codes with their Emergency Communication System (ECS) or is already specified in the site's fire alarm system plans and a site risk analysis is already incorporated into the emergency communication design as part of their overall design is then complete.

K101.2.1 Retroactive emergency communication system upgrade requirements. The option of upgrading a Fire alarm system to the new National Fire Alarm and Signaling Codes for those sites applicable that in the past required emergency HazMat responses or activated their Hazardous Materials Management Plan (HMMP) the local authority having jurisdiction can review the present status of the site/facility with their fire code official and based on the site's risk analysis a system upgrade can be applied.

SECTION K102
REFERENCED STANDARDS

ICC IFC-06 International Fire Code K101.1, K101.2
NFPA 72-2010 National Fire Alarm Code K101.1, K101.2, K101.2.1

Commenter's Reason: This Appendix with its provisions could be a **key element** that could be used to protect millions throughout our nation by giving those governments, communities or tribes etc. who are presently **ICC compliant** the opportunity to enhance emergency communication within their communities by using these new codes.

For many years our nation waited for codes as such to catch up to the NEW state-of-the-art technology being used in emergency communication systems. Just imagine how much deliberation took place when the NFPA they decided to change the name of their new codes that now might have others confused. Within the codes you might find upgrades to one-way, two-way and mass emergency communication systems etc. that many have been waiting for, for many years. Depending on when you have the opportunity to read this proposed appendix you might discover that due to overlapping code development cycles between organizations the printed form of these new code showing you these upgrades may not yet be available so… I recommend that you use the Internet to find updated NFPA information if you would like to do some research.

Since this new terminology maybe a concern, background information is available through the internet by searching for articles such as Emergency Communications Systems and or the new NFPA 72-2010 codes. If you are interested in some detailed information, you could try to contact somebody at the NFPA that you might know who sat on the NFPA 72 development committee who is familiar with the final ratification of these new NFPA 72/National Fire Alarm and Signaling Codes, Emergency Communication Systems specifications etc. and he or she might be able to fill you in or…at least tell you where you can find these new codes changes on their website, that is if you did not already find what you were looking for.

In the past awareness about emergency communication issues were brought to the ICC IFC attention in the attempt to establish a standard within the IFC so emergency communication/notifications systems being a outside annunciator devices /speakers etc. could be installed by code, but now that the NFPA 72 committee has moved forward… in my opinion I think it does not make any sense to have duplicate codes in the IFC, so that is why this proposed appendix with these new codes I believe should now be used.

What did it take for our Federal Government to get involved? Did you know that it actually took a Presidential Executive Order 13407 followed by Congress's involvement with requirements to start to upgrade our national standards to reflect the new state-of-the-art technology in emergency communications? As an end result our Department of Homeland Security is now involved through an agency that presently falls under their umbrella that is called the Federal Emergency Management Agency (FEMA) and in layman's terms, now has a goal to provide alert and warnings throughout our infrastructure no matter what the crisis by using communication systems that could then provide life-saving information no matter where you are located or what time of the day it might be, such as during a natural or man-made disaster/ event… or in times of crisis. This federal government program is commonly known today as the Integrated Public Alert Warning System (IPAWS).

Do you agree? Washington with all of their wisdom forgot the basics, it appears that they forgot that when it comes to upgrading the alert/warning, emergency communication systems used for early warning mass notification everything starts with codes/specifications and implementation of systems with requirements at the local government level. Now do you realize why these upgraded NFPA 72/National Fire Alarm and Signaling Codes are so important?

Understanding why DHS's CFATS and the SARA Title III classifications are being used as guidelines to start a site's analysis are a very important part of this appendix. In this case you need a benchmark based on a time factor of how long it will take local first responders from the first millisecond of the event to be on scene, to then mitigate the event.

As you will discover our federal government gave an industry a wake-up call. The industry that many knew is now changing and by the time you read this proposal you might already be familiar with the following Federal Law, Pub.L.109-295 publicly known as our Department of Homeland Security's (DHS) and their Chemical Facility Anti-Terrorism Standards (CFATS). Keep in mind that DHS is a Security department and not a Code organization. I think you will quickly understand why CFATS is being used as a guideline if not simply contact the Department of Homeland Security and have them explain to you their Top Screening process that they used and how they determined their multiple tier structure to identify certain sites of concern. Once you understand their methods I feel that you will be able to see why this appendix is so important.

The short version back in 2008 after an official release the national media reported that more than 7,000 sites were chosen by using DHS's Top Screening process based on their tier structure as being sites of potential high-risk for terrorist attack. By the time code officials read this information some of the DHS security inspections at these sites that were on the schedule to start in January 2009 should already be completed. DHS should be the first to see how many of these sites with hazardous substances actually have any outside emergency communication warning devices/systems in place and operational to warn the surrounding public who could be outside exposed to the atmosphere when an event containing hazardous substances takes place at their facility that for many years others "assumed" such early warning devices were being installed. Having emergency communication notification systems in place with the ability to warn the public before exposure is one of the reasons for proposing this appendix. For too many years the mind-set has been that the general public will be sitting in their homes or have their electronic devices turned on just waiting for emergency warnings when in reality they are discovering that depending on the geographical area and the time of day that numbers will vary. Note that each geographical area of a site of interest that could be applicable is different and that is why a site analysis study is required. The most important part of our general public which are those who are less fortunate, our poor, the handicapped and those with special needs have a problem. Emergency Communication Systems used for outside early warning notification have the potential of reaching a large percentage of the affected population almost immediately unlike other means that could be subject to system loads and possible time delays. Another factor that has been increasing is the demand on our electrical grid and at times there are areas within our nation who might already be without electrical service (a major power outage), and or do not have telecom, broadcast, or cable connectivity. As the public starts to do their math and these deficiencies are known is strange how quiet it is now getting. Who was responsible for doing the math?

You probably are questioning why the terms SARA Title III is used as a guideline benchmark, it is simple many elected officials understand the term SARA Title III rather than the H classification being used in present code. Since governments, communities or tribes etc. will be involved in the decision-making on whether or not to adopt this proposed Appendix the term SARA that is an abbreviation for Superfund Amendments and Reauthorization Act, which is more universally understood by elected officials or others who participate in their (LEPC) Local Emergency Planning Committees, this terminology should make it easier for fire code officials to work with local governments to determine which sites located within their communities these upgrades and or new installation requirements will apply. Since fire code officials may not be familiar with the new technology in the world of emergency communication, in order to relieve the fire code official of additional burdens as it pertains to the acoustical designs and decision making a site's risk analysis, being the basis of site emergency communication design will be done by others, unless the fire code official is qualified and he or she would like to get involved.

For the second part of this requirement for installation being that if the site's designer already incorporated the new NFPA 72 codes to be known as National Fire Alarm and Signaling Codes, Emergency Communication System codes in the IFC H classification of a site/facility/structure and the acoustical designs including the decision making as it pertains to a site's risk analysis is already in their site design plans, and everything has been accounted for, thus meeting local government and fire code official approval everything should be Good-To-Go.

Please note that designers have been doing acoustical studies/designs for many years and emergency communication systems are being used throughout the world. Now our fire code officials will have an opportunity to have a closer working relationship with their local governments as being the Authority Having Jurisdiction (AHJ) to ensure that all related code preparedness and public safety communication concerns are met.

As discussions at the local level will always seem to continue on how to activate the emergency communications system, being the trigger, that is why a site analysis of the facility/building/structure is done first because each site maybe unique. These are decisions that are made after the appendix is adopted.

As you consider this proposed appendix for approval please keep in mind that this appendix addresses the ability of a community to adopt the appendix so they can use these new NFPA codes to ensure that early warning emergency communication is available for those who may be outside fully exposed to the atmosphere being that of employees at a site/facility or the public in the surrounding community at site/facilities where these code requirements may apply will then be installed by code. Again in doing so this will address the larger portion of the effectiveness of the notification problem because the majority of the public depending on the geographical area and time of day could be outside of their homes and outside emergency communication early warning notification is essential so that they can protect their families by turning on their electronic devices and waiting for further instructions.

For some areas of our nation emergency communication systems as such are already installed at facilities/sites etc. and even emergency communication systems are being used for public community notification so this appendix may have little or no impact on those who choose to adopt this appendix.

Please consider this proposed Appendix with it's provisions/requirements that will give those governments, communities or tribes who are presently ICC compliant the opportunity to protect their communities, families, loved ones and especially those with special needs by using these new codes that many have been waiting for, for so many years.

Cost Impact: The cost impact of this code proposal will depend on many factors such as when this code is adopted, site inspections are done in order to determine what is required after doing a site analysis, the acoustical design and or other actions are performed in order to determine the cost of construction since the emergency communications system in some applications could also be considered an add-on, even an estimated cost of construction cannot honestly be determined at this time because each site will be different.

ICCFILENAME: JACOBY-F2-APPENDIX K.DOC

Public Hearing Results

Note: The following analysis was not in the Code Change monograph but was published on the ICC website at http://www.iccsafe.org/cs/codes/Documents/2009-10cycle/ProposedChanges/Standards-Analysis.pdf :

Analysis: Review of the proposed new standard P.L. 109-295 indicated that, in the opinion of ICC staff, the standard did not comply with ICC standards criteria, Sections 3.6.2.11 and 3.6.3.2.

Committee Action: **Disapproved**

Committee Reason: The committee felt that the proposal was vague and unenforceable and contains mostly commentary, making it difficult to determine what is required. The committee reiterated its suggestion from its action on a similar proposal in the 2007-2008 cycle that existing technology, such as "Reverse 911", that provide better notification can be used to accomplish many of the proponent's goals without creating the need for outside sirens which already mean something different (weather alert, volunteer fire department alert, etc.) to the public and would generate confusion.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Michael Jacoby, Seven Valleys, PA, representing self, requests Approval as Modified by this Public Comment.

Replace the proposal as follows:

APPENDIX K
EMERGENCY COMMUNICATION SYSTEMS
(HAZARDOUS SUBSTANCE)

The provisions contained in this appendix are not mandatory unless specifically referenced in the adopting ordinance.

SECTION K101
GENERAL

K101.1 Scope. This appendix contains provisions that are being made available for adoption by governments, communities or tribes, being local and regional authorities having jurisdiction, giving them an opportunity to adopt the new National Fire Alarm and Signaling Codes in NFPA72-2010 Edition Chapter 24 Emergency Communication System (ECS) in its entirety, to be used in the protection of their communities.

SECTION K102
REFERENCED STANDARDS

NFPA 72-2010	National Fire Alarm and Signaling Code Chapter 24	K101.1

Commenter Reason: At the time this proposal was made in late October 2009 the printed version of the new NFPA 72 National Fire Alarm and Signaling Codes just became available a few days before the hearings and I feel that many did not have ample time to review these new standards in their entirety.

Also after a January 2010 Commission Report that was reported by the media … preparedness issues I feel will now be at the top of the agenda for many throughout our nation.

I will now try to clarify what my requirement is in this proposal. For those who would like to adopt this appendix it will give those who in the past adopted ICC IFC codes and had or now have emergency communication concerns, an opportunity to use the provision within this appendix so that they can adopt the NFPA 72-2010 new **Chapter 24** in its entirety as requirements, that can then be use to protect their communities.

From this point on, I feel that further detailed justification for this proposed Appendix is no longer necessary, but I will still be making my general reasons-comments available for voting members so that they can decide whether or not this proposal has merit and should be made available to local communities to protect the public and their first responders.

Sadly to say many areas already invested into an old concept dating back many years that assumes that the general public will be sitting by their telephones or in front of their entertainment devices that are subject to power outages, satellite (atmospheric) and hard wiring connectivity issues etc. during natural or man made emergencies or in extreme times of crisis, and that is why others throughout our nation for a long time have been looking at these problems which has resulted in the identification of a series of information and messaging needs in emergency communication so that local and regional Authorities Having Jurisdiction (AHJ) now have codes/specifications available as they try to protect their communities.

This appendix is addressing local preparedness issues and system upgrades.

Whether or not you agree with Emergency Voice Alarm Communications (EVAC) HazMat Alerting (HA) emergency or mass communication/ notification system concepts I am sure that you realize that system upgrades when available are beneficial.

I will continue to reinforce my reason for why this appendix is so important by using the following Real Time example:

Ironically while I am preparing my comments for justification, parts of our nation are without power, and last reported the numbers are now into the hundreds of thousands while others experienced heavy snowfall, ice, downed telephone lines with more snow on the way. It is now being reported that many of the surrounding states, up to five are already in a state of emergency that includes Washington DC, breaking their national records and in one of the surrounding areas it was reported the snowfall was up to 40 inches, in other areas they've been without power for days and believe it or not more snow is being forecast in 72 hours. Last reported in some areas it will still… take days to restore power.

I am hoping that by now you understand why these emergency communication upgrades were made to our emergency and mass notification systems, and why it is so important for those who are ICC IFC compliance to have the opportunity of using the new National Fire Alarm and Signaling Codes to protect their communities if so desired?

Cost Impact: The cost of adoption should be zero.

Final Action: AS AM AMPC____ D

F236-09/10, Part I
Appendix K (New)

NOTE: PART II DID NOT RECEIVE A PUBLIC COMMENT AND IS ON THE CONSENT AGENDA. PART II IS REPRODUCED ONLY FOR INFORMATIONAL PURPOSES FOLLOWING ALL OF PART I.

Proposed Change as Submitted

Proponent: Sean DeCrane, Cleveland Fire Department, representing International Association of Fire Fighters

PART I – IFC

Add new appendix as follows:

APPENDIX K
BUILDING INFORMATION SIGN

The provisions contained in this appendix are not mandatory unless specifically referenced in the adopting ordinance.

SECTION K 101
GENERAL

K101.1 Scope New buildings shall have a building information sign(s) that shall comply with Sections 505.3.1 through 505.3.7. Existing buildings shall be brought into conformance with Sections K101.1 through K101.9 when one of the following occurs:

1. The fire department conducts an annual inspection intended to verify compliance with this section of the code, or any required inspection.
2. When a Change in Use or Occupancy has occurred.

   Exceptions:

   1. Utility occupancies
   2. One and Two-family dwellings

K101.1.1 Sign location. The building information sign shall be placed on one of the following:

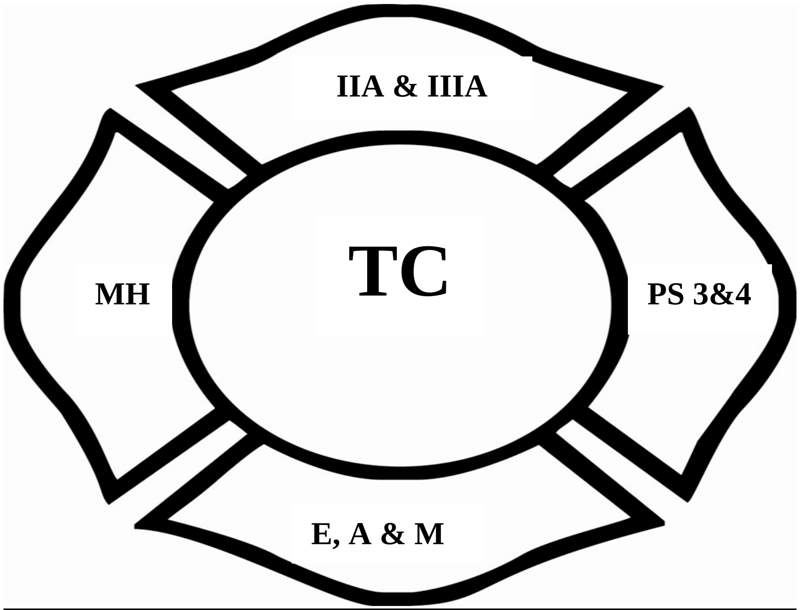
1. The entry door or sidelight at a minimum height of 42" above the walking surface on the address side of the building or structure;
2. The exterior surface of the building or structure no further than 3' from the entrance door, on either side of the entry door, at a minimum height of 42" above the walking surface on the address side of the building or structure;
3. Conspicuously placed, inside an enclosed entrance lobby, on any vertical surface within 10 feet of the entrance door at a minimum height of 42" above the walking surface;
4. Located inside the building's fire command center;
5. Located on the exterior of the fire alarm panel or immediately along side the panel door on the wall if the alarm panel is located in the enclosed main lobby.

K101.1.2 Sign features. The building information sign shall consist of:

1. White reflective background with red letters;
2. Durable material;
3. Numerals shall be Roman or Latin numerals, as required, and/or alphabet letters;
4. Permanently affixed to the building or structure in an approved manner.

K101.1.3 Sign shape. The building information sign shall be a Maltese Cross as shown in Figure K101.1.3

Top Wing



Bottom Wing

FIGURE K101.1.3
BUILDING INFORMATION SIGN

K101.1.4 Sign size and lettering. The minimum size of the building information sign and lettering shall be in accordance with the following:

1. The width and height shall be 6 inches by 6 inches
2, The height or width of each Maltese cross wing area shall be 1 1/8 inches and have a stroke width of ½ inch;
3. The center of the Maltese cross a circle of oval 3 ⅛ inches in diameter and has a stroke width of ½ inch;
4. All roman numerals and alphabetic designations, shall be 1 ¼ inch height and have a stroke width of ¼ inch.

K101.2 Sign designations. Designations shall be made based upon the construction type, content, hazard, fire protection systems, life safety and occupancy. Where multiple designations occur within a classification Category, the designation used shall be based on the greatest potential risk.

K101.3 Construction type (TOP WING). The construction types shall be designated by assigning the appropriate Roman numeral, and letter, placed inside the top wing of the Maltese cross. The hourly rating provided is for the structural framing in accordance with Table 601 of the *International Building Code*,

Construction Type	**Hourly Rating**
IA - Non-Combustible Construction -	3 Hour Rating
IB –Non-Combustible Construction -	2 Hour Rating
IIA – Non-Combustible Construction -	1 Hour Rating
IIB – Non-Combustible Construction -	0 Hour Rating
IIIA – Non-Combustible/Combustible Construction -	1 Hour Rating
IIIB – Non-Combustible/Combustible Construction -	0 Hour Rating
IV – Heavy Timber Construction -	
VA – Combustible Construction -	1 Hour Rating
VB – Combustible Construction –	0 Hour Rating

K101.4 Fire protection systems (Right Wing). The fire protection systems shall be designated by determining its level of protection and assigning the appropriate designation to the right wing of the Maltese cross. Where multiple systems are provided, all shall be listed:

AS – Automated Fire Sprinkler System installed throughout;
DS – Dry Sprinkler System and designated areas

FAS – Fire Alarm System
FP – Fire Pump
FW – Fire Wall and designated areas
PAS – Pre-Action Sprinkler System and designated floor
PS – Partial Automatic Fire Sprinkler System, and designate floor;
CES – Chemical Extinguishing System and designated area,
CS – Combination Sprinkler and Standpipe System;
S – Standpipe System;
NS – No system installed

K101.5 Occupancy type (Bottom Wing). The occupancy of a building or structure shall be designated in accordance with the occupancy classification found in Section 302.1 of the *International Building Code* and the corresponding designation shall be placed in the bottom wing of the Maltese cross. When a building or structure contains a mixture of uses and occupancies; all uses and occupancies shall be identified.

A – Assembly
B – Business
E – Educational
F – Factory or Industrial
H – High Hazard
I – Institutional
M – Mercantile
R – Residential
S – Storage

K101.6 Hazards of content (Left Wing). The hazards of building contents shall be designated by one of the following classifications as defined in NFPA 13 and the appropriate designation shall be placed inside the left wing of the Maltese cross:

LH - Light Hazard
MH - Moderate Hazard
HH - High Hazard

K101.7 Tactical Considerations (Center Circle). The Center Circle shall include the name of the local Fire Service and when required the letters TC for Tactical Considerations. When fire fighters conduct pre-plan operations, a unique situation(s) for tactical considerations shall be identified and the information provided to the fire dispatch communications center to further assist fire fighters in identifying that there is special consideration(s) for this occupancy. Special consideration designations include, but are not limited to:

1. Impact resistant drywall
2. Impact resistant glazing, such as blast or hurricane type glass
3. All types of roof and floor structural members including but not limited to post tension concrete, bar joists, solid wood joists, rafters, trusses, cold-formed galvanized steel, I-joists and I-beams; Green roof with vegetation, soil & plants
4. Hazardous materials, explosives, chemicals, plastics, etc;
5. Solar Panels and DC electrical energy
6. HVAC system; and smoke management system for pressurization and exhaust methods
7. Other unique characteristic(s) within the building that are ranked according to a potential risk to occupants and firefighters

K101.8 Sign classification maintenance, Building information sign maintenance shall comply with each of the following:

1. Fire departments in the jurisdiction shall define the designations to be placed within the sign.
2. Fire departments in the jurisdiction shall conduct annual inspections to verify compliance with this section of the code and shall notify the owner, or the owners agent, of any required updates to the sign in accordance with fire department designations and the owner, or the owner's agent, shall comply within thirty (30) days.
3. The owner of a building shall be responsible for the maintenance and updates to the sign in accordance to fire department designations.
4. The owner of a building shall notify the fire department of any changes that possibly effect the classifications, of the system, within thirty (30) days of the changes and the Fire Department shall conduct an inspection.

5. The owner of a building shall change the effected classification posted on the sign within thirty (30) days of the changes.

K101.9 Training. Jurisdictions shall train all fire department personnel on Sections K101.1 through K101.9

Reason: This Building Information Sign (BIS) is designed to be utilized in the crucial initial response of fire fighters to a structure fire. Similar to the Emergency Response Guidebook, published by the Department of Transportation, the BIS placard is designed to be utilized within the initial response time frame of an incident. Firefighters are trained to size-up a situation as early as possible after notification. The outward appearances of a building can be deceiving and the type of construction may not appear to be what it really is. This is becoming a more frequent occurrence within many communities.. Having the BIS placard will allow responding fire companies to make an informed tactical decision. The responding fire company will be able to identify the type of construction, hazard level of the contents, structural framework, occupancy of the building and the building fire protection system features , as well as he extent of the protection,

In the fire service there are many times we are dispatched to a location or area without an address, I.e. A fire company is dispatched in the vicinity of: Main St. and 5th Ave.. placing this information electronically will not address those incidents. Once the fire company has located the building or structure, the company officer can relay the correct address to the Dispatching Center and exit the apparatus to begin an assessment by making tactical decisions from the BIS building placard. The company officer cannot afford to wait until Dispatch sends an electronic form of the placard to t a mobile computer unit. This sign will give the arriving fire officer information to rapidly begin his/her assessment.

Another instance where a BIS placard is valuable for a Mutual Aid response to your community. Mutual Aid fire companies do not always share the same Dispatching Centers therefore they would not have the ability to receive the electronic communication. Placing this placard in designated locations will allow arriving Mutual Aid companies to begin proper tactical assessments.

Also within the Tactical Considerations (TC) section, the BIS placard will allow fire fighters to identify additional considerations. Just by seeing that there are additional TC considerations would give firefighters pause to consider unique aspects of the situation, such as:

Are there special needs for the occupants?
Is the interior constructed of impact resistant dry wall which will make wall breeching very difficult?
Is there hurricane glazing?
Is there an above ground 1500 gallons fuel oil tank in the basement?

Does the building contain dimension lumber, trusses, I-joists, cold formed steel, etc. in the roof or floors members?

These TC concerns can be identified and placed within the Tactical Considerations section of the BIS placard. The National Institute for Occupational Safety and Health (NIOSH) released an Alert Report, ‘Preventing Injuries and Deaths of Fire Fighters Due to Truss System Failures[1] and made recommendations to identifying structures by suggesting that building owners and managers “Consider placing building construction information outside the building. Include information about roof and floor type (presence of trusses, materials used), roof loads (heating, ventilation, and air conditioning (HVAC) units, sprinkler systems, utilities, hazardous materials stored on site and emergency contact numbers. Use and follow the proper building codes.”

This Building Information Sign has brought many people together from various private industries and public agencies such as:

Structural Building Component,
Steel & Wood industries,
Building officials, and the
Fire Service,

So as to collaborate on a BIS system that is comprehensive and meets the need of the fire service for information that allows for a quicker building assessment on the fire ground. This addresses a key question that has been asked for quite some time -- “How do we provide building information to the fire service?”. With this Building Information Sign we will be providing fire fighters crucial information at the most important time period. Fire Officers will be able to make decisions-based tactics on the knowledge provided within this building BIS placard or be prompted by other Tactical Considerations to request more information from the dispatch center.

Bibliography:
1. NIOSH Alert – “Preventing Injuries and Deaths of Fire Fighters Due to Truss System Failures” April 2005

Cost Impact: The code change proposal will have a minimal increase to the cost of construction.

ICCFILENAME: DECRANE-F3-APPENDIX K.DOC

Public Hearing Results

PART I- IFC

Committee Action: **Approved as Submitted**

Committee Reason: The committee agreed with the proponent's reason statement and felt that this would be a useful appendix tool for the fire department. The committee also pointed out that sections dealing with symbol size and lettering size need to be correlated because, as written, the lettering side would be larger than the symbol wing space into which it must be placed.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jeffrey Shapiro, PE, International Code Consultants, representing National Multi Housing Council, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

K101.8 Sign classification maintenance. Building information sign maintenance shall comply with each of the following:

1. Fire departments in the jurisdiction shall define the designations to be placed within the sign.
2. Fire departments in the jurisdiction shall conduct annual inspections to verify compliance with this section of the code and shall notify the owner, or the owner's agent, of any required updates to the sign in accordance with fire department designations and the owner, or the owner's agent, shall comply within thirty (30) days.
3. The owner of a building shall be responsible for the maintenance and updates to the sign in accordance to fire department designations.
4. ~~The owner of a building shall notify the fire department of any changes that possibly effect the classifications, of the system, within thirty (30) days of the changes and the Fire Department shall conduct an inspection.~~
5. ~~The owner of a building shall change the effected classification posted on the sign within thirty (30) days of the changes.~~

(Portions of proposal not shown remain unchanged.)

Commenter's Reason: It is inappropriate for Appendix K to place a burden (and legal liability) on the owner to identify changes that might "possibly" effect the classifications assigned by Appendix K. Building owners are not typically knowledgeable about building construction, firefighting tactics or other topics contemplated by the warning sign, and they may not even occupy the building. If the fire department wants to use this system, it is incumbent upon them to do the required inspections and advise the owner what to post on the sign. The Annex provides for that without the need to include Items 4 and 5.

Final Action: AS AM AMPC____ D

NOTE: PART II REPRODUCED FOR INFORMATIONAL PURPOSES ONLY – SEE ABOVE

PART II – IBC GENERAL

Add new appendix as follows:

APPENDIX L
BUILDING INFORMATION SIGN
SECTION L101
GENERAL

L101.1 Scope New buildings shall have a building information sign(s) that shall comply with Sections 505.3.1 through 505.3.7. Existing buildings shall be brought into conformance with Sections L101.1 through L101.9 when one of the following occurs:

1. The fire department conducts an annual inspection intended to verify compliance with this section of the code, or any required inspection.
2. When a Change in Use or Occupancy has occurred.

Exceptions:

1. Utility occupancies
2. One and Two-family homes

L101.1.1 Sign location. The building information sign shall be placed on one of the following:

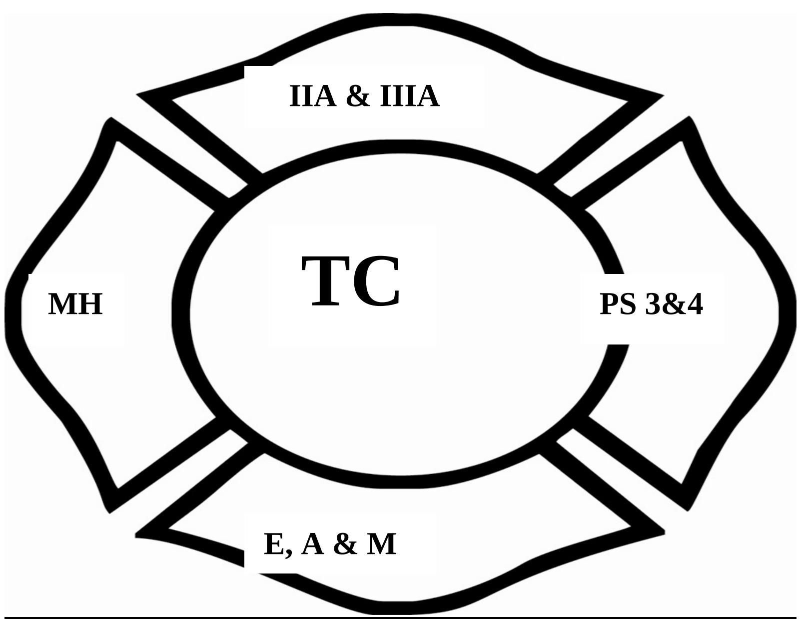
1. The entry door or sidelight at a minimum height of 42" above the walking surface on the address side of the building or structure;
2. The exterior surface of the building or structure no further than 3' from the entrance door, on either side of the entry door, at a minimum height of 42" above the walking surface on the address side of the building or structure;
3. Conspicuously placed, inside an enclosed entrance lobby, on any vertical surface within 10 feet of the entrance door at a minimum height of 42" above the walking surface;
4. Located inside the building's fire command center;
5. Located on the exterior of the fire alarm panel or immediately along side the panel door on the wall if the alarm panel is located in the enclosed main lobby.

L101.1.2 Sign features. The building information sign shall consist of:

1. White reflective background with red letters;
2. Durable material;
3. Numerals shall be Roman or Latin numerals, as required, and/or alphabet letters;
4. Permanently affixed to the building or structure in an approved manner.

L101.1.3 Sign shape. The building information sign shall be a Maltese Cross as shown in Figure L101.1.3

Top Wing



Bottom Wing

FIGURE L101.1.3
BUILDING INFORMATION SIGN

L101.1.4 Sign size and lettering. The minimum size of the building information sign and lettering shall be in accordance with the following:

1. The width and height shall be 6 inches by 6 inches
2, The height or width of each Maltese cross wing area shall be 1 1/8 inches and have a stroke width of ½ inch;
3. The center of the Maltese cross a circle of oval 3 ⅛ inches in diameter and has a stroke width of ½ inch;
4. All roman numerals and/or alphabetic designations, shall be 1 ¼ inch height and have a stroke width of ¼ inch.

L101.2 Sign designations. Designations shall be made based upon the construction type, content, hazard, fire protection systems, life safety and occupancy. Where multiple designations occur within a classification Category, the designation used shall be based on the greatest potential risk.

L101.3 Construction type (TOP WING). The construction types shall be designated by assigning the appropriate Roman numeral, and letter, placed inside the top wing of the Maltese cross. The hourly rating provided is for the structural framing in accordance with Table 601 of the *International Building Code*,

Construction Type	**Hourly Rating**
IA - Non-Combustible Construction -	3 Hour Rating
IB –Non-Combustible Construction -	2 Hour Rating
IIA – Non-Combustible Construction -	1 Hour Rating
IIB – Non-Combustible Construction -	0 Hour Rating
IIIA – Non-Combustible/Combustible Construction -	1 Hour Rating
IIIB – Non-Combustible/Combustible Construction -	0 Hour Rating
IV – Heavy Timber Construction -	
VA – Combustible Construction -	1 Hour Rating
VB – Combustible Construction –	0 Hour Rating

L101.4 Fire protection systems (RIGHT WING). The fire protection systems shall be designated by determining its level of protection and assigning the appropriate designation to the right wing of the Maltese cross. Where multiple systems are provided, all shall be listed:

AS – Automated Fire Sprinkler System installed throughout;
DS – Dry Sprinkler System and designated areas
FAS – Fire Alarm System
FP – Fire Pump
FW – Fire Wall and designated areas
PAS – Pre-Action Sprinkler System and designated floor
PS – Partial Automatic Fire Sprinkler System, and designate floor;
CES – Chemical Extinguishing System and designated area,
CS – Combination Sprinkler and Standpipe System;
S – Standpipe System;
NS – No system installed

L101.5 Occupancy type (Bottom Wing). The occupancy of a building or structure shall be designated in accordance with the occupancy classification found in Section 302.1 of the *International Building Code* and the corresponding designation shall be placed in the bottom wing of the Maltese cross. When a building or structure contains a mixture of uses and occupancies; all uses and occupancies shall be identified.

A – Assembly
B – Business
E – Educational
F – Factory or Industrial
H – High Hazard
I – Institutional
M – Mercantile
R – Residential
S – Storage

L101.6 Hazards of content (Left Wing). The hazards of building contents shall be designated by one of the following classifications as defined in NFPA 13 and the appropriate designation shall be placed inside the left wing of the Maltese cross:

LH - Light Hazard
MH - Moderate Hazard
HH - High Hazard

L101.7 Tactical considerations (Center Circle). The Center Circle shall include the name of the local Fire Service and when required the letters TC for Tactical Considerations. When fire fighters conduct pre-plan operations, a unique situation(s) for tactical considerations shall be identified and the information provided to the fire dispatch communications center to further assist fire fighters in identifying that there is special consideration(s) for this occupancy. Special consideration designations include, but are not limited to:

1. Impact resistant drywall
2. Impact resistant glazing, such as blast or hurricane type glass
3. All types of roof and floor structural members including but not limited to post tension concrete, bar joists, solid wood joists, rafters, trusses, cold-formed galvanized steel, I-joists and I-beams; Green roof with vegetation, soil & plants
4. Hazardous materials, explosives, chemicals, plastics, etc;
5. Solar Panels and DC electrical energy
6. HVAC system; and smoke management system for pressurization and exhaust methods
7. Other unique characteristic(s) within the building that are ranked according to a potential risk to occupants and firefighters

L101.8 Sign classification maintenance, Building information sign maintenance shall comply with each of the following:

1. <u>Fire departments in the jurisdiction shall define the designations to be placed within the sign.</u>
2. <u>Fire departments in the jurisdiction shall conduct annual inspections to verify compliance with this section of the code and shall notify the owner, or the owners agent, of any required updates to the sign in accordance with fire department designations and the owner, or the owner's agent, shall comply within thirty (30) days.</u>
3. <u>The owner of a building shall be responsible for the maintenance and updates to the sign in accordance to fire department designations.</u>
4. <u>The owner of a building shall notify the fire department of any changes that possibly effect the classifications, of the system, within thirty (30) days of the changes and the Fire Department shall conduct an inspection.</u>
5. <u>The owner of a building shall change the effected classification posted on the sign within thirty (30) days of the changes.</u>

<u>**L101.9 Training.** Jurisdictions shall train all fire department personnel on Sections L101.1 through L101.9</u>

Reason: This Building Information Sign (BIS) is designed to be utilized in the crucial initial response of fire fighters to a structure fire. Similar to the Emergency Response Guidebook, published by the Department of Transportation, the BIS placard is designed to be utilized within the initial response time frame of an incident. Firefighters are trained to size-up a situation as early as possible after notification. The outward appearances of a building can be deceiving and the type of construction may not appear to be what it really is. This is becoming a more frequent occurrence within many communities.. Having the BIS placard will allow responding fire companies to make an informed tactical decision. The responding fire company will be able to identify the type of construction, hazard level of the contents, structural framework, occupancy of the building and the building fire protection system features , as well as he extent of the protection,

In the fire service there are many times we are dispatched to a location or area without an address, I.e. A fire company is dispatched in the vicinity of: Main St. and 5th Ave.. placing this information electronically will not address those incidents. Once the fire company has located the building or structure, the company officer can relay the correct address to the Dispatching Center and exit the apparatus to begin an assessment by making tactical decisions from the BIS building placard. The company officer cannot afford to wait until Dispatch sends an electronic form of the placard to t a mobile computer unit. This sign will give the arriving fire officer information to rapidly begin his/her assessment.

Another instance where a BIS placard is valuable for a Mutual Aid response to your community. Mutual Aid fire companies do not always share the same Dispatching Centers therefore they would not have the ability to receive the electronic communication. Placing this placard in designated locations will allow arriving Mutual Aid companies to begin proper tactical assessments.

Also within the Tactical Considerations (TC) section, the BIS placard will allow fire fighters to identify additional considerations. Just by seeing that there are additional TC considerations would give firefighters pause to consider unique aspects of the situation, such as:

Are there special needs for the occupants?
Is the interior constructed of impact resistant dry wall which will make wall breeching very difficult?
Is there hurricane glazing?
Is there an above ground 1500 gallons fuel oil tank in the basement?

Does the building contain dimension lumber, trusses, I-joists, cold formed steel, etc. in the roof or floors members?

These TC concerns can be identified and placed within the Tactical Considerations section of the BIS placard. The National Institute for Occupational Safety and Health (NIOSH) released an Alert Report, 'Preventing Injuries and Deaths of Fire Fighters Due to Truss System Failures[1] and made recommendations to identifying structures by suggesting that building owners and managers "Consider placing building construction information outside the building. Include information about roof and floor type (presence of trusses, materials used), roof loads (heating, ventilation, and air conditioning (HVAC) units, sprinkler systems, utilities, hazardous materials stored on site and emergency contact numbers. Use and follow the proper building codes."

This Building Information Sign has brought many people together from various private industries and public agencies such as:

Structural Building Component,
Steel & Wood industries,
Building officials, and the
Fire Service,

So as to collaborate on a BIS system that is comprehensive and meets the need of the fire service for information that allows for a quicker building assessment on the fire ground. This addresses a key question that has been asked for quite some time -- "How do we provide building information to the fire service?". With this Building Information Sign we will be providing fire fighters crucial information at the most important time period. Fire Officers will be able to make decisions-based tactics on the knowledge provided within this building BIS placard or be prompted by other Tactical Considerations to request more information from the dispatch center.

Bibliography:
1. NIOSH Alert – "Preventing Injuries and Deaths of Fire Fighters Due to Truss System Failures" April 2005

Cost Impact: The code change proposal will have a minimal increase to the cost of construction.

PART II-IBC GENERAL
Committee Action: **Disapproved**

Committee Reason: The committee felt that the proposed appendix should not be placed in the IBC because it is predominantly fire department specific in much of its content (i.e., pertaining to FD training, tactics, procedures, etc.).

Assembly Action: **None**

F237-09/10
Appendix K (New)

Proposed Change as Submitted

Proponents: Patrick Siegman, Principal, Nelson, Nygaard Consulting Associates, representing the Congress for the New Urbanism; Peter Swift, Owner, Swift and Associates, representing the Congress for the New Urbanism; John Norquist, CEO, Congress for the New Urbanism

Add new Appendix as follows:

APPENDIX K
STREET DESIGN FOR LIFE SAFETY

The provisions contained in this appendix are not mandatory unless specifically referenced in the adopting ordinance.

SECTION K101
GENERAL

K101.1 Intent. The purpose of this appendix is allow jurisdictions to adopt performance-based requirements for fire apparatus access roads, in order to achieve all of the following purposes:

1. Establish the minimum requirements consistent with nationally recognized good practice for providing a reasonable level of life safety and property protection from the hazards of fire, explosion or dangerous conditions in new and existing buildings, structures and premises and to provide safety to fire fighters and emergency responders during emergency operations.
2. On the new and existing fire apparatus access roads required by and regulated by this code, establish requirements consistent with nationally and internationally recognized good practice for achieving a reasonable level of overall life safety, by taking into account and balancing the need to prevent road traffic deaths and injuries and the need to safeguard against the hazards of fire, explosions and other dangerous conditions.

K101.2 Scope. If this appendix is adopted by a jurisdiction, then the following changes to the current provisions of the code come into effect within the jurisdiction:

101.2 Scope. This code establishes regulations affecting or relating to structures, processes, premises and safeguards regarding:

1. The hazard of fire and explosion arising from the storage, handling or use of structures, materials or devices;
2. Conditions hazardous to life, property or public welfare in the occupancy of structures or premises;
3. Conditions hazardous to life, property or public welfare on or relating to the design of fire apparatus access roads, including the hazards of traffic, fire, explosion and other dangerous conditions;

~~3.~~ 4. Fire hazards in the structure or on the premises from occupancy or operation;
~~4.~~ 5. Matters related to the construction, extension, repair, alteration or removal of fire suppression or alarm systems.
~~5.~~ 6. Conditions affecting the safety of fire fighters and emergency responders during emergency operations.

101.3 Intent. The purpose of this code is to establish the minimum requirements consistent with nationally recognized good practice for providing a reasonable level of life safety and property protection from the hazards of fire, explosion or dangerous conditions in new and existing buildings, structures and premises and to provide safety to fire fighters and emergency responders during emergency operations. Additionally, on the new and existing fire apparatus access roads required by and regulated by this code, the purpose of this code is to establish requirements consistent with nationally and internationally recognized good practice for achieving a reasonable level of overall life safety, by taking into account and balancing the need to prevent road traffic deaths and injuries and the need to safeguard against the hazards of fire, explosions and other dangerous conditions.

503.2.1 Dimensions. Fire apparatus access roads shall have an unobstructed width ~~of not less than 20 feet (6096 mm), exclusive of shoulders, except for approved security gates in accordance with Section 503.6,~~ and an unobstructed vertical clearance ~~of not less than 13 feet 6 inches (4115 mm).~~ that permits passage of the jurisdiction's fire apparatus and, wherever necessary, provides adequate space for deploying the jurisdiction's fire apparatus and for conducting fire and rescue operations.

~~**503.2.2 Authority.** The fire code official shall have the authority to require an increase in the minimum access widths where they are inadequate for fire or rescue operations.~~

503.2.4 Turning radius. The required turning radius of a fire apparatus access road shall ~~be determined by the fire code official.~~ provide for the passage of the jurisdiction's fire apparatus.

503.2.7 Grade. The grade of the fire apparatus access road shall be ~~within the limits established by the fire code official based on the fire department's apparatus.~~ limited to grades that permit passage by, and, wherever necessary, fire and rescue operations by, the jurisdiction's fire apparatus.

503.2.8 Design for road traffic safety. Fire apparatus access roads shall be designed and maintained so as to minimize road traffic deaths and injuries, while maintaining adequate provision for the passage of fire apparatus and for fire and rescue operations. To achieve these goals, fire apparatus access roads shall be designed and maintained to both: (a) permit passage of the jurisdiction's fire apparatus and, wherever necessary, provide adequate space for deploying the jurisdiction's fire apparatus and conducting fire and rescue operations; and (b) minimize excess and inappropriate vehicle speeds.

Reason: This proposed code change provides an appendix that allows, but does not require, a jurisdiction to substitute revised material for current provisions of the code. That is, if the appendix is adopted by a jurisdiction, then the jurisdiction has elected to substitute revised materials for current provisions of the code. This appendix is intended to allow jurisdictions to take an approach to the design of fire apparatus access roads that improves overall life safety, by allowing jurisdictions to adopt roadway designs that strike the best possible balance between reducing the hazards of fire and reducing road traffic deaths and injuries, given the jurisdiction's own particular circumstances and particular choice of fire apparatus.

The text below attempts to provide clear and succinct answers to the questions asked for in the "Supporting Information" Section of the Code Change Proposal Instructions. That is, the following paragraphs state the purpose of the proposed code change, justify changing the current code provisions and seek to explain why the proposed code change is superior to the current provisions of the code.

1. **What is the purpose of this proposed code change (e.g., clarify the code; revise outdated material; substitute new or revised material for current provision of the code; add new requirements to the code; delete current requirements, etc.)?**

Response: This proposed code change provides an appendix that allows, but does not require, a jurisdiction to substitute revised material for current provisions of the code. That is, if the appendix is adopted by a jurisdiction, then the jurisdiction has elected to substitute revised materials for current provisions of the code. This approach will allow jurisdictions to take an approach to the design of fire apparatus access roads that we believe improves overall life safety, by allowing jurisdictions to adopt roadway designs that strike the best possible balance between reducing the hazards of fire and reducing road traffic deaths and injuries, given the jurisdiction's own particular circumstances and particular choice of fire apparatus. By allowing, but not requiring, jurisdictions to adopt this proposed appendix, the ICC will make it possible for jurisdictions to demonstrate the efficacy of this approach, without taking the more far-reaching step of simply altering the basic code.

2. **What is the justification for changing the current code provisions? Why is the proposal superior to the current provisions of the code? Proposals that add or delete requirements shall be supported by a logical explanation which clearly shows why the current code provisions are inadequate or overly restrictive, specifies the shortcomings of the current code provisions and explains how such proposals will improve the code.**

Response: The current International Fire Code specifies dimensions for fire apparatus access roads. Three key points about fire apparatus access roads should be noted:

1. The code requires that at least one fire apparatus access road be provided for every facility, building or a portion of the building hereafter constructed or moved into within a jurisdiction.
2. The code defines a fire apparatus access road as a road that provides fire apparatus access from a fire station to a facility, building or portion thereof.
3. The code defines fire apparatus access road as a general term inclusive of all other terms such as fire lane, public street, private street, parking lot lane and access roadway.

Therefore, since at least one fire apparatus access road must reach from a fire station to every building and facility constructed once the code is adopted, **the current International Fire Code specifies the key dimensions of many, if not most, public and private streets.**
This is significant not only for fire safety, but also for road safety. A substantial body of traffic safety research literature has found conclusively that the dimensions of streets significantly affect road safety. Therefore, **the current International Fire Code sets specifications for the design of many, if not most, public and private streets, and these specifications significantly affect traffic safety.**

Since the essential purpose of the International Fire Code is to provide for a reasonable level of life safety and property protections from the hazards of fire, explosion or dangerous conditions in new and existing buildings, structures and premises and to provide safety to fire fighters and emergency responders during emergency operations, the code may not always be thought of as a code that has significant and far-reaching effects on road safety. The reality, however, is that the International Fire Code does significantly affect road design, and therefore, significantly affects road traffic deaths and injuries.

We believe that the International Code Council can substantially advance the cause of improving overall life safety by taking the following actions:

1. ***Embrace the goal of improving overall life safety***, including preventing not only the tragedies caused by fire, structural collapse and other hazards that have long been explicitly focused on by code enforcement and fire officials, but also road traffic deaths and injuries.
2. ***Dedicate itself to reducing the burden of global road traffic deaths and injuries***, by committing itself to work in partnership with a broad range of organizations and governments to develop and implement road safety strategies, plans and codes.
3. ***Work together with road safety organizations to thoroughly review the existing codes promulgated by the International Code Council to ensure that the codes embrace internationally recognized good practices for protecting life safety, including not only reducing the hazards of fire, explosion and other dangerous conditions in buildings, but also reducing road safety hazards.***

While the International Code Council may never wish to expand its mission to include the task of writing full road safety codes, the Council can and we believe should work closely with road safety organizations to ensure that building codes and regulations, such as the fire apparatus access road provisions of the International Fire Code, allow for and encourage best practices in road safety.

The attached code change proposal is submitted in the spirit of cooperation between code enforcement and fire officials and road safety professionals. It was drafted out of our concern that the current provisions of the International Fire Code for fire apparatus access roads do not strike the best possible balance between reducing the hazards of fire and other building-related hazards, and reducing road traffic deaths and injuries. This submission is intended as a first step in bringing road safety professionals and fire service professionals together to work on an area of mutual concern: fire apparatus access roads are not only the areas where firefighters must set up equipment and fight conflagrations, but also the site of innumerable traffic deaths and injuries. The design of fire apparatus access roads (that is, the design of many public and private streets) is necessarily a balancing act, where there are frequently conflicts, tensions and trade-offs between the goals of improving road safety and improving fire safety. The very best design for bringing fire engines quickly to the scene of an incident, or the very best design for providing room to deploy equipment at the scene of a fire, is often not the best design for ensuring low motor vehicle speeds and pedestrian safety at a school crosswalk, or on a quiet residential street.

In drafting this code change proposal, we sought to recognize these tensions and trade-offs regarding fire apparatus access roads, and then to draft a code change proposal that would allow jurisdictions to do a better job of overcoming these conflicts. This code change proposal is intended to allow jurisdictions to design roads for overall life safety, including both fire safety and road safety. It is based on the following principles:

1. The necessary minimum dimensions of fire apparatus access roads are driven in large part by the size, weight, configuration and capabilities of a jurisdiction's fire apparatus.
2. The necessary minimum dimensions of fire apparatus access roads also depend on the staffing, strategies and tactics employed by a jurisdiction.
3. The characteristics of fire apparatus, and the staffing, strategies, and tactics of firefighters and emergency responders, vary widely from jurisdiction to jurisdiction, both internationally and within nations.
4. Roadway dimensions and design significantly affect road safety.
5. Therefore, the roadway designs that can be used by a jurisdiction to improve road safety on fire apparatus access roads vary depending on the fire apparatus employed by that community. Designs for road safety that work well in one jurisdiction may introduce significant difficulties for fire fighting in another jurisdiction where the fire apparatus that is in use is significantly larger, less maneuverable or less capable of deploying in a smaller space.
6. Therefore, rather than employing a one-size-fits-all approach to fire apparatus access roads, which assumes that all jurisdictions around the world and across the nation employ similar fire apparatus, this proposed code change recommends a performance-based approach.
7. Employing a more performance-based approach will make it possible to better balance the goals of improving road safety and improving fire and building safety, while taking into account the major differences between jurisdictions in fire apparatus, staffing, strategies and tactics.

We note that the existing provisions for fire apparatus access roads in Section 503 contain a mix of prescriptive and performance-based requirements. This proposed code change moves further in the direction of a performance-based approach, in the interest of making it more feasible to adopt roadway design solutions that resolve conflicts between road safety and fire safety, are carefully tailored to the fire apparatus in use in a jurisdiction, and improve overall life safety.

As background, the following sections briefly review several considerations that are crucial for designing streets that improve overall life safety. These sections briefly review:

- the magnitude of road traffic deaths and injuries
- road safety risk factors
- the relationship between street design and road safety
- examples of roadway design elements that improve road safety
- the tensions and trade-offs between accommodating needed access for and operations of fire apparatus, and designing streets that improve road safety

First, what is the magnitude of the road traffic safety problem, and why should the ICC be concerned about it?

Why should the International Code Council be concerned about road safety?

The Commission for Global Road Safety succinctly describes the reasons why all citizens, and particularly those of us who dedicate their professional lives to improving public safety, should focus our attention on road safety. According to the Commission's 2006 report, *Make Roads Safe*[1]:

1 Commission for Global Road Safety. *Make Roads Safe*. London, United Kingdom. Commission for Global Road Safety, 2006, p. 2. [Accessed June 1, 2009]. Available at http://www.makeroadssafe.org/publications/Documents/mrs_report_2007.pdf

Deaths and injuries from road traffic crashes are a major and growing public health epidemic. The World Health Organization has estimated that in 2002 almost 1.2 million people died in road crashes worldwide and as many as 50 million were injured. Unless action is taken, global road deaths are forecast to double by 2020 and yet many of these deaths and injuries are known to be preventable…
High income countries have developed effective road safety measures after decades of trial and error and human tragedy. While more effort is still needed in the industrialised nations the major challenge now is to ensure through early intervention that low and middle income countries do not have to experience the same bitter learning curve…
The World Report on road traffic injury prevention, published by WHO and the World Bank in 2004, details the key road injury 'risk factors', the major contributing factors to road crashes and injury severity, including drink driving; lack of helmet use; seat belt non compliance; excessive speed; and poor infrastructure design and management.

As a leading international organization -- if not the leading international organization -- devoted to building a safer world, the International Code Council can play an important role in solving this epidemic. At a minimum, even if it seeks no active role, the ICC will nonetheless be involved, because by specifying the key dimensions of so many public streets (i.e., the dimensions of fire apparatus access roads), the ICC's codes now play a major role in street design and therefore in road safety.

What Are Road Safety Risk Factors?
As the Commission for Global Road Safety's *Make Roads Safe* report notes, road safety specialists frequently refer to risk factors.

Primary Risk
The report notes that, "Primary risk describes the factors that contribute to the risk of occurrence of a road crash." Two of the four primary risk factors are *behavioral factors*, which are influenced by roadway dimensions and design, and the *road environment*, which is directly determined by roadway dimensions and design.[2]
According to the report, regarding behavioral factors:
Excessive or inappropriate speed is a key contributor to crash risk. Speed choice is influenced by the legal speed limit, but also by road layout...
According to the report, regarding road environment:
Road safety engineering and traffic management make a direct contribution to reduction of crash risk. Crash risk is increased by lack of attention to safety in both planning and design of new road networks and new roads. Road design affects road user behavior and crash risk through the speed the drivers will perceive as appropriate, through detailed design factors such as curves...
In modern road systems, vulnerable road users are disadvantaged because such systems are largely designed for the motor vehicle. The absence of footpath and cycle tracks, or traffic calming measures to reduce speed where pedestrians and cyclists mix with motorized traffic, increases the risk of a crash occurring and its severity.

Secondary Risk
"Secondary risk", the report explains, "includes the likelihood of injury occurring and its severity." As with primary risk, two of the major risk factors are behavioral factors, which are influenced by roadway dimensions and design, and the road environment, which is directly determined by roadway dimensions and design. As the report explains:
Impact speed is a crucial determinant of injury severity for vulnerable road users. For example, 90% of pedestrian survive impacts with cars at speeds up to 30 km/hour [18 mph], but more than half will die at speeds of 45 km/hour [27 mph] or more…
[F]or vehicle occupants also, injury severity increases with impact speed. The probability of fatal injury increases from close to zero to almost 100% as the change in impact speed increases from 20 km/hour to 100 km/hour…
Road design can also provide protection for vulnerable road users by reducing impact speed through traffic calming measures.

Other traffic safety research arises similar conclusions. For example, other research studies have found that when people walking are hit by a car:
- At 20 mph, only 5 percent of walkers are killed, most injuries are slight, and 30 percent suffer no injury;
- At 30 mph, 45 percent of walkers are killed, and many are seriously injured;
- At 40 mph, 85 percent of walkers are killed.[3]

Understanding the links between the dimensions of fire apparatus access roads and the likelihood of road traffic deaths and injuries on these roads
The transportation safety research literature makes clear that:
1. The behavior of motor vehicle drivers, bicyclists, pedestrians and other road users is substantially affected by the dimensions of streets.
2. Key roadway dimensions which have been found to significantly affect driver behavior include the following:
    a. roadway widths,
    b. lane widths,
    c. the presence or absence of raised medians, pedestrian refuges and similar measures (note that feasibility of including such measures in a roadway design is often dependent upon the requirements for roadway widths in the vicinity of these measures)
    d. the presence or absence of roundabouts, traffic circles, splitter islands and similar intersection design measures (again, note that feasibility of such intersection designs is highly dependent upon the requirements for roadway widths in the vicinity of these measures)
    e. turning radii (a.k.a. horizontal curvature) at curves in a roadway,
    f. turning radii (i.e., horizontal deflection) at roundabouts, traffic circles, median islands and channelized turns,
    g. curb radii at intersections,

3. The roadway dimensions and features described above affect important aspects of driver and pedestrian behavior. For example, the presence or absence of a raised median on a roadway affects the ability of drivers to make passing maneuvers, midblock turns or to drift into oncoming traffic.

---

[2] Ibid. p. 60.
[3] Limpert, Rudolph. *Motor Vehicle Accident Reconstruction and Cause Analysis*. Fourth Edition. Charlottesville, VA. The Michie Company, 1994, p. 663. See also *Killing Speed and Saving Lives*, United Kingdom Dept. of Transportation, London, England.

4. It is particularly important to note that the key roadway dimensions mentioned above affect the speed at which motor vehicle drivers choose to drive. As described above, motor vehicle speed is a key determinant of both the likelihood of a crash occurring and crash severity.
5. Because the dimensions of streets strongly affect the behavior of motorists, bicyclists, pedestrians and other road users, the dimensions of streets significantly affect traffic safety.

Section 503.2 of the current code sets specifications for the dimensions of fire apparatus access roads, including specifying the following key dimensions:

fire apparatus access roads shall have an unobstructed width of not less than 20 feet;
the required turning radii of fire apparatus access roads shall be determined by the fire code official.

While these two specifications are brief, their effect is far-reaching. By setting specifications for the key dimensions of road width and turning radii, Section 503.2 of the code sets specifications for many of the roadway dimensions and street design features (mentioned above) which are known to significantly affect traffic safety.

The following paragraphs provide several examples of the relationship between these two crucial street dimensions (roadway width and turning radii) and the ability to include important design features for traffic safety in a roadway design. In many circumstances, an absolute requirement to provide an unobstructed width of not less than 20 feet at every point along a roadway creates significant conflicts with the need to include roadway design features that improve traffic safety.

Often, these conflicts can be and have been resolved through careful design that consciously balances the need for traffic safety and the needs of firefighters to reach incidents and conduct fire and rescue operations. For example, while particular critical points along a roadway may be intentionally designed with a width of less than 20 foot clear, in order to reduce vehicle speeds and improve traffic safety, other areas along the same block will be provided with at least 20 foot clear, in order to provide, wherever necessary, sufficient space to set up equipment and fight fires.

The proposed appendix, by creating performance-based standards for fire apparatus access roads, will assist in the process of reconciling these conflicts. It provides more flexibility for street design, while still ensuring that streets are designed to allow for the passage of fire apparatus, and space to conduct fire and rescue operations.

Street Design for Traffic Safety: Examples

A few examples of roadway designs that can significantly improve traffic safety, but that frequently require roadway designs with less than 20 foot clear (at some, though not all places along a roadway) include the following:

1. Modern roundabouts
2. Raised medians
3. Low-volume local streets

Each is described in turn below.

1. Modern Roundabouts: The California Department of Transportation recently concluded, "The modern roundabout is now recognized nationally as an intersection type and traffic control treatment capable of providing unique and significant operational and safety benefits over a wide range of traffic volume and conditions. In particular, national research has confirmed that the single-lane version is especially effective in reducing collision frequency and/or severity for all highway users."[4]

Safety of modern roundabouts: Both overseas and in the United States, modern roundabouts have achieved a 50% to 90% reduction in injury accidents compared with intersections using stop control or traffic signals. The most comprehensive survey of roundabout safety in the United States was carried out in 1997 by the Transportation Research Board, and found that at intersections which were converted to roundabouts, overall crashes were reduced by 37% and injury accidents by 51%. The study also broke the results down for large roundabouts with three-lane entries, and smaller roundabouts with one- or two-lane entries. At these smaller roundabouts, crash reductions were even more pronounced: total crashes fell by 51%, with injury crashes reduced by 73%.

Capacity: roundabouts can often offer higher traffic-moving capacity than traffic signals, which in many circumstances leads to significantly reduced delays. The Transportation Research Board survey of intersections converted to roundabouts in the United States, for example, found that in the eight cases where vehicle delays had been measured, rush hour delays had been reduced by an average of 77%.

[4] *California Department of Transportation Design Information Bulletin #80-01: Roundabouts*. October 3, 2003, p. 1. [Accessed June 1, 2009]. Available at http://www.dot.ca.gov/hq/oppd/dib/dib80-01.pdf.

A typical modern roundabout in University Place, WA. At the roundabout entry, the clear width provided is only approximately 13 feet: this is an intentional design element to keep vehicle speeds low. Photo: IMG0032.jpg

Another modern roundabout near a school in Montpelier, VT. Again, note that the entry widths are kept to no more than 13 feet, to ensure low speeds both at the pedestrian crosswalks and within the intersection. Photo: IMG0027.jpg

The conflict between the current code requirement for 20 foot clear width at all points along every fire apparatus access road and the design of roundabouts occurs primarily with the design of roundabouts with one-lane entries. Roundabouts *are* designed to ensure that the largest fire apparatus (as well as tractor-trailer trucks and other large vehicles) that will use the roundabout are accommodated. However, as explained in

Roundabouts: an Informational Guide, the Federal Highway Administration's widely-used guide to roundabout design:

> *Roundabouts operate most safely when the geometry forces traffic to enter and circulate at slow speeds. Horizontal curvature and narrow pavement widths are used to produce this reduced-speed environment.* [5]

Furthermore, the Guide explains:

> *To maximize the roundabout's safety, entry widths should be kept to a minimum..The design should provide the minimum width necessary for capacity and accommodation of the design vehicle in order to maintain the highest level of safety. Typical entry widths for single-lane entrances range from 4.3 to 4.9m (14 to 16 ft); however, values…lower than this range may be required for site-specific design vehicle and speed requirements for critical vehicle paths.*

Thus, to design safe single-lane roundabouts, it is routinely necessary that at the roundabout entries, entry widths must be kept below 20 foot clear. This particular circumstance occurs only for a short distance at the intersection entry. However, it is a critical dimension and one that constantly conflicts with a requirement of 20 foot unobstructed width at all points along fire apparatus access roads.

2. Landscaped medians: There are important advantages to raised and landscaped medians, beyond their aesthetic appeal. In general, published studies conclude that on major roadways, raised central medians provide significant safety benefits when compared to undivided roads and roads with two-way left-turn lanes.

For example, examining overall crash rates – both midblock and intersection – for suburban arterials, Bowman & Vecellio's comprehensive study[6] found a rate of 373 vehicular crashes per million vehicle miles for roadways with a raised median, versus 676 vehicular crashes per million vehicle miles (or some 80% higher) for roadways with a two-way left-turn lane. Overall rates of rear end, right angle, head-on and left-turn crashes were all significantly reduced by the use of a median. Medians also ease crossings for pedestrians, and studies have found medians to be significantly safer for them. On suburban arterials, Bowman & Vecellio found the pedestrian crash rate for suburban arterials with raised medians to be 6.3 per million vehicle miles, versus 12.9 pedestrian crashes per million vehicle miles for those with two-way left-turn lanes.
The conflict that occurs here with the requirement for 20 foot clear is that many roadways only have room within the right-of-way for, and also function most safely (from the point of view of traffic safety) with one traffic lane and one bicycle lane in each direction on each side of the median. This results in a roadway cross section typically provides 17 feet of clear width on each side of the median.

---

3. Local Street Standards: Low-volume local streets are often purposefully designed to enforce low-driving speeds, obviating the need for future retrofits with speed bumps and other harsh traffic calming measures that can severely impact fire apparatus. For best traffic safety result, these minor residential streets are consciously designed to maintain average speeds of 20 mph or less. To achieve this, low-volume local streets are designed as traditional "yield streets". As the Institute of Transportation Engineers' Residential Streets, Third Edition explains:

> *Yield flow occurs when two-way traffic is impossible where parked vehicles are present. Thus, some motorists must stop and yield the right-of-way to oncoming vehicles. For decades prior to the 1960's, yield flow was the widely accepted norm for local streets. …Most local streets with low ADT [average daily traffic] may have yield-flow operation.*[7]

The AASHTO Greenbook, the standard reference on the geometric design of streets, also explicitly endorses yield streets:

> *The level of user inconvenience occasioned by the lack of two moving lanes is remarkably low in areas where single-family units prevail… In many residential areas a 26-ft.-wide roadway is typical. This curb-face-to-curb-face width provides for a 12-ft. center travel lane and two 7-ft. parking lanes. Opposing conflicting traffic will yield and pause on the parking lane area until there is sufficient width to pass*.[8]

The traffic safety research literature finds that yield streets result in a strong reduction in injury accident rates. Recent research compared injury accidents per mile per year on local streets against thirteen physical characteristics.[9] Street width was found to be significantly related to injury accidents, with the authors concluding that, "as street width widens, accidents per mile per year increases exponentially." The study's regression analysis found that a typical 36-foot wide residential street has 0.16 accidents per mile per year as opposed to 0.03 accidents per mile per year for a 24 foot wide street. This difference is about a 487 percent increase in accident rates (see figure, below). The safest streets were the narrow, 24-foot wide streets, with parking allowed on both sides, resulting in a clear width of approximately 10 feet.

Photo: 4THORDER.JPG

On low-volume local streets, providing widths of less than 20 foot clear can clearly provide numerous traffic safety benefits. The conflict between creating yield streets to meet this traffic safety goal, and the goal of ensuring safe access for fire and rescue operations, has been reconciled in numerous different ways by different jurisdictions. Frequent solutions include requiring that such streets always be through streets (rather than cul-de-sacs); requiring such streets to provide locations with 20 foot clear width at regular intervals (e.g., at all fire hydrants), so that areas exist to allow fire engines to set up and hook up hoses; and limiting building heights on such streets, so that is not necessary to deploy aerial ladders.

Cost Impact: The code change proposal will not increase the cost of construction

ICCFILENAME: SIEGMAN-SWIFT-NORQUIST-F1-APPENDIX K.DOC

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The committee agreed with the proponent's reason statement and felt that the proposal would provide a good starting point for community planning that takes into account the need for road traffic safety in fire apparatus access road design.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

John Norquist, representing Congress for the New Urbanism (CNU) and self, requests Approval as Submitted.

F237 (Appendix K), is an optional, performance-based guidance to fire code officials on street design. It provides flexibility based on local conditions and desires without jeopardizing public safety. For example, instead of a strict 20-foot-clear requirement, Appendix K recognizes street widths and vertical clearances that permit “passage of the jurisdiction's fire apparatus and, wherever necessary, provides adequate space for deploying the jurisdiction's fire apparatus and for conducting fire and rescue operations.” This is not overreaching, nor does it contain extraneous information; this is a guide that is flexible enough to be applied as local conditions merit or require, across the United States. It also is flexible enough to apply in countries that adopt the IFC, but whose urban development patterns and cultural norms greatly differ from the U.S. It should be adopted as is. As such, more detailed descriptions of street design conditions are merited as background information for guidance in good street design elements.

Public Comment 2:

Carl D. Wren, Austin TX Fire Department, representing self and Page Dougherty representing self, request Approval as Modified by this Public Comment:

Modify the proposal as follows:

APPENDIX K
STREET DESIGN GUIDELINES FOR ALTERNATIVE FIRE APPARTUS ACCESS ~~SAFETY~~

~~The provisions contained in this appendix are not mandatory unless specifically referenced in the adopting ordinance.~~ This Appendix is for information purposes and is not intended for adoption.

SECTION K101
GENERAL

K101.1 Intent. The purpose of this appendix is to ~~allow~~ provide guidance to jurisdictions ~~to~~ that choose to adopt a performance-based ~~requirements~~ design approach for fire apparatus access roads in cooperation with the design community, ~~in order to achieve all of the following purposes:~~
1~~. Establish the minimum requirements consistent with nationally recognized good practice for providing a reasonable level of life safety and property protection from the hazards of fire, explosion or dangerous conditions in new and existing buildings, structures and premises and to provide safety to fire fighters and emergency responders during emergency operations.~~
~~2~~ The design guidance in this appendix can be utilized to evaluate ~~On the~~ new and existing fire apparatus access roads required by ~~and regulated by~~ this code.~~,~~ It can be used to establish design criteria ~~requirements~~ that are consistent with nationally and internationally recognized good practices ~~for~~ in an effort to ~~achieving a reasonable level of~~ improve traffic ~~overall life~~ safety, by taking into account ~~and balancing the need to~~ methods for preventing roadway traffic deaths and injuries ~~and the need to safeguard against the~~ while providing access for emergency responders who work to mitigate the hazards of fire, explosions and other emergencies ~~dangerous conditions~~.

~~**K101.2 Scope.** If this appendix is adopted by a jurisdiction, then the following changes to the current provisions of the code come into effect within the jurisdiction:~~

K101.2 ~~Scope~~ Goals. This ~~code establishes regulations~~ appendix addresses access and traffic safety concerns affecting or relating to structures, processes, premises and safeguards that impact or potentially impact ~~regarding~~:

~~1. The hazard of fire and explosion arising from the storage, handling or use of structures, materials or devices;~~
~~2. Conditions hazardous to life, property or public welfare in the occupancy of structures or premises;~~
~~3. Conditions hazardous to life, property or public welfare on or relating to the design of fire apparatus access roads, including the hazards of traffic, fire, explosion and other dangerous conditions;~~
~~4. Fire hazards in the structure or on the premises from occupancy or operation;~~
~~5. Matters related to the construction, extension, repair, alteration or removal of fire suppression or alarm systems.~~
~~6~~ 1. ~~Conditions affecting t~~The safety of fire fighters and emergency responders in route to, during, and returning from an emergency ~~operations~~.
2. ~~Permit s~~Safe passage of the jurisdiction's fire apparatus
3. The adequacy of space for deploying the jurisdiction's fire apparatus and conducting fire and rescue operations
4. The approach and departure angles for the apparatus, and the inside and outside turning radii.
5. Appropriate vehicle speeds during normal traffic conditions that can enhance the safety of vehicles drivers and passengers as well as pedestrians.

~~**101.3 Intent.** The purpose of this code is to establish the minimum requirements consistent with nationally recognized good practice for providing a reasonable level of life safety and property protection from the hazards of fire, explosion or dangerous conditions in new and existing buildings, structures and premises and to provide safety to fire fighters and emergency responders during emergency operations. Additionally, on the new and existing fire apparatus access roads required by and regulated by this code, the purpose of this code is to establish requirements consistent with nationally and internationally recognized good practice for achieving a reasonable level of overall life safety, by taking into account and balancing the need to prevent road traffic deaths and injuries and the need to safeguard against the hazards of fire, explosions and other dangerous conditions.~~

~~503.2.2~~ K101.3 Authority. The fire code official ~~shall~~ needs to have the authority to work ~~require an increase~~ in conjunction with the jurisdiction's traffic engineer to provide the ~~minimum~~ access widths ~~where they are inadequate~~ needed for fire or rescue operations. The jurisdiction also a needs to address other commercial vehicle requirements such as trash, recycling vehicles, and moving vans so that their presence will not delay emergency response vehicles.

~~503.2.1~~ K101.4 Dimensions. Fire apparatus require access roads ~~shall have an~~ of sufficient unobstructed widths ~~of not less than 20 feet (6096 mm)~~, exclusive of shoulders, to allow the passage of and effective deployment of the jurisdiction's emergency apparatus~~, except for approved security gates in accordance with Section 503.6,~~ and an unobstructed vertical clearance of not less than 13 feet 6 inches (4115 mm).

~~503.2.4~~ K101.5 Turning radius. The required turning radius of a fire apparatus access road shall be ~~determined by the fire code official~~ based on the turning radius of both the in-service and the reserve apparatus used by the fire department, and other commercial vehicles that will operate in the area. ~~provide for the passage of the jurisdiction's fire apparatus.~~

~~503.2.7~~ K101.6 Grade. The grade of the fire apparatus access road shall be ~~within the limits established by the fire code official~~ based on the fire department's apparatus and the limitations of the apparatus related to ascending and transitioning from a flat surface to the grade permitted by the jurisdiction, and descending from a flat surface to the grade permitted by the jurisdiction. In addition, a transitioning distance may be required from the flat surface to the full grade. ~~limited to grades that permit passage by, and, wherever necessary, fire and rescue operations by, the jurisdiction's fire apparatus.~~

~~503.2.8~~ K101.7 Design for road traffic safety. Fire apparatus access road~~s shall be~~ design~~ed and maintained~~ should be influenced by the nature of the area being served, including building dimensions, building occupancies and uses, pedestrian traffic, bicycle traffic, and parking patterns.~~, so as to minimize road~~ The potential design impact on traffic safety should be evaluated to identify possible improvements that help to minimize inappropriate vehicle speeds for the area but do not prevent ~~deaths and injuries, while maintaining~~ adequate access ~~provision~~ for ~~the passage of~~ fire apparatus and for fire and rescue operations. ~~To achieve these goals, fire apparatus access roads shall be designed and maintained to both: (a) permit passage of the jurisdiction's fire apparatus and, wherever necessary, provide~~ Adequate access includes ~~adequate~~ the space necessary for deploying the jurisdiction's fire apparatus and conducting fire and rescue operations~~; and (b) minimize excess and inappropriate vehicle speeds~~.

Commenter's Reason (WREN): This code change was moved by Mr. Crawford of the IFC Code Development Committee with the idea to continue the discussion between the fire service and project developers, engineers and planners. Along with several fire service representatives I have been engaged in a dialogue with the Congress for the New Urbanism (CNU) for over two (2) years, and like Mr. Dougherty and Mr. Crawford, I would also encourage discussion of projects by all the stakeholders with an interest.

The original proposal and this comment are intended to be appendix material. The proposal was intended to be an adoptable appendix but it was not written in mandatory language throughout. This comment proposes to make the appendix a guidance document, to provide a potential process for dealing with this complex subject by both fire code officials and developers in order to further the dialog. I hope the on-going discussions will offer the possibility of a future change with mandatory language that would be mutually acceptable to the urbanist community and to the fire service.

If adopted, this code change would generate a new appendix worded as follows:

K101.1 Intent. The purpose of this appendix is to provide guidance to jurisdictions that choose to adopt a performance-based design approach for fire apparatus access roads in cooperation with the design community.

The design guidance in this appendix can be utilized to evaluate new and existing fire apparatus access roads required by this code. It can be used to establish design criteria that are consistent with nationally and internationally recognized good practices in an effort to improve traffic safety, by taking into account methods for preventing roadway traffic deaths and injuries while providing access for emergency responders who work to mitigate the hazards of fire, explosions and other emergencies.

K101.2 Goals. This appendix addresses access and traffic safety concerns affecting or relating to structures, processes, premises and safeguards that impact or potentially impact:

1. The safety of fire fighters and emergency responders in route to, during, and returning from an emergency.
2. Safe passage of the jurisdiction's fire apparatus
3. The adequacy of space for deploying the jurisdiction's fire apparatus and conducting fire and rescue operations
4. The approach and departure angles for the apparatus, and the inside and outside turning radii.
5. Appropriate vehicle speeds during normal traffic conditions that can enhance the safety of vehicles drivers and passengers as well as pedestrians.

K101.3 Authority. The fire code official needs to have the authority to work in conjunction with the jurisdiction's traffic engineer to provide the access widths needed for fire or rescue operations. The jurisdiction also a needs to address other commercial vehicle requirements such as trash, recycling vehicles, and moving vans so that their presence will not delay emergency response vehicles.

K101.4 Dimensions. Fire apparatus require access roads of sufficient unobstructed widths, exclusive of shoulders, to allow the passage of and effective deployment of the jurisdiction's emergency apparatus and an unobstructed vertical clearance of not less than 13 feet 6 inches (4115 mm).

K101.5 Turning radius. The required turning radius of a fire apparatus access road shall be based on the turning radius of both the in-service and the reserve apparatus used by the fire department, and other commercial vehicles that will operate in the area.

K101.6 Grade. The grade of the fire apparatus access road shall be based on the fire department's apparatus and the limitations of the apparatus related to ascending and transitioning from a flat surface to the grade permitted by the jurisdiction, and descending from a flat surface to the grade permitted by the jurisdiction. In addition, a transitioning distance may be required from the flat surface to the full grade.

K101.7 Design for road traffic safety. Fire apparatus access road design should be influenced by the nature of the area being served, including building dimensions, building occupancies and uses, pedestrian traffic, bicycle traffic, and parking patterns. The potential design impact on traffic safety should be evaluated to identify possible improvements that help to minimize inappropriate vehicle speeds for the area but do not prevent adequate access for fire apparatus and for fire and rescue operations. Adequate access includes the space necessary for deploying the jurisdiction's fire apparatus and conducting fire and rescue operations.

I hope that the membership will bring forward this Public Comment or Mr. Dougherty's comment and support Approved as Modified by the one of these two Public Comments.

Commenter's Reason (DOUGHERTY): This code change was moved by Mr. Crawford of the IFC Code Development Committee with the idea to establish a discussion between the fire service and project developers, engineers and planners. I would also encourage discussion of projects by all the stakeholders with an interest in the project.

Unfortunately, the code change proposal as approved has a lot of unneeded text in it that is more like commentary language than code. Most of the proposal is not written in mandatory language, as it is intended as a discussion guide. There are also portions of the proposal that do no more than restate the intent of the code as found in Chapter 1 and Chapter 5 of the IFC .

In discussing my concerns with the proponents of F237 and Mr. Crawford regarding the technical deficiencies, I offered to edit the original proposal to make it read more like a code should read and maintain the main concerns of the proponent: When developing a project, the concepts of livable – walkable communities that encourage people to use alternate modes of transportation, reduce traffic and the resulting traffic accidents and fatalities, to get people out walking within the community improving the health of the community, to reduce the carbon foot print in the community - reducing green house gasses and global warming, to produce sustainable housing (green buildings) that are energy efficient. With all of these it is felt that a better designed community can be the result.

The resulting modification was reviewed by the Congress for New Urbanization (CNU) and Mr. Crawford in an effort to provide an appendix that is simple and can achieve the goals of all concerned.

I urge the membership to bring forward the Public Comment; overturn the committee action to Approve as Submitted, and support Approved as Modified by the Public Comment as shown in this proposal.

Note: Mr. Crawford and I attended the CNU Conference in November 2009 to assist them in establishing a dialogue with the fire service. While at the conference we attended a meeting with the fire service and the CNU regarding access issues, which I thought was beneficial to both groups. I have also submitted a Public Comment for Disapproved. If the modified proposal is not acceptable to the membership I would then ask for disapproval. The language in the proposal approved by the committee does not belong in the code or Appendix and needs to be rejected.

Public Comment 3:

Page Dougherty representing self, requests Disapproval.

Commenter's Reason: The code change was "Approved as Submitted" by the committee in the final minutes of the code hearings. It was brought to the committee's attention that the text of the proposal was filed with direct cut of paste of existing code text, including the existing section numbers. The language used was also pointed out to be more commentary type language than that used in code.

Mr. Crawford, who made the motion to Approve F237, indicated that code users need to reach out to the submitter's group to establish a dialogue with firefighters and their group. This has been done as Mr. Crawford and I attended the group's conference in November, 2009 to establish that dialogue and also attended a meeting of that group and the fire service from the Oregon and Washington areas.

The code change as Approved is terrible code language and does little more that provide a laundry list of items that should be included in the discussion between the development community and the fire service. It should not be accepted by the membership as written.

Note: An additional Public Comment has been submitted in an attempt to remove the commentary type language, rearrange the issues to be discussed in a code like manner, and most importantly notes that the Appendix should not be adopted as part of a Code.

If the other Public Comment meets the concerns regarding the issues, vote for it over the Approved version of F237, If you do not like the Public Comment then I ask for your support of a Disapproval vote to prevent the Approved text form being placed in the code.

Remember this is the ONLY CHANCE we have TO REMOVE the F 237-09/10 text as approved for the 2012 IFC

Public Comment 4:

Daniel E. Nichols, New York State Div. of Code Enforcement and Administration, requests Disapproval.

Commenter's Reason:

The committee approved this 'as a starting point', but the proposal has requirements that are located in confusing locations, based on unidentified standards, as well as being detrimental to fire department apparatus.

If a jurisdiction were to adopt this appendix, the following issues would be raised:

<u>K101.2</u>

Modifies 101.2- Scope of the IFC- This would make the fire code official responsible for the hazards of traffic that occur on fire apparatus access roads, including 'other dangerous conditions.'

Modifies 101.3- Intent of the IFC- This would make the design of existing fire apparatus access roads subject to construction requirements. Currently, IFC Section 503.1 only applies the design criteria to newly required fire apparatus access roads.

Modifies 503.2.1- Dimensions- States that the 20 feet would be deleted and adds 'the passage of fire apparatus'. The passage of fire apparatus is not the sole intent of the 20 feet; it is so fire apparatus can pass one another when navigating a fireground as well as to go around a vehicle that has pulled over to allow the fire apparatus to proceed. Another concern is the term 'Wherever necessary, provides adequate space for deploying apparatus. Where will this be? What about other buildings built along the road at a later date? What happens when the fire department's vehicles change? The 20 feet has been long recognized as the required width to effectively operate fire apparatus.

Today's fire apparatus is much larger than a generation ago; mainly because of increased safety features within the apparatus (enclosed cabs, side impact protection, aerial apparatus stability), the need for multiple-use apparatus that decreases the number of vehicles but make each one larger (quint-type and rescue-pumper apparatus), and new environmental concerns. The environmental concerns are based on new Environmental Protection Agency (EPA) requirements on diesel engines that require larger-sized engines to be placed in fire apparatus to more effectively control pollutants. The larger engines have made apparatus wider to facilitate the space for the engine and the associated cooling. As an example, a 1950's city engine was about 80" wide, a mid-1990's city engine was about 92" wide plus 10" for mirrors. Today's fire apparatus utilizes about 100" wide, with an additional 10" for mirror. In short, two late-model fire engines will have only about 20" of space to pass with the current 20 feet requirement. Anything less than 20 feet changes the original purpose of fire apparatus access roads.

On-street parking is a principle of the new urbanism movement. Because of the need for parallel parking, rapid increases of 'double-parkers' due to no dedicated parking within immediate proximity of the residences, and largely unregulated parking of larger vehicles, on-street parking is an additional issue that effects fire apparatus access where the minimum width is generally diminished anyway. Add the issue of snow removal in colder climates and on-street parking becomes a real hindrance to narrow roads.

The appendix material does not give the appropriate guidance to take into account the above issues, as well as others dealing with need for considerations of future fire department apparatus purchases, vehicle height and access to buildings. It also does not give the review and approval process that other performance-based designs have, such as the criteria in the alternate methods and materials process in Chapter 1 of the IFC or as developed in the *ICC Performance Code*.

I ask that the membership consider disapproving this code change. I want to also remind the ICC membership that F16 was disapproved by the committee for reasons (in part) of the fire code official not being in control of the width of roads and F17 was approved to prohibit traffic-calming devices unless approved by the fire code official because of the known reduction of fire apparatus access created by contemporary road designs.

Final Action: AS AM AMPC____ D

F241-09/10

4603.6.1 (New), 4603.6.1.1 (New), 4603.6, Table 4603.1

Proposed Change as Submitted

Proponent: Tom Lariviere, Chairman – Joint Fire Service Review Committee

1. Add new text as follows:

4603.6.1 Group A. A manual fire alarm system that activates the occupant notification system in accordance with Section 907.6 shall be installed in Group A occupancies having an occupant load of 300 or more. Portions of Group E occupancies occupied for assembly purposes shall be provided with a fire alarm system as required for the Group E occupancy.

> **Exception:** Manual fire alarm boxes are not required where the building is equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1 and the occupant notification appliances will activate throughout the notification zones upon sprinkler water flow.

4603.6.1.1 System initiation in Group A occupancies with an occupant load of 1,000 or more. Activation of the fire alarm in Group A occupancies with an occupant load of 1,000 or more shall initiate a signal using an emergency voice/alarm communications system in accordance with Section 907.6.2.2.

> **Exception:** Where approved, the prerecorded announcement is allowed to be manually deactivated for a period of time, not to exceed 3 minutes, for the sole purpose of allowing a live voice announcement from an approved, constantly attended location.

(Renumber subsequent sections.)

2. Revise as follows:

4603.6 Fire alarm systems. An *approved* manual, automatic or manual and automatic fire alarm system shall be installed in existing buildings and structures in accordance with Sections 4603.6.1 through ~~4603.6.7~~ 4603.6.8 and provide occupant notification in accordance with Section 907.6 unless other requirements are provided by other sections of this code.

> **Exception:** Occupancies with an existing, previously *approved* fire alarm system.

TABLE 4603.1
OCCUPANCY AND USE REQUIREMENTS

Section	Use			Occupancy Classification																		
	High Rise	Atrium or Covered Mall	Under ground Building	A	B	E	F	H-1	H-2	H-3	H-4	H-5	I-1	I-2	I-3	I-4	M	R-1	R-2	R-3	R-4	S
4603.6.1				R																		
~~4603.6.1~~ 4603.6.2						R																
~~4603.6.2~~ 4603.6.3													R									
~~4603.6.3~~ 4603.6.4														R								
~~4603.6.4~~ 4603.6.5															R							
~~4603.6.5~~ 4603.6.6																		R				
~~4603.6.6~~ 4603.6.7																			R			
~~4603.6.7~~ 4603.6.8																					R	

(Portions of table and notes not shown remain unchanged)

Reason: A study of multiple casualty fires in assembly occupancies has shown that similar conditions existed in all of the fires. These conditions include interior finish, exiting and occupant notification issues. The IFC addresses egress and interior finish issues retroactively in existing buildings. While the IFC contains retroactive fire alarm provisions in Groups E, R and I, there are currently no requirements for fire alarm systems in existing Group A occupancies. In the Beverly Hills Supper Club Fire (1977) and the Coconut Grove Fire (1942) one important factor resulting in 657 fatalities was the lack of occupant notification. In both these fires, multiple assembly rooms created conditions where the occupants of the buildings were not aware of fire conditions elsewhere in the building. Delayed occupant notification resulted in the fire condition blocking exit routes that would have been available earlier in the incidents.

This proposal will require a manual fire alarm system in existing Group A buildings with an occupant load of 300 or more.

Section 4603.6 is revised to include the new sections in the reference.

Table 4603.1 is revised to include the new sections in the reference.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: LARIVIERE-F34-4603.6.1.doc

Public Hearing Results

Note: This code change was contained in the errata posted on the ICC website. Please go to http://www.iccsafe.org/cs/codes/Pages/09-10ProposedChanges.aspx.

Committee Action: Disapproved

Committee Reason: The committee felt that the proposal would be in conflict with the action taken on code change F100-09/10 which clarifies the same requirements for new Group A occupancies and provides for Group A occupancies that are separated from one another.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Joe Pierce (Chairman), Dallas Fire Department, representing Joint Fire Service Review Committee, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

4603.6.1 Group A. A manual fire alarm system that activates the occupant notification system in accordance with Section 907.6 shall be installed in Group A occupancies ~~having an~~ where the occupant load ~~of~~ due to the assembly occupancy is 300 or more. Group A occupancies not separated from one another in accordance with Section 707.3.9 of the *International Building Code* shall be considered as a single occupancy for the purposes of applying this section. Portions of Group E occupancies occupied for assembly purposes shall be provided with a fire alarm system as required for the Group E occupancy.

> **Exception:** Manual fire alarm boxes are not required where the building is equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1 and the occupant notification appliances will activate throughout the notification zones upon sprinkler water flow.

(Portions of proposal not shown remain unchanged)

Commenter's Reason: This proposal was Disapproved at the Code Development Hearing because it was not consistent with the Committee's action on F100-09/10. This Public Comment revises the text so that it is consistent with the F100-09/10 which revised Section 907.2.1. Therefore, the second sentence is added which refers to considering all Group A occupancies when they are not separated with fire-rated construction.

The need to install fire alarms systems in large existing Group A occupancies exists. We hear of tragic incidents in these facilities all too often. Now that this proposal is correlated with 907.2.1, it should be approved so that occupants in existing Group A occupancies can be protected as well.

Analysis: The text of Section 907.2.1 resulting from the Approval as Submitted of code change F100-09/10 (appears on the Final Action Hearing Consent Agenda), reads as follows:

907.2.1 (IBC [F] 907.2.1) Group A. A manual fire alarm system that activates the occupant notification system in accordance with Section 907.6 shall be installed in Group A occupancies where the occupant load due to the assembly occupancy is 300 or more. Group A occupancies not separated from one another in accordance with Section 707.3.9 of the *International Building Code* shall be considered as a single occupancy for the purposes of applying this section. Portions of Group E occupancies occupied for assembly purposes shall be provided with a fire alarm system as required for the Group E occupancy.

Exception: Manual fire alarm boxes are not required where the building is equipped throughout with an automatic sprinkler system installed in accordance with Section 903.3.1.1 and the occupant notification appliances will activate throughout the notification zones upon sprinkler water flow.

Final Action: AS AM AMPC____ D

INTERNATIONAL RESIDENTIAL CODE – BUILDING

RB7-09/10
R301.1.1, Chapter 44

Proposed Change as Submitted

Proponent: Julie Ruth, PE, JRuth Code Consulting, representing the American Architectural Manufacturers Association

1. Revise as follows:

R301.1.1 Alternative provisions. As an alternative to the requirements in Section R301.1 the following standards are permitted subject to the limitations of this code and the limitations therein. Where engineered design is used in conjunction with these standards, the design shall comply with the *International Building Code*.

1. American Forest and Paper Association (AF&PA) *Wood Frame Construction Manual* (WFCM).
2. American Iron and Steel Institute (AISI) *Standard for Cold-Formed Steel Framing—Prescriptive Method for One- and Two-Family Dwellings* (AISI S230).
3. ICC-400 *Standard on the Design and Construction of Log Structures*.
4. American Architectural Manufacturers Association/National Sunroom Association (AAMA) 2100 – *Specification for Sunrooms* for the construction of sunroom additions in areas of Seismic Design Category A and B only.

2. Add new standard to Chapter 44 as follows:

AAMA
2100-10 Specification for Sunrooms

Reason: The 2009 *International Residential Code* defines a sunroom as "A one-story structure attached to a *dwelling* with a *glazing area* in excess of 40 percent of the gross area of the structure's *exterior walls* and roof." These structures are typically constructed in one of two manners: 1) using typical wood framing techniques, or 2) using a stick system that consists of prefabricated framing of aluminum, fiberglass, wood or other materials, with glass or opaque wall or roof panels, and steel or aluminum connections.

The first technique can be done in accordance with the current provisions of the IRC for wood framed construction. There are not now, however, any provisions in the IRC for the second method of constructing a sunroom other than by engineering analysis or demonstrating equivalence to the current provisions of the *International Residential Code* by some other means. This proposal seeks to add testing of sunrooms to the provisions of AAMA/NSA 2100 - 10 *Specification for Sunrooms* to the available options for approval of sunroom construction in the IRC.

In 2002 the American Architectural Manufacturers Association, the National Sunroom Association and the National Patio Association published the first U.S. standard for the construction of sunroom – AAMA/NPEA/NSA 2100 – 02. The standard established five different categories of sunrooms based upon the intended use of the space, and established specific design criteria for them, based upon those same categories and intended end use. The document establishes specific parameters for a test structure, including minimum depth, width, slope of roof, etc., while relying upon documents such as the local building code and ASCE 7 to determine the minimum design loads that the testing is to be based upon.

As the document began to be used and proposed for inclusion in various codes (it is now referenced in the 2007 Florida Building Code) the members of the AAMA Sunroom Council became aware of improvements that were needed. These improvements included revisions that would bring the document more tightly in line with the requirements of AAMA/WDMA/CSA 101/I.S.2/A440 for the design, testing and labeling of windows, glass doors and skylights, and revisions that would bring the foundation requirements more closely in line with the requirements of the *International Residential Code*. AAMA/WDMA/CSA 101/I.S.2/A440 – 08 is referenced in the 2009 edition of the International Residential Code, International Building Code and International Energy Conservation Code for these products.

The standard is currently undergoing revision to incorporate the improvements mentioned above. If the revision is completed by the Code Development Hearings in Baltimore, we will ask the IRC Building and Energy Committee to approve it at that time. If not, we will have the revision complete and the next edition of the standard published and readily available before the 2010 Final Action Hearings for the 2012 International Residential Code for consideration by the active members of the ICC at that time.

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: A review of the standard proposed for inclusion in the code, AAMA 2100, for compliance with ICC criteria for referenced standards given in Section 3.6 of Council Policy #CP 28 will be posted on the ICC website on or before September 24, 2009.

ICCFILENAME: RUTH-RB-3-R301.1.1-CH 44

Public Hearing Results

Analysis: Review of proposed new standard indicated that, in the opinion of ICC Staff, the standard did not comply with ICC standards criteria, Sections 3.6.3.1. and 3.6.2.11.

Committee Action: **Disapproved**

Committee Reason: The committee feels this is confusing and the standard does not comply with the ICC criteria. The revision to the standard is not complete. Also, there are issues with the electrical provisions that might be a conflict with respect to the standard.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Julie Ruth, PE, JRuth Code Consulting, representing the American Architectural Manufacturers Association, request Approval as Submitted.

Commenter's Reason: RB7, as originally submitted, added reference to AAMA/NSA 2100-10 to the IRC for the structural design of sunrooms. AAMA/NSA 2100-10 was intended to be an update to AAMA/NSA/NPEA 2100-02 *Specification for Sunrooms*, which has become widely used within the sunroom industry since its publication 8 years ago. The standard was disapproved by the IRC committee because the revision was not yet complete, the standard was not yet "published and readily available" and sufficient information regarding the consensus process used for the development and revision of the standard had not yet been provided to the ICC staff for them to make a determination regarding it.

AAMA/NSA/NPEA 2100 establishes criteria for five different categories of sunrooms, which range from "A roof or a covering of an outdoor space" with openings "enclosed with insect screening or 0.5 mm (20 mil) maximum thickness plastic film" (Category I) to "a roof or a covering of an outdoor space with enclosed walls that is designed to be heated and/or cooled and is open to the main structure" (Category V). The intent of AAMA 2100 is to define the design load and testing criteria for each category of sunrooms, relevant to the applicable model code, and also the intended use of the space.

The criteria include requirements for the structural design and testing of sunrooms to the wind, live, dead and snow load requirements of the applicable model building code. This Public Comment seeks recognition of AAMA/NSA/NPEA 2100 for the structural design of these special spaces.

During the initial efforts to revise and update AAMA/NSA/NPEA 2100, the members of AAMA staff were not able to locate contact information for the National Patio Enclosures Association. Since that time we have received that information. The NPEA is now participating in the process of updating AAMA/NSA/NPEA 2100 with AAMA and NSA, and the revised document will be designated AAMA/NSA/NPEA 2100-10.

Analysis: The standard proposed for reference in the code, AAMA/NSA/NPEA 2100 was not completed and readily available at the time of the Code Development Hearings in Baltimore. ICC Council Policy CP#/28-05, Code Development, Section 3.6.3.1, requires that the standard must be completed and readily available at the time of these Final Action Hearings in order to be considered for inclusion in the code.

Final Action: AS AM AMPC____ D

RB13-09/10
R301.2.1.1

Proposed Change as Submitted

Proponent: Gary Ehrlich, PE, National Association of Home Builders (NAHB)

Revise as follows:

R301.2.1.1 Design criteria. In regions where the basic wind speeds from Figure R301.2(4) equal or exceed ~~100 miles per hour (45 m/s) in *hurricane-prone regions*, or~~ 110 miles per hour (49m/s)~~ elsewhere~~, the design of buildings shall be in accordance with one of the following methods. The elements of design not addressed by those documents in Items 1 through 4 shall be in accordance with this code.

1. American Forest and Paper Association (AF&PA) *Wood Frame Construction Manual for One- and Two-Family Dwellings* (WFCM); or
2. International Code Council (ICC) *Standard for Residential Construction in High-Wind Regions* (ICC-600); or

3. *Minimum Design Loads for Buildings and Other Structures* (ASCE-7); or
4. American Iron and Steel Institute (AISI), *Standard for Cold-Formed Steel Framing—Prescriptive Method For One- and Two-Family Dwellings (AISI 230).*
5. Concrete construction shall be designed in accordance with the provisions of this code.
6. Structural insulated panel (SIP) walls shall be designed in accordance with the provisions of this code.

Reason: The purpose of this proposal is to restore the IRC scope limit for construction in high-wind areas to the original 110 miles per hour for all areas of the country. Without this revision, houses in areas along the Atlantic and Gulf coasts where the basic wind speed is 100 or 105 miles per hour will need to be engineered or designed to prescriptive requirements intended for areas at risk for Category 4 and 5 hurricanes.

As justification for the original code change made during the 2004-2005 Code Development Cycle (RB31-04/05) the Institute for Building and Home Safety (IBHS) cited four issues: roof sheathing nails, wind bracing requirements, toe-nailed uplift connections, and wall-to-wall connections at the floor line. In lieu of pursuing individual modifications to resolve these issues within the IRC, the proponent simply lowered the ceiling for using prescriptive design provisions along the Atlantic & Gulf coasts. We believe this is excessive and not supported by the observed performance of housing properly constructed to previous editions of the IRC in extreme wind events (hurricanes). At no time did the proponents ever provide documented evidence of failures of structures constructed to the previous IRC provisions. Nor did they provide technical justification in the form of engineering calculations or structural research to support their contentions. However, the 2004-2005 Code Development Cycle coincided with the four 2004 Florida hurricanes (Wilma, Ivan, Charley and Frances) and with Katrina and Rita in 2005. This led to significant political and emotional pressure on the code development community to increase the stringency of building codes, whether or not they were technically justified or appropriately targeted to the risk of severe wind events in those areas subject to the new provisions.

In the subsequent code development cycles, individual changes have been made to address all four issues raised by IBHS. The 2006 IRC increased the minimum roof sheathing nail size from 6d to 8d common nails for all roofs, and the gable and eave end zone nail spacing was tightened for dwellings in the 100mph region. The wall bracing provisions in the 2009 IRC have been reorganized, improved, and clarified and many new construction details provided. Most importantly, a new wind bracing table is provided which ties the required wall bracing for wind resistance to the wind loads determined using ASCE 7-05. Finally, a requirement for a continuous load path at the roof-to-wall, floor-to-floor, and floor-to-foundation connections at braced wall panels was added.

The 2009 IRC also provides requirements for wind resistance of exterior wood sheathing and for the installation of vinyl siding and foam sheathing. These new requirements further increase the resistance of structures built under the IRC to wind damage.

We question the age of the damaged structures used for justifying the code change reducing the IRC scope. The Federal Emergency Management Agency Summary Reports on Building Performance from the 2004 hurricane season and from Hurricane Katrina in 2005 indicated that structures built to the 2000 and 2003 IRC performed extremely well. The 2004 hurricane report stated (p.13), “no structural failures were observed to structures designed and constructed to the wind design requirements of…the 2000 IBC/IRC…” The Hurricane Katrina report stated (p.4-8), “Most structural failures observed…appeared to be the result of inadequate design and construction methods commonly used before IBC 2000 and IRC 2000 were adopted and enforced.” Finally, a study conducted by the Texas Windstorm Insurance Association after Hurricane Rita showed there was substantially less damage and substantially fewer insurance claims in those areas where the 2000 or 2003 IBC and IRC were adopted and enforced.

NAHB estimates show that complying with the ICC-600 Standard for Residential Construction in High Wind Regions or the AF&PA Wood Frame Construction Manual where required by the IRC can add as much as $10,000 to the cost of a home. We believe these additional requirements make it extremely difficult to construct affordable housing along the Atlantic and Gulf coasts and place an onerous burden on builders and homeowners, and particularly on first-time home buyers. This added cost of construction will have the effect of keeping residents of these areas in older homes which do not have the robust construction provided by the IRC prescriptive provisions and which will be substantially more susceptible to structural failures, water infiltration and damage to personal property in high wind events.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: EHRLICH-RB-2-R301.2.1.1

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The committee feels that the concerns with respect to roof sheathing nails, wind bracing, uplift connectors and wall-to-wall connections have been resolved and it is appropriate to restore the 110 mph basic wind speed as the threshold for high wind design.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

T. Eric Stafford, representing Institute for Business and Home Safety, requests Disapproval.

Commenter's Reason: We are requesting disapproval of RB13-09/10 standing on its own. Our support of this code change is contingent upon approval of code changes RB154-09/10 and/or RB156-09/10. RB154-09/10 and RB156-09/10 propose new requirements to improve the roof-to-wall connections for wind loads for buildings built to the IRC. With the approval of RB154-09/10, we would drop our objection to this proposal.

Final Action: AS AM AMPC____ D

RB16-09/10
301.2.2.6 (New), R1001.3, R1001.4, R1003.3, R1003.4, Table R1001.1

Proposed Change as Submitted

Proponent: Homer Maiel, PE, CBO, City of San Jose, CA, representing ICC Tri-Chapter (Peninsula, East Bay, Monterey Bay Chapters)

1. Add new text as follows:

R301.2.2.2.6 Masonry or concrete chimneys. Masonry or concrete chimneys shall be reinforced and anchored to the building in accordance with Sections R1001.3, R1001.4, R1003.3 and R1003.4

2. Revise as follows:

R1001.3 Seismic reinforcing. Masonry or concrete chimneys in Seismic Design ~~Category~~ Categories C, D_0, D_1 or D_2 shall be reinforced. Reinforcing shall conform to the requirements set forth in Table R1001.1 and Section R609, Grouted Masonry.

R1001.4 Seismic anchorage. Masonry or concrete chimneys in Seismic Design Categories C, D_0, D_1 or D_2 shall be anchored at each floor, ceiling or roof line more than 6 feet (1829 mm) above *grade*, except where constructed completely within the exterior walls. Anchorage shall conform to the requirements of Section R1001.4.1.

R1003.3 Seismic reinforcing. Masonry or concrete chimneys shall be constructed, anchored, supported and reinforced as required by this chapter. In Seismic Design ~~Category~~ Categories C, D_0, D_1 or D_2 masonry and concrete chimneys shall be reinforced and anchored as detailed in Section R1003.3.1, R1003.3.2 and R1003.4. In Seismic Design ~~Category~~ Categories A and B ~~or C~~, reinforcement and seismic anchorage is not required.

R1003.4 Seismic anchorage. Masonry ~~and~~ or concrete chimneys and foundations in Seismic Design ~~Category~~ Categories C, D_0, D_1 or D_2 shall be anchored at each floor, ceiling or roof line more than 6 feet (1829 mm) above *grade*, except where constructed completely within the exterior walls. Anchorage shall conform to the requirements of Section R1003.4.1.

TABLE R1001.1
SUMMARY OF REQUIREMENTS FOR MASONRY FIREPLACES AND CHIMNEYS

(Portions of table not shown remain unchanged)

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 square foot = $0.0929m^2$.

NOTE: This table provides a summary of major requirements for the construction of masonry chimneys and fireplaces. Letter references are to Figure R1001.1 which shows examples of typical construction. This table does not cover all requirements, nor does it cover all aspects of the indicated requirements. For the actual mandatory requirements of the code, see the indicated section of text.

a. The letters refer to Figure R1001.1.
b. Not required in Seismic Design ~~Category~~ Categories A and B ~~or C~~.

Reason: The IBC Chapter 21 requirements for reinforcing and anchorage of masonry and concrete chimneys were extended to Seismic Design Category C by code change S193-07/08. That change appears in 2009 IBC Sections 2111.3 and 2111.4. This proposal intends to make the IRC minimum requirements for reinforcing and anchorage match the IBC because the effects of earthquakes and the risks to life safety from chimney collapse are independent of the code under which the chimney is permitted and constructed. Seismic Design Category C is defined in IRC Table R301.2.2.1.1 as the range of 0.33g S_{DS} 0.50g for soil Site Class D. Assuming soil Site Class D, this S_{DS} range represents a mapped short period (S_S) spectral response acceleration range of 0.32g S_S 0.55g. Earthquakes generating these moderate levels of short period ground motion (e.g., Nisqually Washington Earthquake (2001), Napa California Earthquake (2000), Coalinga California Earthquake (1983) have repeatedly caused collapse or partial collapse of large numbers of unreinforced or unanchored masonry chimneys. In at least two earthquakes, Borah Peak Idaho (1983) and Landers California Earthquake (1992), masonry chimney and fireplace collapses have resulted in fatalities.

To accomplish this change, a new section R301.2.2.2.6 is added to specify that the masonry or concrete chimneys in Seismic Design Category C must comply with sections R1001.3, R1001.4, R1003.3 and R1003.4. In each of those four sections, Category C is added to the list of Seismic Design Categories where chimney reinforcing and anchorage is necessary.

In R1003.3, Category C is deleted from the list of Seismic Design Categories where chimney reinforcement and anchorage are not required.

In Table R1001.1, footnote "b" is revised to delete Seismic Design Category C to be consistent with the changes to sections R1001.3, R1001.4, R1003.3 and R1003.4. Footnote "b" is used at two locations in Table R1001.1, in item H (vertical reinforcing) and in item S (anchorage).

In R1001.3, R1003.3, and R1003.4 and Table R1001.1 footnote "b" an editorial change is made to correct the word "Category" to the plural "Categories" as is currently used in section R1001.4 when more than one category is listed. Another editorial change occurs in R1003.4 where the word "and" between the words "masonry" and "concrete" is changed to "or" to match the wording used in the other three sections.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: Maiel-RB-3-R301.2.2.2.6-Ch 10

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee feels that the failures may have been noncompliance rather than inadequate code. No data or substantiation was submitted to show that the code is inadequate.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Homer Maiel, PE, CBO, City of San Jose, representing ICC Tri-Chapter (Peninsula, East Bay, Monterey Chapters), requests Approved as Submitted.

Commenter's Reason: The Tri-Chapter continues to support RB16 as submitted. During the Preliminary Code Hearings in Baltimore, speakers from the Tri-Chapter as well as speakers from the FEMA and experts on earthquake evaluation and response spoke on behalf of the original code change proposal as submitted. Both the proponents and opponents of this code change proposal agreed that there were thousands of masonry chimney failures following prior small earthquakes throughout the United States. The documented ground motions for prior small earthquakes, such as the Nisqually Earthquake in Washington, the Napa Earthquake in California, the Landers Earthquake in California, and the Coalinga Earthquake in California, and the Borah Peak Earthquake in Idaho, are all examples of small earthquakes that created "short period" ground accelerations in the range of 0.32g<Ss< or = 0.55g. Short Period ground accelerations in this range are characteristic of Seismic Design Category "C" (SDC C). This code change specifically calls for minimal longitudinal steel reinforcement and attachment at the roof level of masonry chimneys to prevent documented chimney collapses following small and moderate earthquakes.

The proposed code change should also be approved as submitted in order to provide the same minimum protection of occupants of residential buildings constructed under the IRC as is provided for all buildings constructed under the IBC. The mitigation of the very real dangers posed from falling chimneys during minor earthquakes should not be a function of which code they were built under.

The IRC Committee failed to understand that this code change proposal is not designed to prevent masonry chimney failures during small earthquake events, but rather addresses the more important life-safety issue of chimney collapse. The collapse of masonry chimneys that are not reinforced with longitudinal steel and are not properly anchored at the roof structure of the building have contributed to excessive property damage, injury and even death following small earthquake events. Even when only a portion of a chimney falls, those pieces have the potential to kill and injure people in the vicinity of the chimney.

Finally, the Tri-Chapter does not agree that the thousands of documented chimney failures are due to "poor workmanship" alone and that this is cause to reject the proposed code change. In fact, by requiring minimum longitudinal reinforcement of masonry chimneys and by requiring attachment of masonry chimneys at the roof line we fully expect that the construction of masonry chimneys will receive better inspection and be more likely to be built to withstand small and moderate earthquakes without the potential for collapse.

In summary, we encourage all ICC voting members to support this code proposal as submitted. Minimal longitudinal reinforcement of masonry chimneys and attachment of masonry chimneys at the roof line of buildings in SDC "C" is a proven and cost effective solution to prevent the collapse of masonry chimneys in small and moderate earthquakes and to reduce property damage and save lives.

Final Action: AS AM AMPC____ D

RB19-09/10
Table R302.1

Proposed Change as Submitted

Proponent: Steven Orlowski, National Association of Home Builders (NAHB)

Revise table as follows:

TABLE R302.1
EXTERIOR WALLS

EXTERIOR WALL ELEMENT		MINIMUM FIRE-RESISTANCE RATING	MINIMUM FIRE SEPARATION DISTANCE
Walls	(Fire-resistance rated)	1 hour-tested in accordance with ASTM E 119 or UL 263 with exposure to both sides	<3 ~~5~~ Feet
	(Not fire-resistance rated)	0-Hours	>3 ~~5~~ Feet
Projections	(Fire-resistance rated)	1-Hour on the underside	<2 ~~4~~ Feet
	(Not fire-resistance rated)	0-Hours	>3 ~~5~~ Feet
Openings	Not Allowed	N/A	< 3 Feet
	25% Maximum of Wall Area	0-Hours	3 Feet
	Unlimited	0-Hours	5 Feet
Penetrations	All	Comply with Section R302.4	< 5 Feet
		None Required	5 Feet

Reason: The purpose of this proposed change is to retain the original fire separation distances to the dimensions used in *2003 International Residential Code*. During the 2004/2005 Code Development Cycle, the Code Committee disapproved this change given that the proponent failed to provide supporting evidence or data to sustain the increase in the fire separation distance. The committee's decision was overturned at the final action hearings without any additional substantiation being brought forth by the proponent. To this day, there are no known reports or studies that demonstrate the previously allowed 3 foot separation distance from the property line and 6 foot separation between structures failed to provide the minimum required safe distance for fire separation.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: ORLOWSKI-RB-4-T. R302.1

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee feels there is no compelling reason to change the 5 feet separation distance. This is consistent in the Assembly Action on RB184-09/10. The ICC membership voted for the 5 feet separation in past code cycles and the committee supports that.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Steve Orlowski, National Association of Home Builders (NAHB), requests Approved as Submitted.

Commenter's Reason: The committee voted against this proposal during the public hearings, stating that the ICC membership had voted against any decrease in the fire separation distance. Yet, there was a successful floor vote by the ICC membership on a similar proposal (RB184) submitted by the fire service. NAHB urges the attendees at the final action hearings to approve this code change that would reinstate the decreased fire separation distances that were previously permitted in the 2003 IRC, based on the premise that the 2009 IRC requires residential sprinklers in all one- and two- family dwellings and townhouses. The code should be written on the basis of what is required in the model code and not on the possibilities of what may or may not be required at the state and local level when it is adopted.

Final Action: AS AM AMPC____ D

RB20-09/10
R302.1

Proposed Change as Submitted

Proponent: Don Davies, Salt Lake City Corporation, representing the Utah Chapter of ICC

Revise as follows:

R302.1 Exterior walls. Construction, projections, openings and penetrations of *exterior walls* of *dwellings* and accessory buildings shall comply with Table R302.1. Structures without exterior walls at adjoining lot lines shall not have roof projections within 5'-0" of the lot line.

Exceptions:

1. Walls, projections, openings or penetrations in walls perpendicular to the line used to determine the *fire separation distance*.
2. Walls of *dwellings* and *accessory structures* located on the same *lot*.
3. Detached tool sheds and storage sheds, playhouses and similar structures exempted from permits are not required to provide wall protection based on location on the *lot*. Projections beyond the *exterior wall* shall not extend over the *lot line*.
4. Detached garages accessory to a *dwelling* located within 2 feet (610 mm) of a *lot line* are permitted to have roof eave projections not exceeding 4 inches (102 mm).
5. Foundation vents installed in compliance with this code are permitted.

Reason: There are currently no provisions in the residential code to limit the roof projection for carports and patio covers where there is no exterior wall adjoining the lot line. Since carports and patio covers have openings exceeding 25% they must be placed at least 5 feet from the lot line as required in I.R.C. Table R302.1. Fire-resistance rating of the projections beyond the exterior walls is addressed in I.R.C. Table R302.1; but in the instance where there is no wall, rating a portion of the roof covering serves no useful purpose and is not addressed by Table R302.1 which deals with exterior walls.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: DAVIES-RB-1-R302.1

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee feels this change is not needed as Table R302.1 already addresses projections. Also, referring to structures is vague and a list of specific structures would be more appropriate.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Don Davies, Salt Lake City Corporation, representing Utah Chapter, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R302.1 Exterior walls. Construction, projections, openings and penetrations of *exterior walls* of *dwellings* and accessory buildings shall comply with Table R302.1. ~~Structures~~ Carports and Patio covers without exterior walls at adjoining lot lines shall not have roof projections within 5'-0" of the lot line.

Exceptions:

1. Walls, projections, openings or penetrations in walls perpendicular to the line used to determine the *fire separation distance*.
2. Walls of *dwellings* and *accessory structures* located on the same *lot*.
3. Detached tool sheds and storage sheds, playhouses and similar structures exempted from permits are not required to provide wall protection based on location on the *lot*. Projections beyond the *exterior wall* shall not extend over the *lot line*.
4. Detached garages accessory to a *dwelling* located within 2 feet (610 mm) of a *lot line* are permitted to have roof eave projections not exceeding 4 inches (102 mm).
5. Foundation vents installed in compliance with this code are permitted.

Commenter's Reason: Table R302 addresses projections from an exterior wall, but where no wall exists as in a carport or a patio cover, there is no point of reference from which the projection measurement is taken. Measuring from a post or a beam, assuming that as the exterior wall, is problematic since the post or beam may be in the center of the carport or on the opposite side from the property line side. Allowing a carport to project to within 24" of the lot line with one-hour rated protection for 36" of the carport soffit makes no sense. Without a wall, the extended projection will direct heat and flames to a structure on an adjoining lot, and the protection intended by this portion of the code will not be provided. Simply stating a minimum distance to where the carport can project is a straight forward approach and meets the intent of the code. The term structures were deemed too vague by the committee, so we are using the terms carports and patio covers to address their concerns.

Final Action: AS AM AMPC____ D

RB22-09/10
R302.2, R302.2.4

Proposed Change as Submitted

Proponent: Michael Gardner, representing the Gypsum Association; Jason Thompson, PE, National Concrete Masonry Association (NCMA), representing the Masonry Alliance for Codes and Standards (MACS)

Revise as follows:

R 302.2 Townhouses. Each townhouse shall be considered a separate building and shall be separated by fire-resistance-rated wall assemblies meeting the requirements of Section R302.1 for exterior walls.

Exception: A common ~~1-hour~~ 2-hour fire-resistance-rated wall assembly tested in accordance with ASTM E 119 or UL 263 is permitted for townhouses if such walls do not contain plumbing or mechanical equipment, ducts or vents in the cavity of the common wall. The wall shall be rated for fire exposure from both sides and shall extend to and be tight against exterior walls and the underside of the roof sheathing. Electrical installations shall be installed in accordance with Chapters 34 through 43. Penetrations of electrical outlet boxes shall be in accordance with Section R302.4.

R 302.2.4. Structural independence. Each individual townhouse shall be structurally independent.

Exceptions:

1. Foundations supporting *exterior walls* or common walls.
2. Structural roof and wall sheathing from each unit may fasten to the common wall framing.
3. Nonstructural wall and roof coverings.
4. Flashing at termination of roof covering over common wall.
5. Townhouses separated by a common 1~~-hour~~ 2-hour fire-resistance-rated wall as provided in Section R302.2.

Reason: (Gardner) Lost in the outcome of last fall's debate on residential sprinklers was the impact it made on the common walls that are often used to separate townhouse units. One of the approved proposals that incorporated sprinkler systems into townhouses reduced the rating on the common wall that can be used between townhouse units from two hours to one hour. This proposal is intended to restore the two hour rating to the common wall.

The 2009 IRC permits townhouses a structural independence exemption if they are separated by a common one-hour rated wall that complies with Section 302.2. The 2009 IRC also contains no mandatory sound transmission requirements for common walls. As a consequence, the 2009 IRC will permit two adjacent three story townhouse units to be separated by a common wall that displays no structural independence characteristics and has an STC rating of approximately 33.

Because of the reduced rating, a fire that overwhelms the sprinkler system in a room abutting the common wall will display an increased potential to adversely impact the structural integrity of the common wall and the adjacent townhouse units. In addition, the lack of a robust sound barrier between units creates the potential for a less than acceptable living environment.

The 2006 IRC required the common wall to maintain a two-hour rating. While the 2006 IRC also contained a structural independence exemption, the common two-hour wall required by the code provided an obvious level of increased fire protection not evidenced in the 2009 IRC. The 2006 code, by mandating a two-hour rating, also required the use of a wall that would automatically display a minimum STC rating almost 10 points higher than the minimum wall required by the 2009 code.

The code has never permitted the common wall that may be constructed by the exception to R 302.2 to display a rating that is lower than the rating that would be achieved by the standard charging language in R302.2. That section has historically required townhouses to be evaluated as separate buildings and to be constructed with separate and parallel exterior walls that separate the two adjacent units. The 2009 IRC now permits the common wall to have a lower rating than the basic walls prescribed by the code and also permits the common wall to be constructed without the structural independence characteristics required by R302.2.

Reason: (Thompson) Code change RB66-07/08 required townhouses constructed in accordance with the International Residential Code to be provided with automatic sprinkler protection. While this new requirement added a fire safety feature to townhouses the code change also reduced the level of fire safety that existed in the code by reducing the fire resistance rating required for the common wall separating dwelling units in townhouses. This code change will restore the previous IRC code requirement that the common wall separating dwelling units in townhouses to have a minimum fire resistance rating of 2-hours. There are several reasons why the common wall fire resistance rating needs to be returned to 2-hours.

First, Code Change RB66-07/08 justified the addition of mandatory sprinkler protection for townhouses based on sprinklers being the best tool for providing additional fire safety in residential occupancies. Given that the 2006 IRC already had an established level of fire safety for residential occupancies utilizing townhouse construction with 2-hour fire rated construction for the common wall, the goal for improving fire safety with the addition of sprinkler protection was not fully achieved. The existing level of fire safety was diminished by the reduction in the fire resistance rating of the common wall from 2-hours to 1-hour.

Second, Code Change RB66-07/08 created an inconsistency in the IRC. If two separate one and two family dwellings are constructed on individual lots and each built at the property line, Section R302.1 and Table R302.1 will require the exterior wall of each structure to be built with a 1-hour fire resistance rating using a fire exposure from both sides. The net result is that both dwellings are separated from the other adjacent, closely located dwelling by wall construction with a total cumulative fire resistance of 2-hours. Yet, if these same two individual structures are physically connected at the property line by a common wall the code permits the fire resistance rating between townhouse units to be reduced to 1-hour. The level of fire safety for these two dwelling configurations is not consistent

This code change achieves the full level of fire safety provided for in residential occupancies through the use of sprinkler protection and built-in fire resistant construction. It also will eliminate the fire safety inconsistency in the IRC between dwelling units built at property lines and dwelling units constructed as townhouses and connected at property lines by a common wall.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: GARDNER-RB-3-THOMPSON-RB-1-R302.2

Public Hearing Results

Committee Action: Disapproved

Committee Reason: The committee recognizes there are similar occupancies in the IBC that allows 1-hour rated separation with fire sprinkler systems. The 1-hour rating should be retained as an incentive to local jurisdictions to retain the fire-sprinkler system.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Michael Gardner, Gypsum Association, requests Approval as Submitted.

Commenter's Reason: We continue to have concerns about the reduction of the hourly rating on the common wall that can be used to separate adjacent townhouse units constructed to the IRC.

Reducing the wall rating places the occupants of the units at greater risk in the event of a sprinkler system failure. It also creates the opportunity for a builder to install a code-compliant common wall with a low STC rating.

Section R302.2 requires townhouses to be considered as separate buildings and to be separated by fire-resistant exterior walls. Because the units are less than 5 feet apart, two independent one-hour walls have to be erected to separate adjacent units.

Prior to 2009, a historical exception to that language allowed the use of a two-hour common wall to separate adjacent units. In 2009, the exception was changed to permit the use of a one-hour common wall; however, the requirement in the body of R302.2 requiring two one-hour walls was not modified. The reduction in rating for the common wall was justified by the language added to the 2009 IRC that required sprinkler systems to be installed in all townhouse units.

Because sprinklers are required in all townhouse construction, the reduction in hourly rating for the common wall is not justified as the exception permitting the one-hour common wall now creates a life safety threshold that is lower than that required by the basic code language of Section R302.2.

Public Comment 2:

Jason Thompson, PE, National Concrete Masonry Association, representing Masonry Alliance for Codes and Standards, requests Approval as Submitted.

Commenter's Reason: As pointed out in the reasoning statement for RB22, last code cycle code change RB66-07/08 justified the addition of mandatory sprinkler protection for townhouses based on sprinklers being the best tool for providing additional fire safety in residential occupancies. However, the existing level of fire safety was diminished in the IRC when RB66 also allowed a reduction in the fire resistance rating of the common wall from 2-hours to 1-hour. In addition code change RB66-07/08 created an inconsistency in the IRC when two separate one and two family dwellings are constructed on individual lots and each built at the property line. The IRC requires the exterior wall of each structure to be built with a 1-hour fire resistance rating with the net result that both dwellings are separated from the other adjacent, closely located dwelling by exterior wall construction with a total cumulative fire resistance of 2-hours. The level of fire safety for two dwelling separated by a common party wall configuration is not consistent with two dwellings separated by individual exterior walls. This code change eliminates this reduction in fire safety for dwellings built with a common wall and removes the inconsistency in the code for the fire resistance rating of walls between dwellings built with separate exterior walls and with common party walls.

Also, requiring the common wall between townhouses to have a 2-hour fire resistance rating is consistent with the requirements for party walls in the IBC. Section 706.1.1 of the IBC requires walls at property lines of adjacent buildings, and used for joint service between buildings, to be constructed as fire walls. IBC Table 706.4 requires fire walls and party walls between Group R-3 occupancies to have a 2-hour fire resistance rating with no reduction in the fire resistance rating for sprinkler protection. Common walls between townhouses (R-3 occupancies) in the IRC should also have 2-hour fire resistance ratings even though the townhouses are provided with sprinkler protection.

Finally the committee reason for disapproval is also not fully valid. The committee claims "there are similar occupancies in the IBC that allows 1-hour rated separation with fire sprinkler systems". That may be true for interior walls separating dwelling units in Group R-2 occupancies. However, building codes have always placed added emphasis on minimizing fire spread between separately owned properties as evidenced by the fire resistance requirements for exterior walls in Table 602 of the IBC and Table R302.1 of the IRC. Where these tables require the exterior walls to have a fire resistance rating no reduction in the fire resistance rating is permitted for fire sprinkler systems. The common wall between townhouses in the IRC, which serves as the exterior wall between separately owned properties, should have a fire resistance rating consistent with other exterior walls and with no reduction permitted for sprinkler protection.

Public Comment 3:

Rick Davidson, representing self, requests Approval as Submitted.

Commenter's Reason: The reduction in the fire rating for the walls separating townhouses to one-hour when only partial sprinkler systems are used is dangerous and short sited.

When the IRC Committee approved this code change, they stated that the IBC permitted reductions in fire ratings in sprinklered buildings so that reduction should be permitted in the IRC. But what the Committee failed to remember is that systems required in the IBC must be monitored and require periodic inspection. Systems permitted in the IRC do not have these safeguards.

Sprinkler systems required by the IRC are not required to be installed in concealed spaces such as attics and crawl spaces or in *attached garages*. Fires that occur or spread to these areas will not have sprinkler protection and the reduction in the fire rating between dwelling units through these areas is not warranted.

This exception allows only a one-hour wall between garages where previously either two one-hour or one two-hour wall would have been required. And no sprinkler protection is required in a garage.

This exception creates a huge inconsistency in exterior wall requirements between townhouses and single- or two-family dwellings that may be built near a lot line and don't enjoy the same reductions in fire ratings as townhouses do.

Sprinkler systems are not infallible. The National Fire Protection Association published a report in June 2007 entitled *"**U.S. EXPERIENCE WITH SPRINKLERS AND OTHER AUTOMATIC FIRE EXTINGUISHING EQUIPMENT**"* by John R. Hall, Jr. In that report Mr. Hall states: *"Based on 2002-2004 fires reported to U.S. fire departments, when sprinklers cover the area of fire origin, they operate in 93% of all reported structure fires large enough to activate sprinklers. When they operate, they are effective 97% of the time, resulting in a combined effectiveness reliability of 90%."*

Sprinkler systems can be shut off. The recent mortgage crises has resulted in scattered townhouse units being foreclosed and water services in these dwelling units shut off by the water utility both for nonpayment and because the dwelling units are not heated, again possibly for non-payment. This is done without the knowledge of the local building departments and even if the building departments knew of the utility shut offs; they are powerless to require a utility to provide service to a nonpaying customer. This results in occupied townhouses separated from non-occupied townhouses that have no sprinkler protection and only a 1-hour fire wall between them. Unoccupied dwellings are presumed to have a higher fire risk due to the potential for arson or vandalism and allowing the reduction in passive fire protection is inappropriate, dangerous, and short sited.

Passive fire protection will always be there.

Public Comment 4:

Rick Thornberry, P.E., The Code Consortium, representing Cellulose Insulation Manufactures Association (CIMA), requests Approval as Submitted.

Commenter's Reason: The International Residential Code Development Committee gave two basic reasons for recommending disapproval of this code change which would have restored the 2-hour fire-resistance rating for the common wall between townhouses allowed in the Exception to

R302.2 to the requirement that each townhouse have a minimum 1-hour fire-resistance rated exterior wall where they are adjacent to each other based on Table R302.1. They are as follows:

1. The Committee recognized that there are similar occupancies in the IBC that allow 1-hour rated separations with fire sprinkler systems.
2. The 1-hour rating should be retained as an incentive to local jurisdictions to retain the fire sprinkler system.

Regarding Item 1, basically the only time the IBC allows a 1-hour reduction in required separations where automatic sprinkler systems are installed is when the sprinkler system is an NFPA 13 sprinkler system. However, the IRC will allow an NFPA 13D or equivalent sprinkler system. As we all know, an NFPA 13D sprinkler system is primarily a life safety system and not a full property protection system. This is clearly stated in Section 1.2 Purpose of NFPA 13D as follows:

1.2.1 The purpose of this standard shall be to provide a sprinkler system that aids in the detection and control of residential fires and thus provides improved protection against injury and life loss.

1.2.2 A sprinkler system designed and installed in accordance with this standard shall be expected to prevent flashover (total involvement) in the room of fire origin, where sprinklered, and to improve the chance for occupants to escape or be evacuated.

But the wall provided to separate adjacent townhouses is not only intended to provide for life safety protection but also property protection so that a total burnout on one side of the wall will not effect the occupancy of the other side. Reducing the rating from 2-hours to 1-hour will significantly increase the likelihood that a total burnout could burn through the wall and cause fire damage and property loss to the townhouse on the opposite side. This is especially important since NFPA 13D sprinkler systems do not require that sprinklers be provided in the attic. Yet the attic will have a significant common space adjacent to the common wall serving both townhouses on each side of the wall. So if a fire gets into or starts in the attic, there is a significantly greater potential that the 1-hour wall currently allowed by the code will be breached.

It should also be noted that the common wall was originally required to have a 2-hour fire-resistance rating since townhouses are considered separate buildings. So the wall acted like a fire wall. This was allowed in lieu of the two 1-hour exterior walls previously noted above. Fire walls in accordance with the IBC also create separate buildings. Table 706.4 in the IBC specifies the minimum fire-resistance rating for fire walls. In no case is a fire wall allowed to have a fire-resistance rating less than 2-hours, even for Group R-3 occupancy buildings.

Regarding Part 2 of the Committee Reason, there should be no need to provide this trade-off as an incentive to local jurisdictions to retain the fire sprinkler system requirements in the IRC. The IRC needs to be treated as an entire code and it must be assumed that the code requirements act as an overall system to provide the required level of protection. This protection level should be based on the code as an entirety and not on the assumption that a jurisdiction may decide to make a modification or an amendment to the IRC when it adopts it for enforcement in that jurisdiction. Such an incentive, in our opinion, is unwise since it relies on the owners of the buildings on opposite sides of the common wall to maintain their automatic sprinkler systems in an operative condition at all times. Unfortunately, there is no supervision required for these systems and no fire department connection is provided for the fire department to boost the sprinkler system water supply as is typical of an NFPA 13 sprinkler system. Furthermore, the water supply to the system could be shut off for repairs and not turned back on since no supervision of the control valve supplying the water supply to the sprinkler system is required if the valve is locked open. Obviously, the owner of the townhouse would have the key to the lock on the valve so there would be nothing to prevent the owner from unlocking the lock and closing the valve for whatever reason. And it is not uncommon for the valve to remain closed since there is no supervisory reminder that the valve remains closed. It could easily be forgotten after the repairs have been made to the system.

There is also the question of the reliability of the sprinkler system water supply. Will it be available at all times when there is the possibility of a fire occurring? This is especially important in high seismic activity areas where fires often start soon after an earthquake and the water supplies in many cases are out of service due to main breaks and loss of power for extended periods of time.

In conclusion, we believe the reduction from 2-hours to 1-hour for the common wall separating townhouses as an Exception to the otherwise required 1-hour exterior walls for each townhouse is not justified for sprinkler systems installed based on NFPA 13D or an equivalent sprinkler system design. Thus, we strongly urge the Class A voting members to overturn the Committee's recommendation for disapproval and vote to approve this code change.

Final Action: AS AM AMPC____ D

RB23-09/10

R302.2.1, Figures R302.2.1(1)-R302.2.1(2)-R302.2.1(3) (New)

Proposed Change as Submitted

Proponent: Larry Wainright, Qualtim, Inc., representing the Structural Building Components Association (SBCA)

1. Revise as follows:

R302.2.1 Continuity. The fire-resistance-rated wall or assembly separating *townhouses* shall <u>have a fire-resistance rating that is</u> ~~be~~ continuous from the foundation to the underside of the roof sheathing, deck or slab. The fire-resistance rating shall extend the full length of the wall or assembly, including wall extensions through and separating attached enclosed *accessory structures*. <u>Where the fire-resistance-rated wall or assembly is not continuous, the fire resistance rating shall be deemed continuous provided one of the following conditions is met:</u>

<u>1.</u> <u>A minimum one hour fire-resistance rating is provided on the floor or roof assembly that interrupts the fire-resistance rated wall. Fireblocking shall be provided per Section R302.11 (see Figure R302.2.1(1)). Or</u>

<u>2.</u> <u>Where an unrated floor or roof assembly interrupts the fire-resistance rated wall, the fire-resistance rating shall be deemed continuous provided:</u>

<u>2.1.</u> <u>Where two one-hour walls are provided, a minimum of one 2x full height fireblock shall be installed in each of the one-hour walls as shown in Figure R302.2.1(2).</u>

<u>2.2.</u> <u>Where one two-hour wall is provided, a minimum of two 2x full height fireblocks shall be installed on each side of the two-hour walls as shown in Figure R302.2.1(3).</u>

2. Add new figures as follows:

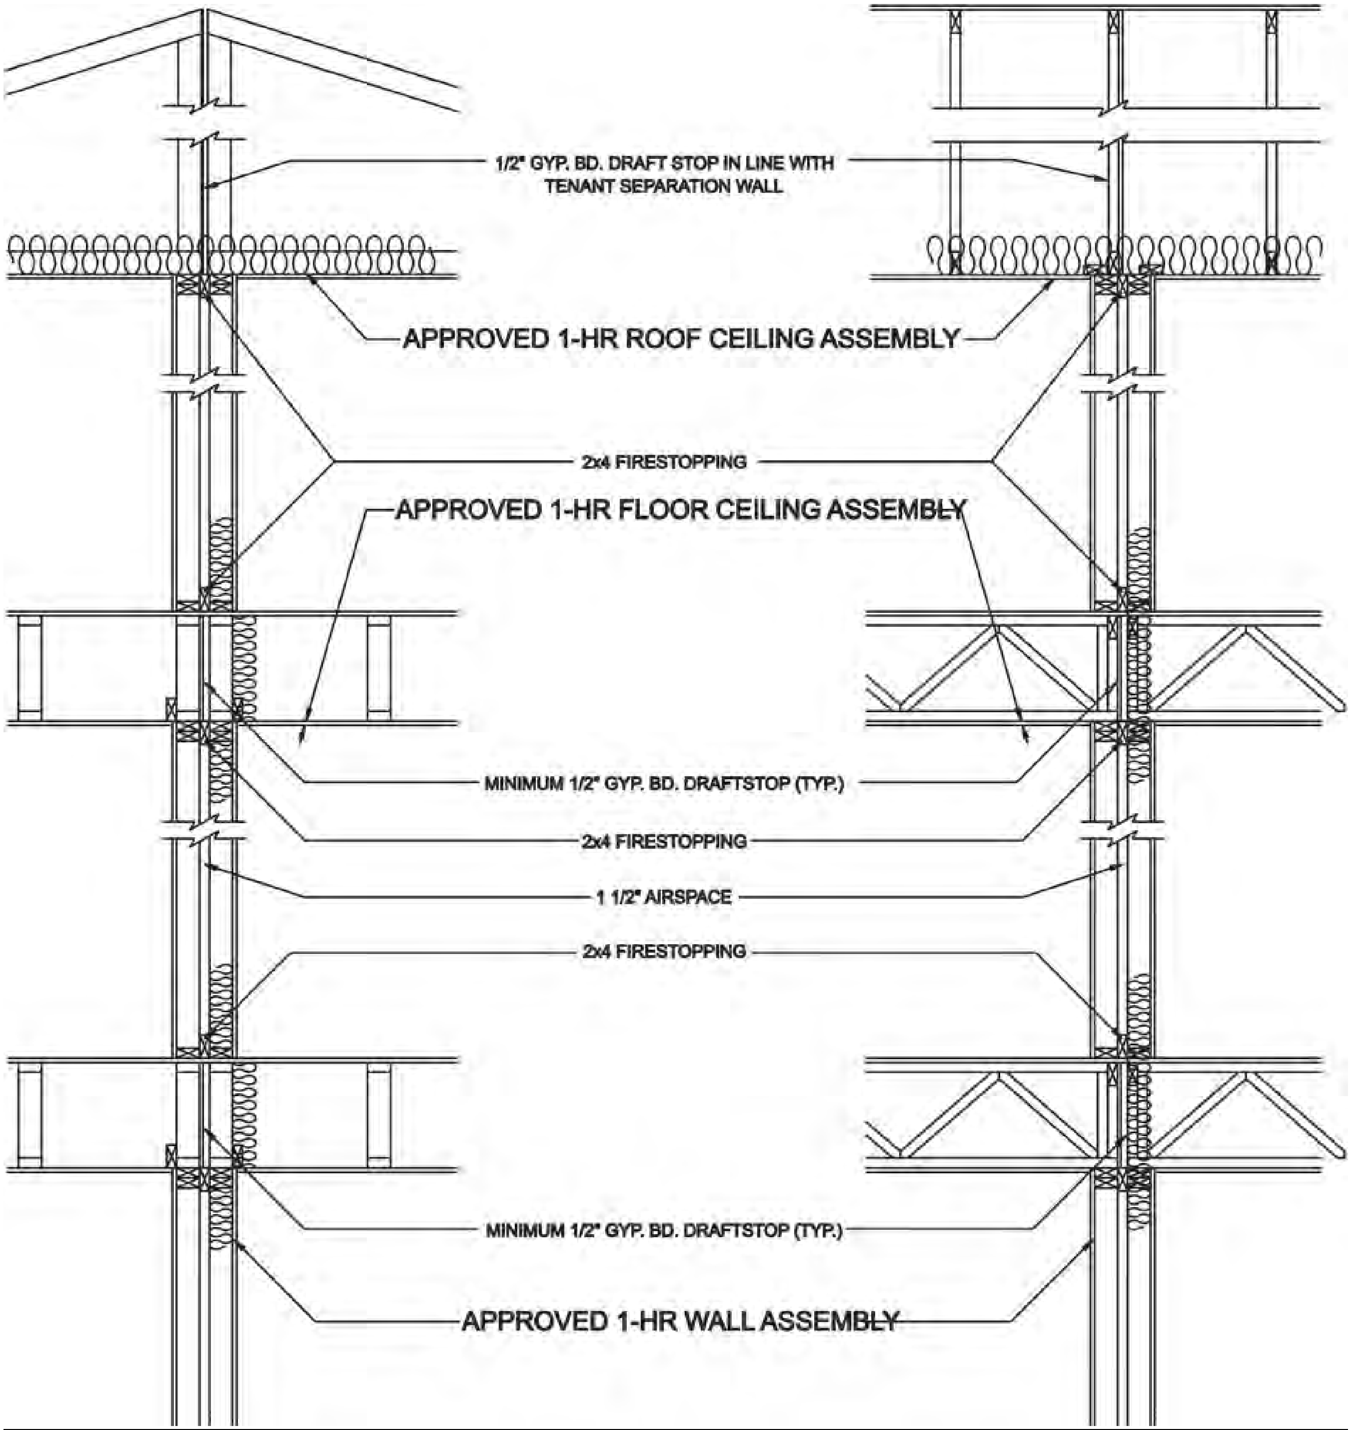

FIGURE R302.2.1(1)
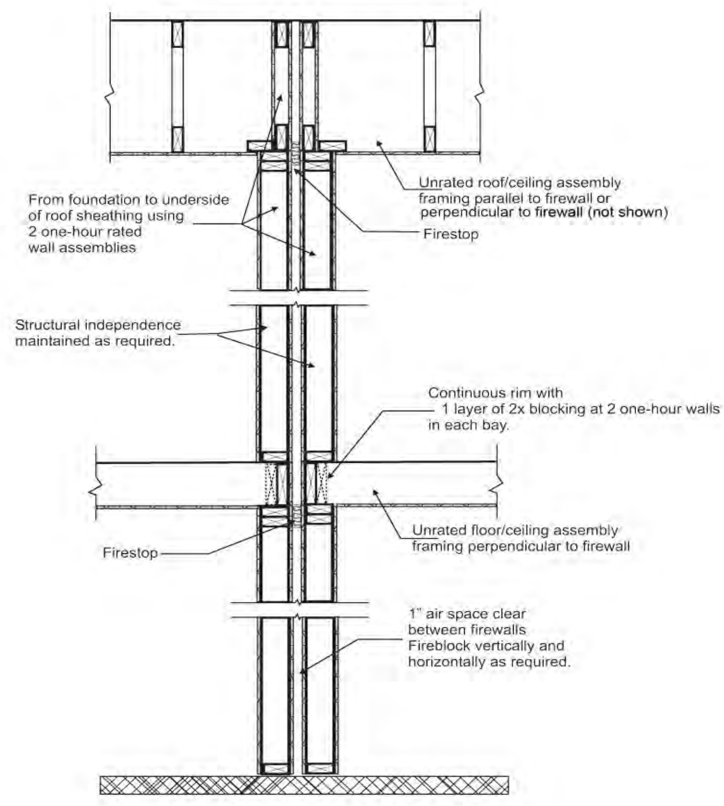
Example assemblies that can be used to make up a one-hour rated system for separation between occupancies



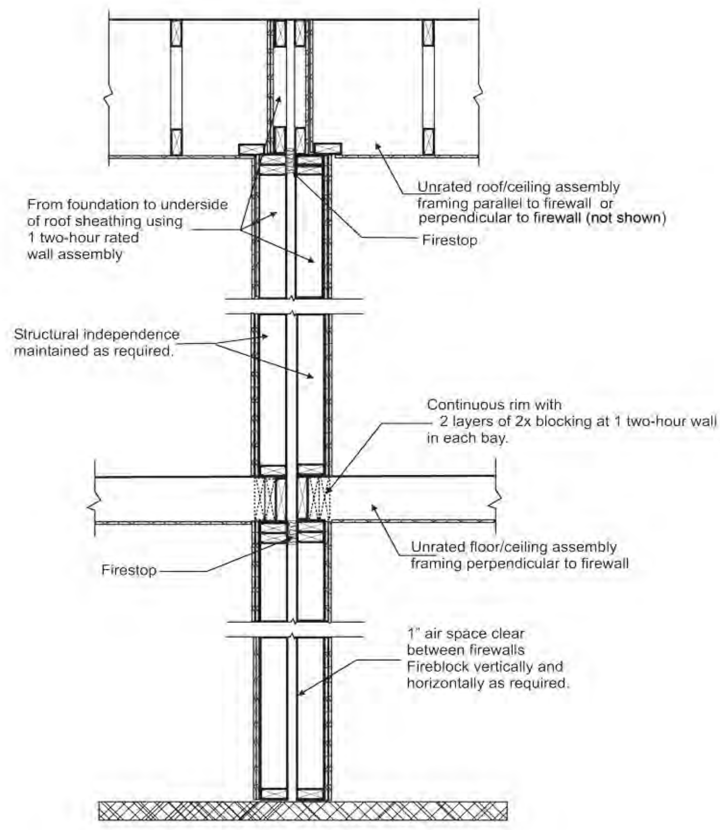


FIGURE R302.2.1(2)

FIGURE R302.2.1(3)

Reason: The purpose of this code change is to clarify an existing provision within the code and to provide a prescriptive solution to that provision. First, it is necessary to clarify that is the fire-resistance rating of the wall assembly that needs to be continuous from the foundation to the underside of the roof sheathing, not necessarily the framing itself. Second, the prescriptive solution gives some guidance on one way the fire-resistance rating can be maintained, while allowing for framing members to bear on the wall. The use of full height blocking to attain the required fire-resistance rating is based on the use of sacrificial material and char rates based on ASTM E119 testing. Under ASTM E119 test conditions, lumber will char at a rate of 1 inch per 30-40 minutes. Therefore, at least 2 inches of sacrificial material is required to achieve the one hour rating. Likewise, 4 inches is required to achieve a 2 hour rating. Further information can be found in an article published and located at the following link: www.sbcmag.info/Archive/2006/sep/0609_code.pdf

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: WAINRIGHT-RB-3-R302.2.1

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The language of this change is unclear and confusing. The details are not clear how they relate to tested assemblies. There are a lot of terms that are not defined. The figures limit the prescriptive solution to one specific way and there may be many others that would be acceptable. This should be reworked and brought back.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Larry Wainright, Qualtim, Inc., representing Structural Building Components Association (SBCA), requests Approval as Modified by this Public Comment.

Replace proposal as follows:

R302.2 Townhouses. Each *townhouse* shall be considered a separate building and shall be separated by fire-resistance-rated wall assemblies meeting the requirements of Section R302.1 for exterior walls.

> **Exception:** A common 1-hour fire-resistance-rated wall assembly tested in accordance with ASTME 119 or UL 263 is permitted for townhouses if such walls do not contain plumbing or mechanical equipment, ducts or vents in the cavity of the common wall. The wall shall be rated for fire exposure from both sides and shall extend to and be tight against exterior walls,<u> floor assemblies, ceiling assemblies </u>and the underside of the roof sheathing. Electrical installations shall be installed in accordance with Chapters 34 through 43. Penetrations of electrical outlet boxes shall be in accordance with Section R302.4.

R302.2.1 Continuity. The fire-resistance-rated wall<u>s</u> and/or assembl<u>ies</u>~~y~~ separating *townhouses* shall <u>form a continuous fire-resistance rating that is</u> ~~be~~ continuous from the foundation to the underside of the roof sheathing, deck or slab. The fire-resistance rating shall extend the full length of the wall or assembly, including wall extensions through and separating attached enclosed *accessory structures*.

<u>Where a roof or floor assembly breaks the continuity of the fire-resistance rated wall, fire blocking shall extend from the top of the wall framing to the bottom of the floor or roof sheathing above. The following shall be considered acceptable fire blocking materials when designed and installed in the interstitial space above the fire-resistance rated wall:</u>

1. Two layers of 2 inch nominal lumber fire blocking,
2. Two layers of 1-1/8 inch engineered rimboard,
3. Two layers of 5/8 inch Type X gypsum wallboard,
4. Two layers of 23/32 inch wood structural panels or
5. Other approved materials with equivalent fire resistance.

Commenter's Reason: The purpose of this public comment is to clarify an existing provision within the code. First, it is necessary to clarify that it is the fire resistance rating of the wall assembly that needs to be continuous from the foundation to the underside of the roof sheathing, not necessarily the framing itself. Second, when the framing is not continuous, direction is given to provide some guidance on how the fire resistance rating can be maintained, while allowing for roof and floor assembly framing members to bear on the fire-resistance rated wall. In townhouse construction, shorter floor framing spans are usually achieved by spanning to the common walls thereby increasing design efficiencies and potentially lowering the cost of construction.

While disapproved at the code development hearings, the committee asked that this be reworked and brought back. There were several concerns with the original proposal. First, the details originally provided have been removed because they caused some confusion and only provided one possible solution to this problem; and while wood trusses were shown in the details, the provisions would apply equally to all framing types. Second, it is important to reiterate that fire blocking is necessary to insure that if a fire gets in the floor/ceiling cavity, it cannot continue unimpeded into the separation wall. Third, the fire blocking in the floor/ceiling cavity above the separation wall needs to be sufficient to maintain the fire resistance rating of the wall. The use of full height fire blocking to attain the required fire-resistance rating is based on the use of sacrificial material and char rates based on ASTM E119 testing. Under ASTM E119 test conditions, lumber will char at a rate of 1 inch per 30-40 minutes. Therefore, at least 2 inches of sacrificial material is required to achieve the one hour rating. Further information regarding this testing can be found in an article published and located at the following link: www.sbcmag.info/Archive/2006/sep/0609_code.pdf.

Final Action: AS AM AMPC____ D

RB24-09/10

R302.2.2

Proposed Change as Submitted

Proponent: Jeffrey Anderson, representing the Chesterfield County Department of Building Inspections, Chesterfield, VA

Revise as follows:

R302.2.2 Parapets. Parapets constructed in accordance with Section R302.2.3 shall be constructed for *townhouses* as an extension of exterior walls or common walls in accordance with the following:

1. Where roof surfaces adjacent to the wall or walls are at the same elevation, the parapet shall extend not less than 30 inches (762 mm) above the roof surfaces.
2. Where roof surfaces adjacent to the wall or walls are at different elevations and the higher roof is not more than 30 inches (762 mm) above the lower roof, the parapet shall extend not less than 30 inches (762 mm) above the lower roof surface.

   Exception: A parapet is not required in the two cases above when the roof is covered with a minimum class C roof covering, and the roof decking or sheathing is of noncombustible materials or *approved* fire-retardant-treated wood for a distance of 4 feet (1219 mm) on each side of the wall or walls, or one layer of 5/8-inch (15.9 mm) Type X gypsum board is installed directly beneath the roof decking or sheathing, supported by a minimum of nominal 2-inch (51 mm) ledgers attached to the sides of the roof framing members, for a minimum distance of 4 feet (1219 mm) on each side of the wall or walls and there are no openings or penetrations in the roof within 4 feet (1219 mm) of the exterior or common walls.

3. A parapet is not required where roof surfaces adjacent to the wall or walls are at different elevations and the higher roof is more than 30 inches (762 mm) above the lower roof. The common wall construction from the lower roof to the underside of the higher roof deck shall have not less than a 1-hour fire-resistance rating. The wall shall be rated for exposure from both sides.

Reason: This change is proposed to provide consistency between the IRC and the IBC. Specifically, to make IRC Section R302.2.2 consistent with IBC Section 705.11(4). This change would make townhouse construction consistent between both the IRC and the IBC for this type construction.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: ANDERSON-RB-1-R302.2.2

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: This change would impose severe restrictions on penetration at the roof. This does not mirror the IBC requirement on this issue.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Steve Orlowski, National Association of Home Builders (NAHB), requests Approval as Modified by this Public Comment:

Modify the proposal as follows

R302.2.2 Parapets. Parapets constructed in accordance with Section R302.2.3 shall be constructed for *townhouses* as an extension of exterior walls or common walls in accordance with the following:

1. Where roof surfaces adjacent to the wall or walls are at the same elevation, the parapet shall extend not less than 30 inches (762 mm) above the roof surfaces.
2. Where roof surfaces adjacent to the wall or walls are at different elevations and the higher roof is not more than 30 inches (762 mm) above the lower roof, the parapet shall extend not less than 30 inches (762 mm) above the lower roof surface.

   Exception: A parapet is not required in the two cases above when the roof is covered with a minimum class C roof covering, and the roof decking or sheathing is of noncombustible materials or *approved* fire-retardant-treated wood for a distance of 4 feet (1219 mm) on each side of the wall or walls, or one layer of 5/8-inch (15.9 mm) Type X gypsum board is installed directly beneath the roof decking or sheathing, supported by a minimum of nominal 2-inch (51 mm) ledgers attached to the sides of the roof framing members, for a minimum distance of 4 feet (1219 mm) on each side of the wall or walls and there are no openings or penetrations in the roof within 4 feet (1219 mm) of the ~~exterior or~~ common walls.

3. A parapet is not required where roof surfaces adjacent to the wall or walls are at different elevations and the higher roof is more than 30 inches (762 mm) above the lower roof. The common wall construction from the lower roof to the underside of the higher roof deck shall have not less than a 1-hour fire-resistance rating. The wall shall be rated for exposure from both sides.

Commenter's Reason: NAHB urges the attendees of the final action hearing to overturn the committees action and approve this proposal as modified. One of the concerns that the fire service reports is the spread of fires along the roof of adjoined dwellings, like townhouses. To allow penetrations to be within four feet of the firewall, defeats the purpose of requiring fire retardant lumber or 5/8 type x gypsum on the underside of the roof membrane. Any opening within the four feet poses as a potential hazard which will allow the passage of flames to impinge upon the adjoining dwelling unit. This code change will have a minimum impact on the cost of construction and will result in lowering the number of fire that spread along the roof.

Final Action: AS AM AMPC____ D

RB26-09/10
R302.5.1

Proposed Change as Submitted

Proponent: Sean DeCrane, Cleveland, OH Fire Department, representing the Cleveland Fire Department and the International Association of Fire Fighters

Revise as follows:

R302.5.1 Opening protection. Openings from a private garage directly into a room used for sleeping purposes shall not be permitted. Other openings between the garage and residence shall be equipped with solid wood doors not less than 13/8 inches (35 mm) in thickness, solid or honeycomb core steel doors not less than 13/8 inches (35 mm) thick, or 20-minute fire-rated doors <u>equipped with a self-closing device</u>.

Reason: There are times when proposed code submittals require a very lengthy substantiation, and then there are times when code change proposals just make sense. I would believe this is one of those times where a code change proposal makes a lot of sense. We are seeking a requirement to install items for very minimal costs yet great life saving potentials.

As we place greater amounts of thermoplastics in our homes and garages, especially kids' toys, we are increasing the fuel load and toxic by-products. The most obvious by-product of incomplete combustion is carbon monoxide. We know how deadly carbon monoxide is to the occupants of homes. Carbon monoxide is also a by-product of the internal combustion engine. Especially during the winter months the fire service responds to numerous cases of potential carbon monoxide incidents. With an open door between the living quarters and the garage, where the car is warming up for the trip to work, we are allowing the free flow of carbon monoxide from the garage into the home. Some may not believe there is a concern with this situation and may also point out some difficulty in reporting the data of exactly how many individuals were killed by these incidents. Creating and submitting code proposals is about the present but also the future. With the reversal of the code requirement of a self closing door we are allowing millions of homes to be built with a potential safety hazard. Carbon monoxide is a silent and deadly killer and in many incidents the victims do not realize they are slowly being exposed to potentially life threatening levels of carbon monoxide. This is one of the reasons the ICC membership voted to require the installation of carbon monoxide detectors.

We know that requirement of carbon monoxide detectors will save lives. In fact, I have seen numerous responses where a detector alerted an occupant to the presence of dangerous amounts of carbon monoxide, which in turn, allowed them to notify the fire department. With a lack of a requirement of a self closing door we have the potential of creating a Peter Cried wolf situation that will be played out across the country. A self closing door helps to protect the occupants of a home from the dangers in the garage. During the fall and winter months many occupants warm their car before leaving for work or to run an errand. With the increase use of remote starters many of these individuals are engaging their vehicle without visual contact. This creates a potential for the migration of carbon monoxide to the living quarters, even if this amount is not in a lethal range it will be in range to initiate a response from the CO detector, thereby, requiring a response from the local fire department. A response to requires fire fighters and equipment and incurs costs. It also places a responding company in emergency mode while responding increasing the risks to those fire fighters and other drivers at an increased risk. If the fire service downgrades responses to CO alarms then we risk the potential of placing citizens at risk who are truly experiencing a CO emergency. The argument is not to remove the detectors but to place an added protection of a self closing door between the living quarters and the garage.

Even if an individual does not believe that Carbon Monoxide is a true threat there are additional products of combustion that are far deadlier than CO. Hydrogen Cyanide is increasingly being identified as a potential life hazard in fire incidents. In a report published by the Cyanide Poisoning Treatment Coalition, it is reported when the National Institute of Occupational Safety and Health completed their studies of the tragic Station Night Club fire in Warick, RI they found "Within seconds of the ignition of the fire, concentrations of the toxic products carbon monoxide and hydrogen cyanide soared and oxygen levels plummeted to create conditions incompatible with sustaining life"[1]. The report noted "that hydrogen cyanide is approximately 35 times more toxic than carbon monoxide during acute exposure". In tests conducted and referenced by the report, "a series of experiments the Swedish National Testing and Research Institute (SNTRI), assessed the emission of hydrogen cyanide and carbon monoxide under both non-flaming (i.e. pyrolizing) and flaming (i.e. fire) conditions during burning of wool, nylon, synthetic rubber, melamine, and polyurethane foam. The results show that all of these substances liberated high quantities of cyanide when burned-particularly under pyrolizing conditions characterized by low oxygen". If we take a step back and look at most garages, when the garage door is closed, they are box structures that will allow smoke and the by-products of a fire to travel in the least restrictive path, the open door. An open door between the garage and living quarters allows the easy access for the highly toxic by-products of combustion.

To summarize, deadly by-products of combustion, accidental carbon monoxide poisonings from vehicles and needless nuisance alarms are strong, and compelling, arguments to support this code change proposal requiring self closing doors between the garage and living areas in one and two-family homes.

[1] *Smoke Perceptions, Myths and Misunderstandings*, Cyanide Poisoning Treatment Coalition

Cost Impact: The code change proposal will minimally increase costs of construction.

ICCFILENAME: DECRANE-RB-3-R302.5.1

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: There is no data presented to substantiate the need for the door closer. This is a fire-rated door in a non-rated wall assembly and there is no reason for sealing or a closer. Other doors are permitted without a closer. The owner can disable this manually upon the certificate of occupancy.

Assembly Action: **Approved as Submitted**

Individual Consideration Agenda

This item is on the agenda for individual consideration because the proposal received a successful assembly action and public comments were submitted. Note that the assembly action, Approved as Submitted, will be the initial motion on the floor for consideration when this item is called.

Public Comment 1:

George Kellogg, City of Rocklin, representing The Sacramento Valley Association of Building Officials, requests Approval as Submitted.

Commenter's Reason: In disapproving this proposed code change the committee mentioned three general areas of concern that included lack of substantiation for the closure, a separation that has no special significance, and a safety device that can be disable. The proposal would have added the requirement for a self closing device to a door between an attached garage and a dwelling unit. From personal experience, in forensic follow up on a fire that involved the house-garage separation, I have seen how the assembly of the old UBC, that included a self closing door, performed. The assembly performed well, slowing the fire that started in the attached garage, allowing the fire department time to arrive and save the residence. The fire had spread though a fixture into the attic but was stopped at the wall between the garage and the kitchen which included a closed fire door. Eventual fire breaching occurred at the ceiling openings rather than the door. Bottom line here is that the rated closed door made a real difference. That someone can disable a safety device should never be a reason for not providing it in the first place. Regarding the committee's comment that other doors are permitted without a closer, I hope no one is mistaking other doors in a residence as being the same situation as the door between the garage and the house. The code itself in the present form makes specific requirements for this door in the separation between the garage and dwelling unit.

Public Comment 2:

Rick Davidson, representing self, requests Disapproval.

Commenter's Reason: This proposal was disapproved by the IRC Committee.

Almost annually, the membership is faced with a proposal to require closers on doors between the house and garage. The membership has consistently voted these proposals down. Primary among the reasons for these proposals being turned down is the lack of any documentation indicating closers on these doors increases the safety of the buildings. In fact, certain legacy codes, including the code on which the IRC was based, did not require closers on these doors and there is no documentation to indicate that homes built under these codes are any less safe than ones that were not.

With this proposal, one argument seems to be the proponents feeling that it "Makes Sense". But what "makes sense" to one person may not "make sense" to someone else. Code changes should be based on need supported with necessary documentation, not just on whimsy.

As is sometimes the case, anecdotal testimony is given to support proposals. But anecdotal testimony is not credible if it is not backed up by studies, statistics and research. There is almost always an equal amount of anecdotal evidence to suggest the contrary.

In this case, it has been argued without substantiation that people will throw open the door to a garage fire and leave it open and allowing the fire to spread into the house. For years the fire service has taught that whenever someone suspects a fire on another side of a door that they should feel the temperature of the door and not open it if they believe there is a fire on the other side. Has this teaching gone by the wayside?

This door will ordinarily be closed for security or to keep out heat or cold. Most people understand the concept of containing a fire in a garage and will close the door if, for some reason, they had opened it.

The code does not require a fire separation between the dwelling and garage. It only requires that gypsum board be placed on the garage side of the wall between the house and garage. Gypsum board joints are not required to be treated. Doors between the house and garage are not required to be rated. The proposal requires that these non-rated doors have ***self-closing*** devices. The term as it is applied here is undefined. Remember, these are not rated doors. A self closing device could mean spring hinges or it could mean a screen door spring or a rope, pulley, and a weight. There is no guidance in the language to encourage uniform enforcement. The language doesn't state that the self-closing device must be "approved". Therefore the building owner is fully within their rights to use whatever type of closer will slam the door shut.

And, the argument is made that the door is necessary to stem the flow of carbon monoxide into the home when cars are started in a garage to warm up and more than half of the space given to the argument focuses on carbon monoxide. Testimony was given at the Baltimore hearings that cold engines give off more carbon monoxide adding more danger. This is all anecdotal testimony.

The amount of carbon monoxide given off by cold engines is overstated. According to the US Environmental Protection Agency and in recognition of the fact that cold engines give off more CO, the 1990 Clean Air Act calls for 1994 and later cars and light trucks to meet federal carbon monoxide standards at 20 degrees Fahrenheit whereas the old rules required those standards be met at 75 degrees Fahrenheit. So the risk of increased CO levels emitting from cold engines is significantly reduced. Additionally, new car engines warm quickly reducing the time when any elevated levels of CO may occur.

Furthermore, following are excerpts from an article entitled:

The Role of Catalytic Converters in Automobile Carbon Monoxide Poisoning[*] A Case Report by Bradley Vossberg, MD and Judah Skolnick, MD, FCCP
[*] From the Frazier Rehab Center, Jewish Hospital Health Network, Louisville, KY.

> *Inhaling motor vehicle exhaust fumes is a common method used by people attempting to commit suicide; however, the decreased carbon monoxide concentrations found in the exhaust of late-model automobiles equipped with catalytic converters are changing the clinical presentation of exhaust inhalation.*
>
> *Closed-environment exposure to MVEGE from automobiles not equipped with catalytic converters can result in death within 30 min. The introduction of catalytic converters beginning with 1975 new-car models dropped CO emission rates to 6.00 g/min. By 1989, the average new-car CO emission at idling was 0.22 g/min. The catalytic conversion process removes CO, hydrocarbons, and nitrogen oxide; the resultant emission is a more desirable mixture of nitrogen, CO_2, and water.* ***Contemporary three-way catalytic converters eliminate > 99% of CO emissions.***
>
> *Given the increased efficiency of modern catalytic converters, patients presenting with closed-environment MVEGE exposure may have much lower HbCO levels than would have been previously expected; in some cases, the HbCO level may be normal. Other important factors to be considered are the role of supplemental O_2 given at the scene and the time taken to obtain the HbCO level.*

More findings related to carbon monoxide poisoning can be found in a technical paper entitled "***Reducing the Risk of Accidental Death Due to Vehicle-Related Carbon Monoxide Poisoning***" by **Linsey C. Marr, Glenn C. Morrison, William W. Nazaroff, and Robert A. Harley,** *Department of Civil and Environmental Engineering, University of California, Berkeley, California.* This technical paper reports on studies and analysis of computer modeling undertaken to determine the risk of death from CO poisoning in homes and garages from automobile exhaust. Among the findings: "The risk of death ranged from 16-21% for a 3-hr exposure ***in*** a garage to 0% for a 1-hr exposure in a house."

With any study with so many variables, one can question the validity of the study. This one is no different. Among the difficulties in modeling the conditions were numerous variables including:

- Age and condition of the motor vehicle
- Air exchange rates for the garage and dwelling
- Size of the garage and dwelling
- Length of time the vehicle is running
- Amount of fuel in the fuel tank
- Age and health of the individual
- Temperature and weather conditions
- Newer vehicles have more effective catalytic converters
- Socioeconomic factors may result in older, less efficient vehicles stored outside or garages with higher air exchange rates

But the study was based on very conservative conditions and it was pointed out that the risks may actually be overestimated.

The study points out that unintentional CO deaths from automobiles do occur. But most all of these deaths occurred ***in*** the garage. The most frequent cause of CO deaths were a driving into a garage (often under the influence of alcohol or drugs) and leaving the engine running (42% of deaths) and starting the car to perform vehicle maintenance (25%) or to provide heat (23%).

Importantly, the study points out that even these deaths are dropping at a rate of about 7% a year as older vehicles are replaced by newer, more efficient ones. In fact, in the technical paper by **M. Shelef** titled "***Unanticipated benefits of automotive emission control: Reduction in fatalities by motor vehicle exhaust gas***" SAE Technical Paper No. 922335, Society of Automotive Engineers: Warrendale, PA, 1992, Shelef argued that reducing CO poisoning deaths may be the biggest benefit from current motor vehicle emission control programs, even though the programs are motivated by concentration standards for outside air.

After reading the various reports and studies on automobile carbon monoxide emissions, it is difficult to come to any conclusion that automobile generated carbon monoxide creates any sort of hazard in the home that would be mitigated by putting closers on garage doors and the proponent has provided no statistical evidence that it does.

But beyond that, it is necessary to look at what you are asked to believe is common practice. That is that a home occupant would start their car parked in a cold garage, go into the home leaving the door open, and allow the carbon monoxide as well as the noise and cold air to enter the house unabated and ignored. Then you are further led to believe that the homeowner would allow this to happen long enough for carbon monoxide levels to build to dangerous levels all the while forgetting why they started the automobile in the first place. This is a fairy tale.

I suggest that people will not leave the door to a frigid garage open, they will not want the cold air and noise to infiltrate their home, and they will not leave the automobile running for extended periods of time but will continue on with whatever caused them to start the automobile in the first place.

Last, the argument is made that the door is necessary to protect the occupants of the dwelling from hydrogen cyanide. The example is then given of the Station Night Club fire and the deaths that resulted from that tragedy. But comparing the circumstances surrounding an old overcrowded night club and a new dwelling are like comparing apples and horse shoes. They are two different types of structures housing two different occupancies.

Homes have multiple smoke alarms. If a fire occurs in a garage and smoke enters the home by whatever means, the smoke alarms would sound allowing the occupants to exit. There is no technical data to support the notion that a garage door would frequently be left open and that fires spread into dwellings through these open doors.

As code officials, we are morally and ethically obligated to explain to a homeowner why a code requirement exists. How can we, with any honesty, tell a homeowner that they must comply with a rule that has no basis in fact? It "makes sense" that we shouldn't require the public to spend money to correct a problem that doesn't exist. Please support the IRC Committee's action for disapproval.

Final Action: AS AM AMPC____ D

RB31-09/10
R302.7 (New), R502.14 (New), Table R502.14 (New)

Proposed Change as Submitted

Proponent: Dennis Pitts, American Forest and Paper Association

Add new text and table as follows:

R302.7 Floors. Floor assemblies, not required elsewhere in this code to be fire resistance rated, shall be provided with a ½ inch (12.7 mm) gypsum wallboard ceiling membrane.

Exception:

1. Floor assemblies protected by an automatic sprinkler system in accordance with NFPA13, NFPA 13R, NFPA13D, or Section R313.
2. Floor assemblies having a minimum fire resistance of 15 minutes, supporting at least 50% of the full design load, and complying with one of the following:
   2.1. Tested in accordance with ASTM E119 or UL 263, or;
   2.2. Determined in accordance with *International Building Code* Section 721.
3. Floor assemblies located directly over a crawl space.
4. Floor assemblies complying with Section R502.14.
5. A portion of a floor assembly area not greater than 100 square feet per story.

R502.14 Fire resistant assemblies. Wood floor assemblies shall comply with the provisions of Section R302.7 or any one of the following:
1. Wood floor assemblies using dimension lumber equal to or greater than 2 inches in thickness by 8 inches in width, nominal.
2. Wood floor assemblies using structural composite lumber, complying with ASTM D5456, equal to or greater than 1 ½” in thickness by 7 ¼” in width.
3. Wood floor assemblies having a minimum fire resistance time of 15 minutes determined from any of the following options or the sum of the times from any combination thereof:
   3.1. Time assigned to a ceiling membrane or membranes in Table 502.14.
   3.2. Finish rating time for a ceiling membrane not listed in 502.14.
   3.3. Time to structural failure of framing members, supporting at least 50% of the full design load, and complying with one of the following:
      3.3.1. Tested in accordance with ASTM E119 or UL 263, or;
      3.3.2. Determined in accordance with *International Building Code* Section 721.

TABLE R502.14
TIME ASSIGNED TO CEILING MEMBRANES

DESCRIPTION OF FINISH	TIME (MINUTES)[A]
3/8” gypsum *board*	*10*
½” gypsum board	*15*
5/8” gypsum board	20
½” Type X gypsum board	25
5/8” Type X gypsum board	40
Double 3/8” gypsum board	25
3/8” wood structural panel	5
½” wood structural panel	10
5/8” wood structural panel	15

a. Times for individual membranes are additive.

Reason: The fire service has asked for minimum fire resistance of floor/ceiling systems equivalent to 2x lumber floor construction. The basis of the requirements assume that a floor/ceiling assembly constructed using 2x lumber and loaded to 50% of full design load will provide 15 minutes of structural fire resistance as confirmed by recent UL testing reported in *Structural Stability of Engineered Lumber in Fire Conditions*.

The proposed R302.7 provides a simple method of meeting this 15 minute requirement for all floor assemblies by requiring ½” gypsum wallboard as a protective ceiling membrane. Exceptions to this requirement are provided.

The proposed R502.14 provides additional methods of meeting this 15 minute requirement for wood floor framing, including different options for ceiling membrane protection recognized in IBC 721.6, finish ratings from approved ASTM E119 test reports, fire test results from ASTM E119 tests, structural fire resistance calculations per IBC 721.1, or any combination of these provisions.

The proposed Table R502.14 is taken from IBC Table 721.6.2(1).

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: PITTS-RB-3-R302.7-R502.14

Public Hearing Results

Committee Action: Disapproved

Committee Reason: The committee feels this is a good start and the proponent should work with the proponents of RB85-09/10 through RB88-09/10 to bring back a solution that protects the firefighters and the occupants. The modification that was ruled out of order would be a good basis to begin for rework and bring back. There should be ways other than fire-rating to achieve the solution. Also, this change would force the use of dimensional lumber.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Jonathan Humble, AIA, American Iron & Steel Institute, representing American Iron and Steel Institute and Steel Framing Alliance, requests Approval as Modified by this Public Comment.

Replace proposal as follows:

R302.7 Floor separation. Floor assemblies within dwelling units shall have a minimum of ½ inch (12.7 mm) gypsum board applied to the underside of the framing members in accordance with R702.3, when not required elsewhere in this code. This provision shall not supersede Sections R302.3, R302.4 or R302.5 where fire resistance ratings or greater thicknesses of gypsum board are required. Penetrations through the gypsum board shall be allowed for stairways, ducting, piping, and electrical and telecommunications outlet boxes, wiring and conduits.

Exceptions:

1. Floor assemblies located over crawl spaces, where the crawl space does not contain mechanical equipment or water heater(s).
2. Dwellings protected with an automatic sprinkler system designed and installed in accordance with NFPA 13D or in accordance with Section P2904.

(Renumber remaining sections)

Commenter's Reason: We propose to modify the original proposal with a product and provision neutral approach to code enforcement. At the 2009 code hearings there were five (5) proposals on the same subject. Each had their own spin on the approach to a design which would accomplish the goal of providing the fire service with some separation of spaces from spaces where framing members that are normally exposed in dwellings today. In this case that separation is gypsum board, not unlike the protection outlined in IRC Section R302.6. Unfortunately, it was the number of variations and subsequent opinions of preference which convinced the code development committee to recommend disapproval for all five of those proposals (e.g. RB31, RB85, RB86, RB87, and RB88).

The modification acts on the following aspects:

Title:
The title chosen is "floor separation" which more appropriately describes the intent.

Neutral Approach:
The modification before you attempts to neutralize those original opinions by focusing on the basic applications necessary for that separation. The modification is product neutral, meaning it applies to all light frame constructions without exception. In addition, the provision is proposed for inclusion into Chapter 3 which further retains that neutrality.

Coordination:
The modification coordinates the other provisions which require gypsum board by referencing the specific sections and the priority, in the second sentence.

Penetrations:
The modification also addresses the impact of stairs, ducting, piping and electrical wiring and conduit penetrating the gypsum board ceiling, in the third sentence.

Exceptions
The modification includes only those exceptions that were found to be a common theme amongst the five original proposals, and practical for this application.

Public Comment 2:

Larry Wainright, Qualtim, Inc, representing Structural Building Components Association (SBCA), requests Approval as Modified by this Public Comment.

Replace proposal as follows:

R302.7 Fire protection of floors. Floor assemblies, not required elsewhere in this code to be fire resistance rated, shall be provided with a ½ inch (12.7 mm) gypsum wallboard membrane, 5/8 inch (15.9 mm) wood structural panel membrane, or equivalent on the underside of light frame construction, steel bar joists and wood chord / metal web joists.

Exceptions:

1. Floor assemblies located directly over a space protected by an automatic sprinkler system in accordance with Section P2904, NFPA 13D, NFPA 13R or NFPA 13.
2. Floor assemblies located directly over a crawl space not intended for storage or fuel-fired appliances.
3. Portions of floor assemblies can be unprotected when complying with the following:
   3.1 The aggregate area of the unprotected portions shall not exceed 80 square feet per story
   3.2 Fire blocking in accordance with Section R302.11.1 shall be installed along the perimeter of the unprotected portion to separate the unprotected portion from the remainder of the floor assembly.

NFPA 13R—07 Installation of Sprinkler Systems in Residential Occupancies Up to and Including Four Stories in height.

Commenter's Reason: RB31-09/10 merely proposes to require a minimum of ½" gypsum wallboard, or equivalent on all unprotected floor assemblies with exceptions for sprinklered buildings, certain crawlspaces and other limited areas that would otherwise be difficult to cover due to obstructions. SBCA's position on this subject is to provide a requirement that applies equally to all building component types and does not provide a competitive advantage to specific types of construction where they would be exempt from the requirements.

The following link shows statistics of firefighter deaths. It is a global report that shows all firefighter deaths and their causes from 1980-2008. This report shows that less than 5% of all firefighter deaths occur from injuries sustained in structural collapses. http://www.sbcindustry.com/images/fire/firefatalstats.pdf

The following spreadsheet is a list of NIOSH reports showing firefighter fatalities that involved a structural collapse. Of those reports, 11 involved firefighter deaths from the collapse of solid sawn lightweight construction and 9 (with potentially 2 more) involved I-joists, MPC wood trusses, and steel trusses combined. This shows that there is no compelling evidence to suggest that engineered products are any more dangerous than solid sawn materials in real fire situations.
Links to the full NIOSH reports are included for more details.

Total:	11	9 (with potential 2 more)			

Public Comment 3:

Larry Wainright, Qualtim, Inc, representing Structural Building Components Association (SBCA), requests Approval as Modified by this Public Comment.

Replace proposal as follows:

R302.7 Fire protection of floors. Floor assemblies, not required elsewhere in this code to be fire resistance rated, shall be provided with a ½ inch (12.7 mm) gypsum wallboard membrane, 5/8 inch (15.9 mm) wood structural panel membrane, or equivalent on the underside of light frame construction, steel bar joists and wood chord/steel web joists.

Exceptions:

1. Floor assemblies located directly over a space protected by an automatic sprinkler system in accordance with Section P2904, NFPA13D, NFPA 13R or NFPA 13.
2. Floor assemblies located directly over a crawl space not intended for storage or fuel-fired appliances.
3. Portions of floor assemblies can be unprotected when complying with the following:
   3.1 The aggregate area of the unprotected portions shall not exceed 80 square feet per story
   3.2 Fire blocking in accordance with Section R302.11.1 shall be installed along the perimeter of the unprotected portion to separate the unprotected portion from the remainder of the floor assembly.
4. Solid sawn wood joists of at least 2x10 nominal.
5. Metal Plate Connected Wood trusses

NFPA 13R—07 Installation of Sprinkler Systems in Residential Occupancies Up to and Including Four Stories in height.

Commenter's Reason: This public comment merely proposes to require a minimum of ½" gypsum wallboard, or equivalent on all unprotected floor assemblies with exceptions for sprinklered buildings, certain crawlspaces and other limited areas that would otherwise be difficult to cover due to obstructions. In addition, solid sawn 2x10 lumber and MPC Wood Trusses are exempted. SBCA's position on this subject is to provide a requirement that applies equally to all building component types and does not provide a competitive advantage to specific types of construction where they would be exempt from the requirements. Recognizing that this may not be possible, this comment offers a compromise where those products that survive the longest in fires are exempted.

Final Action: AS AM AMPC____ D

RB35-09/10

R302.11, M1501.2 (New)

Proposed Change as Submitted

Proponent: Julius Ballanco, PE, JB Engineering and Code Consulting, P.C., representing In-O-Vate Technologies, Inc.

1. Revise as follows:

R302.11 Fireblocking. In combustible construction, fireblocking shall be provided to cut off all concealed draft openings (both vertical and horizontal) and to form an effective fire barrier between stories, and between a top *story* and the roof space.

Fireblocking shall be provided in wood-frame construction in the following locations:

1. In concealed spaces of stud walls and partitions, including furred spaces and parallel rows of studs or staggered studs, as follows:
   1.1. Vertically at the ceiling and floor levels.
   1.2. Horizontally at intervals not exceeding 10 feet(3048 mm).
2. At all interconnections between concealed vertical and horizontal spaces such as occur at soffits, drop ceilings and cove ceilings.
3. In concealed spaces between stair stringers at the top and bottom of the run. Enclosed spaces under stairs shall comply with Section R302.7.
4. At openings around vents, pipes, ducts, cables and wires at ceiling and floor level, with an *approved* material to resist the free passage of flame and products of combustion. The material filling this annular space shall not be required to meet the ASTM E 136 requirements.
5. For the fireblocking of chimneys and fireplaces, see Section R1003.19.
6. Fireblocking of cornices of a two-family *dwelling* is required at the line of *dwelling unit* separation.
7. At penetrations of walls by dryer exhaust duct at the dryer location in accordance with Section M1501.2.

2. Add new text as follows:

M1501.2 Dryer exhaust duct penetrations. Where a clothes dryer exhaust duct is located within a framed wall, the penetration of the wall membrane at the location of the dryer shall have the annular space sealed with noncombustible material, approved fire caulking, or a noncombustible dryer exhaust duct wall receptacle.

Reason: This change corrects the concerns expressed during the last cycle. I have modified the proposed change to remove penetration of rated walls, since such penetrations are not permitted by the Code. The remaining issues have been addressed as suggested by the Code Committee.

The difference between a dyer exhaust duct penetration and other penetration is that it is in close proximity to a fuel fired appliance or electric heating appliance. Dryers are more prone to fire than other appliances. To protect the structure, it is important to have a higher level of protection.

The language in this change is consistent with the requirements found in the International Mechanical Code.

The CPSC identified 15,600 fires associated with dryers in a single year. Studies have shown that metal ducts protect the structure from the spread of fire. Additionally, noncombustible material or fire caulk around the annular space prevents the fire from spreading into the wall or ceiling cavity. The same can be accomplished with manufactured noncombustible receptacles. The noncombustible receptacles also allow for the proper storage and recoil of the transition flexible duct to a metal duct.

Cost Impact: The code change proposal may increase the cost of construction.

ICCFILENAME: BALLANCO-RB-1-R302.11

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee feels this is product driven and it would limit the options available to seal around the dryer duct exhaust. This change would require protection around a penetration in a non-rated wall assembly.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Julius Ballanco, PE, JB Engineering and Code Consulting P.C., representing In-O-Vate Technologies, Inc, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R302.11 Fireblocking. In combustible construction, fireblocking shall be provided to cut off all concealed draft openings (both vertical and horizontal) and to form an effective fire barrier between stories, and between a top *story* and the roof space.

Fireblocking shall be provided in wood-frame construction in the following locations:

1. In concealed spaces of stud walls and partitions, including furred spaces and parallel rows of studs or staggered studs, as follows:
   1.1. Vertically at the ceiling and floor levels.
   1.2. Horizontally at intervals not exceeding 10 feet (3048 mm).
2. At all interconnections between concealed vertical and horizontal spaces such as occur at soffits, drop ceilings and cove ceilings.
3. In concealed spaces between stair stringers at the top and bottom of the run. Enclosed spaces under stairs shall comply with Section R302.7.
4. At openings around vents, pipes, ducts, cables and wires at ceiling and floor level, with an *approved* material to resist the free passage of flame and products of combustion. The material filling this annular space shall not be required to meet the ASTM E 136 requirements.
5. For the fireblocking of chimneys and fireplaces, see Section R1003.19.
6. Fireblocking of cornices of a two-family *dwelling* is required at the line of *dwelling unit* separation.
7. At penetrations of walls by dryer exhaust duct at the dryer location in accordance with Section M1501.2.

M1501.2 Dryer exhaust duct penetrations. Where a clothes dryer exhaust duct is located within a combustible framed wall, the penetration of the wall membrane at the location of the dryer shall have the annular space sealed with one of the following methods or materials:

1. ~~with~~ N~~n~~oncombustible material,
2. A~~a~~pproved fire caulking, putty, or foam,
3. ~~or a~~ A noncombustible dryer exhaust duct wall receptacle
4. 2 inch nominal lumber isolating the wall cavity space above the penetration.

Commenter's Reason: The Committee thought the original proposal did not include all of the available options. The modification adds the option of firestopping with 2 inch nominal lumber. This is a current method that should be maintained. The fire caulking has also been expanded to include putty or foam.

There was also concern that this would prohibit plastic dryer boxes. This modification would clarify that plastic boxes could be installed. The wall cavity above the plastic box would have to be isolated with 2 inch nominal lumber above the box, or fire caulk, putty, or foam could be added above the plastic box.

Final Action: AS AM AMPC____ D

RB38-09/10
R305.1

Proposed Change as Submitted

Proponent: Rick Davidson, City of Maple Grove, MN

Revise as follows:

R305.1 Minimum height. Habitable space, hallways, ~~bathrooms, toilet rooms,~~ laundry rooms and portions of basements containing these spaces shall have a ceiling height of not less than 7 feet (2134 mm). <u>Bathrooms and toilet rooms shall have a ceiling height of not less than 6 feet 8 inches (2036 mm) including above a minimum area 30 inches (762 mm) by 30 inches (762 mm) at the showerhead in showers or tubs equipped with showerheads.</u>

Exceptions:

1. For rooms with sloped ceilings, at least 50 percent of the required floor area of the room must have a ceiling height of at least 7 feet (2134 mm) and no portion of the required floor area may have a ceiling height of less than 5 feet (1524 mm).
2. ~~Bathrooms shall have a minimum ceiling height of 6 feet 8 inches (2036 mm) at the center of the front clearance area for fixtures as shown in Figure R307.1. The ceiling height above fixtures shall be such that the fixture is capable of being used for its intended purpose. A shower or tub equipped with a showerhead shall have a minimum ceiling height of 6 feet 8 inches (2036 mm) above a minimum area 30 inches (762 mm) by 30 inches (762 mm) at the showerhead.~~
<u>2.</u> <u>The ceiling height above water closets and lavatories shall be permitted to be of any height.</u>

Reason: First section R305.1 sets a minimum ceiling height for bathrooms and toilet rooms at 7 feet. Then Exception 2 reduces that ceiling height in bathrooms (but not toilet rooms) to 6'8" at the center of the front clearance area for fixtures shown in Figure R307.1 and in tubs and showers with showerheads. It is safe to assume that toilet rooms should have been included in this section. It is probably also safe to assume that ceiling heights in bathrooms and toilet rooms need only be 6'8" at any location in the room, not just in the most used areas of the room. It isn't reasonable to think that the ceiling heights in these rooms should be 7 feet but only 6'8" near the fixtures, but this is what the text implies. Since bathrooms and toilet rooms do not have "required floor areas" but rather "clearance area for fixtures", Exception 1 does not apply to bathrooms and toilet rooms. That exception only applies to required floor area. Therefore, Exception 2 is really not an exception to the charging language but is the charging language and should not be in an exception. This proposal corrects that flaw.

The third exception that states "The ceiling height above fixtures shall be such that the fixture is capable of being used for its intended purpose" is unenforceable and any attempt at enforcement would be arbitrary. It is unenforceable because "capable of being used for its intended purpose" is not defined and is subject to discretionary action. The converse would be what ceiling height is acceptable over a water closet? Is 5 feet acceptable? What about 5 ½ feet? Or, 6 feet? And, if in your opinion an acceptable height is 6 feet and you encounter a situation where the height is 5 ½ feet, how do you enforce your opinion? If it can't be enforced it shouldn't be in the code. There is no basis on which to write a correction order no matter what the height above the fixtures is. The language will result in a lack of uniformity. It will lead to confusion as to what is an acceptable height. It will create conflicts between building departments, contractors, and homeowners. The proposed language specifically calls out water closets and lavatories because those are the only fixtures illustrated in Figure 307.1 besides tubs/showers and there are specific height requirements for tub/showers that are retained. Because of the reasons stated and because the market will likely dictate what an acceptable height is, this proposal deletes the offending language and permits the homeowner to decide what height is most appropriate.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: DAVIDSON-RB-6-R305.1

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee feels that this change will cause confusion and would permit a ceiling height that is unusable.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Rick Davidson, representing self, requests Approval as Modified by this Public Comment.

Modify the proposal as follows

R305.1 Minimum height. Habitable space, hallways, laundry rooms and portions of basements containing these spaces shall have a ceiling height of not less than 7 feet (2134 mm). Bathrooms and toilet rooms shall have a ceiling height of not less than 6 feet 8 inches (2036 mm) including above a minimum area 30 inches (762 mm) by 30 inches (762 mm) at the showerhead in showers or tubs equipped with showerheads.

Exceptions:

1. For rooms with sloped ceilings, at least 50 percent of the required floor area of the room must have a ceiling height of at least 7 feet 2134 mm) and no portion of the required floor area may have a ceiling height of less than 5 feet (1524 mm).
2. ~~The ceiling height above water closets and lavatories shall be permitted to be of any height~~
2. The ceiling height above fixtures shall be such that the fixture is capable of being used for its intended purpose.

Commenter's Reason: The current language creates an odd set of circumstances for bathrooms and toilet rooms in that it first requires that ceiling height in these rooms are 7 feet. Then by exception #2, the ceiling height is reduced to 6 feet 8 inches "at the center of the front clearance area for fixtures". Read literally, one could reduce the ceiling height in the most used areas of the room to 6 feet 8 inches but the remainder and least used spaces would need to be 7 feet. Clearly the intent is to permit the entire area within bathrooms and toilet rooms to have ceiling heights of 6 feet 8 inches.

There was concern expressed at the Baltimore hearings how the rules for sloped ceilings would be impacted by this change. However, the rules relating to sloped ceilings only apply to rooms that have a required floor area, such as a bedroom. Bathrooms and toilet rooms do not have a required floor area, only clearance area at the fixtures.

There was also concern that deleting the remaining portion of exception #2 that references ceiling heights at fixtures would leave the ceiling height above fixtures unregulated. To eliminate that concern, the current language is retained.

The net result of this code change is that it permits ceiling heights in all bathrooms and toilet rooms to be 6 feet 8 inches throughout the room and not just in front of the fixtures and continues to regulate the height above fixtures by permitting it to be of a height capable of being used.

Public Comment 2:

Rick Davidson, representing self, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R305.1 Minimum height. Habitable space, hallways, bathrooms, toilet rooms~~,~~ laundry rooms and portions of basements containing these spaces shall have a ceiling height of not less than 7 feet (2134 mm). ~~Bathrooms and toilet rooms shall have a ceiling height of not less than 6 feet 8 inches (2036 mm) including above a minimum area 30 inches (762 mm) by 30 inches (762 mm) at the showerhead in showers or tubs equipped with showerheads.~~

Exceptions:

1. For rooms with sloped ceilings, at least 50 percent of the required floor area of the room must have a ceiling height of at least 7 feet (2134 mm) and no portion of the required floor area may have a ceiling height of less than 5 feet (1524 mm).
2. ~~The ceiling height above water closets and lavatories shall be permitted to be of any height.~~
2. Bathrooms shall have a minimum ceiling height of 6 feet 8 inches (2036 mm) at the center of the front clearance area for fixtures as shown in Figure R307.1. The ceiling height above water closets, bathtubs without showerheads and lavatories shall be permitted to be of any height. A shower or tub equipped with a showerhead shall have a minimum ceiling height of 6 feet 8 inches (2036 mm) above a minimum area 30 inches (762 mm) by 30 inches (762 mm) at the showerhead.

Commenter's Reason: This modification addresses only the matter of the ceiling height above fixtures. The **proposal** states that the ceiling height above water closets, bathtubs without showerheads, and lavatories can be of any height. The committee disapproved this proposal because they said it "would cause confusion and would permit a ceiling height that is unusable." Is the proposed language confusing? It simply states that the ceiling height above certain fixtures can be of any height. The language is clear. There is no confusion. Would it permit a ceiling height that is unusable? That question could be answered with a question. Would someone spend the money to design and construct a bathroom with unusable fixtures? Not likely.

Can we enforce what we have? Is the current language confusing? Would it permit a ceiling height that is unusable?

Current language in the code states that the "ceiling height above fixtures shall be such that the fixture is capable of being used for its intended purpose." This language is unenforceable as it relies on the physical stature of the user, the posture of the user, and how the fixture is used to determine what height is sufficient. But those limitations are moving targets and are limitless in their combination. It is therefore impossible to plan check a plan with a lowered ceiling height above a fixture. If one were to attempt to do so, what height is acceptable? Would the field inspector agree? The building department could adopt a policy but policies can't be enforced in court. The must be based on some type of physiologic evidence. It is unknown if there exists a study on the amount of ceiling height that is needed for a six foot male while sitting on a water closet, presuming the water closet would only be sat on by a male. So is the current language confusing? It certainly is.

The reason why the offending language was put into the code was to permit fixtures to be placed in cramped locations, most often in remodeled homes. The only thing this proposal changes is that it takes the building department off the hook regarding arguments on the appropriate ceiling height above plumbing fixtures and places that responsibility on the person who will be using the fixtures, the homeowner.

For purposes of uniformity, the proposed amendment provides clearer direction regarding this issue using a language format already found in the code.

Final Action: AS AM AMPC____ D

RB39-09/10
R308.4

Proposed Change as Submitted

Proponent: William E. Koffel, Koffel Associates, Inc., representing the Glazing Industry Code Committee (GICC)

Revise as follows:

R308.4 Hazardous locations. The following shall be considered specific hazardous locations for the purposes of glazing:

1. Glazing in all fixed and operable panels of swinging, sliding and bifold doors.

   Exceptions:

   1. Glazed openings of a size through which a 3-inch diameter (76 mm) sphere is unable to pass.
   2. Decorative glazing.

2. Glazing in an individual fixed or operable panel adjacent to a door where the nearest vertical edge is within a 24-inch (610 mm) arc of the door in a closed position and whose bottom edge is less than 60 inches (1524 mm) above the floor or walking surface.

   Exceptions:

   1. Decorative glazing.
   2. When there is an intervening wall or other permanent barrier between the door and the glazing.
   3. Glazing in walls on the latch side of and perpendicular to the plane of the door in a closed position.
   4. Glazing adjacent to a door where access through the door is to a closet or storage area 3 feet (914 mm) or less in depth.
   5. Glazing that is adjacent to the fixed panel of patio doors <u>which is not required to be safety glazing by another section</u>.

3. Glazing in an individual fixed or operable panel that meets all of the following conditions:
   3.1. The exposed area of an individual pane is larger than 9 square feet (0.836 m2); and
   3.2. The bottom edge of the glazing is less than 18 inches (457 mm) above the floor; and
   3.3. The top edge of the glazing is more than 36 inches (914 mm) above the floor; and
   3.4. One or more walking surfaces are within 36 inches (914 mm), measured horizontally and in a straight line, of the glazing.

   Exceptions:

   1. Decorative glazing.
   2. When a horizontal rail is installed on the accessible side(s) of the glazing 34 to 38 inches (864 to 965) above the walking surface. The rail shall be capable of withstanding a horizontal load of 50 pounds per linear foot (730 N/m) without contacting the glass and be a minimum of 11/2 inches (38 mm) in cross sectional height.
   3. Outboard panes in insulating glass units and other multiple glazed panels when the bottom edge of the glass is 25 feet (7620 mm) or more above *grade*, a roof, walking surfaces or other horizontal [within 45 degrees (0.79 rad) of horizontal] surface adjacent to the glass exterior.

4. All glazing in railings regardless of area or height above a walking surface. Included are structural baluster panels and nonstructural infill panels.
5. Glazing in enclosures for or walls facing hot tubs, whirlpools, saunas, steam rooms, bathtubs and showers where the bottom exposed edge of the glazing is less than 60 inches (1524 mm) measured vertically above any standing or walking surface.

   Exception: Glazing that is more than 60 inches (1524 mm), measured horizontally and in a straight line, from the waters edge of a hot tub, whirlpool or bathtub.

6. Glazing in walls and fences adjacent to indoor and outdoor swimming pools, hot tubs and spas where the bottom edge of the glazing is less than 60 inches (1524 mm) above a walking surface and within 60 inches (1524 mm), measured horizontally and in a straight line, of the water's edge. This shall apply to single glazing and all panes in multiple glazing.
7. Glazing adjacent to stairways, landings and ramps within 36 inches (914 mm) horizontally of a walking surface when the exposed surface of the glazing is less than 60 inches (1524 mm) above the plane of the adjacent walking surface.

   Exceptions:

   1. When a rail is installed on the accessible side(s) of the glazing 34 to 38 inches (864 to 965 mm) above the walking surface. The rail shall be capable of withstanding a horizontal load of 50 pounds per linear foot (730 N/m) without contacting the glass and be a minimum of 11/2 inches (38 mm) in cross sectional height.
   2. The side of the stairway has a guardrail or handrail, including balusters or in-fill panels, complying with Sections R311.7.6 and R312 and the plane of the glazing is more than 18 inches (457 mm) from the railing; or
   3. When a solid wall or panel extends from the plane of the adjacent walking surface to 34 inches (863 mm) to 36 inches (914 mm) above the walking surface and the construction at the top of that wall or panel is capable of withstanding the same horizontal load as a *guard*.

8. Glazing adjacent to stairways within 60 inches (1524 mm) horizontally of the bottom tread of a stairway in any direction when the exposed surface of the glazing is less than 60 inches (1524 mm) above the nose of the tread.

   Exceptions:

   1. The side of the stairway has a guardrail or handrail, including balusters or in-fill panels, complying with Sections R311.7.6 and R312 and the plane of the glass is more than 18 inches (457 mm) from the railing; or
   2. When a solid wall or panel extends from the plane of the adjacent walking surface to 34 inches (864 mm) to 36 inches (914 mm) above the walking surface and the construction at the top of that wall or panel is capable of withstanding the same horizontal load as a *guard*.

Reason: After several attempts, Exception #5 was added to the 2009 Edition of the IBC. The rationale submitted in RB42-07/08 was that "it is unlikely that the sliding doors will be reversed by the owner and people are familiar with their home environments." There was not corresponding proposal submitted to address eh issue in the same manner within dwelling units covered by the IBC.

The original rationale is flawed for the following reasons:

1. The new language "patio doors" instead of the original language "sliding doors" extends the application to far more doors.
2. The assumption that the people are familiar with their home environment does not take into consideration guests and horseplay activities.
3. The exception is too broad in nature and could be read to override the other provisions. For example, what if the panel is part of a hot tub enclosure? What if the panel is less than 18 inches above the floor?
4. The proponent based the rationale in part on Exception No. 3 but that exception only applies when the wall is perpendicular to the door.

We do not have injury data to support this proposal since historically the panel was required to be safety glazing. However, there was no technical substantiation to the change proposed last cycle to eliminate the requirement for safety glazing.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: KOFFEL-RB-1-R308.4

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee feels this change is unnecessary and it contains a circular reference.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Thomas S. Zaremba, Roetzel & Andress, representing Glazing Industry Code Committee (GICC), requests Approval as Submitted.

Commenter's Reason: R308.4 defines "hazardous locations" and, by doing so, defines where safety glazing must be used. R308.4.2 deals with hazardous locations involving glazing in fixed or operable panels adjacent to doors. Exception #5 to R308.4.2 currently provides that "[g]lazing that is adjacent to the fixed panel of patio doors" are not hazardous and, therefore, exempt from safety glazing requirements. This proposal would limit the applicability of this exemption to those applications where safety glazing is not required by any other provision of R308.4.

This change to exception #5 is needed to ensure that the exception is properly applied. If the proposed language is not added, exception #5 could well be interpreted to eliminate the use of safety glazings in a number of applications where it is otherwise required by R308.4.

For example, what if the glass panel at issue is part of a hot tub enclosure that meets the definition of a hazardous location in R308.4.5? Or, what if the glass panel at issue is less than 18 inches above the floor and otherwise meets the definition of a hazardous location in R308.4.3? In the absence of exception #5, both applications clearly require the use of safety glazing and for very good reasons. However, when exception #5 is applied, it could be interpreted to allow the use of non-safety glazing as part of a hot tub enclosure. Likewise, it could be interpreted to permit non-safety glazing in the panel that is less than 18 above a floor. Adding the proposed language to exception #5 will narrow its application and ensure that, when it is applied, it will not swallow other rules governing where safety glazing must be used.

Historically, exception #5 to R308.4.2 was added to the 2009 Edition of the IRC through RB42-07/08. It was based on the rationale that "it is unlikely that … sliding doors will be reversed by the owner and people are familiar with their home environments." That rationale was, however, flawed for several reasons:

1. The new language "patio doors" instead of the original language "sliding doors" extends the safety glazing exception to far more doors.
2. The assumption that people are familiar with their home environment does not take into consideration guests, rental units, or accidental impacts, for example, resulting from horseplay, that can result in human impact with "[g]lazing that is adjacent to the fixed panel of patio doors."
3. RB42-07/08 was based, in part, on the rationale used to substantiate the existence of exception # 3; however, exception #3 only applies when the wall is perpendicular to the door. Exception #5, as currently written, contains no such limitation.

Given the flawed rationale leading up to the adoption of exception #5 to R308.4.2, its application should be limited to only those situations where it is not in conflict with any other rule governing the use of safety glazing.

Final Action Agenda voters are urged to vote against the standing motion to disapprove in order to vote in favor of a motion to adopt RB39 "As Submitted."

Final Action: AS AM AMPC____ D

RB42-09/10
RB310.1.5

Proposed Change as Submitted

Proponent: Rick Davidson, City of Maple Grove, MN

Add new text as follows:

<u>**R310.1.5 Identification.** Windows installed as an emergency escape and rescue opening and meeting the requirements of Sections R310.1.1 thru R310.1.4 shall be identified as an "Emergency Escape and Rescue Opening". The identification shall be affixed to the frame or glass of the window as to be visible during inspection. The identification shall be of a type which once applied cannot be removed without being destroyed.</u>

Reason: How do confirm that a window has safety glazing? You look for identification. How do you determine the grade of a floor joist? You look for a grade stamp. How do you confirm the R value of an insulation batt? You look for a label. Why, so the component can be identified in the field as meeting a specific standard or requirement. How do you identify whether or not a window meets emergency egress requirements? We might try measure it and then decide if it is compliant or require additional information from the contractor or window supplier. We don't require any identification for windows used as emergency escape and rescue openings like we do with most other building components. This makes it difficult to verify compliance in the field with egress requirements. Manufacturers identify windows that meet egress requirements in their catalogs. That can be verified at plan review. But a disconnect occurs when that window, or one that is close in size, is installed in the field. Field inspectors cannot carry with them the manufactures literature for the dozens or hundreds of window manufacturers. They can only rely on field measurements. Herein lays the problem. There are numerous windows specified by manufacturers as having clear openable areas that meet egress requirements or that are hundredths of a square foot greater or lesser than required. Field inspectors cannot measure these openings to the exactness necessary to determine if windows that are close to meeting requirements are of the appropriate size. We already require windows to be identified for safety glazing and energy compliance reasons. Placing identification on the window that it meets egress requirements will have a minimal increase in cost and will greatly improve timely validation and compliance in the field.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: DAVIDSON-RB-8-R310.1.5

Public Hearing Results

Committee Action: Disapproved

Committee Reason: Based upon the proponent's request for disapproval. The proponent will work with industry on this issue and bring this back later.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Rick Davidson, representing self, requests Approval as Modified by this Public Comment.

Modify the proposal as follows

R310.1.5 Identification. ~~Windows installed as an emergency escape and rescue opening and meeting the requirements of Sections R310.1.1 thru R310.1.4 shall be identified as an "Emergency Escape and Rescue Opening". The identification shall be affixed to the frame or glass of the window as to be visible during inspection. The identification shall be of a type which once applied cannot be removed without being destroyed.~~ <u>Where windows are used to meet the requirements of this section, they shall be provided with a manufacturer's designation or mark that provides one of the following:</u>

<u>1.</u> <u>the net clear opening area, the net clear opening height, and the net clear opening width of the window or</u>
<u>2.</u> <u>shall be identified as meeting emergency escape and rescue requirements with a manufacturer's designation or mark that reads "Emergency Escape and Rescue Opening 5.0 sq. ft" or Emergency Escape and Rescue Opening 5.7 sq. ft." as applicable or similar language to indicate that the window meets the requirements of this section. The manufacturer's designation or mark shall be affixed to the window as to be visible for inspection and shall be of a type which once applied cannot be removed without being destroyed.</u>

Commenter's Reason: It was requested that this proposal be disapproved by the IRC Committee in Baltimore to enable a dialogue to occur with window manufacturers. Concern was expressed by the manufacturer's that identifying windows as "Emergency Escape and Rescue Openings".

It must be pointed out that most window manufacturers' already have statements in their literature that clearly indicate which of their windows meet or exceed national egress requirement.

Some manufacturers already provide a manufacturer's designation or mark. Following are pictures taken of labels found on some window brands that would meet the proposed rule and excerpts from the websites of several manufacturer's that illustrate those points.

Please note that the information from the manufacturers clearly states that their windows meet or exceed national egress requirements. If there truly was a concern about liability, it isn't demonstrated by the information on the manufacturer's own websites and advertising information.

The proposed amendment provides two options for identifying that the window meets egress requirements. The designation or mark may either provide the height, width, and opening dimensions or a statement that it meets either the 5.0 or 5.7 square foot opening requirements. The designation or mark is not required to be a permanent label. The label may be a paper label but must be designed so that it cannot be transferred from one window to another. This will enable the field inspector the ability to approve windows without the need to measure them with the same accuracy as the manufacturer and without the need to perform multiplication of fractional numbers in the field. The terms "manufacturer's designation" and "mark" are defined in the code. The term "once applied cannot be removed without being destroyed" is already used in the code to describe other labels, designations, or marks.

> ***MANUFACTURER'S DESIGNATION.*** *An identification applied on a product by the manufacturer indicating that a product or material complies with a specified standard or set of rules. (See also "Mark" and "Label.")*
>
> ***MARK.*** *An identification applied on a product by the manufacturer indicating the name of the manufacturer and the function of a product or material. (See also "Manufacturer's designation" and "Label.")*

Why can't the field inspector measure the windows in the field? If you review the hundreds of sizes and styles of windows available from dozens of manufacturers, it is apparent that there are thousands of windows that meet or come close to meeting egress requirements. You will find that some windows are exactly 5.7 square feet or 5.0 square feet. And there are others that are just a few hundredths of a square foot more or less. Herein lays the problem. Manufacturers measure window openings to the $1/16^{th}$ or to the hundredths of an inch. This degree of accuracy cannot be achieved in the field. Incorrectly measuring the window size by even a $1/16^{th}$ of an inch can give the impression that a window meets or fails to meet egress requirements when the opposite is true. Validating this takes time and can lead to unnecessary expense and delays. And if one window brand is approved that is just short of meeting minimum standards, the door is open for every other window manufacturer who has a window just slightly below minimum to request the same treatment.

Identifying windows as meeting egress requirements will also provide consumers, contractors, sales people and others concerned about a window used as an emergency escape and rescue opening the information they need to make informed decisions regarding the window without the need to search a catalog or website. It will also help to increase awareness of egress requirements.

The information that would go on the label is already in the manufacture's printed literature. It doesn't require the manufacturer to generate new information. The manufacturer need not indicate that the window complies with egress requirements if they so choose even though their catalogs may already state that certain windows meet national egress requirements.

The code requires labels on windows for energy code compliance and compliance with safety glazing. Almost every building product used today is identified with labels, designations or marks in one way or another. Windows used for egress purposes should be no different.

To find compatible Circle Top, arch and other shaped windows, see the specialty window section beginning on page 37.

Cottage Style Units

Available for these heights, up to TW3862, in all widths. Contact dealer for lead times.

- * Unobstructed glass height is for single sash only.
- ♦ These units meet or exceed the following dimensions: Clear Openable Area of 5.7 sq. ft., Clear Openable Width of 20" and Clear Openable Height of 24."
- • Rough opening dimensions may need to be increased to allow for use of building wraps, flashing, sill panning, brackets, fasteners or other items. See page 7 for more details.
- • "Unit Dimension" always refers to outside frame to frame dimension.
- • Dimensions in parentheses are in millimeters.
- • When ordering, be sure to specify color desired: White, Sandtone, Terratone® or Forest Green.

NOTE: These sizes with Design Pressure Upgrade are rated at +50/-55.

CASEMENT: TRADITION PLUS WOOD—CLAD WOOD

+ Tempered Glass Standard
*Stationary Only

Bolded Bookcodes indicate unit meets Egress Requirements for IRC code. State and local egress codes may differ. Always refer to local building codes for complete requirements. Check with local officials to ensure compliance before installing the unit.

CHAPTER 1A

CLAD ULTIMATE CASEMENT (CUCA)
CLAD ULTIMATE PUSH OUT CASEMENT (CUPCA)

Product Information

NOTE:

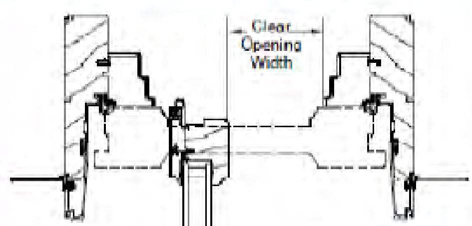
Specifications and technical data are subject to change without notice.
Allow 1/16" (2) tolerance on all measurements.
Metric measurements are shown in parenthesis.
For accessories dimensions and applications see the Accessories section of this manual.
For technical assistance about Marvin products you may call 1-800-346-3363 or visit our website: www.marvin.com.

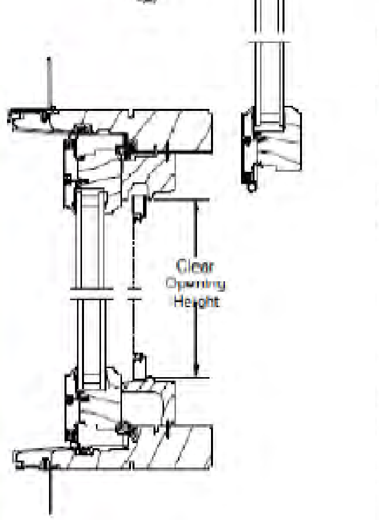
CUCA Hardware:

- Casement operator includes a crank hardware system that allows the window to open to a full 90 degrees with a minimal reduction of egress net clear opening. Single arm operators, steel coated with Egard®. Operation force at handle is 5lbs. or less.
- Casement hinges allow the user the ability to slide the sash across the frame opening so the sash exterior will rotate toward the user for easy washability. Hinges are steel coated with Egard™ and the standard track is stainless steel. Frame OM width of 20" (508) to under 24" (610) use 18" (457) wash/egress hinge. Frame OM width greater than 24" (610) use 22" (559) wash/egress hinge. Frame OM width less than 20" (508) use dyad hinge (dyad hinges do not have special easy washability feature) .

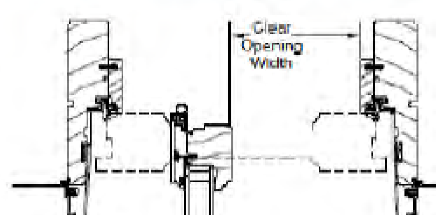
Egress Information

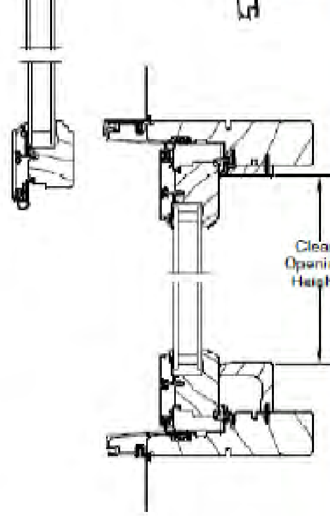
Ultimate Casement - Operator





Ultimate Push Out Casement - Operator





International Building Code - 2003 and 2006
Section 1009 Emergency Escape and Rescue

1009.2 Minimum size: Emergency escape and rescue openings shall have a minimum net clear opening of 5.7 square feet ($0.53 m^2$). Exception: The minimum net clear opening for emergency escape and rescue openings on the ground level at grade is 5.0 square feet ($0.46 m^2$)

1009.2.1 Minimum dimensions: The minimum net clear opening height dimension shall be 24 inches (610 mm). The net clear opening width dimension shall be 20 inches (508 mm). The net clear opening dimensions shall be the result of normal operation of the opening.

1009.3 Maximum height from the floor: Emergency escape and rescue opening shall have the bottom of the clear opening not greater than 44 inches (1118 mm) measured from the floor.

1009.4 Operational constraints: Emergency escape and rescue openings shall be operational from the inside of the room without the use of keys or tools. Bars, grilles, grates, or similar devices are permitted to be placed over emergency escape and rescue openings provided the minimum net clear opening size complies with Section 1009.2 and such devices shall be releasable or removable from the inside without the use of a key, tool, or force greater than that which is required for normal operation of the escape and rescue opening.

Code restrictions may vary depending on your local building codes.

T Tempered glass is standard.

Egress Notes:

E = Window meets minimum clear opening of 24" height, 20" width, and 5.7 ft². Check all applicable local codes for emergency egress requirements.

E1 = Window meets minimum clear opening of 24" height, 20" width, and 5.0 ft². Check all applicable local codes for emergency egress requirements.

E2 = With optional egress hardware, window meets minimum clear opening of 24" height, 20" width, and 5.7 ft². Check all applicable local codes for emergency egress requirements.

E3 = With optional egress hardware, window meets minimum clear opening of 24" height, 20" width, and 5.0 ft². Check all applicable local codes for emergency egress requirements.

See Design Data pages in this section for clear opening dimensions.

Clear opening (egress) information does not take into consideration the addition of a Rolscreen (or any other accessory) to the product. You should consult your local building code to ensure products with Rolscreens meet egress requirements.

[a] These sizes meet or exceed emergency escape and rescue opening requirements per 2006 IRC (International Building Code). **Minimum size:** emergency escape and rescue openings shall have a minimum net clear opening of **5.7** sq. ft. [**5295** cm²]. **Exception:** minimum net clear opening for emergency escape and rescue grade-floor openings shall be 5.0 sq. ft. [4645 cm²]. **Minimum dimensions:** the minimum net clear opening width dimension shall be 20" [508mm]. The minimum net clear opening height dimension shall be 24" [610mm]. **Maximum height from floor:** emergency escape and rescue openings shall have the bottom of the clear opening not greater than 44" [1118mm] measured from the floor. Verify local or state emergency escape and rescue opening sizes with your local building inspector.

[b] These windows, with the hinged screen option, meet or exceed emergency escape and rescue opening requirements.

[c] These windows meet or exceed emergency escape and rescue opening requirements if installed lower in the wall so the "Floor to Bottom of Clear Opening Height" does not exceed 44" [1118mm].

[d] Clear opening width and height dimensions are rounded down to the nearest 1/16" [2mm].

[e] Floor to bottom of clear opening dimensions are based on 82" [2083mm] jamb height of Collections Center Hinged French Doors and Inswing French Doors. Dimensions are rounded to the nearest 1/16" [2mm].

[f] Sq. Ft. [cm²] Overall Unit Area is calculated on the jamb dimension.

[g] Clear opening width is calculated with sash open 90°.

Final Action: AS AM AMPC____ D

<u>Proposed Change as Submitted</u>

Proponent: Homer Maiel, PE, CBO, City of San Jose, CA, representing the ICC Tri-Chapter (Peninsula, East Bay, Monterey Bay Chapters)

Revise as follows:

R311.3.2 Floor elevations for other exterior doors. Doors other than the required egress door shall be provided with landings or floors not more than 7 ¾ inches (196 mm) below the top of the threshold <u>provided the door does not swing over the landing or floor</u>.

> **Exceptions:** A landing is not required where a stairway of two or fewer risers is located on the exterior side of the door, provided the door does not swing over the stairway.

Reason: This revision is needed to make sure that Section R311.3.2 is consistent with Section R311.3.1. Tripping hazards will be equal regardless of whether a door is or is not a required egress door. The Exception to this section indicates that the door should not be swung over one-riser or two-riser stairway. However, the main body of the section fails to address that a door should not swing over a lower landing, as Section R311.3.1 clearly states.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: MAIEL-RB-4-R311.3.2

<u>Public Hearing Results</u>

Committee Action: **Disapproved**

Committee Reason: Based on proponent's request for disapproval. The proposal would require the door to not swing or not have a floor or landing. The proponent should rework and bring back later.

Assembly Action: **None**

<u>Individual Consideration Agenda</u>

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Homer Maiel, P.E., CBO., City of San Jose, representing ICC Tri-Chapter (Peninsula, East Bay, Monterey Bay Chapters), requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R311.3.2 Floor elevations for other exterior doors. Doors other than the required egress door shall be provided with landings or floors not more than 7 3/4 inches (196 mm) below the top of the threshold provided the door does not swing over the landing or floor. <u>For doors that swing over the landing or floor, the threshold shall comply with Section R311.3.1.</u>

> **Exceptions:** A landing is not required where a stairway of two or fewer risers is located on the exterior side of the door, provided the door does not swing over the stairway.

Commenter's Reason: The Tri-Chapter recommends the following modification to RB45 in order to address the condition when a door, other than the main egress door, swings over a landing or floor. We believe that this presents the same hazard as would exist with the primary egress door and that the landing or floor should be limited to no more than 1 1/2 inches below the top of the threshold. The proposed Amendment to the original code change proposal addresses this condition by adding a sentence to the original code change proposal that states "<u>For doors that swing over the landing or floor, the threshold shall comply with Section R311.3.1</u>." The Reason Statement for the original code change proposal does not change, with the exception that the additional threshold condition associated with the condition of the door swinging over a landing or floor is addressed.

Final Action: AS AM AMPC____ D

RB46-09/10
R311.7.4.1, R311.7.4.2, R311.7.4.2.1 (New), R311.7.43

Proposed Change as Submitted

Proponent: Rick Davidson, City of Maple Grove, MN

1. Revise as follows:

R311.7.4.1 Riser height. The maximum riser height shall be 73/4 inches (196 mm). The riser shall be measured vertically between leading edges of the adjacent treads. The greatest riser height within any flight of stairs shall not exceed the smallest by more than 3/8 inch (9.5 mm). Risers shall be vertical or sloped from the underside of the leading edge of the tread above at an angle not more than 30 degrees (0.51 rad) from the vertical. Open risers are permitted provided that the opening between treads does not permit the passage of a 4-inch diameter (102 mm) sphere.

> **Exception:** The opening between adjacent treads is not limited on stairs with a total rise of 30 inches (762 mm) or less.

R311.7.4.2 Tread depth. The minimum tread depth shall be 10 inches (254 mm). The tread depth shall be measured horizontally between the vertical planes of the foremost projection of adjacent treads and at a right angle to the tread's leading edge. The greatest tread depth within any flight of stairs shall not exceed the smallest by more than 3/8 inch (9.5 mm). Consistently shaped winders at the walkline shall be allowed within the same flight of stairs as rectangular treads and do not have to be within 3/8 inch (9.5 mm) of the rectangular tread depth. ~~Winder treads shall have a minimum tread depth of 10 inches (254 mm) measured between the vertical planes of the foremost projection of adjacent treads at the intersections with the walkline. Winder treads shall have a minimum tread depth of 6 inches (152 mm) at any point within the clear width of the stair. Within any flight of stairs, the largest winder tread depth at the walkline shall not exceed the smallest winder tread by more than 3/8 inch (9.5 mm).~~

2. Add new text as follows:

R311.7.4.2.1 Winder treads. Winder treads shall have a minimum tread depth of 10 inches (254 mm) measured between the vertical planes of the foremost projection of adjacent treads at the intersections with the walkline. Winder treads shall have a minimum tread depth of 6 inches (152 mm) at any point within the clear width of the stair. Within any flight of stairs, the largest winder tread depth at the walkline shall not exceed the smallest winder tread by more than 3/8 inch (9.5 mm).

3. Revise as follows:

R311.7.4.3 ~~Profile~~ Nosings . The radius of curvature at the nosing shall be no greater than 9/16 inch (14 mm). A nosing not less than 3/4 inch (19 mm) but not more than 11/4 inches (32 mm) shall be provided on stairways with solid risers. The greatest nosing projection shall not exceed the smallest nosing projection by more than 3/8 inch (9.5 mm) between two stories, including the nosing at the level of floors and landings. Beveling of nosings shall not exceed 1/2 inch (12.7 mm). ~~Risers shall be vertical or sloped under the tread above from the underside of the nosing above at an angle not more than 30 degrees (0.51 rad) from the vertical. Open risers are permitted, provided that the opening between treads does not permit the passage of a 4-inch diameter (102 mm) sphere.~~

> **Exception~~s~~:**
>
> ~~1.~~ A nosing is not required where the tread depth is a minimum of 11 inches (279 mm).
> ~~2. The opening between adjacent treads is not limited on stairs with a total rise of 30 inches (762 mm) or less.~~

Reason: Language related to risers is relocated from the section on "Profile" to the section on "Risers", which is more appropriate. This change is strictly cut and paste. The language on winder treads is made into its own subsection of Treads to enable the user of the code to more easily find that text. The purpose of this code change is to ease use of the code.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: DAVIDSON-RB-5-R311.7.4

Public Hearing Results

Committee Action: **Approved as Modified**

Modify the proposal as follows:

R311.7.4.1 Riser<u>s</u> ~~height~~. The maximum riser height shall be 73/4 inches (196 mm). The riser shall be measured vertically between leading edges of the adjacent treads. The greatest riser height within any flight of stairs shall not exceed the smallest by more than 3/8 inch (9.5 mm). Risers shall be vertical or sloped from the underside of the ~~leading edge~~ <u>nosing</u> of the tread above at an angle not more than 30 degrees (0.51 rad) from the vertical. Open risers are permitted provided that the opening between treads does not permit the passage of a 4-inch diameter (102 mm) sphere.

Exception: The opening between adjacent treads is not limited on stairs with a total rise of 30 inches (762 mm) or less.

R311.7.4.2 Tread<u>s</u> ~~depth~~. The minimum tread depth shall be 10 inches (254 mm). The tread depth shall be measured horizontally between the vertical planes of the foremost projection of adjacent treads and at a right angle to the tread's leading edge. The greatest tread depth within any flight of stairs shall not exceed the smallest by more than 3/8 inch (9.5 mm). ~~Consistently shaped winders at the walkline shall be allowed within the same flight of stairs as rectangular treads and do not have to be within 3/8 inch (9.5 mm) of the rectangular tread depth.~~

R311.7.4.2.1 Winder treads. Winder treads shall have a minimum tread depth of 10 inches (254 mm) measured between the vertical planes of the foremost projection of adjacent treads at the intersections with the walkline. Winder treads shall have a minimum tread depth of 6 inches (152 mm) at any point within the clear width of the stair. Within any flight of stairs, the largest winder tread depth at the walkline shall not exceed the smallest winder tread by more than 3/8 inch (9.5 mm). <u>Consistently shaped winders at the walkline shall be allowed within the same flight of stairs as rectangular treads and do not have to be within 3/8 inch (9.5 mm) of the rectangular tread depth.</u>

R311.7.4.3 Nosings. The radius of curvature at the nosing shall be no greater than 9/16 inch (14 mm). A nosing not less than 3/4 inch (19 mm) but not more than 11/4 inches (32 mm) shall be provided on stairways with solid risers. The greatest nosing projection shall not exceed the smallest nosing projection by more than 3/8 inch (9.5 mm) between two stories, including the nosing at the level of floors and landings. Beveling of nosings shall not exceed 1/2 inch (12.7 mm).

Exception:

A nosing is not required where the tread depth is a minimum of 11 inches (279 mm).

Committee Reason: The committee feels this change makes the code easier to use by breaking out the winder text into its own section. The modification corrects the term "leading edge" to "nosing" and moves the winder walking criteria into the new winder section.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jake Pauls, representing self, requests Disapproval.

Commenter's Reason: The approval of this code change leaves the RB46 badly broken and it should be disapproved. There are other code change proposals that deal with the issues better, specifically RB47-09/10 dealing with treads, with separate sections for separate topics:
R311.7.4.2 Tread Depth
R311.7.4.2.1 Uniformity of Rectangular Tread Depths
R311.7.4.2.2 Uniformity of Winder Treads

Complementing the foregoing proposal is E75-09/10 Part 2 which also deals with separate requirements for the separate topics:
R311.7.4.3 Nosing and Riser Profile
R311.7.4.3.1 Nosing Projection Size
R311.7.4.3.2 Nosing Projection Uniformity
R311.7.4.3.3 Open Risers

Proposal RB46 leaves different topics within the same section, thus making use of the code more difficult and compliance less likely both at the design and construction process and at inspection.

Notably, the IRC BE Code Change Committee took a different approach than did the IBC Means of Egress Code Change Committee on this matter. The latter's action on E75-09/10 Part I was approved as submitted with the differentiation of sections recommended also for E75-09/10 Part II. The IRC BE Committee disapproved E75-09/10 Part II. As such, the IRC will remain broken—or at least not fixed to the extent warranted and to the extent fixed for the IBC.

Thus, with the IRC BE Committee's action, there is an inadequate response to a major safety problem with many home stairs. Moreover, this problem is still badly dealt with in the guides ICC publishes for builders and inspectors (Residential Inspector's Guide Based on the 2006 IRC, Chapters 1-11, and Home Builders' Jobsite Codes: a Pocket Guide to the 2009 International Residential Code). If the ICC-sanctioned writers of guides cannot even get the intent and content of the code requirements right, then what can we expect from ordinary users?

Note that the two Committees saw the problem differently in their reason statements for E75-09/10. The IBC Means of Egress Committee said, "By breaking the current text into smaller sections the proposal clarifies the requirements for stair nosings and risers." The IRC BE Committee said, "The committee feels the code already addresses this and it is an enforcement and education issue. There is a concern about correlation of this with the previous action on RB46-09/10. The committee suggests both parties work together and bring this back later."

The problem here is not having the proponents working together, it is a problem of the IRC and IBC committees not working together on exactly the same issues. Clearly in the view of this commenter, the IRC BE Committee does not understand the problem. A bad code is a bad code and we should not rely on enforcement and education to overcome the code's defects.

As this is simply a reformatting issue and not a technical change, why is there such backwardness on the part of the IRC BE Committee? This is now a matter for membership. Do you want the inadequate change proposed in this proposal, RB46-09/10, or do you want the IRC clarified as proposed in RB47-09/10 and its complementary change E75-09/10? The choice is very simple, do you want ICC and ICC Code users saddled with an inadequate code for another three years or do you want to have it fixed properly? If you want it fixed properly, you should vote in favor of this comment and disapprove RB46-09/10.

More important, as spelled out in detail in the comment on RB47, confusion over what the Code requires is costing dearly in terms of flawed stair design, construction and inspection. There are many needless injuries caused by the bad formatting of the IRC's requirements. Again, there is no technical change here—and thus no cost involved in getting better benefit out of the IRC. Vote to disapprove RB46-09/10, a proposed change that does not provide the needed improvement in code clarity and public safety.

Final Action: AS AM AMPC____ D

RB47-09/10

R311.7.4.2, R311.7.4.2.1 (New), R311.7.4.2.2 (New)

Proposed Change as Submitted

Proponent: Jake Pauls, representing self

1. Revise as follows:

R311.7.4.2 Tread depth. The minimum tread depth shall be 10 inches (254 mm). The tread depth shall be measured horizontally between the vertical planes of the foremost projection of adjacent treads and at a right angle to the tread's nosing ~~leading edge~~. ~~The greatest tread depth within any flight of stairs shall not exceed the smallest by more than 3/8 inch (9.5 mm). Consistently shaped winders at the walkline shall be allowed within the same flight of stairs as rectangular treads and do not have to be within 3/8 inch (9.5 mm) of the rectangular tread depth. Winder treads shall have a minimum tread depth of 10 inches (254 mm) measured between the vertical planes of the foremost projection of adjacent treads at the intersections with the walkline. Winder treads shall have a minimum tread depth of 6 inches (152 mm) at any point within the clear width of the stair. Within any flight of stairs, the largest winder tread depth at the walkline shall not exceed the smallest winder tread by more than 3/8 inch (9.5 mm).~~

2. Add new text as follows:

R311.7.4.2.1 Uniformity of rectangular tread depths. The greatest tread depth, measured horizontally between nosings of treads as specified in R311.7.4.2 and including the top tread, within each flight of stairs shall not exceed the smallest by more than 3/8 inch (9.5 mm).

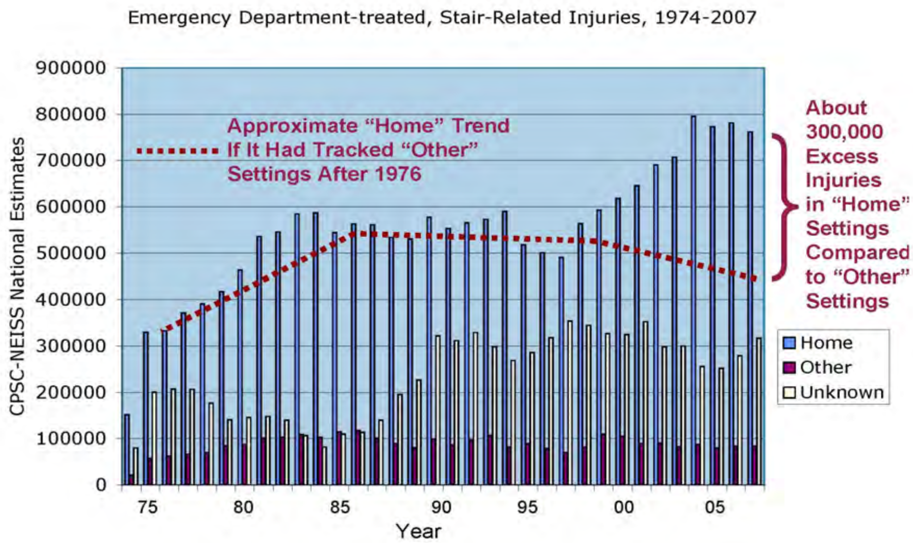
R311.7.4.2.2 Uniformity of winder treads. Consistently shaped winders at the walkline shall be allowed within the same flight of stairs as rectangular treads and do not have to be within 3/8 inch (9.5 mm) of the rectangular tread depth. Winder treads shall have a minimum tread depth of 10 inches (254 mm) measured between the vertical planes of the foremost projection of adjacent treads at the intersections with the walkline. Winder treads shall have a minimum tread depth of 6 inches (152 mm) at any point within the clear width of the stair. Within any flight of stairs, the largest winder tread depth at the walkline shall not exceed the smallest winder tread by more than 3/8 inch (9.5 mm).

Reason: There is no technical change to the requirement in this proposal. It is a clarification of intent by separating out and labeling the separate issues of tread depth and the uniformity of tread depths for rectangular and winder treads, the only two forms of tread addressed in the current code. This proposed change, along with another for R311.7.4.3, is intended to clear up what appears to be widespread confusion resulting in flawed design, inspection, and ICC training plus published guidance regarding the need for every step of a flight to have uniform tread depth (or run) dimensions, measured horizontally, nosing to nosing. (Note that the change also incorporates the change of term "leading edge of tread" to "nosing" as that term was defined in the last cycle and is the term used in R311.7.4.3.) For consistency and to utilize defined terms, "nosing" should be the standard term used here.

A far too common error in design and construction of stairways is the lack of attention to keeping all tread depths, especially the top one in a flight, uniform in size, particularly where projecting nosings are provided on a flight of stairs installed as a manufactured unit which does not include the top or landing nosing projection. ICC IRC guides for inspection and for the homebuilding industry (published by ICC in conjunction with NAHB) fail to even mention these important rules. These two ICC publications are listed in the Bibliography.

The resulting non-uniformities in tread depths, with a larger top tread followed by smaller treads in the flight make the stair flight orders of magnitude more dangerous for descent-direction users. This pervasive systemic defect has also become so concerning to leading stairway safety professionals such as myself that a special website page has been created simply to deal with this issue. See http://web.me.com/bldguse/Site/Stairways.html for information on this including the graph provided below as Figure 1 showing a large increase in the number of home stair-related injuries identified in the CPSC NEISS national estimates for the USA in the last several years. Excerpts of text from the Stairways website page are also quoted below as are excerpts from an American Society of Safety Engineers 2008 Professional Development Conference paper by Pauls and Harbuck. The full ASSE conference paper is freely accessible as a PDF download from the Downloads area of my website, http://web.me.com/bldguse/Site/Downloads.html. Generally, it is suspected that with recent greater use of manufactured stair flights, the incidence of systemic, top-of-flight non-uniformities has grown with resulting significant increases in home stair-related injuries.

Figure 1. Growth of Home Stair-related Injuries in USA in Recent Years.



On the Stairways website page, referenced above, is the following text and photograph (here identified as Figure 2) of a typical dwelling unit stairway with the systemic top-of-flight defect in tread depth non-uniformity. Below Figure 2 is an additional photograph, Figure 3, showing what a stair flight looks like it very likely conforms to the uniformity requirements but which should be properly measured, at least at the top three steps, to confirm that there is not a rare coincidence of both larger tread depth and larger rise dimensions at the top step. Here follows the text from the website which has been publicly available since May 2009.

"While more investigation is required, it appears that a major reason for the recent 'excess' injuries related to home stairs might be a systemic defect on many home stairways (as well as some in other settings) in the USA and Canada. This defect is a non-uniformity of the nosing projection at the top of stair flights; due to the omission of a $10 nosing piece, at the landing level, at the time of stairway construction. This makes the top tread below the landing effectively larger than all the steps below it.

This common defect greatly increases the risk of an 'overstepping misstep' on the second or third step down the flight. Such missteps can lead to a very serious fall down the stair flight, with resulting injuries.

This is why we should now give our stairways 'a second look.' Specifically we should perform the simple 'crouch and sight' test. Do this from the landing above the stair flight you wish to check. Crouch down so you are able to see all the stair nosings (the leading edges) line up. If the top, landing nosing does not line up with all the other step nosings, your stair likely has the systemic defect. Here is a home stairway with the systemic defect."

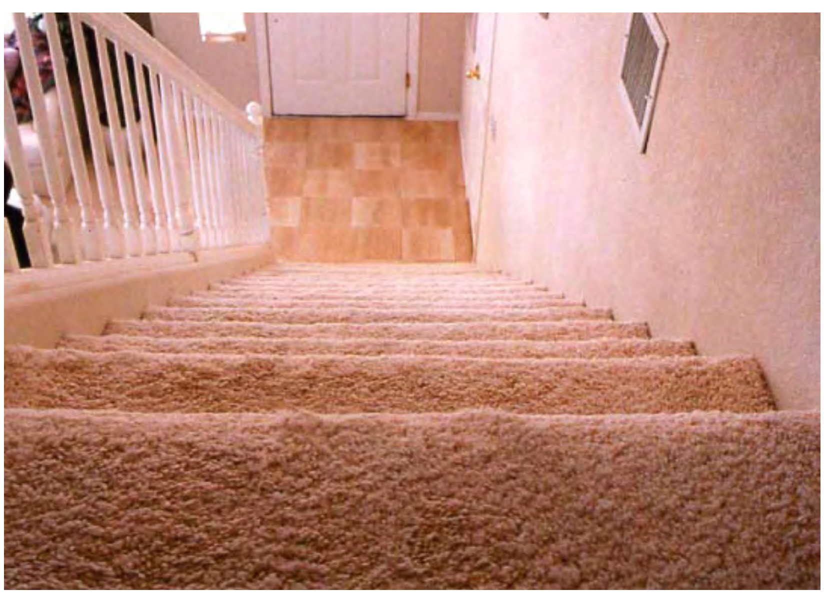


Figure 2. Typical Dwelling Unit Stairway with the Systemic, Top-of-Flight Defect.

The "Stairways" page of the website goes on to provide advice specifically for homeowners who perform the "crouch and sight" test and discover that their stairway has the systemic, top-of-flight defect.

"If your home stairway has this defect—which results from the non-uniformities of nosing projections and of what are called 'tread depth' or 'run' dimensions—and your home was recently constructed, call your local building inspection authorities and request that the stairway be re-inspected for building code compliance. Both the non-uniform nosing projection and the non-uniform tread depth or run are building code violations, for example under widely used codes in the USA.

If there has been a fall and significant injury on the non-uniform stair flight, you might also want to confer with an attorney (experienced in dealing with stair-related injury cases), especially if the home was recently constructed.

Much more information on this (and other) safety problems with stairways is found in the downloadable files associated with this website. See especially the latest papers and presentations by Jake Pauls on home stairways in the two most recently posted folders.

•Home Stairway Safety and Codes (Posted February 2009)

•Presentations at MUTN Conference in BC, Canada, April 2009

Also, in early summer 2009, watch this website for an announcement of the availability of an educational DVD package, based on the one-day workshop at the MUTN Conference in BC, Canada, in April 2009. (Contact Jake Pauls for purchase information.)"

Figure 3. Dwelling Unit Stair Very Likely Not Having the Systemic, Top-of-Flight Defect.

Any ICC chapter wishing to have their members participate in a one-day workshop (also slated for presentation in Eastern Canada on September 14, 2009) should contact Jake Pauls. It is available in a not-for-profit mode. Code authorities should be prepared to deal knowledgeably with consumers who, upon discovering the systemic defect in their homes (after performing their own "crouch-and-sight" test), contact their local building department and ask for a re-inspection of their home stairways. If there has been an injurious fall on such a stairway they should also be prepared to deal with resulting legal actions that might name the local building department as a third party defendant. They should know how to perform the measurements of the stair step geometry that are of a quality expected in such litigation actions. These measurement techniques, usually requiring use of a spirit level or electronic level, are all described in the workshop materials posted on the above-mentioned website Downloads area and on the DVD of the Spring 2009 workshop noted above. These measurement techniques are consistent with the ICC requirements both as currently stated and as further clarified if this proposal is accepted.

In order to begin stopping all future misinterpretations of the IRC requirements for tread depth uniformity, it is hoped that all code enforcement authorities heed very carefully the current and clarified requirements of R311.7.4.2 as well as of R311.7.4.3.

Bibliography

Pauls, J. and Harbuck, S. (2008). Ergonomics-based Methods of Inspecting, Assessing and Documenting Environmental Sites of Injurious Falls Resulting from Missteps on Small Elevation Differences, Slopes and Steps. *Proceedings of the American Society of Safety Engineers Professional Development Conference & Exposition*, Las Vegas, NV, 2008. (Downloadable as file, "Pauls-Harbuck-ASSE-paper.pdf," from folder, "Home Stairway Safety and Codes," accessible from the Downloads area of http://web.me.com/bldguse/Site/Downloads.html.)

Cost Impact: The code change proposal will not increase the cost of construction. (The nosing piece required to comply with both the current code and the code as amended by this proposal costs about $10 per flight in terms of material, in oak, at retail level.)

ICCFILENAME: PAULS-RB1-311.7.4.2

Public Hearing Results

Committee Action: Disapproved

Committee Reason: Based on the committee's previous action on RB46-09/10. The committee prefers the rewrite of RB46-09/10.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

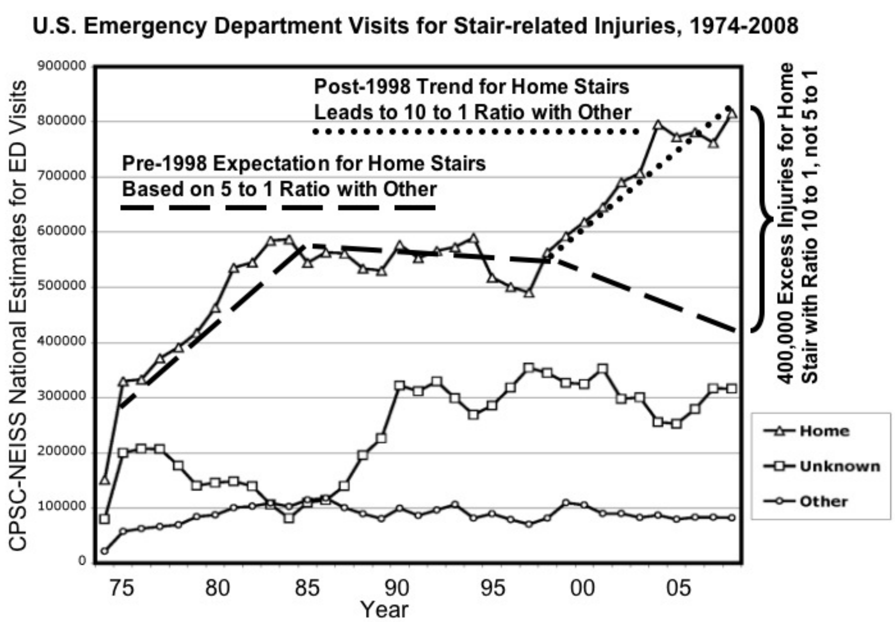
Public Comment:

Jake Pauls, representing self, requests Approval as Submitted.

Commenter's Reason: First, this change is an improvement over RB46-09/10 and reference should be made to my comment on RB46-09/10 which should be disapproved so RB47-09/10 can be approved instead along with E75-09/10 Part II. Both RB47-09/10 and E75-09/10 Part II should be approved as submitted.

RB47-09/10 solves a problem created by the current inadequate organization of tread geometry requirements in the IRC by simply breaking the text into more manageable sections, with each section dealing with a particular issue. E75-09/10 Part II does the same for riser geometry. Neither changes the requirements in the particular sections so there is no cost impact. However, clarity thus achieved will reduce design, construction and enforcement costs while contributing to safety levels that were intended by the rules but which are not being achieved. See the evidence of the home stairway safety problem below, in Figure 1 and the discussion of the five apparent reasons for the poor safety record of home stairways. One of the five reasons is addressed by this comment (and by the approval of RB47-09/10 and E75-09/10 Part II); other of my comments address some of the other reasons.

Figure 1. Growth of Home Stair-related Injuries in USA in Recent Years
This is an update, including data for 2008, of Figure 1 in proposal RB47-09/10



Rather than repeat the extensive justification provided for RB47-09/10, this comment focuses on newer data and improved presentation of the data (as in Figure 1) coming from the US Consumer Product Safety Commission (CPSC) National Electronic Injury Surveillance System (NEISS).

Five reasons have been identified recently for the diverging injury records for home stairways and for stairways in all other settings. The former are rising rapidly (approaching a growth rate of over 4 percent, about five times US population growth) in a trend begun at about the time the ICC started affecting residential codes in the USA through its production and promotion of the International Residential Code. The latter are now dropping at a notable rate (about 2 percent reduction per year at a time of about 1 percent a year of population growth in the USA). These factors, in no particular order, are:

(A) Significantly lower ICC standard for maximum rise and minimum tread depth for home stairs (the result of the code-development compromise and the code-adoption compromise).
(B) The systemic top-of-flight defect in many homes' (and some other buildings') stairs partly due to ICC's failure to provide clearly stated code requirements and to include the rules preventing this in their inspection guides.
(C) ICC's adoption of seriously compromised requirements for handrails for home stairways.
(D) An apparent deterioration in enforcement/inspection quality generally in relation to homes, partly influenced by the widespread perception—possibly nurtured by ICC leaders—that the builders' work should receive minimal scrutiny in view of their "Strategic Partnership."
(E) The concurrent deterioration of movement performance of population capability generally with the effects of reduced physical activity, overweight and obesity. (In a public health model, this should lead to increased—*not decreased*—compensation with the design and construction of critical built environment features such as stairways, particularly in the home settings where the most vulnerable populations and use conditions are common and easily predicted.)
(F)

This comment, and Proposal RB47-09/10, address the second of these reasons, i.e., (B). This defect with many home stairs is caused by the failure to have a uniform tread depth on all the steps of a stair when the floor or landing nosing projection is less than that of all the other treads in the flight. Figure 2 shows such a badly constructed stair in a new US home. The defect is easily identified without any tools; the inspector (or builder) need only do the simple "crouch and sight test" from the upper landing to check to see if all the nosings line up as they will do with a code-complying stair. (See also the website, http://web.mac.com/bldguse/Site/Stairways.html for additional information on this problem and its elimination.)

Figure 2. Typical Home Stair with Top-of-Flight, Tread Uniformity Defect

The re-organization of R311.7.4.2 by separates different topics into new sections, R311.7.4.2.1 Uniformity of rectangular tread depths and R311.7.4.2.2 Uniformity of winder treads. My proposal E75-09/10 Part II complements proposal RB47-09/10 by dealing with the important matter of nosing projection uniformity, the main mechanism for making the tread depths consistent for all steps of a flight. (The IBC Means of Egress Committee got proposal E75-09/10 Part I right with their approval while the IRC BE Committee got the corresponding IRC proposal, E75-09/10 Part II wrong with their disapproval.)

These proposals do not introduce technical changes. Rather these are badly needed clarifications of the Codes' intent and requirements which are clumped together in the current codes so that important features are missed by designers, builders and enforcers. The separate issues should be given separate sections so they are not lost in a mass of text.

Note that the Code is so broken that even the experts who write two of ICC guides get this matter wrong. They completely miss the important rules that are separated into distinctive sections with the approval of RB47-09/10. (Those two guides, purchased from ICC as recently as January 2010 to confirm they are still defective, are the Residential Inspector's Guide Based on the 2006 IRC, Chapters 1-11, and Home Builders' Jobsite Codes: a Pocket Guide to the 2009 International Residential Code.)

Of all the five reasons for increased home stair-related injuries, the systemic top-of-flight defect is the most potent. It increases the risk of a misstep and fall near the top of the stair flight by orders of magnitude (one or more factors of ten). This is the simplest of all five defects to prevent. The cost is very small, about 10 dollars of material for the landing or floor level nosing piece. The benefit of this small fix—which the codes demand but which builders and inspectors too often miss—is many, many times greater.

Again, proposal RB75-09/10 should be adopted as submitted along with E75-09/10 Part II. (Note, as addressed in a separate comment on RB74-09/10, that code change proposal should be disapproved; it does a very inadequate job in fixing the organization of the code requirements for reasonable clarity.)

For additional detail, refer to the substantiation provided with proposal RB75-09/10.

Final Action: AS AM AMPC____ D

RB48-09/10
R311.7.3 (New), R311.7.5

Proposed Change as Submitted

Proponent: David W. Cooper, Stair Manufacturing and Design Consultants, representing the Stairway Manufacturers'

1. Add new text as follows:

<u>**R311.7.3 Vertical rise.** A flight of stairs shall not have a vertical rise larger than 12 feet (3658 mm) between floor levels or landings.</u>

2. Revise as follows:

R311.7.5 Landings for stairways. There shall be a floor or landing at the top and bottom of each stairway. <u>The minimum width perpendicular to the direction of travel shall be no less than the width of the flight served. The edges of landings may be curved or segmented. Landings used to turn the direction of travel less than 90 degrees but no less than 60 degrees shall not be considered winder treads provided the depth at the walk line is no less than 18 inches and the minimum depth is no less than 6 inches (152 mm). Where the stairway has a straight run the minimum depth in the direction of travel need not exceed 36 inches (914 mm).</u>

> **Exception:** A floor or landing is not required at the top of an interior flight of stairs, including stairs in an enclosed garage, provided a door does not swing over the stairs. ~~A flight of stairs shall not have a vertical rise larger than 12 feet (3658 mm) between floor levels or landings. The width of each landing shall not be less than the width of the stairway served. Every landing shall have a minimum dimension of 36 inches (914 mm) measured in the direction of travel.~~

Reason: There are certain attributes of landings that are intended to be or need to be regulated by the code but this section currently needs improvements to consistently determine the allowed dimensions or shape of landings. The common interpretations currently referenced in the commentary have been used to develop this proposal. Further the fractured arrangement of text following the exception is eliminated and prevents confusion of requirement and exception.

1. The **Vertical rise** section being added is actually relocated without change from below the exception in **R311.7.5**. The name and text is technically consistent with the IBC. The information in this section is needed to calculate the number of risers between levels, the riser height, and the tread depth of each flight or stair in a stairway. For this reason, if such a requirement is needed, it should be included with the essential elementary sections that precede the tread and riser sections to assure understanding and compliance.
2. The revision adds text to **R311.7.5** that clarifies what dimension is actually the width or widths of the landing. By stating that width is perpendicular to the direction of travel the shape of landings and the intent to allow curved and segmented corners as stated in the commentary is covered. The required sizes are not changed and remain the same.
3. Differentiation between angular shaped landings and winder treads is also needed and provided by the additional text. The text defines the minimum size that is comparable and slightly exceeds the minimum distance of travel the user experiences on the most common 90-degree landing. Please see figures 1, 2, and 3 attached. It is easy to see that the shape of the landing can be inconsequential to its width and its use in the stairway provided the minimum criteria suggested here are achieved. The clear differentiation between landings and winders stated here is important because landings separate flights and winders do not. Stair components regulated “within a flight” such as handrails, riser height, tread depth, dimensional uniformity, etc. are all dependent upon a determination that currently requires better description for consistent understanding.

R311.5.7 Stairway Landings

Figures 1,2, & 3 below illustrate the minimum dimensions proposed of a stairway landing that turns less than 90 degrees.
Note: The outside of each landing is shown with both segmented and curved options that would clarified if the minimum width of the landing described as "measured perpendicular to the line of travel" by this proposal is clarified.

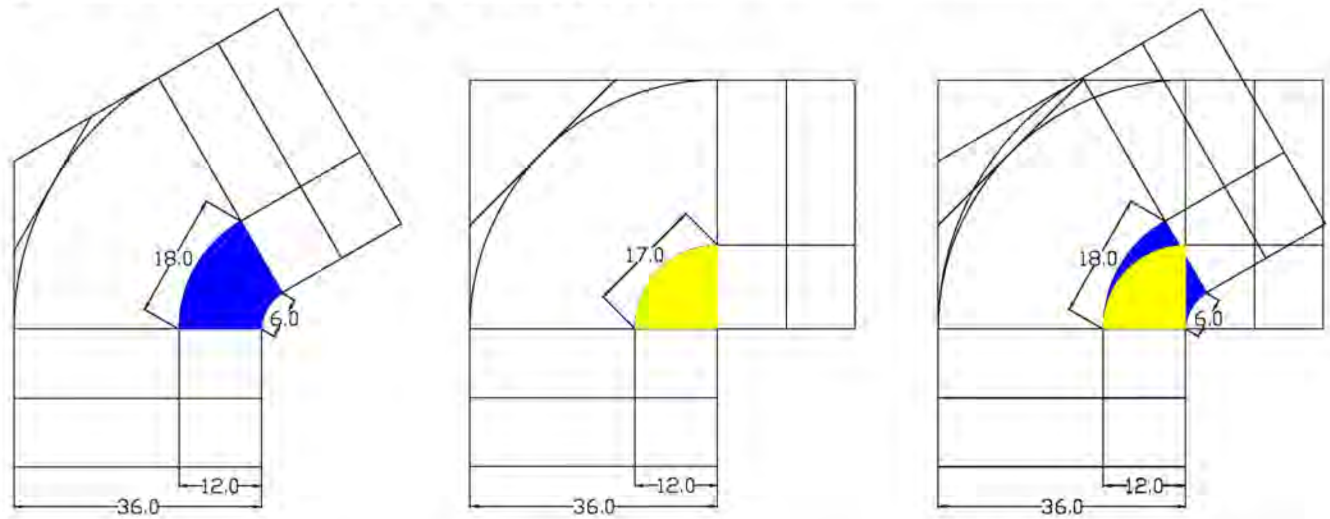


Figure 1:
Proposed 60 degree minimum Landing. The critical area inside of the walk line is shaded.

Figure 2:
Convetional 90 degree Landing. The total area inside of the walk line is shaded

Figure 3:
The 60 and 90 degree landings are shown superimposed . The total area inside of the walk line of the 60 degree winder is clearly comparable to that of conventional landings when the suggested minimum dimensions are applied.

4. The needed exception remains in tact without change.
5. Please note all the text deleted following the exception has been incorporated within **R311.7.5** or relocated under **Vertical rise** as stated above.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: COOPER-RB-3-R311.7.3-R311.7.5

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee feels that the definition of winders historically works for the geometry that is here. If the proposed geometry is specific to a specific type of stairway then a new code section specifically addressing the problem is needed. The last sentence is such that it would allow a landing less than 36 inches. This should be reworked and brought back.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

David W. Cooper, Stair Manufacturing and Design Consulting, representing Stairway Manufacturers' Association, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R311.7.3 Vertical rise. A flight of stairs shall not have a vertical rise larger than 12 feet (3658 mm) between floor levels or landings.

R311.7.5 Landings for stairways. There shall be a floor or landing at the top and bottom of each stairway. The minimum width perpendicular to the direction of travel shall be not less than the width of the flight served. Landings of shapes other than square or rectangular shall be permitted provided ~~The edges of landings may be curved or segmented. Landings used to turn the direction of travel less than 90 degrees but no less than 60 degrees shall not be considered winder treads provided~~ the depth at the walk line and the total area is not less than that of a quarter circle with a radius equal to the required landing width. ~~is no less than 18 inches and the minimum depth is no less than 6 inches (152 mm).~~ Where the stairway has a straight run the minimum depth in the direction of travel shall be not less than ~~need not exceed~~ 36 inches (914 mm).

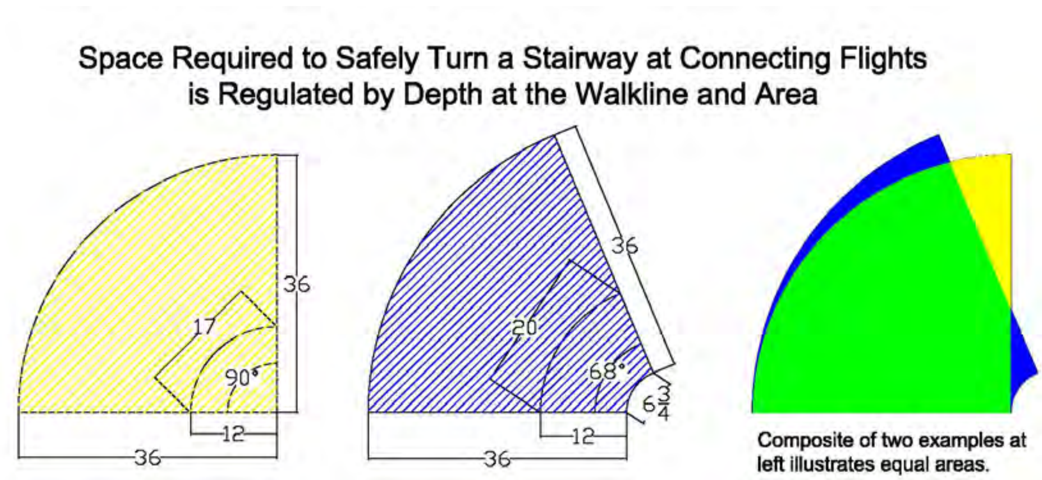
Exception: A floor or landing is not required at the top of an interior flight of stairs, including stairs in an enclosed garage, provided a door does not swing over the stairs.

Commenter's Reason: In Baltimore the committee commented in agreement with the addition of the new vertical rise section and the proponent's reason. They also liked the clarification that landing width is perpendicular to the direction of travel. Part of the confusion in the current text is the reference to width and no correlation with depth. Tread depth is measured in the direction of travel and depth is so associated. The depth of landings is clarified by using the term "depth in the direction of travel" in the last sentence. These solutions remain in tact in this modification and are supported in the proponent's original statement. It is important to understand that although the minimum stairway width is 36 inches the minimum landing size is related to the width of the flight served.

The intent of the original proposal was to clarify that landings of different shapes are not to be excluded if they provide sufficient space to serve as landings. The original drawings submitted clearly identify that other shapes can provide the same space or more than that of square or rectangular landings at the turn. The commentaries clearly state it is not the intent to require that a stairway landing be shaped as a square or rectangle. Although the original language of the proposal provides specific requirements the same intent has been accomplished and simplified in this modification to allow ease of enforcement without measuring angles.

The requirement now essentially relates that the landing be designed with concern for the gait of the user at the walkline by providing a depth at the walkline of not less than that which would be experienced on a rectangular landing. Further more the provision for an area equivalent to the relevant portion of a square landing has been added slightly increasing the size from the original proposal. Please see that the two landings illustrated below have the same width and area but are of different shapes allowing the safe turning of the stair at an angle of less than 90 degrees with out resorting to winder treads. In this example both landings would be considered acceptable minimum size landings for a stairway that is 36 inches wide.

Finally the committees concern to modify the language of the last sentence has also been addressed. (Please see the drawings submitted below) This modification provides clarification of the most common enforcement practices and substantially improves the interpretation and enforcement of the code.



Final Action: AS AM AMPC____ D

RB49-09/10
R311.7.7.1

Proposed Change as Submitted

Proponent: David W. Cooper, Stair Manufacturing and Design Consultants, representing the Stairway Manufacturers'

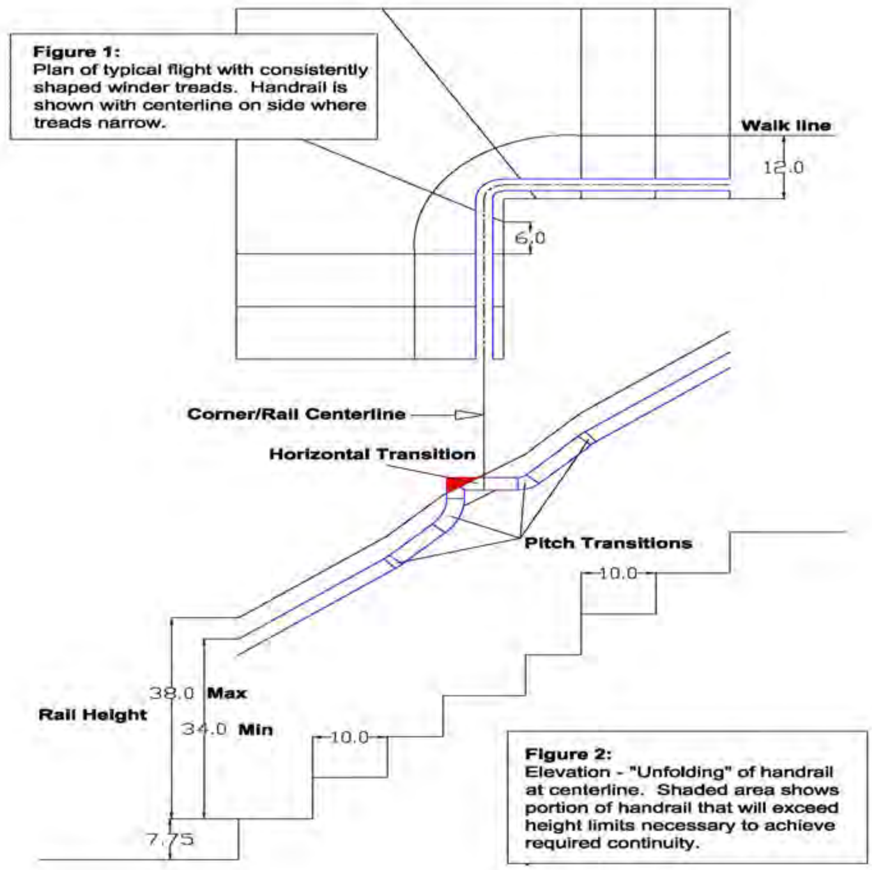
Revise as follows:

R311.7.7.1 Height. Handrail height, measured vertically from the sloped plane adjoining the tread nosing, or finish surface of ramp slope, shall be not less than 34 inches (864 mm) and not more than 38 inches (965 mm).

Exceptions:

1. The use of a volute, turnout, or starting easing shall be allowed over the lowest tread.
2. When handrail fittings or bendings are used to provide continuous transition between flights, transitions at winder treads, the transition from handrail to guardrail, or used at the start of a flight, the handrail height at the fittings or bendings shall be permitted to exceed the maximum height.

Reason: Winder treads do not separate flights and the handrail transitions that must occur above them are not considered included by the text of this exception. As the original proponent of this exception adopted in 2007 this was an oversight. When using readily available fittings and bendings to provide continuity of the handrail above winder treads, especially at the side of the stair where the treads are narrower the height of the handrail may exceed the limits of 34 to 38 inches. The radical changes of angle in the short distances are best understood by studying this condition in elevation. Figure 1 shows a typical stairway plan and Figure 2 illustrates the unfolding of the elevation of the handrail and stair geometry. This additional condition should be included as it is of the same nature as those conditions already recognized and cited in the exception.



Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: COOPER-RB-2-R311.7.7.1

Public Hearing Results

Committee Action: Approved as Submitted

Committee Reason: The committee feels this is a good change that is a necessary addition to clarify the condition of continuity of the handrail at windows.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jake Pauls, representing self, requests Disapproval.

Commenter's Reason: RB49-09/10 is a bad code change. It permits significant discontinuities in handrail continuity at points in a stairway where such continuity is especially important, for example in moving between rectangular and winder treads. It makes a dangerous part of the stairway more dangerous**.**

Here it should be noted that the Stairway Manufacturers' Association (SMA) has contributed a great deal to reducing the usability and safety of required handrails for stairways. This is yet another step away from reasonably safe stairways because it allows ones handhold—to the limited extent that a handhold is even possible with the railing sections SMA favors, particularly the Type II railings—to be broken as a angular transition is introduced instead of a smooth curve. Smooth curves were traditionally possible when stairway design and construction was the highest example of the art and technology of joinery. It was done in wood as well as metal, there are even excellent examples of smooth transitions or curves being done in Type I handrails of wood. Figure 1 shows an extreme example of how badly handrails are done on some new home stairways at winders. Not only does the configuration look awful, it is even worse to hold on to than to look at. This change permits and encourages this kind of crude design and construction. If the stairway industry is going to mix rectangular and winding steps it should spend some effort to rediscovering how traditional craftsmen accomplished much more elegant and functional solutions to the problem of curved handrails. Moreover they did it without computers, using only pencil and paper.

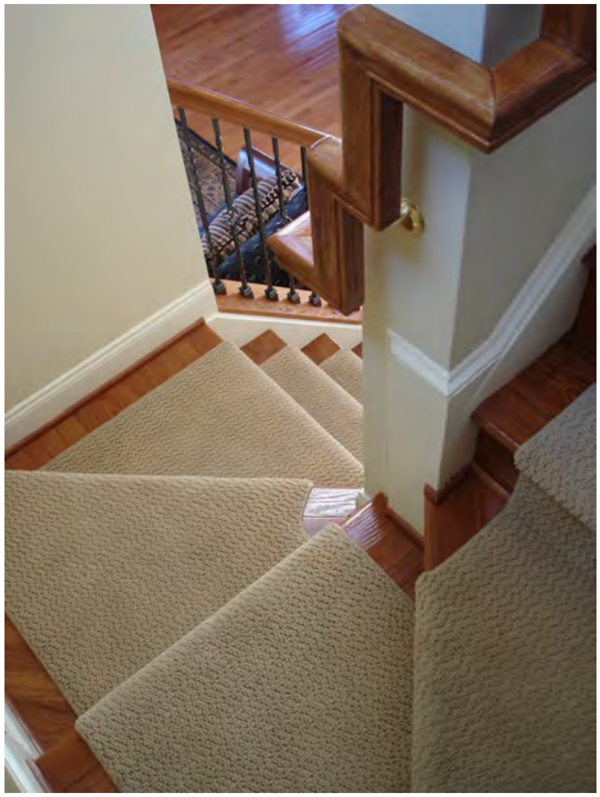


Figure 1. Crude fittings permitted at winders by relaxed Code rules.

Final Action: AS AM AMPC____ D

RB51-09/10
R312.1, R312.2

Proposed Change as Submitted

Proponent: Rick Davidson, City of Maple Grove, MN

Revise as follows:

R312.1 Where required. Guards shall be located along ~~open-sided walking surfaces, including~~ open sides of decks, porches, balconies, raised floor surfaces, stairs, ramps and landings~~,~~ that are located more than 30 inches ~~measured vertically to~~ above the floor or grade below ~~at any point within 36 inches (914 mm) horizontally to the edge of the open side. Insect screening shall not be considered as a guard.~~

Guards shall be provided on porches, balconies, and decks enclosed with insect screening when the porch, balcony, or deck floor is located more than 30 inches (762 mm) above the floor or grade below.

R312.2 Height. Required guards ~~at open-sided walking surfaces, including stairs, porches, balconies or landings,~~ shall be not less than 36 inches (914 mm) high ~~measured vertically above the adjacent walking surface, adjacent fixed seating or the line connecting the leading edges of the treads~~.

Exceptions:

1. Guards on the open sides of stairs shall have a height not less than 34 inches (864 mm) measured vertically from a line connecting the leading edges of the treads.
2. Where the top of the guard also serves as a handrail on the open sides of stairs, the top of the guard shall not be not less than 34 inches (864 mm) and not more than 38 inches (965 mm) measured vertically from a line connecting the leading edges of the treads.

Reason: The current language referencing "open sided walking surfaces" is vague, undefined and unenforceable. It isn't clear if this means ***any*** surface upon which someone could walk, defined walking surfaces, or only those surfaces that are part of a dwelling. One could interpret a driveway adjacent a stepped lot line being a regulated "open sided walking surface" and require a guard along its entire length. One could interpret the upper surface of a retaining wall as a walking surface requiring a guard. If a yard is a walking surface, one could interpret egress window wells as needing a guard. Is this what is intended? Conceivably we could have guards crisscrossing residential lots in willy nilly fashion whenever we have elevation changes. If a retaining wall exists on my neighbors property and there is a 3 foot drop from the top of this wall to the grade below and my driveway or my sidewalk is within 36 inches of this retaining wall, is a guard required even if the elevation change does not occur on my property? It would seem so! The code requires that I measure up to 36 inches away from the walking surface. Then, is it his responsibility to install the guard or is it mine? His lot creates the perceived hazard, not mine. If I install the guard on my property, there is still space on the other side of the guard to walk. Is the neighbor also required to install a guard? If my deck is 24 inches above grade below and 2 feet from my lot line and my neighbor has a 16 inch high retaining wall adjacent the lot line, does my deck require a guard? Is it me that creates the hazard or is it my neighbor? Who is responsible for the guard?

The new language addressing insect screening changes the original intent of these terms. When the code states that insect screening shall not be considered a guard, is it implying that windows must have fall protection and that screening does not constitute a guard? One must ask not just how a building official might interpret this language but how might a jury interpret this language if faced with a fall from a window that had only window screening. Might they conclude the code required additional protection?

Last, the code requires that guard height be measured from "adjacent fixed seating". How far must a fixed seat be from the edge of the surface in question before it isn't considered "adjacent"? Must it be in contact with the guard? If I say my house is adjacent to the park, do I mean my house is on the immediate border of the park or some short distance away? And, if I have a fixed seat next to the edge of a walking surface, is it an open walking surface that would require a guard or not? I can no longer walk on the surface near the elevation change.

This is a horribly worded code section that cannot be understood by the public and cannot be easily interpreted by the building official. The language is vague, ambiguous, and confusing. That is the worst kind of language to try to enforce.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: DAVIDSON-RB-7-R312.1

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee feels that although there isn't a specific definition of open sided walking surfaces, it is understood what a walking surface is and the difference is not significant enough to limit to the items proposed. This change would delete the fixed seating requirements. The committee likes getting rid of open sided walking surface. The proponent should get together with the proponent of E100-09/10, Part II and rework and bring back.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment 1:

Rick Davidson, representing self, requests Approval as Submitted.

Commenter's Reason: The requirements for guards in the 2006 IRC were clear, succinct, and direct. It read:

> ***Guards.*** *Porches, balconies, ramps or raised floor surfaces located more than 30 inches (762 mm) above the floor or grade below shall have guards not less than 36 inches (914 mm) in height. Open sides of stairs with a total rise of more than 30 inches (762 mm) above the floor or grade below shall have guards not less than 34 inches (864 mm) in height measured vertically from the nosing of the treads.*

Guards were only required for "porches, balconies, ramps or raised floor surfaces" and "open sides of stairs".

It was clear that the rule did not apply to retaining walls, landscaping features, driveways, or any other location on the property except for those locations specifically listed.

Then the code was "improved". The language in the 2009 IRC reads:

> ***Where required.*** *Guards shall be located along open-sided walking surfaces, including stairs, ramps and landings, that are located more than 30 inches (762 mm) measured vertically to the floor or grade below at any point within 36 inches (914 mm) horizontally to the edge of the open side. Insect screening shall not be considered as a guard.*

Now the code requires guards "along open-sided walking surfaces". Interpreted literally, virtually any place on the lot, inside or outside of the dwelling could be considered a "walking surface". No longer is the guard requirement applicable to something that is constructed as a part of the dwelling but physical features of the site may also trigger guard requirements. Comments made during the hearings in Baltimore suggested that it was the intent of the language to require guards along retaining walls. This opens the door to requiring guards around window wells and the difficulties that creates. There is no direction given in the language to provide guidance for interpretation and there will be no uniformity in its enforcement.

This is a huge departure from what was required in the 2006 IRC that limited guards to features normally considered part of the dwelling.

Even the IRC Committee is confused about the language. In their reason statement for disapproving this code change they stated: "The committee feels that although there isn't a specific definition of open sided walking surfaces, it is understood what a walking surface is and the difference is not significant enough to limit to the items proposed." Then they further stated: "The committee likes getting rid of open sided walking surface." And last, "The proponent should get together with the proponent of e100-09/10, Part II and rework and bring it back."

The language that is proposed is the same language that was in the first three editions of the IRC. It covered all of those scenarios likely found in residential dwelling construction.

The current language also creates confusion regarding the use of insect screening. The 2006 IRC language was patterned after that found in the IBC and read: "Porches and decks which are enclosed with insect screening shall be equipped with guards where the walking surface is located more than 30 inches (762 mm) above the floor or grade below." It was clear that the intent was to prohibit screening that was commonly used in screen porches and similar structures from meeting the requirements of a guard.

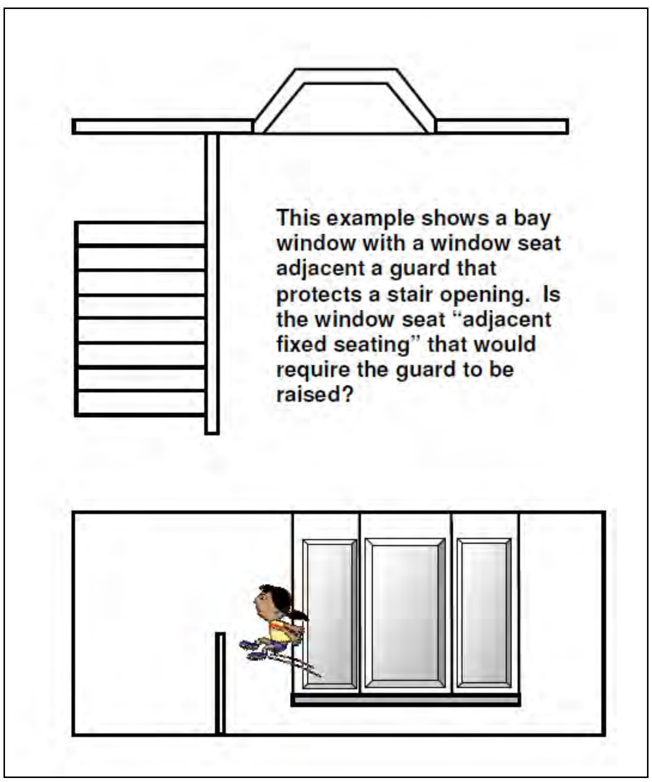
The language in the 2009 IBC has not changed. It continues to read: "1013.4 Screen porches. Porches and decks which are enclosed with insect screening shall be provided with *guards* where the walking surface is located more than 30 inches (762 mm) above the floor or grade below." It is clear that the screening language in the IBC applies only to screen porches.

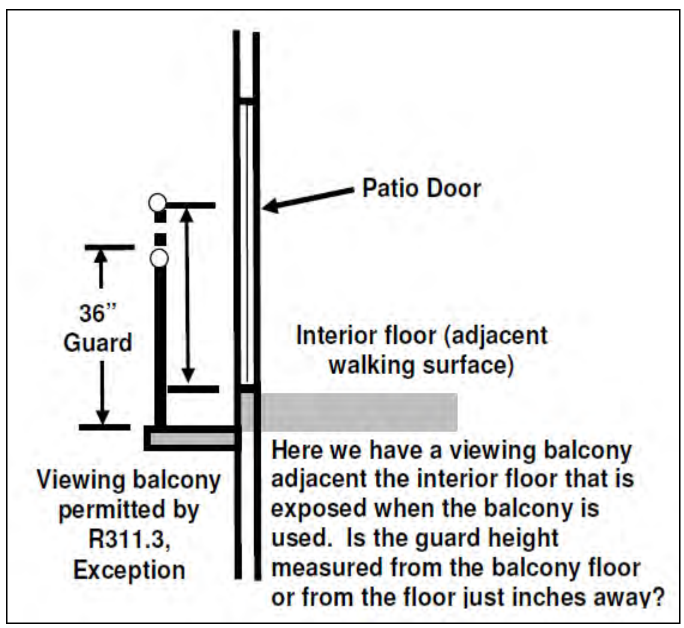
The new language in the IRC simply states: "Insect screening shall not be considered as a guard." There is no qualifying language that references screen porches. It states that screening can't be used as a guard along "open sided walking surfaces". Now we are back to what constitutes an "open sided walking surface". The language is already being challenged in the courts to include certain windows. Since the most common application of insect screening is for windows, it is reasonable to make that connection. That should not be the direction of the code. The language in the IRC is significantly different than that found in the IBC.

The last issue that the proposal addresses is that of measuring the height of guards from "adjacent fixed seating". There has been no data to support the notion that fixed seating occurring near a guard is dangerous. And isn't it much more likely that moveable seating and other furnishings will be placed adjacent guards also creating a "hazard" and they are unregulated. The 2009 language is a solution looking for a problem. As the rule applies to decks, people have decks so they can sit outside and enjoy the views and fresh air, not the inside of a guard. And it isn't uncommon to have window seats near a guard as shown in one of the following illustrations. The hypocrisy is that the window seat could be next to an open window with no regulation but a guard that may be considered "adjacent" would need to tower 36 inches above the window seat.

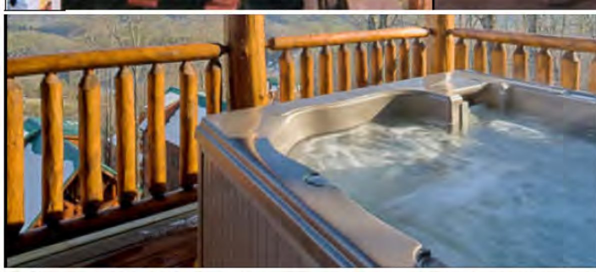
Because the code requires that guards be able to resist a single concentrated load of 200 pounds at any point along the top of the guard, attaching a five or six foot tall guard to meet this requirement becomes expensive and unnecessary for residential construction.

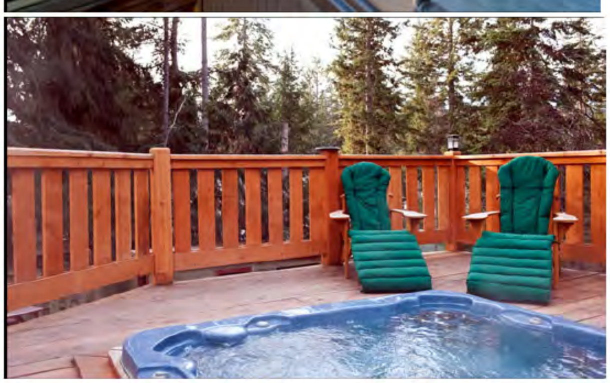
The current language creates all sorts of unintended consequences, is confusing and difficult to interpret, and removed language from the code that was never shown to be a problem.



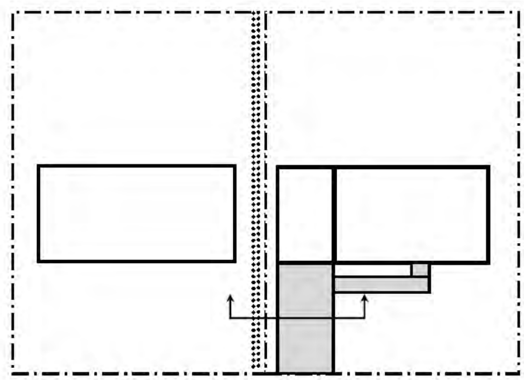


This picture illustrates two issues that arise with the current language on guards. First, we have a walking surface that is more than 30 inches above a point within 36 inches of the open side of the walking surface. Therefore a guard 36 inches high is required. Then we have adjacent fixed seating in the form of the seating around the edge of the hot tub. The seating is 42 inches above the walking surface. Therefore the total height of the guard at this location will be 78 inches. The IRC requires that the guard be able to resist a "single concentrated load (of 200 pounds) applied in any direction along the top." This will require some very substantial mounting hardware to attach the guard to the patio to resist such forces.





Each of these photos illustrates a possible application of a guard next to adjacent fixed seating. In all of the pictures one could interpret the code to require that the guard be 36 inches higher than the adjacent fixed seating. In the photo to the lower left, the edge of the hot tub is approximately 6 inches above the floor of the deck. Therefore the railing should be raised for that portion of the railing that is considered "adjacent the fixed seating.



If the retaining wall is more than 30 inches high, must a guard be placed along the driveway which creates an open sided walking surface if the edge of the driveway is less than 36 inches from the wall? The retaining wall is on the neighbor's property. Who must install the guard, the owner creating the hazard or the owner creating the walking surface? Could the owner of the driveway place a guard along the driveway or must it be installed at the lot line?

Public Comment 2:

Gerald Anderson, City of Overland Park, KS, requests Approval as Modified by this Public Comment.

Replace proposal as shown:

R312.1 Where required. Guards shall be located along open-sided walking surfaces,~~ including~~ on stairs, ramps ~~and~~ landings, decks, porches, balconies and other raised floor surfaces~~,~~ that are located more than 30 inches measured vertically to the floor or grade below at any point within 36 inches (914 mm) horizontally to the edge of the open side. Insect screening shall not be considered as a guard.

Guards shall be provided on porches, balconies, and decks enclosed with insect screening when the porch, balcony, or deck floor is located more than 30 inches (762 mm) above the floor or grade below.

R312.2 Height. Required guards ~~at open sided walking surfaces, including stairs, porches, balconies or landings,~~ shall be not less than 36 inches (914mm) high. ~~measured above the adjacent walking surface, adjacent fixed seating or the line connecting the leading edges of the treads~~.

Exceptions:

1. Guards on the open sides of stairs shall have a height not less than 34 inches (864 mm) measured vertically from a line connecting the leading edges of the treads.
2. Where the top of the guard also serves as a handrail on the open sides of stairs, the top of the guard shall not be not less than 34 inches (864 mm) and not more than 38 inches (965 mm) measured vertically from a line connecting the leading edges of the treads.

Commenter's Reason: As the original proponent has stated, the current code language regarding "open sided walking surfaces" is vague, undefined and unenforceable. The primary problem is that the code doesn't restrict where one might find an open sided walking surface. As the code is currently written one might find an open sided walking surface along a small retaining wall out in the middle of a yard. The code has never required a guard in such a space. This change is needed in order to more clearly specify where guards are required.

Final Action: AS AM AMPC____ D

RB60-09/10
R315, R315.1.1, R315.1.2, R315.1.3, Chapter 44

Proposed Change as Submitted

Proponent: Scott Dornfeld, City of Delano, MN

1. Delete without substitution:

~~**SECTION R315**~~
~~**CARBON MONOXIDE ALARMS**~~

~~**R315.1 Carbon monoxide alarms.** For new construction, an approved carbon monoxide alarm shall be installed outside of each separate sleeping area in the immediate vicinity of the bedrooms in *dwelling units* within which fuel-fired *appliances* are installed and in dwelling units that have attached garages.~~

~~**R315.2 Where required in existing dwellings.** Where work requiring a *permit* occurs in existing *dwellings* that have attached garages or in existing dwellings within which fuel-fired *appliances* exist, carbon monoxide alarms shall be provided in accordance with Section R315.1.~~

~~**R315.3 Alarm requirements.** Single station carbon monoxide alarms shall be listed as complying with UL 2034 and shall be installed in accordance with this code and the manufacturer's installation instructions.~~

2. Delete standard as follows:

UL
~~2034-2008 Standard for Single and Multiple Station Carbon Monoxide Alarms~~

Reason: A new rule should never be imposed unless it can be shown that there is a significant hazard posed that can be directly influenced by the rule. It is not the goal of the I-Codes, the stated purpose of which is to provide minimum standards, to eliminate all hazards such that no one will ever be killed or injured as a result of the design of or a defect in a building. It is simply too expensive and impractical to do so. Such is the case with the addition of carbon monoxide requirements in the IRC that nationwide will increase costs to homeowners in the hundreds of millions of dollars with a potentially negligible impact on CO deaths. Additionally, it requires that the alarms be installed any time work is done and a permit is required. This means if I have my house reroofed, I must install CO alarms (but not smoke alarms). I would be required to install them if I have an attached garage even when studies show the likelihood of carbon monoxide poisoning occurring from motor vehicles is extremely low and even if portions of the garage are permanently open to the outside.

Following are some excerpts taken from a publication by the Consumer Product Safety Commission entitled ***"Non-Fire Carbon Monoxide Deaths Associated with the Use of Consumer Products 2003 and 2004 Annual Estimates".***

P. 4 - During 2004, the most recent year for which nearly complete data are available, there were an estimated 162 carbon monoxide (CO) poisoning deaths associated with the use of a consumer product under the jurisdiction of the U.S. Consumer Product Safety Commission (CPSC). There were an estimated 154 fatalities in 2003. Carbon monoxide poisonings referred to in this report do not include those where the CO gas resulted from a fire or a motor vehicle, were intentional in nature or were directly work-related.

Comment: The number of CO deaths was often cited as being in the thousands, not 150-160, which is the accurate number.

\+ Data collection for 2003 and 2004 is incomplete. Italicized estimates may change in the future.
* No reports received by CPSC staff.
Source: U.S. Consumer Product Safety Commission / EPHA.
CPSC Death Certificate File, CPSC Injury or Potential Injury Incident File, CPSC In-Depth Investigation File, National Center for Health Statistics Mortality File, 1999 - 2004.
Note: Reported average percentages by product may not add to total due to rounding.

P. 6 - Of the 47 estimated deaths in 2003 and 2004 that were associated with LP gas heating systems, 32 (68%) involved unvented portable propane heaters. These unvented portable propane heaters were fueled by a propane tank and were not a component of an installed heating system. Unvented portable propane heaters were either camping heaters that used disposable propane tanks, one pound propane bottles, or tank top heaters that used bulk tanks larger than one pound.

Comment: Unvented portable propane heaters cannot be used as a primary heat source in a building. Therefore these incidents likely occurred when they were used for temporary heat or in locations outside a home such as a camping unit. Requiring CO alarms in homes will have no impact on CO deaths that occur in camping trailers and locations other than the home. Requiring CO alarms in homes because someone might bring an unvented heater into their house and improperly use it is unwarranted.

P. 6 - In 2003 and 2004, an estimated 11 CO deaths (3% of the 316 total consumer product estimate) were associated with charcoal or charcoal grills; an estimated eight deaths (3% of the total consumer product estimate) were associated with a gas water heater; gas grills, camp stoves and lanterns were associated with an estimated eight deaths (3% of the total consumer product estimate); gas ranges and ovens were associated with an estimated seven deaths (2% of the total consumer product estimate); and three deaths were either associated with consumer products that did not fit into the categories given above or there was insufficient detail to categorize the appliance. One fatality was associated with a propane-fueled refrigerator, one was associated with a product simply defined as a "propane appliance" and another as a "gas-fueled appliance".
These incidents were categorized as "Other appliances". Additionally, in 2003 and 2004 an estimated 12 deaths were associated with multiple appliances (4% of the total consumer product estimate). The multiple appliances category included all incidents where multiple fuel-burning products were used simultaneously such that a single source of the CO could not be determined. Of the 12 multiple appliance fatalities, six were associated with a generator and another product. These other products were a kerosene heater (three deaths), an LP gas heater (two deaths) and a wood stove. Other fatalities where multiple products were simultaneously used and associated with a CO poisoning death involved a portable propane heater and a gas-powered snow thrower; a portable propane heater and a propane lantern; a kerosene heater and a propane heater; a natural gas heater and hot water heater; a propane furnace and a propane oven in a travel camper; and a natural gas furnace and natural gas oven.

Comment: While it may seem cruel, at times one needs to invoke the "any idiot rule". The code should not require CO alarms to deal with people operating charcoal grills or lawn mowers in their living rooms.

P. 6 - An estimated 112 CO poisoning deaths (35% of the estimated total from 2003 and 2004) were associated with engine-driven tools, which includes generators, riding mowers, a concrete cutter, a gas-fueled welder, power washers, a water pump, an air compressor and an ATV. Generator associated deaths comprise the majority of this category. There were an estimated total of 91 generator-related CO poisoning deaths in 2003 and 2004 (81% of all engine-driven tool fatalities and 29% of the total consumer product estimate).

P. 7 - Of the 123 liquid fueled appliance-related fatalities in 2003 and 2004, 112 (91%) were associated with all engine-driven tools (generators, lawn mowers, power washers, concrete saws, etc.). Generators accounted for 91 of the estimated 123 fatalities (74%) in the Liquid Fueled Appliances category.

P. 11 - Table 6 shows that in 2003 and 2004, an estimated 230 CO poisoning deaths occurred in homes, including manufactured and mobile homes. From 2002-2004, an annual average of 72 percent of CO poisoning deaths occurred in homes, including manufactured and mobile homes. In 2003 and 2004, an estimated 45 deaths took place in temporary shelters, such as tents, recreational vehicles, cube vans, seasonal cabins, and trailers (including horse trailers). In 2002- 2004, an annual average of 17 percent of CO poisoning deaths took place in temporary shelters. In 2003 and 2004, 25 of the 45 estimated deaths in temporary shelters were most commonly associated with portable gas or LP gas heating or cooking appliances. Generator usage in a temporary shelter was the second largest product category with an estimated 11 deaths in 2003 and 2004. Other scenarios included charcoal and charcoal grills, LP gas lanterns, kerosene heaters and a kerosene cooker. A consistently small percentage of deaths occurred in passenger vans, trucks, or automobiles in which victims were spending the night. For 2003 and 2004, of the estimated 13 CO fatalities in this category, nine were associated with portable LP gas heaters.

Comment: CO alarm requirements in the IRC would not impact incidents in mobile homes, tents, RV's, seasonal cabins, trailers, passenger vans, trucks, and automobiles.

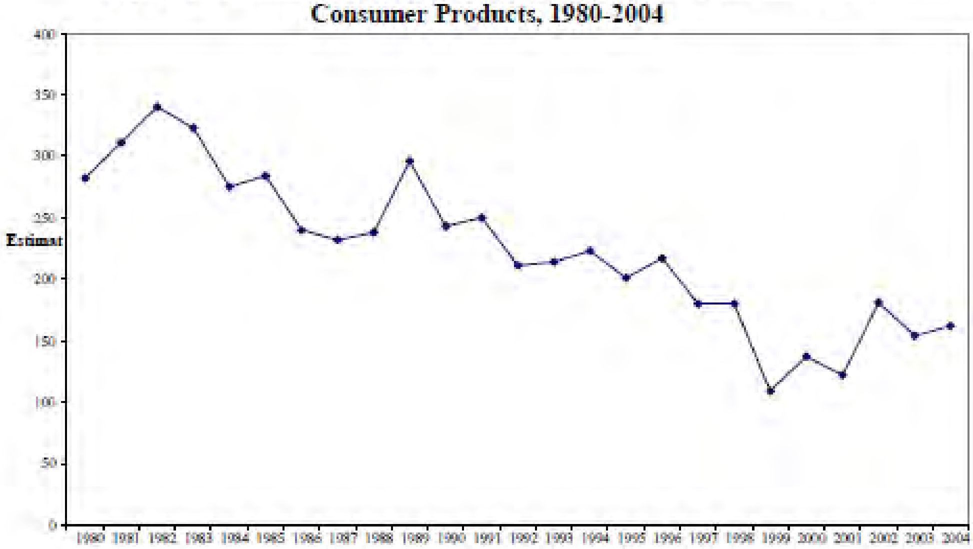
Figure 1: Estimated Non-Fire CO Poisoning Deaths Associated with Consumer Products, 1980-2004



Reading through even these brief excerpts, one wonders if requiring CO alarms would have any impact on CO related deaths at all given the circumstances surrounding most deaths. Furthermore, the number of deaths decreased without government regulation from 340 in 1982 to 162 in 2004. This decrease occurred during a time when the population increased from about 225 million to 296 million in 2004. The steadily decreasing number of deaths and their location doesn't indicate that requiring CO alarms would have any statistical impact on deaths.

Regarding the matter of CO deaths and attached garages, following are excerpts from an article entitled:
The Role of Catalytic Converters in Automobile Carbon Monoxide Poisoning[*] A Case Report by Bradley Vossberg, MD and Judah Skolnick, MD, FCCP
[*] From the Frazier Rehab Center, Jewish Hospital Health Network, Louisville, KY.

Inhaling motor vehicle exhaust fumes is a common method used by people attempting to commit suicide; however, the decreased carbon monoxide concentrations found in the exhaust of late-model automobiles equipped with catalytic converters are changing the clinical presentation of exhaust inhalation.

Closed-environment exposure to MVEGE from automobiles not equipped with catalytic converters can result in death within 30 min. The introduction of catalytic converters beginning with 1975 new-car models dropped CO emission rates to 6.00 g/min. By 1989, the average new-car

CO emission at idling was 0.22 g/min. The catalytic conversion process removes CO, hydrocarbons, and nitrogen oxide; the resultant emission is a more desirable mixture of nitrogen, CO_2, and water. Contemporary three-way catalytic converters eliminate > 99% of CO emissions.

Given the increased efficiency of modern catalytic converters, patients presenting with closed-environment MVEGE exposure may have much lower HbCO levels than would have been previously expected; in some cases, the HbCO level may be normal. Other important factors to be considered are the role of supplemental O_2 given at the scene and the time taken to obtain the HbCO level.

Attached garages do not pose a risk. By definition, an attached garage is three walls and a roof. A garage door is not required. There are no requirements that the garage be air tight or enclosed to a degree that would create any danger, even if CO levels were high.

Clearly, expecting CO alarms to have any positive impact on CO death rates is extremely optimistic and likely unrealistic. If we are going to require the public to spend their money on safety related devices, surely we can find a more productive area on which to spend it.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: DORNFELD-RB-2-R315

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee feels that deleting carbon monoxide detectors would weaken the code relative to life safety. Carbon monoxide detectors are within the intent of the IRC and the ICC membership voted to place them into the code.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Rick Davidson, representing self, requests Approval as Submitted.

Commenter's Reason: One of the most egregious acts that our organization can impose on the public is the adoption of rules that provide little or no benefit to improving life, health and safety yet increase the cost of owning a home.

The rule requiring the installation of carbon monoxide alarms is one of those acts.

There have been attempts at placing carbon monoxide alarms in the code for perhaps a decade. The membership has voted every one of them down because there was no factual evidence to indicate that there was a problem that warranted or could be solved by costly regulation.

Is carbon monoxide a problem? There is no question that carbon monoxide kills people. But is it a problem in homes worthy of expensive corrective action? And are corrective actions available that will change the number of deaths that occur? Adopting rules aimed at preventing deaths may make people feel good but if they don't achieve their intended purpose, they are a costly failure.

Unlike some issues, there is a wealth of information available regarding carbon monoxide deaths. The Consumer Product Safety Commission regularly produces a document, the most recent of which is entitled "Non-Fire Carbon Monoxide Deaths Associated with the Use of Consumer Products 2006 Annual Estimates."

The report states that 180 accidental carbon monoxide deaths occurred in 2006 in the US. To put the number of CO deaths in perspective, how does the number of CO deaths compare with other accidental deaths? Compared to the 180 CO deaths in 2006:

784 people died in bicycle accidents in 2005 (nearly 4 ½ times more than died of CO poisoning).
3,579 people died from accidental drowning in 2006.
20,823 people died from accidental falls in 2006.
43,313 people died in auto crashes in 2008.
3,320 people died in fires in 2008.
18,573 people were murdered in 2006.
27,531 people died from accidental poisoning in 2006.
31 people died from dog attacks in 2006

The number of accidental CO deaths pales compared too many other common types of accidental deaths.

But, if we take a position that accidental CO deaths are a problem, is the solution of putting CO alarms in new homes going to have an impact, any impact, on the number of CO deaths.

The CPSC 2006 report listed a number of key findings. Among them:

- *"There were an estimated 180 unintentional non-fire CO poisoning deaths associated with consumer products under CPSC's jurisdiction. The estimated annual average from 2004-2006 was 181 deaths."*
- *"Engine-Driven Tools were associated with the largest percentage of non-fire CO poisoning fatalities at 58 percent (104 deaths). Heating Systems-related CO fatalities were associated with 28 percent (50 deaths) and five of the remaining six product categories [Charcoal Grills or Charcoal (10 deaths), Gas Water Heaters (4 deaths), Gas Grills, Camp Stoves, Lanterns (4 deaths), Other Appliances (1 deaths), and Multiple Appliances (7 deaths)] combined were associated with a total of 14 percent. There were no reported deaths in the Gas Ranges/Ovens category."*

Comment: 180 accidental CO deaths occurred. 58% of the CO deaths were a result of engine-driven tools. How many could have been prevented if CO alarms were in new homes? Some of these deaths occurred in garages, tents, campers and locations other than the home. If one subtracts the 104 deaths from engine-driven tools, 10 deaths from charcoal grills, and 4 deaths from gas grills, camp stoves, and the like, that leaves only 62 deaths occurring from heating systems, water heaters, and other appliances likely to be found in a home. Clearly, CO alarms would have prevented few if any of the 114 CO deaths attributed to engine-driven tools, camps stoves, charcoal grills and similar devices not found in homes. That leaves 62 deaths that may have been impacted by CO alarms.

• *"Of the estimated 104 CO fatalities in 2006 that were associated with Engine-Driven Tools, 82 percent (85 deaths) involved generators. Additionally, generator usage was associated with three of the estimated seven multiple appliance CO poisoning fatalities."*
• *"There is a statistically significant increasing trend in consumer product-related non-fire CO fatalities from 1999 to 2006 that is attributable to generators."*

Comment: Generators are not a home appliance and should not be operated in a home. Should homes be provided with CO alarms because someone may run engine driven tools in their home? Where does this stop? Is the solution to this problem putting alarms in homes or are there better solutions such as public education or better labeling and instructions for engine-driven tools. The entire US population should not have to pay hundreds of millions of dollars to install CO alarms in their homes because 50 people operated gas powered tools or charcoal grills inside their homes.

• *"Of the estimated 50 Heating Systems-related fatalities in 2006, 90 percent involved gas heating. Natural gas heating accounted for 46 percent of heating system-related fatalities, liquefied petroleum (LP or propane) gas heating accounted for 38 percent, and an additional six percent were only identified as unspecified gas heating. Kerosene/oil heating and unspecified heating systems accounted for the remaining eight percent."*

Comment: Since the adoption and enforcement of model codes in rural areas of the country is sporadic to non-existent, those areas are seen as less likely to benefit from a CO alarm mandate because there is no agency to educate the public or enforce rules. Because of the cost of installing gas lines, natural gas is usually only available in communities or more highly developed areas. Rural areas are more dependent on propane, fuel oil, and kerosene. Of the 50 estimated CO deaths attributable to heating systems, 23 occurred with a natural gas appliance. The remainder of the deaths was attributed to propane, fuel oil, and kerosene. These deaths are more likely to have occurred in areas that wouldn't be reached by code adoption. How many of these 50 estimated deaths could be saved with a CO alarm mandate?

• *"Seventy-one percent of the estimated 180 CO deaths in 2006 occurred in a home; while an estimated 17 percent of deaths occurred in tents, campers, and other temporary shelters."*

Comment: 31 of the 180 CO deaths occurred outside the home. Requirements for CO alarms would have no impact on these deaths.

•*"CO poisoning fatalities in isolated locations account for a larger proportion of all CO fatalities (13% in 2004 through 2006) than the proportion of the U.S. population living in isolated areas (4%). The disparity is even higher at isolated non-home locations which account for 25 percent of all CO fatalities occurring at non-home locations."*

Comment: The model codes are not adopted uniformly across all areas of the country. Often, rural areas are not governed by codes. This statistic indicates that more isolated areas have a greater incidence of CO deaths. Could it be that rural areas have less supervision of building construction that leads to more CO deaths? What other explanations are there? What impact would a CO alarm mandate have on these areas?

• *"… for non-engine driven tool products, the mortality rate has decreased by 16 percent since 1999/2000, from 3.67 in 1999/2000 down to a 3.08 average mortality rate in 2004 through 2006."*

Comment: So with no requirements for CO alarms in the I-Codes, the mortality rate has decreased by 16% since 2000. With the number of deaths decreasing at a steady pace, how necessary is it to require CO alarms?

The report goes on to say:

"Of the estimated 19 deaths in 2006 that were associated with LP gas heating systems, 11 (58%) involved unvented portable propane heaters. These unvented portable propane heaters were fueled by a propane tank and were not a component of an installed heating system. Unvented portable propane heaters were either camping heaters that used disposable propane tanks, one pound propane bottles, or tank top heaters that used bulk tanks larger than one pound."

And,*"…an estimated 10 CO deaths (6% of the 180 total consumer product estimate) were associated with charcoal or charcoal grills"*

"…an estimated four deaths (2% of the total consumer product estimate) were associated with a subcategory of products which include gas grills, camp stoves, and lanterns; and one death was either associated with a consumer product that did not fit into the categories given above or there was insufficient detail to categorize the appliance involved. This latter incident involved the use of a grill inside a house, but it is unclear whether the grill was a gas grill or a charcoal or wood burning grill. This incident was categorized as Other Appliances."

"Additionally, in 2006, an estimated seven deaths were associated with multiple appliances (4% of the total consumer product estimate). The Multiple Appliances category includes all incidents where multiple fuel-burning products were used simultaneously such that a single source of the CO could not be determined. Of the estimated seven multiple appliance fatalities, three were associated with the simultaneous use of a gasoline-fueled generator and an LP heater. Of the estimated seven multiple appliance fatalities, six were associated with some type of LP heater."

"An estimated 104 CO poisoning deaths (58% of the estimated total from 2006) were associated with the category of Engine-Driven Tools, which includes generators, riding mowers or garden tractors, pressure washers, a snowmobile, a snow thrower, an air compressor, a water pump, and a non-vehicular internal compression engine."

There is much discussion in the report regarding the type of appliances that cause the CO problems. Often they are found to be old, poorly maintained products. This indicates that the problems aren't in new homes and requiring CO alarms in new homes won't solve these problems.

The current rules require CO alarms if the home contains an attached garage. Presumably, the reason for this requirement is the assumption that automobiles in garages generate sufficient carbon monoxide to be a hazard. There is no data to indicate this is so.

According to the US Environmental Protection Agency and in recognition of the fact that cold engines give off more CO, the 1990 Clean Air Act calls for 1994 and later cars and light trucks to meet federal carbon monoxide standards at 20 degrees Fahrenheit whereas the old rules required those standards be met at 75 degrees Fahrenheit. So the risk of increased CO levels emitting from cold engines is significantly reduced.

Furthermore, following are excerpts from an article entitled:

The Role of Catalytic Converters in Automobile Carbon Monoxide Poisoning* **A Case Report by Bradley Vossberg, MD and Judah Skolnick, MD, FCCP**
* From the Frazier Rehab Center, Jewish Hospital Health Network, Louisville, KY.

> *Inhaling motor vehicle exhaust fumes is a common method used by people attempting to commit suicide; however, the decreased carbon monoxide concentrations found in the exhaust of late-model automobiles equipped with catalytic converters are changing the clinical presentation of exhaust inhalation.*
>
> *Closed-environment exposure to MVEGE from automobiles not equipped with catalytic converters can result in death within 30 min. The introduction of catalytic converters beginning with 1975 new-car models dropped CO emission rates to 6.00 g/min. By 1989, the average new-car CO emission at idling was 0.22 g/min. The catalytic conversion process removes CO, hydrocarbons, and nitrogen oxide; the resultant emission is a more desirable mixture of nitrogen, CO_2, and water.* ***Contemporary three-way catalytic converters eliminate > 99% of CO emissions.***
>
> *Given the increased efficiency of modern catalytic converters, patients presenting with closed-environment MVEGE exposure may have much lower HbCO levels than would have been previously expected; in some cases, the HbCO level may be normal. Other important factors to be considered are the role of supplemental O_2 given at the scene and the time taken to obtain the HbCO level.*

More findings related to automobile carbon monoxide poisoning can be found in a technical paper entitled "***Reducing the Risk of Accidental Death Due to Vehicle-Related Carbon Monoxide Poisoning***" by **Linsey C. Marr, Glenn C. Morrison, William W. Nazaroff, and Robert A. Harley,** *Department of Civil and Environmental Engineering, University of California, Berkeley, California.* This technical paper reports on studies and analysis of computer modeling undertaken to determine the risk of death from CO poisoning in homes and garages. Among the findings: "The risk of death ranged from 16-21% for a 3-hr exposure ***in*** a garage to 0% for a 1-hr exposure in a house."

With any study with so many variables, one can question the validity of the study. This one is no different. Among the difficulties in modeling the conditions were numerous variables including:

Age and condition of the motor vehicle
Air exchange rates for the garage and dwelling
Size of the garage and dwelling
Length of time the vehicle is running
Amount of fuel in the fuel tank
Age and health of the individual
Temperature and weather conditions
Newer vehicles have more effective catalytic converters
Socioeconomic factors may result in older, less efficient vehicles stored outside or garages with higher air exchange rates

But the study was based on very conservative conditions and it was pointed out that the risks may be overestimated.

The study points out that unintentional CO deaths from automobiles do occur. But most all of these deaths occurred ***in*** the garage. The most frequent cause of CO deaths were a driving into a garage (often under the influence of alcohol or drugs) and leaving the engine running (42% of deaths) and starting the car to perform vehicle maintenance (25%) or to provide heat (23%).

Importantly, the study points out that even these deaths are dropping at a rate of about 7% a year as older vehicles are replaced by newer, more efficient ones. In fact, in the technical paper by **M. Shelef** titled "***Unanticipated benefits of automotive emission control: Reduction in fatalities by motor vehicle exhaust gas***" SAE Technical Paper No. 922335, Society of Automotive Engineers: Warrendale, PA, 1992, Shelef argued that reducing CO poisoning deaths may be the biggest benefit from current motor vehicle emission control programs, even though the programs are motivated by concentration standards for outside air.

After reading the various reports and studies on automobile carbon monoxide emissions, it is difficult to come to any conclusion that automobile generated carbon monoxide creates any sort of hazard in the home and the proponent has provided no statistical evidence that it does.

But beyond that, it is necessary to look at what you are asked to believe is common practice. That is that a homeowner would start their car parked in a cold garage, go into the home leaving the door open, and allow the carbon monoxide as well as the noise and cold air to enter the house unabated and ignored. Then you are further led to believe that the homeowner would allow this to happen long enough for carbon monoxide levels to build to dangerous levels, never mind why they started the automobile in the first place which they are supposed to have forgotten. I suggest that people will not leave the door to a frigid garage open, they will not want the cold air and noise to infiltrate their home, and they will not leave the automobile running for extended periods of time but will continue on with whatever caused them to start the automobile in the first place.

The current rules require CO alarms in homes that have any fuel burning appliances. But some appliances have an extremely high safety record when it comes to CO incidents. No deaths were attributed to CO poisoning from gas ranges or ovens in 2006. Only four deaths occurred from water heaters. 2,426,264 people died during 2006. The number of deaths attributable to CO poisoning from water heaters is .0001648% of the total number of deaths. Given the low number of deaths compared to overall US mortality rates, deaths attributable to CO poisoning is statistically irrelevant.

Is there a problem with CO poisoning in the home that occurs to a degree that warrants expensive regulation? I would say that the evidence indicates there is not.

What will this rule cost the American public? If an average of 1 million new homes are built each year and only one alarm is required in each home and if it costs $50 to install that one alarm, the cost to the American public is $50 million! Furthermore, since alarms must be installed in existing homes whenever any permit is required and since there may be 10, 15, 20 homes that have repairs for each new home, the cost can quickly reach the hundreds of millions of dollars. And at the end of the five year life expectancy of the alarms, will they be replaced like they should? If they are, the costs above will double. If there are 20 or 30 lives that are currently lost that could be prevented with CO alarms, is it worth it to the public to spend hundreds of millions of dollars to do that? I suggest is it is not.

It has been argued that several states have adopted CO regulations. That is true and Minnesota is one of them. Deaths attributable to CO poisoning in Minnesota are extremely rate. However, some years ago, the tragic death of a young girl occurred in a home where an older heating system had not been properly maintained. As is often the case, grieving parents fail to take responsibility for what occurred and stated that if carbon monoxide alarms had been required in all homes that perhaps their daughter wouldn't have died. The grandparents of the young girl approached the Minnesota IRC Advisory Committee about placing a mandate in the state building code that adopted the 2006 IRC. However, amendments to the state code needed to pass a need and reasonable test and there were insufficient reasons to require them to be installed. The grandparents then went to several legislators who crafted a poorly worded law that makes CO alarms mandatory in all dwellings in the state except those owned by the state. The state legislature has no burden to prove that their rules are necessary or reasonable. The rule is not in the Minnesota State Building Code and there is no enforcement mechanism. The law sold a few alarms and creates necessary work for some attorneys.

It is important that unnecessary regulation not be approved and that any that has been approved be removed. If you believe in costly unnecessary regulation, then you should vote to maintain CO alarms. If you believe that there should be a reason why rules exist, then you should support this proposal.

Public Comment 2:

Steve Orlowski, National Association of Home Builders (NAHB), requests Approval as Modified by this Public Comment.

Replace proposal as follows:

R315.1 Carbon monoxide alarms. For new construction, an approved carbon monoxide alarm shall be installed outside of each separate sleeping area in the immediate vicinity of the bedrooms in *dwelling units* within which fuel-fired *appliances* are installed and in dwelling units that have attached garages <u>with a communicating opening.</u>

R315.2 Where required in existing dwellings. Where work requiring a *permit* occurs in existing *dwellings* ~~that have attached garages or in existing dwellings within which fuel-fired *appliances* exist~~, carbon monoxide alarms shall be provided in accordance with Section R315.1 <u>for the following:</u>

1. <u>Mechanical or gas work requiring a *permit* in which fuel-fired *appliances* are being replaced or installed.</u>
2. <u>Addition and/or renovation of attached garages with communicating openings requiring building permit.</u>

Commenter's Reason: In an attempt to provide clearer guidance into the requirements for where and when a CO detector is required, NAHB urges the final action assembly to approve the following modification. There are situations where one- and two- family dwellings are constructed with an attached garage that does not open directly into the dwelling unit, such as is found with homes with breezeways that separate the garage from the dwelling but share the same roof. When there is no direct communication between the garage and the dwelling unit or when there is adequate ventilation to reduce the transmission of any potential CO emission from entering the dwelling, CO detection should not be required.

As for the second modification, the original proponent is correct that there are many in the code enforcement community that interpret the existing language to include any work that is performed under a permit , requires existing homes to be equipped with a carbon monoxide detector. The premises for requiring any retrofitting requirement must be tied to the potential cause of the hazard and not an unrelated act. Carbon monoxide detectors should only be required when the work being performed is related to potential causes of carbon monoxide. Bathroom renovation, kitchen upgrades and additions that do not involve fuel-fired appliances should not trigger the installation of carbon monoxide detectors.

Final Action: AS AM AMPC____ D

RB64-09/10

R202 (New), R317.5 (New), R317.5.1 (New), Chapter 44 (New)

<u>Proposed Change as Submitted</u>

Proponent: Marcelo Hirschler, GBH International, representing the American Fire Safety Council

1. Add new text as follows:

<u>**PLASTIC LUMBER.** a manufactured product made primarily from thermoplastic materials (filled or unfilled) and typically supplied in sizes that correspond to traditional lumber board and dimensional lumber sizes.</u>

<u>**R317.5 Plastic lumber.** Plastic lumber used in exterior deck boards shall bear a *label* indicating the required performance levels and demonstrating compliance with the provisions of ASTM D 6662 and ASTM D 7032.</u>

<u>**R317.5.1** Plastic lumber decks shall be installed in accordance with the manufacturer's instructions.</u>

2. Add new standard as follows:

ASTM
<u>D 6662-09</u> <u>Standard Specification for Polyolefin-Based Plastic Lumber Decking Boards</u>

Reason: Numerous plastic lumber decks are used throughout the US, but the IRC and IBC do not reference them. Wood-plastic composite decks, complying with ASTM D 7032, are permitted in the IRC (section R317.4). This proposal adds plastic lumber decks, with the requirements from ASTM D 7032 and also the requirements from ASTM D 6662.

ASTM D 6662 is a specification for plastic lumber decking boards that requires the plastic lumber to comply with properties based on the following ASTM standards:
ASTM D 2565 Standard Practice for Xenon-Arc Exposure of Plastics Intended for Outdoor Applications
ASTM D 2915 Standard Practice for Evaluating Allowable Properties for Grades of Structural Lumber
ASTM D 4329 Standard Practice for Fluorescent UV Exposure of Plastics
ASTM D 6109 Standard Test Methods for Flexural Properties of Unreinforced and Reinforced Plastic Lumber and Related Products
ASTM D 6341 Standard Test Method for Determination of the Linear Coefficient of Thermal Expansion of Plastic Lumber and Plastic Lumber Shapes Between −30 and 140°F [−34.4 and 60°C]
ASTM E 84 Standard Test Method for Surface Burning Characteristics of Building Materials

ASTM G 151 Standard Practice for Exposing Nonmetallic Materials in Accelerated Test Devices that Use Laboratory Light Sources
ASTM G 154 Standard Practice for Operating Fluorescent Light Apparatus for UV Exposure of Nonmetallic Materials
ASTM G 155 Standard Practice for Operating Xenon Arc Light Apparatus for Exposure of Non-Metallic Materials

ASTM D 7032 (already referenced in the IRC) is a Standard Specification for Establishing Performance Ratings for Wood-Plastic Composite Deck Boards and Guardrail Systems (Guards or Handrails). It requires the material to comply with flexural properties (ASTM D 6109), accelerated decay (ASTM D 2017), Xenon-arc exposure (ASTM D 2565), resistance to termites (ASTM D 3345), structural lumber grade classifications (ASTM D 2915), and so on.

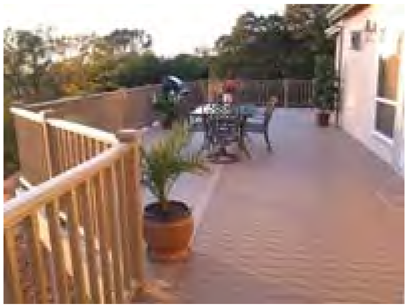
With regard to fire properties, ASTM D 6662 requires that plastic lumber meet ASTM E 84, Steiner tunnel test, with a flame spread index of no more than 200, with a material that is required to remain in place during the test. The wording with regard to ASTM E 84 flame spread testing in ASTM D 6662 is much more explicit than the wording in the test method itself. The following wording is included in the ASTM D 6662 standard: "6.4.2 The test specimen shall either be self-supporting by its own structural characteristics or held in place by added supports along the test specimen surface. The test specimen shall remain in place throughout the test duration, without such severe sagging that it interferes with the effect of the gas flame on the test specimen. Test results are invalid if the bulk of the test specimen melts or drops to the furnace floor."

ASTM D 7032 also requires wood-plastic composite decks to comply with a flame spread index of no more than 200 when tested to ASTM E 84. However, ASTM D 7032 does not have the additional requirements that the material stay in place.

By requiring that plastic lumber comply with the requirements of ASTM D 6662 and ASTM D 7032 the code would include all physical property and fire test requirements associated with both types of decking materials. Just for information: wood normally complies with a flame spread index of no more than 200. ICC ES has an Evaluation criterion for thermoplastic composite lumber products (AC 109), based on ASTM D 7032, which is used for approving plastic lumber decks.

Structural plastic lumber combines the benefits of long lasting, weather resistant plastic lumber with the structural characteristic of dimensional wood lumber. It is made primarily from recycled plastics from post-consumer waste like plastic milk and detergent bottles. It then includes strengthening additives, UV–inhibited pigments, anti-oxidant processing aids and foaming agents for a highly stable material that is superior to wood lumber in some measures.

A few photographs of actual decks follow.



Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: A review of the standard proposed for inclusion in the code, ASTM D 6662-09, for compliance with ICC criteria for referenced standards given in Section 3.6 of Council Policy #CP 28 will be posted on the ICC website on or before September 24, 2009.

ICCFILENAME: HIRSCHLER-RB-4-R202-R317.5

Public Hearing Results

Analysis: Review of the proposed new standard indicated that, in the opinion of ICC staff, the standard did comply with ICC standards criteria.

Committee Action: Disapproved

Committee Reason: The committee feels there are a number of different products this could apply to and just limiting it to deck boards is going to create a number of issues. The definition is too broad, primarily is vague and thermoplastic requires chemical knowledge. Also, the issue of labeling as stated on the committee's previous action on S207-09/10, Part II. This should be reworked and brought back later.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Marcelo M. Hirschler, GBH International, representing American Fire Safety Council, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

1. Revise text as follows:

PLASTIC LUMBER DECKING BOARD. a manufactured product made ~~primarily from thermoplastic~~ of plastic materials (filled or unfilled) which is generally rectangular in cross-section and is typically supplied in sizes that correspond to traditional lumber board and dimensional lumber sizes.

R317.5 PLASTIC LUMBER DECKING BOARDS. Plastic lumber decking boards used in exterior decks ~~deck boards~~ shall bear a label indicating the required performance levels and demonstrating compliance with the provisions of ASTM D 6662 and ASTM D 7032.

R317.5.1 Plastic lumber decking boards ~~decks~~ shall be installed in accordance with the manufacturer's instructions.

2. Add new text as follows:

R502.1.8 EXTERIOR PLASTIC LUMBER DECKING BOARDS. Plastic lumber decking boards used in exterior decks shall comply with the provisions of Section R317.5.

3. Add new standard as follows:

ASTM
D 6662-09 Standard Specification for Polyolefin-Based Plastic Lumber Decking Boards

Commenter's Reason: The technical committee was concerned that if the definition of plastic lumber was introduced into the code, plastic lumber could be considered to be a new material and permitted to be used for applications beyond plastic lumber decking boards. This comment fixes that problem by defining plastic lumber decking boards, and that directly correlates with the intended application in R317.5. The committee was also concerned about the use of the terms "thermoplastic" and "primarily" and they have been eliminated from the definition.

Note that the IRC currently allows wood plastic composites to be used in exterior deck boards and requires them to be labeled (which, of course, would be done on the non exposed surface). The proposed wording exactly mirrors that wording. The applicable acceptance criteria used by ICC Evaluation Services are those of AC 109, Acceptance Criteria for Thermoplastic Composite Lumber Products, which covers not just wood plastic composites but all types of plastic lumber. However, the IRC is silent with regard to plastic lumber decking boards unless they are "made primarily from wood or cellulose-based materials and plastic". Plastic lumber decking boards often contain no wood or cellulose-based materials and are thus excluded from the IRC. This proposal would cover such materials.

The requirements that plastic lumber decking boards have to meet, with this proposal, are not just those of ASTM D 7032 but they will additionally have to meet the requirements of ASTM D 6662, which impose more severe fire testing requirements. As shown in the text below, ASTM D 6662 requires that the boards be tested to ASTM E 84 (Steiner tunnel) and that they pass the same flame spread index as wood deck boards. ASTM D 6662 also states that the ASTM E 84 test specimens are not allowed to fall to the tunnel floor or otherwise interfere with the effect of the gas flame on the test specimen. This is a more severe requirement than the fire test requirement in ASTM D 7032 or than the fire test requirements in many other material specifications.

Text of ASTM D 6662 on fire testing:
6.4 Fire Properties:
6.4.1 The flame spread index of plastic lumber decking boards shall be determined by testing in accordance with Test Method E 84.
6.4.2 The test specimen shall either be self-supporting by its own structural characteristics or held in place by added supports along the test specimen surface. The test specimen shall remain in place throughout the test duration, without such severe sagging that it interferes with the effect of the gas flame on the test specimen. Test results are invalid if the bulk of the test specimen melts or drops to the furnace floor. Appendix X1 of Test Method E 84 provides guidance on mounting methods.
6.4.3 Products shall have a flame spread index no greater than 200 when tested in accordance with Test Method E 84.

NOTE 12 — For combustible construction, codes often require fire performance at least equivalent to that of wood. A maximum flame spread index of 200 when tested in accordance with Test Method E 84 is considered to be equivalent to that of wood. For outdoor applications, there is no requirement specified for smoke developed index.
NOTE 13—Fire retardants are available to increase the resistance to ignitability and flame spread of plastic lumber and shall be incorporated as needed.
6.4.4 The plastic lumber industry has developed a qualification fire test based on end-use of the material in decking. This method, a modification of Test Methods E 108 originally intended for roofing materials, is presented in Appendix X4 along with a commentary for its use.

Text of IRC on wood plastic composite decks:

WOOD PLASTIC COMPOSITE. A composite material made primarily from wood or cellulose-based materials and plastic.

R317.4 Wood plastic composites. Wood plastic composites used in exterior deck boards, handrails and guardrail systems shall bear a label indicating the required performance levels and demonstrating compliance with the provisions of ASTM D 7032.

R317.4.1. Wood plastic composites shall be installed in accordance with the manufacturer's instructions.

R502.1.7 Exterior wood plastic composite deck boards. Wood plastic composites used in exterior deck boards shall comply with the provisions of Section R317.4.

Final Action: AS AM AMPC____ D

RB67-09/10
R322.3.2, R322.3.3

Proposed Change as Submitted

Proponent: Rebecca C. Quinn, RCQuinn Consulting, Inc., representing the Department of Homeland Security, Federal Emergency Management Agency

Revise as follows:

R322.3.2 Elevation requirements.

1. All buildings and structures erected within coastal high hazard areas shall be elevated so that the lowest portion of all structural members supporting the lowest floor, with the exception of ~~mat or raft foundations,~~ piling, pile caps, columns, grade beams and bracing, is:
   1.1. Located at or above the design flood elevation, if the lowest horizontal structural member is oriented parallel to the direction of wave approach, where parallel shall mean less than or equal to 20 degrees (0.35 rad) from the direction of approach, or
   1.2. Located at the base flood elevation plus 1 foot (305 mm), or the design flood elevation, whichever is higher, if the lowest horizontal structural member is oriented perpendicular to the direction of wave approach, where perpendicular shall mean greater than 20 degrees (0.35 rad) from the direction of approach.
2. Basement floors that are below *grade* on all sides are prohibited.
3. The use of fill for structural support is prohibited.
4. Minor grading, and the placement of minor quantities of fill, shall be permitted for landscaping and for drainage purposes under and around buildings and for support of parking slabs, pool decks, patios and walkways.

   Exception: Walls and partitions enclosing areas below the design flood elevation shall meet the requirements of Sections R322.3.4 and R322.3.5.

R322.3.3 Foundations. Buildings and structures erected in coastal high-hazard areas shall be supported on pilings or columns and shall be adequately anchored to those pilings or columns. Pilings shall have adequate soil penetrations to resist the combined wave and wind loads (lateral and uplift). Water loading values used shall be those associated with the design flood. Wind loading values shall be those required by this code. Pile embedment shall include consideration of decreased resistance capacity caused by scour of soil strata surrounding the piling. Pile systems design and installation shall be certified in accordance with Section R322.3.6. ~~Mat, raft or other foundations that support columns shall not be permitted where soil investigations that are required in accordance with Section R401.4 indicate that soil material under the mat, raft or other foundation is subject to scour or erosion from wave-velocity flow conditions.~~ Slabs, pools, pool decks and walkways shall be located and constructed to be structurally independent of buildings and structures and their foundations to prevent transfer of flood loads to the buildings and structures during conditions of flooding, scour or erosion from wave-velocity flow conditions, unless the buildings and structures and their foundation are designed to resist the additional flood load.

Reason: The purpose of this code change is to clarify that an observed practice of using mat or raft foundations that are above eroded grade is not consistent with the regulations of the National Flood Insurance Program (NFIP) regarding foundations in coastal high hazard areas (V Zones). See §60.3(e)(4), below. The NFIP regulations require use of pile or column foundations in V Zones, and do not explicitly provide for use of mat or raft foundations. Note that ASCE 24 *Flood Resistant Design and Construction*, a referenced standard in the IRC, allows use of mat or raft foundations under limited circumstances; notably, it requires that such elements be at or below eroded grade. The language in R322.3.2 does not impose a limitation on the elevation of mats, and rafts and thus could lead to violations of the NFIP requirements which would also have significant cost implications for federal flood insurance premiums. ASCE 24 is permitted to be used as an alternate to the IRC provisions for coastal high hazard areas (see R301.2.4.1 and R322.1.1). In addition, designers may use ASCE 24 as guidance, even if not required.

44 CFR §60.3(e)(4) Provide that all new construction and substantial improvements in Zones V1-30 and VE, and also Zone V if base flood elevation data is available, on the community's FIRM, are elevated on pilings and columns so that . . . *[remainder not shown]*

Cost Impact: The code change proposal has no cost impact because it is consistent with local ordinances that are adopted by local jurisdictions for participation in the NFIP.

ICCFILENAME: QUINN-RB-5-R322.3.2

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee feels that observation of non-compliance of a code provision is not sufficient justification to remove a requirement. The use of mat or raft foundation under limited conditions should remain in the code.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Rebecca C. Quinn, RCQuinn Consulting, Inc., representing Federal Emergency Management Agency, Department of Homeland Security, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R322.3.2 Elevation requirements.

1. All buildings and structures erected within coastal high-hazard areas shall be elevated so that the lowest portion of all structural members supporting the lowest floor, with the exception of ~~mat or raft foundations,~~ piling, pile caps, columns, grade beams and bracing, is:
   1.1. Located at or above the design flood elevation, if the lowest horizontal structural member is oriented parallel to the direction of wave approach, where parallel shall mean less than or equal to 20 degrees from the direction of approach, or
   1.2. Located at the base flood elevation plus one foot (305 mm), or the design flood elevation, whichever is higher, if the lowest horizontal structural member is oriented perpendicular to the direction of wave approach, where perpendicular shall mean greater than 20 degrees from the direction of approach.
2. Basement floors that are below grade on all sides are prohibited.
3. The use of fill for structural support is prohibited.
4. Minor grading, and the placement of minor quantities of fill, shall be permitted for landscaping and for drainage purposes under and around buildings, and for support of parking slabs, pool decks, patios, and walkways.

   Exception: Walls and partitions enclosing areas below the design flood elevation shall meet the requirements of Sections R322.3.4 and R322.3.5.

R322.3.3 Foundations. All buildings and structures erected in coastal high-hazard areas shall be supported on pilings or columns and shall be adequately anchored to <u>such</u> ~~to those~~ pilings or columns. Pilings shall have adequate soil penetrations to resist the combined wave and wind loads (lateral and uplift). Water loading values used shall be those associated with the design flood. Wind loading values shall be those required by this code. Pile embedment shall include consideration of decreased resistance capacity caused by scour of soil strata surrounding the piling. Pile systems design and installation shall be certified in accordance with Section R322.3.6. <u>Spread footing, mat, raft or other foundations that support columns shall not be permitted where soil investigations that are required in accordance with Section R401.4 indicate that soil material under the spread footing, mat, raft or other foundation is subject to scour or erosion from wave–velocity flow conditions. If permitted, spread footing, mat, raft or other foundations that support columns shall be designed in accordance with ASCE 24.</u> Slabs, pools, pool decks and walkways shall be located and constructed to be structurally independent of buildings and structures and their foundations to prevent transfer of flood loads to the buildings and structures during conditions of flooding, scour or erosion from wave-velocity flow conditions, unless the buildings and structures and their foundation are designed to resist the additional flood load.

Commenter's Reason: The original proposal would have completely deleted reference to mat or raft foundations because an observed practice of using mat or raft foundations that are above eroded grade is not consistent with the regulations of the National Flood Insurance Program (NFIP) regarding piling and column foundations in coastal high hazard areas (V Zones). This public comment responds to testimony that mat or raft foundations could be acceptable under the NFIP if designed in accordance with ASCE 24 *Flood Resistant Design and Construction*, a referenced standard in the IRC. The modification proposes to add "spread footing" because the specific language in ASCE 24 consistently refers to use of spread footings along with mat or raft foundations (see ASCE 24 Sec. 4.5.1, 4.5.7, and Sec. 4.5.8).

Final Action: AS AM AMPC____ D

RB72-09/10
R403.1.3

Proposed Change as Submitted

Proponent: Homer Maiel, PE, CBO, City of San Jose, CA, representing ICC Tri-Chapter (Peninsula, East Bay, Monterey Bay Chapters)

Revise as follows:

R403.1.3 Seismic reinforcing. Concrete footings located in Seismic Design Categories D_0, D_1 and D_2, as established in Table R301.2 (1), shall have minimum reinforcement. Bottom reinforcement shall be located a minimum of 3 inches (76 mm) clear from the bottom of the footing.

In Seismic Design Categories D_0, D_1 and D_2 where a construction joint is created between a concrete footing and a stem wall, a minimum of one No. 4 bar shall be installed at not more than 4 feet (1219 mm) on center. The vertical bar shall extend to 3 inches (76 mm) clear of the bottom of the footing, have a standard hook and extend a minimum of 14 inches (357 mm) into the stem wall.

In Seismic Design Categories D_0, D_1 and D_2 where a grouted masonry stem wall is supported on a concrete footing and stem wall, a minimum of one No. 4 bar shall be installed at not more than 4 feet (1219 mm) on center. The vertical bar shall extend to 3 inches (76 mm) clear of the bottom of the footing and have a standard hook.

In Seismic Design Categories D_0, D_1 and D_2 masonry stem walls without solid grout and vertical reinforcing are not permitted.

> **Exception:** In detached one- and two-family *dwellings* which are three stories or less in height and constructed with stud bearing walls~~, plain concrete footings without longitudinal reinforcement supporting walls and~~ isolated plain concrete footings supporting columns or pedestals are permitted.

Reason: In seismic design categories D_0, D_1 and D_2, the flexural demands placed upon footings by the variety of braced wall panels configurations described in IRC Chapter 6, some of which require a hold-down device at one end or each end make the use of plain concrete footings unacceptable. The footing is an integral part of the seismic force load path and deserves to be constructed in as robust a manner as the braced wall panels it is supporting. The exception to use plain concrete isolated footing pads at columns or pedestals is retained because these are not use to support or anchor braced walls unless designed in accordance with accepted engineering practice per Section R602.10.7 Item 2.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: MAIEL-RB-2-R403.1.3

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: This change would make the IRC inconsistent with the IBC and the NEHRP recommendations. The proponent should rework and bring back later.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Homer Maiel, City of San Jose, CA, representing ICC Tri-Chapter (Peninsula, East Bay, Monterey Bay Chapters), requests Approval as Submitted.

Commenter's Reason: In seismic design categories D0, D1 and D2 the flexural demands placed upon footings of stud wall framed detached one- and two-family dwellings make the use of plain concrete footings devoid of any longitudinal reinforcing unacceptable. IRC Section R301.1 specifically states "This code shall result in a system that provides a complete load path that meets all requirements for the transfer of all loads from their point of origin through the load-resisting elements *to the foundation*." The foundation is an integral part of the seismic force-resisting load path and deserves to be constructed in a manner consistent with the seismic-resisting braced wall panels it is supporting. The current specific allowance for absence of any longitudinal reinforcing will also prevent any vertical reinforcing from being placed in the footing, since there is nothing to tie any vertical bar to; consequently the current provision is allowing totally unreinforced footings in dwellings up to three stories in height.

Since the mid-1990's wood light-frame prescriptive provisions for alternative wall bracing using tie-downs (as currently shown in IRC Figure R602.10.3.2) have required that the foundation at these alternative panels utilize one No. 4 bar top and bottom. Also, more recent IBC alternative wall bracing provisions utilizing a portal frame concept (Section 2308.9.3.2) that includes providing tie-downs similarly specifies footings with one No. 4 bar top and bottom. Unfortunately the equivalent portal frame provisions in IRC Section R602.10.3.4 do not address the footing's reinforcement. In addition, tie-downs are also specified in IRC Table R602.12(2) when stone or masonry veneer is installed, and in IRC Section R602.10.1.4.1 when brace wall panels are offset from the end of the wall line, yet neither of these IRC provisions mention minimum footing reinforcement. Further, IRC Section R301.1.1 explicitly allows use of AF&PA Wood Frame Construction Manual (WFCM) as a permitted alternative, but in that document all walls providing lateral resistance are required to use various types of tie-downs. Each time a tie-down is installed, the footing should be capable of resisting the flexural demands induced by that connection, yet the current Section R403.1.3 exception 1 ignores this need.

While we recognize there is a cost of installing this minimum reinforcing, we believe that most builders of dwellings in Seismic Design Categories D0, D1 and D2 are already providing this level of reinforcing, and that the cost of repairing cracks caused to interior and exterior finishes not to mention the foundation itself would far exceed the cost of minimal reinforcement of footings during the original construction.

With regard to any inconsistency of this proposal with the NEHRP Provisions, it must be noted that the applicable NEHRP provision (Sec. 9.4.2.2 Exception 1) has not been updated since its publication in 2004 (FEMA 450-1/2003) while during that period many of the IRC's provisions for the use of tie-downs at the ends of brace wall panels have been added to the code.

Final Action: AS AM AMPC____ D

RB73-09/10

R202 (New), R403.1.6

Proposed Change as Submitted

Proponent: Gary Ehrlich, National Association of Home Builders (NAHB)

1. Add new definitions as follows:

SILL PLATE. A horizontal wood member anchored to the foundation and supporting floor joists.

SOLE PLATE. A horizontal wood member at the bottom of a wood stud wall, attached to a concrete slab.

2. Revise as follows:

R403.1.6 Foundation anchorage. Where wood sill and sole plates and cold-formed steel framed walls are supported directly on continuous foundation~~s~~ walls or monolithic slabs with integral footings required by the provisions of this code, they shall be anchored to the foundation in accordance with this section.

Wood sole plates at all exterior walls ~~on monolithic slabs~~, wood sole plates of *braced wall panels* at building interiors on monolithic slabs with integral footings, and all wood sill plates shall be anchored to the foundation with ½ inch (12.7 mm) diameter anchor bolts spaced a maximum of 6 feet (1829 mm) on center or approved anchors or anchor straps spaced as required to provide equivalent anchorage to the ½-inch-diameter (12.7 mm) anchor bolts. Bolts shall ~~be at least ½ inch (12.7 mm) in diameter and shall~~ extend a minimum of 7 inches (178 mm) into concrete or grouted cells of concrete masonry units. A nut and washer shall be tightened on each anchor bolt. There shall be a minimum of two bolts per plate section with one bolt located not more than 12 inches (305 mm) or less than seven bolt diameters from each end of the plate section. Interior bearing wall sole plates on monolithic slab foundations with integral footings that are not part of a *braced wall panel* shall be positively anchored with *approved* fasteners. Sill plates and sole plates shall be protected against decay and termites where required by Sections R317 and R318. Cold-formed steel framing systems shall be fastened to wood sill plates or anchored directly to the foundation as required in Section R505.3.1 or R603.3.1.

Exceptions:

~~1. Foundation anchorage, spaced as required to provide equivalent anchorage to 1/2-inch-diameter (12.7 mm) anchor bolts.~~

~~2~~ 1. Walls 24 inches (610 mm) total length or shorter connecting offset *braced wall panels* shall be anchored to the foundation with a minimum of one anchor bolt located in the center third of the plate section and shall be attached to adjacent *braced wall panels* at corners as shown in Figure R602.10.4.4(1).
~~3~~ 2. Connection of walls 12 inches (305 mm) total length or shorter connecting offset *braced wall panels* to the foundation without anchor bolts shall be permitted. The wall shall be attached to adjacent *braced wall panels* at corners as shown in Figure R602.10.4.4(1).

Reason: The purpose of this proposal is to revise the language for anchorage of light-frame wood and cold-formed steel stud walls to the foundations of the house. Without these revisions, we are concerned that the code will present an enforcement nightmare for plan reviewers and inspectors, and lead to anchor bolts and continuous footings being required where they are not necessary and have not traditionally been provided.

The ICC Ad-Hoc Committee on Wall Bracing revised this section during the 2007/2008 code cycle with the intent of insuring that sufficient anchorage is provided on braced wall lines and panels inside a dwelling to transfer lateral loads to either monolithic (thickened) slab foundations or continuous footings. While we agree that providing a continuous load path is important, the change was overly broad in its application and will present an enforcement problem. For instance, the first sentence of the 2009 IRC Section R403.1.6 effectively requires all light-frame walls to be provided with anchor bolts to the foundation. Thus, a non-bearing interior partition that is not part of a braced wall line but which just happens to sit atop a foundation wall or continuous foundation (e.g. at a partial basement, crawlspace, or interior knee wall) would be required to be fastened to the wall or footing below with 1/2" diameter anchor bolts at 6 foot spacing. We are also concerned the new language (in particular the change for walls on interior monolithic slabs) does not explicitly permit anchor bolts to be replaced by wedge anchors, expansion bolts, mudsill straps, or other equivalent anchorage, and also that it may require thickened slabs or continuous footings where they have not traditionally been provided or are not required by other sections of the IRC.

Further, there was no technical justification provided for the increased anchorage requirements. Whole-building structural tests have shown that our current methods of construction are stronger than current engineering practice and engineering design standards give them credit for. An actual house in the field tested by researchers in New Zealand performed 50% better than predicted by engineering design, even with sill plates attached only by single nails, rather than anchor bolts. We also note that the bottom plate of a braced wall line on the interior and supported on floor framing (including a raised floor system over a crawlspace or pier-and-beam foundation) can be attached to the framing with 3-16d nails at 16" spacing, but the same plate on a continuous footing will require 1/2" anchor bolts at 7" spacing. Thus, by implementing these new requirements for additional anchor bolts on braced wall lines inside our structures we are essentially contradicting 40 years of research into light-frame wood construction. We are not aware of any racking failures on interior braced wall lines that would justify adding bolts to these lines.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: EHRLICH-RB-5-R202-R403.1.6

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The definition of sill plate and sole plate is unclear. The proponent should get with industry and rework this with the modification that was ruled out of order and bring this back to Final Action.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Gary J. Ehrlich, P.E., National Association of Home Builders, Bonnie Manley, P.E., AISI, representing Steel Framing Alliance, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

SILL PLATE. A horizontal wood member anchored to the foundation and supporting floor joists.

SOLE PLATE. A horizontal wood member at the bottom of a wood stud wall~~, attached to a concrete slab~~.

R403.1.6 Foundation anchorage. Where wood sill and sole plates ~~and cold-formed steel framed walls~~ are supported directly on continuous foundation walls or monolithic slabs with integral footings required by the provisions of this code, they shall be anchored to the foundation in accordance with this section.

<u>Cold-formed steel floor and wall framing shall be fastened to wood sill or sole plates anchored to the foundation in accordance with this section, or shall be anchored directly to the foundation in accordance with Section R505.3.1 or R603.3.1.</u>

Wood sole plates at all exterior walls, wood sole plates of *braced wall panels* at building interiors on monolithic slabs with integral footings, and all wood sill plates shall be anchored to the foundation with 1/2 inch (12.7 mm) diameter anchor bolts spaced a maximum of 6 feet (1829 mm) on center or *approved* anchors or anchor straps spaced as required to provide equivalent anchorage to the 1/2-inch-diameter (12.7 mm) anchor bolts. Bolts shall extend a minimum of 7 inches (178 mm) into concrete or grouted cells of concrete masonry units. A nut and washer shall be tightened on each anchor bolt. There shall be a minimum of two bolts per plate section with one bolt located not more than 12 inches (305 mm) or less than seven bolt diameters from each end of the plate section. Interior bearing wall sole plates on monolithic slab foundations with integral footings that are not part of a *braced wall panel* shall be positively anchored with *approved* fasteners. Sill plates and sole plates shall be protected against decay and termites where required by Sections R317 and R318. ~~Cold-formed steel framing systems shall be fastened to the wood sill plates or anchored directly to the foundation as required in Section R505.3.1 or R603.3.1~~.

Exceptions:

1. Walls 24 inches (610 mm) total length or shorter connecting offset *braced wall panels* shall be anchored to the foundation with a minimum of one anchor bolt located in the center third of the plate section and shall be attached to adjacent *braced wall panels* at corners as shown in Figure R602.10.4.4(1).
2. Connection of walls 12 inches (305 mm) total length or shorter connecting offset *braced wall panels* to the foundation without anchor bolts shall be permitted. The wall shall be attached to adjacent *braced wall panels* at corners as shown in Figure R602.10.4.4(1).

Commenter's Reason: The purpose of this public comment is to address the concerns raised by the IRC-B/E Committee. First, this change implements the floor modification which was ruled out-of-order. The modification, requested by the Steel Framing Alliance, moves the anchorage requirements for cold-formed steel out of the larger paragraph, which mostly concerns wood framing. The relocated paragraph becomes "charging language" which points the user to the appropriate CFS provisions in Chapters 5 and 6. This greatly clarifies the anchorage requirements for cold-formed steel. Second, this change removes the "attached to a concrete slab" language from the sole plate definition. A sole plate can occur at any level of the building, not just at the foundation. The text of Section R403.1.6 makes it clear that the section addresses only those sole plates which do occur at foundation walls or monolithic slabs.

Final Action: AS AM AMPC____ D

RB80-09/10

R404.1.9 (New), R404.1.9.1 (New), R404.1.9.2 (New), R404.1.9.3 (New), R404.1.9.4 (New), R404.1.9.5, R602.10.7

Proposed Change as Submitted

Proponent: Gary Ehrlich, National Association of Home Builders (NAHB)

1. Add new text as follows:

<u>**R404.1.9 Isolated masonry piers.** Isolated masonry piers shall be constructed in accordance with this section and the general masonry construction requirements of Section R606. Hollow masonry piers shall have a minimum nominal thickness of 8 in. (203 mm), with a nominal height not exceeding four (4) times the nominal thickness and a nominal length not exceeding three (3) times the nominal thickness. Where hollow masonry units are solidly filled with concrete or grout, piers shall be permitted to have a nominal height not exceeding ten (10) times the nominal thickness. Footings for isolated masonry piers shall be sized in accordance with Section R403.1.1.</u>

<u>**R404.1.9.1 Pier cap.** Hollow masonry piers shall be capped with 4 inches (102 mm) of solid masonry or concrete, a masonry cap block, or shall have cavities of the top course filled with concrete or grout unless a sill plate of 2-inch (51 mm) minimum nominal thickness and bearing on two face shells is provided. The sill plate shall provide a minimum nominal bearing area of 48 square inches (30 865 square mm). Where required, termite protection for the pier cap or sill plate shall be provided in accordance with Section R318.</u>

<u>**R404.1.9.2 Masonry piers supporting floor girders.** Masonry piers supporting wood girders complying with Tables R502.5(1) and R502.5(2) shall be permitted in accordance with this section. Piers supporting girders for interior bearing walls shall have a minimum nominal dimension of 12 inches (305 mm) and a maximum height of 10 feet (3 048 mm) from top of footing to bottom of sill plate or girder. Piers supporting girders for exterior bearing walls shall have a minimum nominal dimension of 12 inches (305 mm) and a maximum height of 4 feet (1 220 mm) from top of footing to bottom of sill plate or girder. Girders and sill plates shall be anchored to the pier or footing in accordance with Section R403.1.6 or Figure R404.1.5(1).</u>

<u>**R404.1.9.3 Masonry piers supporting braced wall panels.** Masonry piers supporting braced wall panels shall be constructed in accordance with Figure R602.10.7.</u>

<u>**R404.1.9.4 Seismic design of masonry piers.** Masonry piers in all dwellings located in Seismic Design Category D0, D1, D2, and townhouses in Seismic Design Category C, shall be designed in accordance with accepted engineering practice.</u>

<u>**R404.1.9.5 Masonry piers in flood hazard areas.** Masonry piers for dwellings in flood hazard areas shall be designed in accordance with Section R322.</u>

2. Revise as follow:

R602.10.7 Braced wall panel support. *Braced wall panel* support shall be provided as follows:

1. Cantilevered floor joists, supporting *braced wall lines*, shall comply with Section R502.3.3. Solid blocking shall be provided at the nearest bearing wall location. In Seismic Design Categories A, B and C, where the cantilever is not more than 24 inches (610 mm), a full height rim joist instead of solid blocking shall be provided.
2. Raise floor system ~~Elevated~~ post or pier foundations exceeding 4 feet (1 220 mm) in height and supporting *braced wall panels* shall be designed in accordance with accepted engineering practice. Raised floor system masonry pier foundations not exceeding 4 feet (1 220 mm) in height, and isolated masonry piers in basements, shall be permitted to be designed in accordance with Section R404.1.9.
3. Masonry stem walls with a length of 48 inches (1220 mm) or less supporting *braced wall panels* shall be reinforced in accordance with Figure R602.10.7. Masonry stem walls with a length greater than 48 inches (1220 mm) supporting *braced wall panels* shall be constructed in accordance with Section R403.1 *Braced wall panels* constructed in accordance with Sections R602.10.3.2 and R602.10.3.3 shall not be attached to masonry stem walls.

Reason: The purpose of this proposal is to introduce provisions for isolated masonry piers used as foundations for raised wood floor systems. Masonry pier foundations are a common construction method. However, besides a brief mention in R606.6, no other guidance is given for the construction of these piers, other than a reference in R602.10.6 calling for engineered design of piers supporting braced wall panels.

Language is proposed for Chapter 4 to provide prescriptive guidance for isolated masonry piers constructed inside a basement or crawlspace. The language proposed for R404.1.9 for masonry piers is based on the empirical design limits contained in the MSJC. The language is adopted from the paragraph on Foundation Piers in NCMA's TEK Note 5-3A: "Concrete Masonry Foundation Wall Details". Further limits are provided for piers supporting floor girders, braced wall panels, and for piers in high-seismic or flood hazard areas.

The language in R602.10.6 is modified and coordinated with the proposed R404.1.9 language to allow prescriptive design of short exterior masonry piers and of isolated interior masonry piers complying with R404.1.9. Taller masonry piers supporting an elevated deck, sunroom, or other substantially raised portion of a dwelling are relegated to engineered design. It was the original intent of R602.10.6 to address these full-height piers, not to require engineered design for every raised wood floor/crawlspace regardless of pier height.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: EHRLICH-RB-6-R404.1.9-R602.10.7

Public Hearing Results

Committee Action: Disapproved

Committee Reason: The committee likes the concept but feels that there is potential for conflict or unintended consequences with Section R606.6. There is a concern about the sill plate bearing on the face shells. The proponent should rework and bring this back later.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment1:

Gary J. Ehrlich, PE, National Association of Home Builders (NAHB), requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R404.1.9 Isolated masonry piers. Isolated masonry piers shall be constructed in accordance with this section and the general masonry construction requirements of Section R606. Hollow masonry piers shall have a minimum nominal thickness of 8 in. (203 mm), with a nominal height not exceeding four (4) times the nominal thickness and a nominal length not exceeding three (3) times the nominal thickness. Where hollow masonry units are solidly filled with concrete or grout, piers shall be permitted to have a nominal height not exceeding ten (10) times the nominal thickness. Footings for isolated masonry piers shall be sized in accordance with Section R403.1.1.

R404.1.9.1 Pier cap. Hollow masonry piers shall be capped with 4 inches (102 mm) of solid masonry or concrete, a masonry cap block, or shall have cavities of the top course filled with concrete or grout ~~unless a sill plate of 2-inch (51 mm) minimum nominal thickness and bearing on two face shells is provided. The sill plate shall provide a minimum nominal bearing area of 48 square inches (30 865 square mm)~~. Where required, termite protection for the pier cap ~~or sill plate~~ shall be provided in accordance with Section R318.

R404.1.9.2 Masonry piers supporting floor girders. Masonry piers supporting wood girders sized per Tables R502.5(1) and R502.5(2) shall be permitted in accordance with this section. Piers supporting girders for interior bearing walls shall have a minimum nominal dimension of 12 inches (305 mm) and a maximum height of 10 feet (3 048 mm) from top of footing to bottom of sill plate or girder. Piers supporting girders for exterior bearing walls shall have a minimum nominal dimension of 12 inches (305 mm) and a maximum height of 4 feet (1 220 mm) from top of footing to bottom of sill plate or girder. Girders and sill plates shall be anchored to the pier or footing in accordance with Section R403.1.6 or Figure R404.1.5(1). Floor girder bearing shall be in accordance with Section R502.6.

R404.1.9.3 Masonry piers supporting braced wall panels. Masonry piers supporting braced wall panels shall be ~~constructed~~ designed in accordance with ~~Figure R602.10.7~~ accepted engineering practice.

R404.1.9.4 Seismic design of masonry piers. Masonry piers in all dwellings located in Seismic Design Category D0, D1, D2, and townhouses in Seismic Design Category C, shall be designed in accordance with accepted engineering practice.

R404.1.9.5 Masonry piers in flood hazard areas. Masonry piers for dwellings in flood hazard areas shall be designed in accordance with Section R322.

R602.10.7 Braced wall panel support. Braced wall support shall be provided as follows:

1. Cantilevered floor joists, supporting *braced wall lines*, shall comply with Section R502.3.3. Solid blocking shall be provided at the nearest bearing wall location. In Seismic Design Categories A, B and C, where the cantilever is not more than 24 inches (610 mm), a full height rim joist instead of solid blocking shall be provided.
2. Raised floor system post or pier foundations ~~exceeding 4 feet (1 220 mm) in height~~ ~~and~~ supporting *braced wall panels* shall be designed in accordance with accepted engineering practice. ~~Raised floor system masonry pier foundations not exceeding 4 feet (1 220 mm) in height, and isolated masonry piers in basements, shall be permitted to be designed in accordance with Section R404.1.9.~~
3. Masonry stem walls with a length of 48 inches (1220 mm) or less supporting *braced wall panels* shall be reinforced in accordance with Figure R602.10.7. Masonry stem walls with a length greater than 48 inches (1220 mm) supporting *braced wall panels* shall be constructed in accordance with Section R403.1 *Braced wall panels* constructed in accordance with Sections R602.10.3.2 and R602.10.3.3 shall not be attached to masonry stem walls.

Commenter's Reason: The purpose of this public comment is to address the issues raised by the IRC-B/E Committee. The Committee expressed concerns about the provision to allow hollow cells at the top of the pier if a sill plate section is used to support the floor framing. The public comment deletes this language, restoring the solid-bearing requirement. A pointer to the existing Chapter 5 language for bearing of floor framing on concrete and masonry supports is provided.

The Committee was also concerned about potential conflicts with Chapter 6. These masonry pier provisions do not conflict with any of the requirements in Section R606. Chapter 6 is primarily intended for above-grade, full-story walls. Chapter 4 is the proper section for requirements dealing with foundations. Other requirements for masonry foundations such as basement walls and pier-and-curtain wall systems, appear in Chapter 4, as well as the requirements for crawlspaces. Adding requirements to Chapter 4 for masonry piers used as foundation elements maintains this consistency.

These provisions are necessary to insure masonry pier foundations used to support wood floor framing are an accepted code practice. Currently, interpretation of the code is inconsistent, and some jurisdictions have not permitted these systems. This is why the wood industry felt it necessary to submit RB71-09/10 to clarify these pier-and-beam systems are permitted. Further, this proposal will provide engineers with guidance to use in designing masonry pier foundations for IRC applications. This will result in potential savings for homeowners on foundation construction costs.

Public Comment 2:

Gary J. Ehrlich, PE, National Association of Home Builders, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R404.1.9.3 Masonry piers supporting braced wall panels. Masonry piers supporting braced wall panels shall be ~~constructed~~ designed in accordance with ~~Figure R602.10.7~~ accepted engineering practice.

> **Exception:** For one- and two-story buildings where the basic wind speed does not exceed 90mph, the wind exposure category is B or C, the wall height does not exceed 10 feet, the eave-to-ridge height does not exceed 10 feet, and the maximum spacing between braced wall lines does not exceed 30 feet, square masonry piers shall be permitted to support braced wall panels. The masonry piers shall be 16 inches nominal in width and shall not exceed 48 inches in height. The masonry piers shall be grouted solid and reinforced with 1-#4 vertical bar each cell.

R602.10.7 Braced wall panel support. Braced wall support shall be provided as follows:

1. Cantilevered floor joists, supporting *braced wall lines*, shall comply with Section R502.3.3. Solid blocking shall be provided at the nearest bearing wall location. In Seismic Design Categories A, B and C, where the cantilever is not more than 24 inches (610 mm), a full height rim joist instead of solid blocking shall be provided.
2. Raised floor system post or pier foundations ~~exceeding 4 feet (1 220 mm) in height~~ ~~and~~ supporting *braced wall panels* shall be constructed per Section R404.1.9.3 or designed in accordance with accepted engineering practice. ~~Raised floor system masonry pier foundations not exceeding 4 feet (1 220 mm) in height, and isolated masonry piers in basements, shall be permitted to be designed in accordance with Section R404.1.9.~~
3. Masonry stem walls with a length of 48 inches (1220 mm) or less supporting *braced wall panels* shall be reinforced in accordance with Figure R602.10.7. Masonry stem walls with a length greater than 48 inches (1220 mm) supporting *braced wall panels* shall be constructed in accordance with Section R403.1 *Braced wall panels* constructed in accordance with Sections R602.10.3.2 and R602.10.3.3 shall not be attached to masonry stem walls.

(Portions of proposal not shown remain unchanged)

Commenter's Reason: The purpose of this public comment is to provide additional prescriptive guidance for builders and code officials in constructing raised floor systems supported on masonry piers.

A desire was expressed for a prescriptive detail for a reinforced pier to handle lateral loads. Accordingly, we have added language under proposed new Section R404.1.9.3 to allow a 16x16 CMU pier with 4-#4 vertical bars under braced wall lines and braced wall panels in low-wind areas. The prescriptive design was generated using wind loads from the calculations used to develop the wind bracing table in Section R602.10 and using strength design per TMS 402-08 Building Code Requirements for Masonry Structures. All of the strength design load combinations per Section 2.4 of ASCE 7 were considered. The limitations on number of stories, braced wall line spacing, story and ridge heights are necessary to keep the required reinforcing to a minimum.

This additional prescriptive detail will provide building officials with the guidance to be able to review and approve masonry pier foundations without necessarily having to require engineered designs. In addition to keeping with the intent of the IRC to supply prescriptive provisions, this proposal will result in savings for homeowners who will not have to pay additional engineering costs and who will also save on foundation construction costs.

Final Action: AS AM AMPC____ D

RB82-09/10

R405.1, R405.1.1 (New), R405.2, R405.2.1, R405.2, R405.2.2, R405.3

Proposed Change as Submitted

Proponent: James Jorgensen, PE, City of Lenexa, KS, representing the Metropolitan Kansas Chapter of ICC

1. Revise as follows:

R405.1 Concrete or masonry foundations. Drains shall be provided around all concrete or masonry foundations that retain earth and enclose habitable or usable spaces located below *grade*. Drainage tiles, gravel or crushed stone drains, perforated pipe or other *approved* systems or materials shall be installed ~~at or~~ below the floor level of the area to be protected and shall discharge ~~by gravity or mechanical means~~ into an *approved* drainage system in accordance with Section R405.3.. Gravel or crushed stone drains shall extend at least 1 foot (305 mm) beyond the outside edge of the footing and 6 inches (152 mm) above the top of the footing, be at least 12 inches deep, and be ~~covered~~ surrounded by ~~with~~ an *approved* filter membrane material. The top of open joints of drain tiles shall be protected with strips of building paper.~~, and~~ The drainage tiles or perforated pipe shall be placed on a minimum of 2 inches (51 mm) of washed gravel or crushed rock at least one sieve size larger than the tile joint opening or perforation and covered with not less than 6 inches (152 mm) of the same material. Perforated pipe drains shall be covered with an approved filter membrane or an approved filter membrane shall surround the gravel/crushed rock covering the drain. Drains shall be placed level or at a positive slope to the point of collection for removal from the structure.

Exceptions:

1. A drainage system is not required when the foundation is installed on well-drained ground or sand-gravel mixture soils according to the Unified Soil Classification System, Group I Soils, as detailed in Table R405.1.
2. Perforated pipe drains may be placed on top of a concrete footing in lieu of a bed of gravel or rock provided it is below the floor level of the usable space.

2. Add new text as follows:

R405.1.1 Perforated pipe drains. Perforated pipe drains and drain tile shall have a minimum interior diameter of 4 inches.

3. Revise as follows:

R405.2 Wood foundations. Wood foundations enclosing habitable or usable spaces located below *grade* shall be adequately drained in accordance with Sections R405.2.1 ~~through~~, R405.2.~~3~~2 and R405.3.

R405.2.1 Base. A porous layer of gravel, crushed stone or coarse sand shall be placed to a minimum thickness of 4 inches (102 mm) under the *basement* floor. Provision shall be made for automatic draining of this layer and the gravel or crushed stone wall footings. To drain the base layer, interior drains complying with Section R405.1 shall be provided below the base layer, around the perimeter of the enclosed area and connected to the drainage system.

R405.2.2 ~~Vapor retarder~~ Moisture barrier. A 6-mil-thick (0.15 mm) polyethylene ~~vapor retarder~~ moisture barrier shall be applied over the porous layer with the *basement* floor constructed over the polyethylene.

~~R405.2~~ R405.3 Drainage system. In other than Group I soils, an approved drainage system shall be provided to ~~a sump shall be provided to~~ drain the ~~porous~~ base layer and footings. The system shall discharge by gravity or mechanical means and shall be capable of removing any accumulated water and discharging it to an approved location to move water away from the structure. Where drainage is by mechanical means a sump shall be provided. The sump shall be at least 24 inches (610 mm) in diameter or 20 inches square (0.0129 m2), shall extend at least 24 inches (610 mm) below the bottom of the *basement* floor ~~and shall be capable of positive gravity or mechanical drainage to remove any accumulated water. The drainage system shall discharge into an *approved* sewer system or to daylight~~. For gravity drainage systems solid pipe shall be provided between the termination point and the connection at the structure and shall terminate in a manner to facilitate cleaning.

Reason: The foundation drainage requirements in the code need clarification to be a more effective component of the code. These requirements have not been updated for many years. A frequent complaint on existing homes is water infiltration into the basement areas. More and more basement areas are used as primary living space. Repairs to dwellings resulting from ineffective installation of the foundation drainage system are costly and is preventable. The codes lack of clarity on this issue leads to ineffective enforcement.

In R405.1 the location of the drains "at or below" the floor level allows for installations that may be ineffective at removing water from the foundation area by allowing water to enter the usable space before it can be drained away. Clarifying that the drains must be below the floor level (top of the floor surface) provides more clarity. Where gravel or crushed stone drains are used the code does not specify a depth of the drain, only that it extends 6 inches above the level of the footing. Since the minimum floor thickness is 4 inches the drain is above the level of the floor which is ineffective. Many standards that address drainage systems require that stone drains be completely enclose to prevent fines from clogging the drainage system. Simply covering the material with a filter membrane does not prevent fines from clogging the drains.

The term "approved filter membrane" does not provide good direction for code officials or builders. Although my research indicates that many roadway projects use AASHTO M288-00 for class 3 for use in drains and French drains I am not sure if this is what is commonly supplied with prefabricated socks for perforated drains. Clarification can be provided in a future code change.

The current code required gravel and stone drains to be covered with a filter membrane, however; the code is silent on the requirements for the protection of perforated drains. To prevent fines from penetrating the openings in the perforated pipe protection by a filter membrane is required around the pipe or around the stone/gravel covering the pipe.

The requirements for removal of water by gravity or mechanical means as been moved to the section on drainage where it can more comprehensively addressed.

The code does not specify a minimum size for drain tile therefore a minimum size of 4 inches interior diameter has been provided. Three inches may be acceptable for some smaller dwellings with short distances to the point of collection but the cost difference is minimal and 4 inches is more effective.

Drains should not have sharp rises or falls that provide for collection points for fine material leading to clodding of the drains over time, therefore a provision for providing a level or positive slope has been added. Section R405.2.1 has been modified to clarify that to drain the porous layer below the base drains complying the R405.1 are required and they shall be installed around the perimeter of the space and below the base layer. Drainage system R405.3. Current Section R405.2.3 only applies to wood foundations. R405.1 only requires that the drains from the protected area discharge to an approved location without clarifying the process. It is inconsistent for wood foundations to be very specific regarding the sump and drainage of the porous layer and have no clarity for concrete and masonry foundations. R405.3 includes the old language in R405.1 for drainage by gravity or mechanical means and adds clarification that for gravity drains the termination point should be such that it could be cleaned of any accumulated debris at the termination from the house to the termination point.

Cost Impact: There may be a slight increase in the initial cost of construction if a jurisdiction did not previously require that perforated drains or crushed gravel drains be protected with an approved filter membrane or provide a means of draining the base layer under basement floors.

ICCFILENAME: JORGENSEN-RB-1-R405.1

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: This proposal adds many difficult provisions that appear to be arbitrary. Bringing the wood foundation drainage in is not appropriate. There is no justification to increase the drain to 4 inches. Changing vapor retarder to moisture barrier adds confusion and will cause a conflict within the code.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

James Jorgensen, PE, City of Lenexa, KS, representing Kansas City Metropolitan Chapter ICC, requests Approval as Modified by this Public Comment.

Replace proposal as follows:

R405.1 Concrete or masonry foundations. Drains shall be provided around all concrete or masonry foundations that retain earth and enclose habitable or usable spaces located below grade. Drainage tiles, gravel or crushed stone drains, perforated pipe or other approved systems or materials shall be installed at or below the area to be protected and shall discharge by gravity or mechanical means into an approved drainage system. Gravel or crushed stone drains shall extend at least 1 foot (305 mm) beyond the outside edge of the footing and 6 inches (152 mm) above the top of the footing and be covered with an approved filter membrane material. The top of open joints of drain tiles shall be protected with strips of building paper. Perforated drains shall be surrounded with an approved filter membrane or the filter membrane shall cover the washed gravel or crushed rock covering the drain. ~~and the d~~ Drainage tiles or perforated pipe shall be placed on a minimum of 2 inches (51 mm) of washed gravel or crushed rock at least one sieve size larger than the tile joint opening or perforation and covered with not less than 6 inches (152 mm) of the same material.

> **Exception:** A drainage system is not required when the foundation is installed on well-drained ground or sand-gravel mixture soils according to the Unified Soil Classification System, Group I Soils, as detailed in Table R405.1.

Commenter's Reason: The code is silent on the methods for protection of openings in perforated foundation pipes. A filter membrane is required over crushed stone drains and strips of building paper are required over drain tile joint opening; however, the code does not specifically require protection of the perforations in perforated foundation drains. Since the perforations surround perforated drains a statement has been added to require protection around perforated drains with an approved filter membrane. As an option the filter membrane may be placed over the gravel or crushed stone cover over the perforated drains.

Final Action: AS AM AMPC____ D

RB84-09/10

R501.3 (New), Chapter 44 (New)

Proposed Change as Submitted

Proponent: Jeff Hugo, CBO, National Fire Sprinkler Association

1. Add new text as follows:

R501.3 Fire Protection. All new one and two family dwellings using floor framing components or systems composed of prefabricated I joists, trusses, and cold formed steel shall be fire sprinklered throughout according to NFPA 13, NFPA 13R, NFPA 13D or Section P2904.1.

2. Add new standard to Chapter 44 as follows:

NFPA

13R—07 Installation of Sprinkler Systems in Residential Occupancies Up to and Including Four Stories in height

Reason: Lightweight construction consisting of prefabricated I joists, trusses, and cold formed steel are excellent materials in many ways. They save labor, time, natural resources, and call backs. However, widespread fire experience shows that floors framed out of these materials do not have the same durability in the event of a fire as solid sawn lumber and are not only hazardous to the occupants evacuating the home, but especially to responding emergency personnel, such as fire fighters.

Several research studies have been performed showing the potential failures of these flooring assemblies during fires and the potential for floor collapse during fire fighter operations. Additional research has shown the ability of fire sprinklers to prevent the fire from reaching the point where it could cause the same kind of damage. This research shows that with fire sprinkler systems in the home, the prefabricated I joists, trusses and cold formed steel materials are safe to use. But without fire sprinklers, these materials could fail catastrophically during a fire.

This requirement is important to put into the IRC even if the requirement for sprinklers is maintained because there are many jurisdictions that will not accept the blanket requirement for sprinklers, but will maintain this option for using sprinklers with this specific type of construction.

Bibliography:

Tyco Fire Suppression & Building Products. A Technical Analysis: The Performance of Composite Wood Joists Under Realistic Fire Conditions. 2008

Su, J.Z., N.; Bawaly, A.C.; Lougheed, G.D.; Taber, B.C.; Leroux, P.; Proulx, G.; Kashef, A.; McCarthey, C.; Thomas, J.R. Fire Performance of Houses, Phase I. Study of Unprotected Floor Assemblies in Basement Fire Scenarios, Summary Report. 12/15/2008

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: The proposed new standard, NFPA 13R, is currently referenced in the *International Building Code.*

ICCFILENAME: HUGO-RB-1-R501.3

Public Hearing Results

Analysis: Review of the proposed new standard indicated that, in the opinion of ICC staff, the standard did comply with ICC standards criteria.

Committee Action: Disapproved

Committee Reason: Sprinklers are a code requirement and this section is not needed. The committee recognizes some jurisdictions will amend out the sprinklers, but we cannot add requirements based on "what ifs". This proposal does not address light-frame construction and gives no option if there are no sprinklers.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jeff Hugo, CBO, National Fire Sprinkler Association, requests Disapproval.

Commenter's Reason: I disagree with the committee's statement. The codes are full of "what ifs", and it is the building official's job to contemplate these situations to protect the citizens in their communities.

This proposal does address light frame construction; note the section it is quoted in - IRC Section R503.1. No other proponent or proposal could clearly identify or prove by the referenced testing that other than fire sprinklers can adequately protect the light framing construction for the citizens and those who need to enter the structure. According to the referenced testing, the best that could be done is 30 minutes without sprinklers. 30 minutes until collapse, but what is often missed are the reports stating that the minimum live loading is lost in much less time (20 minute range). Response times of fire departments, time to setup and gather information, identify the location of those trapped…is less than 30 minutes the best we can do for our fire fighters?

We know by several years of debating in the IBC and IFC that no vertical or horizontal fire resistive barrier can be effective without proper penetration protection. If covering over light weight construction is preferred over sprinklers, no protection of penetrations is required, leaving the building official, home owner, and fire fighter with a false sense of security. Building officials knowing the IBC will have wide ranging interpretations thus affecting the home builders from jurisdiction to jurisdiction to guess, again. This was not the point of creating a single code.

Lighting, duct openings, vent/drain piping, stairs to name a few, will allow fire to spread through the concealed spaces very quickly. If a covering is preferred, then the IRC debates for years to come will have attempts to draftstop, protect penetrations with listed material, etc., which will add costs beyond the sprinkler system installed to protect the light weight framing.

Final Action: AS AM AMPC____ D

RB85-09/10

R501.3 (New), Chapter 44 (New)

Proposed Change as Submitted

Proponent: Larry Wainright, Qualtim, Inc., representing the Structural Building Components Association

1. Add new text as follows:

R501.3 Fire Protection of Floors: Floors within dwelling units shall be protected on the underside by a minimum of 1/2" gypsum board applied in accordance with Section R702.3.

Exceptions:

1. Crawl spaces where the maximum clear height from the underside of the subfloor to the void space floor is 3 feet or less and is not intended for mechanical equipment use or storage.
2. The building is protected with an automatic sprinkler system designed to NFPA 13, 13D, 13R, or Section P2904 of this code.
3. Floors of any material or combination of materials achieving a 30-minute fire-resistance rating in accordance with ASTM E 119 or UL 263.
4. Floors that are protected by a material or combination of materials in accordance with the test procedures of ASTM E 84 or UL 723 that exhibits a flame spread index not exceeding 25, no evidence of progressive combustion and a flame front that does not progress more than 10 ½ feet (3200 mm) beyond the centerline of the burner at any time during an extended 30 minute test.

2. Add new standard to Chapter 44 as follows:

NFPA
<u>13R—07</u> <u>Installation of Sprinkler Systems in Residential Occupancies Up to and Including Four Stories in height</u>

Reason: This proposal would require the underside of floors to be protected, providing a greater level of fire protection than unprotected floors. This would apply to all construction types, thereby creating no competitive advantage for specific building types.

Cost Impact: The code change proposal will increase the cost of construction.

Analysis: The proposed new standard, NFPA 13R, is currently referenced in the *International Building Code*.

ICCFILENAME: WAINRIGHT-RB-8-R501.3

Public Hearing Results

Analysis: Review of the proposed new standard indicated that, in the opinion of ICC staff, the standard did comply with ICC standards criteria.

Committee Action: Disapproved

Committee Reason: Based on the committee's previous action on RB31-09/10. ASTM E84 is not the appropriate test for structural integrity. The floor furnace test is more appropriate. The proponent should work with the proponent of RB86-09/10 through RB88-09/10 to bring back a solution that protects the fire fighters and the occupants.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Larry Wainright, Qualtim, Inc, representing Structural Building Components Association (SBCA), requests Approval as Modified by this Public Comment.

Replace proposal as follows:

<u>**R501.3 Fire protection of floors.** Floor assemblies, not required elsewhere in this code to be fire resistance rated, shall be provided with a ½ inch (12.7 mm) gypsum wallboard membrane, 5/8 inch (15.9 mm) wood structural panel membrane, or equivalent on the underside of light frame construction, steel bar joists and wood chord / metal web joists and shall be draftstopped in accordance with Section R302.12.</u>

<u>Exceptions:</u>

1. <u>Floor assemblies located directly over a space protected by an automatic sprinkler system in accordance with Section P2904, NFPA 13D, NFPA 13R or NFPA 13.</u>
2. <u>Floor assemblies located directly over a crawl space not intended for storage or fuel-fired appliances.</u>
3. <u>Portions of floor assemblies shall not require protection when complying with the following:</u>
   - <u>3.1 The aggregate area of the unprotected portions shall not exceed 80 square feet per story</u>
   - <u>3.2 Fire blocking in accordance with Section R302.11.1 shall be installed along the perimeter of the unprotected portion to separate the unprotected portion from the remainder of the floor assembly.</u>

Add new standard to Chapter 44 as follows:

<u>**NFPA 13R—07** Installation of Sprinkler Systems in Residential Occupancies Up to and Including Four Stories in height.</u>

Commenter's Reason: RB 85-09/10 merely proposes to require a minimum of ½" gypsum wallboard, or equivalent on all unprotected floor assemblies with exceptions for sprinklered buildings, certain crawlspaces and other limited areas that would otherwise be difficult to cover due to obstructions. SBCA's position on this subject is to provide a requirement that applies equally to all building component types and does not provide a competitive advantage to specific types of construction where they would be exempt from the requirements.

The following link shows statistics of firefighter deaths. It is a global report that shows all firefighter deaths and their causes from 1980-2008. This report shows that less than 5% of all firefighter deaths occur from injuries sustained in structural collapses.
http://www.sbcindustry.com/images/fire/firefatalstats.pdf

The following spreadsheet is a list of NIOSH reports showing firefighter fatalities that involved a structural collapse. Of those reports, 11 involved firefighter deaths from the collapse of solid sawn lightweight construction and 9 (with potentially 2 more) involved I-joists, MPC wood trusses, and steel trusses combined. This shows that there is no compelling evidence to suggest that engineered products are any more dangerous than solid sawn materials in real fire situations.
Links to the full NIOSH reports are included for more details.

Public Comment 2:

Jonathan Humble, representing American Iron & Steel Institute and the Steel Framing Alliance, requests Approval as Modified by this Public Comment.

Replace proposal as follows:

R302.7 Floor separation. Floor assemblies within dwelling units shall have a minimum of ½ inch (12.7 mm) gypsum board applied to the underside of the framing members in accordance with R702.3, when not required elsewhere in this code. This provision shall not supersede Sections R302.3, R302.4 or R302.5 where fire resistance ratings or greater thicknesses of gypsum board are required. Penetrations through the gypsum board shall be allowed for stairways, ducting, piping, and electrical and telecommunications outlet boxes, wiring and conduits.

Exceptions:

1. Floor assemblies located over crawl spaces, where the crawl space does not contain mechanical equipment or water heater(s).
2. Dwellings protected with an automatic sprinkler system designed and installed in accordance with NFPA 13D or in accordance with Section P2904.

(Renumber remaining sections)

Commenter's Reason: We propose to modify the original proposal with a product and provision neutral approach to code enforcement. At the 2009 code hearings there were five (5) proposals on the same subject. Each had their own spin on the approach to a design which would accomplish the goal of providing the fire service with some separation of spaces from spaces where framing members that are normally exposed in dwellings today. In this case that separation is gypsum board, not unlike the protection outlined in IRC Section R302.6. Unfortunately, it was the number of variations and subsequent opinions of preference which convinced the code development committee to recommend disapproval for all five of those proposals (e.g. RB31, RB85, RB86, RB87, and RB88).

The modification acts on the following aspects:

Title:

The title chosen is "floor separation" which more appropriately describes the intent.

Neutral Approach:

The modification before you attempts to neutralize those original opinions by focusing on the basic applications necessary for that separation. The modification is product neutral, meaning it applies to all light frame constructions without exception. In addition, the provision is proposed for inclusion into Chapter 3 which further retains that neutrality.

Coordination:

The modification coordinates the other provisions which require gypsum board by referencing the specific sections and the priority, in the second sentence.

Penetrations:

The modification also addresses the impact of stairs, ducting, piping and electrical wiring and conduit penetrating the gypsum board ceiling, in the third sentence.

Exceptions

The modification includes only those exceptions that were found to be a common theme amongst the five original proposals, and practical for this application.

Final Action: AS AM AMPC____ D

RB86-09/10
R501.3 (New)

Proposed Change as Submitted

Proponent: Sal DiCristina, representing Code Solutions, Inc.

Add new text as follows:

R501.3 Fire floor protection: Floors within dwelling units utilizing light-frame construction shall be protected on the underside by a minimum of 5/8" gypsum board applied in accordance with Section R702.3.

Exceptions:

1. Crawl spaces where the maximum clear height from the underside of the subfloor to the void space floor is 3 feet or less and is not intended for mechanical equipment use or storage.
2. The building is protected with an automatic sprinkler system designed to NFPA 13D or Section P2904 of this code.
3. Floors in which the exposed materials are protected by materials achieving a 30-minute fire-resistance rating in accordance with ASTM E 119 or UL 263.
4. Floors in which the exposed materials on the underside are protected by a fire-retardant coating that shall have, when tested in accordance with ASTM E 84 or UL 723 in the form in which it is applied, a listed flame spread index of 25 with no evidence of significant progressive combustion when the test is continued for an additional 20 minute period. In addition, the flame front shall not progress more than 10 ½ feet (3200 mm) beyond the centerline of the burners at any time the test.

Reason: This proposal is essentially the same as a proposal submitted by Battalion Chief Sean DeCrane of the Cleveland Fire Department with the addition of an exception number 4. We support Chief DeCrane's objectives, however, we believe additional flexibility is needed to provide the required level of protection in the vast array of construction configurations that may be encountered in the field.

The purpose of this additional method of protection is to provide an economical method to protect the underside of a floor without the need to apply a covering membrane that would restrict access. This would be important for unfinished basement and lower levels, or crawl spaces that do not meet exception 1.

It is important to note that the parameters required in proposed Exception 4 prevents the underside of the floor from ignited for a period of at least 30 minutes which matches the level of protection Mr. DeCrane seeks in Section R501.3.

ASTM 84 and UL 723 are already utilized in the IRC in Section R302 Fire Resistant Construction, however, the parameters above exceed those in R302 to ensure that a minimum of 30 minutes of protection is provided to the underside of the floors.

Of greater note is that material meeting the requirements of exception 4 meet or exceed the level of protection provided by fire-retardant treated wood (FRTW) that is permitted by Sections R802.1 and R802.1.3 of the IRC for protected roof framing.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: DICRISTINA-RB-1-R501.3

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: Based on the proponent's request and the committee's previous action on RB85-09/10.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jonathan Humble, American Iron & Steel Institute, representing The Steel Framing Alliance, requests Approval as Modified by this Public Comment.

Replace proposal as follows:

R302.7 Floor separation. Floor assemblies within dwelling units shall have a minimum of ½ inch (12.7 mm) gypsum board applied to the underside of the framing members in accordance with R702.3, when not required elsewhere in this code. This provision shall not supersede Sections R302.3, R302.4 or R302.5 where fire resistance ratings or greater thicknesses of gypsum board are required. RB87-09/10

R501.3 (New)

Proposed Change as Submitted

Proponent: Sean DeCrane, Cleveland, OH Fire Department, representing the International Association of Fire Fighters

Add new text as follows:

R501.3 Fire floor protection. Floors within dwelling units utilizing light-frame construction shall be protected on the underside by a minimum of 5/8" gypsum board applied in accordance with Section R702.3.

Exceptions:

1. Crawl spaces where the maximum clear height from the underside of the subfloor to the void space floor is 3 feet or less and is not intended for mechanical equipment use or storage.
2. The building is protected with an automatic sprinkler system designed to NFPA 13D or Section P2904 of this code.
3. Floors in which the exposed materials are protected by materials achieving a 30-minute fire-resistance rating in accordance with ASTM E 119 or UL 263.

Reason: On August 13, 2006 a Wisconsin fire fighter was killed, and a second fire fighter injured, when the floor they were operating on collapsed sending them into the basement. One fire fighter fell directly into the room of origin and was killed, the second fire fighter landed on the opposite side of a block wall and survived by shielding herself and making an escape through a rear window. They checked the floor to ensure it was safe and solid, just prior to collapse they heard a loud crack. T

The floor they were operating on was unprotected lightweight construction that collapsed without warning. In the ensuing investigation, the National Institute for Occupational Safety and Health released report F2006-26[1]. One of the recommendations is to "modify current building codes to require that lightweight trusses be protected with a fire barrier". This should not only pertain to truss construction. There are additional forms of construction that can be determined to be lightweight, cold form steel, bar joists, wooden engineered I-beam, etc., the recent trend in residential construction is to use products that are financially beneficial. It is the belief of many of us in the fire service that as the industry engineers products to a more finite point we are losing our safety factors.

In their report 2007-12 released May 16, 2008, NIOSH[2] recommended "Ensure fire fighters are trained for extreme conditions such as high winds and rapid fire progression associated with lightweight construction". They further stated, "In this era of new lightweight construction, training procedures covering strategy and tactics in extreme operations conditions, such as high winds and lightweight building construction (i.e. materials and design) are needed for all levels of fire fighters. Lightweight constructed buildings fail rapidly with little warning, complicating rescue efforts. The potential for fire fighters to become trapped or involved in a collapse may be increased. There are twenty-nine actions for fire fighters can take to protect themselves when confronted with buildings utilizing lightweight building components as structural members. They range from looking for signs or indicators that these materials are used in buildings (such as, newer structures, large unsupported spans, and heavy black smoke being generated) to getting involved in newer building code development".

On September 27, 2007 NIOSH released report 2006-24[3] The first recommendation of the report read "Ensure that fire fighters and incident commanders are aware unprotected pre-engineered I-joist floor systems may fail at a faster rate than solid wood joists when exposed to direct fire impingement, and they should plan interior operations accordingly". The discussion of the recommendation is quite lengthy but identifies the advantages of the construction industry using this type of construction but also relates the dangers to fire fighters, "The Illinois Fire Service Institute, at the University of Illinois, conducted tests to help determine the structural stability of sample floor systems. These studies suggest that engineered wooden I-beams can fail in as little as 4 minutes and 40 seconds under controlled test conditions". The report also states that weakened floors are difficult to detect from above as the floor surface may appear intact.

On November 16, 2007, NIOSH released report F2007-07[4]. In this Fire Fighter Death in the Line-of-Duty report, NIOSH recommends "building code officials and local authorities having jurisdiction should consider modifying the current codes to require that lightweight trusses are protected with a fire barrier on both the top and the bottom". The report further states "In this incident, the floor trusses for the first floor did not have any protection on the bottom cord, which immediately exposed the trusses to fire in the basement. Unfinished basements are very common throughout the country. Basements typically house additional fire exposures such as alternative heating sources, hot water heaters, clothes dryers, etc.. It is critical for trusses and lightweight engineered wood I-beams that are used in a load-bearing assembly to be protected with a thermal barrier such as gypsum wallboard. The function of the thermal barrier is a critical factor in the fire performance of the assembly".

In April, 2005, NIOSH released their report "Preventing Injuries and Deaths of Fire Fighters due to Truss System Failures"[5.] In their release they recommended the placement of a labeling system on buildings to indicate the type of construction. While this recommendation will probably not be acceptable to residents of a one or two family home, we can mandate that they increase the protection of the construction type to provide increased safety to the residents and the responding fire fighters.

In fact, NIOSH has been concerned enough with the performance of lightweight floors in fire conditions they released a Workplace Solutions report in February, 2009, *Preventing Deaths and Injuries of Fire Fighters Working Above Fire-Damaged Floor*[6]. Authors of the report recommend; "Builders, contractors, and owners should consider protecting all floor systems, including engineered wood I-joists, by covering the underside with fire-resistant materials".

Many of the opponents of this requirement have made claims that the fire service has failed to provide technical data to support our real world experiences with the lightweight products. Since the previous ICC code cycle there have been three specific reports released by three separate test groups performing tests for different reasons. I have included their results below.

The National Research Council Canada performed a series of tests in creating their report Fire Performance of Houses, Phase I: Study of Unprotected Floor Assemblies in Basement Fire Scenarios, released December 18, 2008. The goal of the report was "With the advent of new materials and innovative construction products and systems for use in construction of houses, there is a need to understand what impacts these materials and products will have on occupant life safety under fire conditions and a need to develop a technical basis for the evaluation of their fire performance".[7] These tests were not intentionally conducted for fire fighter safety but rather to identify the dangers to the civilian occupants and their ability to self evacuate. The report states "With the relatively severe fire scenarios used in the experiments, the times to reach structural failure for the wood I-joist, steel C-joist, metal plate and metal wood truss assemblies were 35-60% shorter than that for the solid wood joist assembly". Additionally, "For the solid wood joist assemblies, the structural failure occurred after deflection of the floor, mainly in the form of OSB subfloor failure (burn through). For all other floor assemblies, after deflection of the floor, the structural failure occurred either in the form of complete collapse into the basement or in the form of a "V" shaped collapse due to joist or truss failure". In keeping with the intent of occupant safety the report also found "One engineered floor assembly, which gave the shortest time to reach structural failure in the open basement scenario, failed structurally in the closed basement doorway scenario before the tenability limits were reached for healthy adults of average susceptibility". This calls into question, if it can not give the occupant time to self evacuate how will it perform when a fire fighter is performing Search and Rescue for that specific occupant. In summarizing the various test results the report found "The time gap between the onset of untenable conditions and the structural failure of the floor assembly was smaller for the engineered floor assemblies than for the solid wood joist assembly used in the experiments". This is very serious for the responding fire fighter performing life saving Search and Rescue for occupants who have lost consciousness due to the untenable conditions. These victims may still be savable but, the performances of the lightweight assemblies indicate that, savable victims may not be reached due to floor compromise.

In 2008 Tyco Fire Suppression & Building Products performed a series of fire tests. The intent of these tests was to demonstrate the impact residential sprinklers will have in improving fire safety in one and two-family occupancies when lightweight construction is present. The results of these tests were released in 2008 as A Technical Analysis: The Performance of Composite Wood Joists Under Realistic Fire Conditions.[8] In the introduction of the report the author states, "One example of the difference in fire performance of a lightweight structural member compared to solid sawn lumber is the behavior of composite wood joists. When a composite wood joist is exposed to fire, the thin oriented strand board used as the web in the joist is quickly consumed, which results in an inability of the joist to carry the load and ultimately a failure of the supported floor assembly". Later in the introduction the report continues "Due to the greater mass per unit of surface area of the solid wood joist, it will support the floor assembly for much longer than its lightweight alternative when exposed to equivalent fire conditions". The first test involving an unsprinklered room fire led to flashover in 7:09 from ignition and floor assembly collapse at the 11:30 mark from ignition. That is roughly four minutes from flashover we had a collapse of almost the entire 16' x 16' floor area. The second test results reached flashover in only 5:15 from ignition, collapse in this test occurred at 8:34 from ignition, a stunning three minutes after flashover. This would be the time the fire fighters are entering the structure for suppression and Search and Rescue efforts.

These reports are still not enough for some critics so I am referencing a third report. Underwriters Laboratories, The Chicago Fire Department and the International Association of Fire Chiefs received a grant from the Department of Homeland Security to conduct a number of tests on various topics but the main issue was to conduct tests, and report the findings, to evaluate the performance of lightweight structural components when exposed to fire and if the components can be protected. They recently issued the subsequent report *Structural Stability of Engineered Lumber in Fire Conditions*.[9] Tests assemblies were subjected to the standards of the ASTM E119 Test Standard. Two assemblies did not include a ceiling, six of the assemblies included a ceiling consisting of ½ inch thick gypsum board and one assembly included a ¾ inch plaster ceiling. A load of 40 psf was placed along two of the four edges and two 300 lb fire fighter mannequins were applied to the floor assembly. Results from the tests indicated that unprotected 12" wooden I-joist reached structural failure at the 5:58 mark in the tests. The resulting failure covered a large area of the floor. The unprotected 2" x 10" wooden I-beams reached structural collapse at the 18:45 mark in the test, a difference of over twelve minutes. These twelve minutes are critical in Search and Rescue. Further tests demonstrated that when ½ inch gypsum was placed on the 12" I-joists the collapse did not occur until the 26:45 mark in the test. Just a simple ½ covering extended the collapse time approximately twenty minutes. When the ½ inch covering was applied to the wooden I-beams the collapse time was extended to 44:45 mark in the test. One important factor to point out regarding these tests is that the fire fighters are a dead load and not a live load. Would a simulated live load of fire fighters transferring additional psi with each step or crawl have contributed to an earlier collapse? When we review the Wisconsin fire where Engineer Arnie Wolf was killed, the fire fighters stated the floor felt solid but suffered a catastrophic collapse when they began their search pattern. These tests clearly outline the performances of the various construction practices and the dangers these performances present to fire fighters. Underwriters Laboratories and the Chicago Fire Department followed these tests with an online educational program, to view go to http://www.uluniversity.us/home.aspx, in an attempt to educate the nation's fire service on the hazards of operating in these environments.

This code change proposal is an attempt to provide a responsible means on residential construction. I have provided examples of fire fighters being killed in occupancies utilizing lightweight construction practices and the subsequent reports detailing the need to protect lightweight construction. I have also provided two reports generated by a neutral governmental agency recommending protection requirements for lightweight construction. These incidents, and others like them, have produced great hardships on the people involved, they have created widows, fatherless children, injured fire fighters and many who bear the pain of fatalities that could have been prevented. I strongly urge your support for this proposed code change.

Floor assembly where Fire Engineer Arnie Wolf was killed

Residential use of cold form steel with penetrations and 24" on center

Even lighterweight materials – Georgia Pacific XJ-85

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: DECRANE-RB-1-R501.3

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: Based on the proponent's request and the committee's previous action on RB85-09/10.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Sean DeCrane, Cleveland, OH, Fire Department, representing the International Association of Fire Fighters; Azarang (Ozzie) Mirkhah, Las Vegas, NV, Fire & Rescue, representing Fire & Life Safety Section of the International Association of Fire Chiefs); Steven Orlowski, National Association of Home Builders, Dennis Pitts American Wood Council, American Forest & Paper Association, requests Approval as Modified by this Public Comment.

Replace proposal as follows:

R501.3 Fire protection of floors. Floor assemblies, not required elsewhere in this code to be fire resistance rated, shall be provided with a ½ inch gypsum wallboard membrane, 5/8 inch wood structural panel membrane, or equivalent on the underside of the floor framing member.

Exceptions:

1. Floor assemblies located directly over a space protected by an automatic sprinkler system in accordance with Section P2904, NFPA13D, or other approved equivalent sprinkler system.
2. Floor assemblies located directly over a crawl space not intended for storage or fuel-fired appliances.
3. Portions of floor assemblies can be unprotected when complying with the following:
   - 3.1 The aggregate area of the unprotected portions shall not exceed 80 square feet per story
   - 3.2 Fire blocking in accordance with Section R302.11.1 shall be installed along the perimeter of the unprotected portion to separate the unprotected portion from the remainder of the floor assembly.
4. Wood floor assemblies using dimension lumber or structural composite lumber equal to or greater than 2-inch by 10-inch nominal dimension, or other approved floor assemblies demonstrating equivalent fire performance.

Commenter's Reason: This public comment was developed in response to the IRC Code Development Committee's comments regarding RB31, RB85, RB86, RB87 and RB88.

Public Comment 2:

Jonathan Humble, American Iron and Steel Institute, representing Steel Framing Alliance, requests Approval as Modified by this Public Comment.

Replace proposal as follows:

R302.7 Floor separation. Floor assemblies within dwelling units shall have a minimum of ½ inch (12.7 mm) gypsum board applied to the underside of the framing members in accordance with R702.3, when not required elsewhere in this code. This provision shall not supersede Sections R302.3, R302.4 or R302.5 where fire resistance ratings or greater thicknesses of gypsum board are required. Penetrations through the gypsum board shall be allowed for stairways, ducting, piping, and electrical and telecommunications outlet boxes, wiring and conduits.

Exceptions:

1. Floor assemblies located over crawl spaces, where the crawl space does not contain mechanical equipment or water heater(s).
2. Dwellings protected with an automatic sprinkler system designed and installed in accordance with NFPA 13D or in accordance with Section P2904.

(Renumber remaining sections)

Commenter's Reason: We propose to modify the original proposal with a product and provision neutral approach to code enforcement. At the 2009 code hearings there were five (5) proposals on the same subject. Each had their own spin on the approach to a design which would accomplish the goal of providing the fire service with some separation of spaces from spaces where framing members that are normally exposed in dwellings today. In this case that separation is gypsum board, not unlike the protection outlined in IRC Section R302.6. Unfortunately, it was the number of variations and subsequent opinions of preference which convinced the code development committee to recommend disapproval for all five of those proposals (e.g. RB31, RB85, RB86, RB87, and RB88).

The modification acts on the following aspects:

Title:
The title chosen is "floor separation" which more appropriately describes the intent.

Neutral Approach:
The modification before you attempts to neutralize those original opinions by focusing on the basic applications necessary for that separation. The modification is product neutral, meaning it applies to all light frame constructions without exception. In addition, the provision is proposed for inclusion into Chapter 3 which further retains that neutrality.

Coordination:
The modification coordinates the other provisions which require gypsum board by referencing the specific sections and the priority, in the second sentence.

Penetrations:
The modification also addresses the impact of stairs, ducting, piping and electrical wiring and conduit penetrating the gypsum board ceiling, in the third sentence.

Exceptions
The modification includes only those exceptions that were found to be a common theme amongst the five original proposals, and practical for this application.

Public Comment 3:

Larry Wainright, Qualtim, Inc, representing Structural Building Components Association (SBCA), requests Approval as Modified by this Public Comment.

Replace proposal as follows:

R501.3 Fire protection of floors. Floor assemblies, not required elsewhere in this code to be fire resistance rated, shall be provided with a ½ inch (12.7 mm) gypsum wallboard membrane, 5/8 inch (15.9 mm) wood structural panel membrane, or equivalent on the underside of light frame construction, steel bar joists and wood chord/steel web joists.

Exceptions:

1. Floor assemblies located directly over a space protected by an automatic sprinkler system in accordance with Section P2904, NFPA 13D, NFPA 13R or NFPA 13.
2. Floor assemblies located directly over a crawl space not intended for storage or fuel-fired appliances.
3. Portions of floor assemblies can be unprotected when complying with the following:
   - 3.1 The aggregate area of the unprotected portions shall not exceed 80 square feet per story
   - 3.2 Fire blocking in accordance with Section R302.11.1 shall be installed along the perimeter of the unprotected portion to separate the unprotected portion from the remainder of the floor assembly.

NFPA 13R—07 Installation of Sprinkler Systems in Residential Occupancies Up to and Including Four Stories in height.

Commenter's Reason: This Public Comment merely proposes to require a minimum of ½" gypsum wallboard, or equivalent, on the underside of light frame construction, steel bar joists and wood chord/steel web joists with exceptions for limited areas, sprinklered buildings and certain crawlspaces. SBCA's position on this subject is to provide a requirement that applies equally to all building component types and does not provide a competitive advantage to specific types of construction where they would be exempt from the requirements. However, if that cannot be achieved, this public comment is one of several that will allow the membership to choose which items they believe need protection.

The following link shows statistics of firefighter deaths. It is a global report that shows all firefighter deaths and their causes from 1980-2008. This report shows that less than 5% of all firefighter deaths occur from injuries sustained in structural collapses.
http://www.sbcindustry.com/images/fire/firefatalstats.pdf

Public Comment 4:

Larry Wainright, Qualtim, Inc, representing Structural Building Components Association (SBCA), requests Approval as Modified by this Public Comment.

Replace proposal as follows:

R501.3 Fire protection of floors. Floor assemblies, not required elsewhere in this code to be fire resistance rated, shall be provided with a ½ inch (12.7 mm) gypsum wallboard membrane, 5/8 inch (15.9 mm) wood structural panel membrane, or equivalent on the underside of light frame construction, steel bar joists and wood chord / steel web joists.

Exceptions:

1. Floor assemblies located directly over a space protected by an automatic sprinkler system in accordance with Section P2904, NFPA 13D, NFPA 13R or NFPA 13.
2. Floor assemblies located directly over a crawl space not intended for storage or fuel-fired appliances.

NFPA 13R—07 Installation of Sprinkler Systems in Residential Occupancies Up to and Including Four Stories in height.

Commenter's Reason: This Public Comment merely proposes to require a minimum of ½" gypsum wallboard, or equivalent, on all unprotected floor assemblies with exceptions for sprinklered buildings and certain crawlspaces. SBCA's position on this subject is to provide a requirement that applies equally to all building component types and does not provide a competitive advantage to specific types of construction where they would be exempt from the requirements.

The following link shows statistics of firefighter deaths. It is a global report that shows all firefighter deaths and their causes from 1980-2008. This report shows that less than 5% of all firefighter deaths occur from injuries sustained in structural collapses.
http://www.sbcindustry.com/images/fire/firefatalstats.pdf

The following spreadsheet is a list of NIOSH reports showing firefighter fatalities that involved a structural collapse. Of those reports, 11 involved firefighter deaths from the collapse of solid sawn lightweight construction and 9 (with potentially 2 more) involved I-joists, MPC wood trusses, and steel trusses combined. This shows that there is no compelling evidence to suggest that engineered products are any more dangerous than solid sawn materials in real fire situations.
Links to the full NIOSH reports are included for more details.

Public Comment 5:

Larry Wainright, Qualtim, Inc, representing Structural Building Components Association (SBCA), requests Approval as Modified by this Public Comment.

Replace proposal as follows:

R501.3 Fire protection of floors. Floor assemblies, not required elsewhere in this code to be fire resistance rated, shall be provided with a ½ inch (12.7 mm) gypsum wallboard membrane, 5/8 inch (15.9 mm) wood structural panel membrane, or equivalent on the underside of light frame construction, steel bar joists and wood chord/steel web joists.

Exceptions:

1. Floor assemblies located directly over a space protected by an automatic sprinkler system in accordance with Section P2904, NFPA 13D, NFPA 13R or NFPA 13.
2. Floor assemblies located directly over a crawl space not intended for storage or fuel-fired appliances.
3. Portions of floor assemblies can be unprotected when complying with the following:
   3.1 The aggregate area of the unprotected portions shall not exceed 80 square feet per story
   3.2 Fire blocking in accordance with Section R302.11.1 shall be installed along the perimeter of the unprotected portion to separate the unprotected portion from the remainder of the floor assembly.
4. Solid sawn wood joists of at least 2x10 nominal.
5. Metal Plate Connected Wood trusses.

NFPA 13R—07 Installation of Sprinkler Systems in Residential Occupancies Up to and Including Four Stories in height

Commenter's Reason: This public comment merely proposes to require a minimum of ½" gypsum wallboard, or equivalent on all unprotected floor assemblies with exceptions for sprinklered buildings, certain crawlspaces and other limited areas that would otherwise be difficult to cover due to obstructions. In addition, solid sawn 2x10 lumber and MPC Wood Trusses are exempted. SBCA's position on this subject is to provide a requirement that applies equally to all building component types and does not provide a competitive advantage to specific types of construction where they would be exempt from the requirements. Recognizing that this may not be possible, this comment offers a compromise where those products that survive the longest in fires are exempted.

The following link shows statistics of firefighter deaths. It is a global report that shows all firefighter deaths and their causes from 1980-2008. This report shows that less than 5% of all firefighter deaths occur from injuries sustained in structural collapses. http://www.sbcindustry.com/images/fire/firefatalstats.pdf.

Public Comment 6:

Larry Wainright, Qualtim, Inc, representing Structural Building Components Association (SBCA), requests Approval as Modified by this Public Comment.

Replace proposal as follows:

R501.3 Fire protection of floors. Floor assemblies, not required elsewhere in this code to be fire resistance rated, shall be provided with a ½ inch (12.7 mm) gypsum wallboard membrane, 5/8 inch (15.9 mm) wood structural panel membrane, or equivalent on the underside of light frame construction, steel bar joists and wood chord/steel web joists.

Exceptions:

1. Floor assemblies located directly over a space protected by an automatic sprinkler system in accordance with Section P2904, NFPA 13D, NFPA 13R or NFPA 13.
2. Floor assemblies located directly over a crawl space not intended for storage or fuel-fired appliances.
3. Portions of floor assemblies can be unprotected when complying with the following:
   3.1 The aggregate area of the unprotected portions shall not exceed 80 square feet per story
   3.2 Fire blocking in accordance with Section R302.11.1 shall be installed along the perimeter of the unprotected portion to separate the unprotected portion from the remainder of the floor assembly.
4. Solid sawn wood joists of at least 2x10 nominal.
5. Metal Plate Connected Wood trusses
6. Cold formed steel trusses.

NFPA 13R—07 Installation of Sprinkler Systems in Residential Occupancies Up to and Including Four Stories in height.

Commenter's Reason: This public comment merely proposes to require a minimum of ½" gypsum wallboard, or equivalent on all unprotected floor assemblies with exceptions for sprinklered buildings, certain crawlspaces and other limited areas that would otherwise be difficult to cover due to obstructions. In addition, solid sawn 2x10 lumber, MPC Wood Trusses and Cold Formed Steel Trusses are exempted. SBCA's position on this subject is to provide a requirement that applies equally to all building component types and does not provide a competitive advantage to specific types of construction where they would be exempt from the requirements. Recognizing that this may not be possible, this comment offers a compromise where those products that survive the longest in fires are exempted.

The following link shows statistics of firefighter deaths. It is a global report that shows all firefighter deaths and their causes from 1980-2008. This report shows that less than 5% of all firefighter deaths occur from injuries sustained in structural collapses. http://www.sbcindustry.com/images/fire/firefatalstats.pdf

Public Comment 7:

Larry Wainright, Qualtim, Inc, representing Structural Building Components Association (SBCA), requests Approval as Modified by this Public Comment.

Replace proposal as follows:

R501.3 Fire Protection of Floors: Floor assemblies, not required elsewhere in this code to be fire resistance rated, shall have a minimum fire resistance of 15 minutes, determined from any of the following options or the sum from any combination thereof:

1. Time assigned to framing members, supporting not less than 50% of the full design load, when tested in accordance with ASTM E119 or UL 263, or determined in accordance with International Building Code Section 721.
2. Time assigned to a ceiling membrane or membranes in Table 501.3.
3. Finish rating time for a ceiling membrane not listed in Table 501.3.
4.

Table R501.3
Time Assigned to Ceiling Membranes

Description of Finish	Time (minutes)[1]
3/8" gypsum board	10
½" gypsum board	15
3/8" wood structural panel	5
½" wood structural panel	10
5/8" wood structural panel	15

[1] Times for individual membranes are additive.

Exceptions:

1. Floor assemblies located directly over a crawl space not intended as a habitable or a storage space and that does not contain fuel-fired appliances.
2. Floor assemblies located directly over a space protected with a sprinkler system designed to NFPA 13, 13D, 13R, or Section R313.
3. A portion of a floor assembly area not greater than 80 square feet per story provided that draft stopping is installed at the perimeter of the unconcealed portion of the floor to separate the concealed spaces from the unconcealed spaces.

NFPA 13R—07 Installation of Sprinkler Systems in Residential Occupancies Up to and Including Four Stories in height.

Commenter's Reason: This public comment merely proposes to require a minimum of a 15 minute fire resistance rating for all floor assemblies not elsewhere required to be fire resistance rated. This can be achieved through ASTM E119 or UL 263 testing and/or the addition of ceiling membranes. This comment would give the building designer flexibility in deciding how to achieve the desired result and would provide the means for creative solutions.

Final Action: AS AM AMPC____ D

RB88-09/10

R502.14 (New), Chapter 44 (New)

Proposed Change as Submitted

Proponent: Joseph Fleming, representing the Boston Fire Department

1. Add new text as follows:

R502.14 Fire floor protection. Floors within dwelling units utilizing light-frame construction shall be protected on the underside by a minimum of 5/8" gypsum board applied in accordance with Section R702.3
Exceptions:

1. Crawl spaces where the maximum clear height is 3 feet or less and is not intended for use or storage.
2. The building is protected with an automatic sprinkler system designed to NFPA 13D or Section P2904 of this code.
3. Floors in which the exposed materials on the underside are protected by a Class A Fire-Retardant Coating as defined by NFPA 703.

2. Add new standard to Chapter 44 as follows:

NFPA
<u>703-09</u> <u>Fire-Retardant Treated Wood and Fire-Retardant Coatings for Building Materials</u>

Reason: When the Building Codes in the US transitioned to lightweight components in order to provide the same structural support at lower costs it was a well intentioned idea. However, it has had tragic unintended consequences in many circumstances. The lightweight components, which provided equivalent performance, at lower cost of construction, to the previously used “heavier components” during normal use, did not provided equivalent performance during structural fires. It may have been assumed that the lighter weight components would survive long enough to let occupants escape but what about occupants who are elderly, handicapped, or trapped because of ineffective smoke alarms. In these cases, firefighters have to conduct search and rescue operations. Often firefighters arrive in the middle of the night with no information about the occupants and must assume that someone needs to be rescued. In these circumstances firefighter’s lives, as well as the occupants they are searching for are being put at an unreasonable risk.

The lightweight construction was considered to provide the same “safety factor” as the older heavier construction because it performed in a similar manner under specific tests designed to measure its ability to support a load during normal conditions. However, it is important to keep in mind that these tests measured only one aspect, albeit a critical aspect, of the material’s safety. (A design with little flexibility due to conservative or incomplete assumptions has little "*robustness*". A design with a lot of flexibility due to liberal and complete assumptions has a lot of "*robustness"*.) The older heavier construction was extremely “robust,” in that it performed for a long time under fire conditions in the same manner that it performed under non-fire conditions. The same cannot be said for light weight construction. The lighter weight construction is not equivalent to the heavier constriction unless it is as “robust” as the heavier construction.

To correct mistakes of the past and to provide better assurance that the light weight construction is equivalent to and as ”robust” as the older heavier construction we must provide extra protection to allow it to perform under fire and non-fire conditions in the same manner that heavier construction material performs.

Specific examples where fire fighters have died, or been injured, due to, structural collapse during fire because of the use of this “less expensive” design have been documented by NIOSH Firefighter Fatality Reports.

Cost Impact: The code change proposal will increase the cost of construction.

Analysis: The proposed new standard, NFPA 703, is currently referenced in the *International Fire Code*.

ICCFILENAME: FLEMING-RB-2-R502.14

Public Hearing Results

Note: The following analysis was not in the Code Change monograph but was published on the ICC website at http://www.iccsafe.org/cs/codes/Documents/2009-10cycle/ProposedChanges/Standards-Analysis.pdf :

Analysis: Review of the proposed new standard indicated that, in the opinion of ICC staff, the standard did comply with ICC standards criteria.

Committee Action: Disapproved

Committee Reason: Based on the proponent's request and the committee's previous action on RB85-09/10.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jonathan Humble, American Iron & Steel Institute, representing The Steel Framing Alliance, requests Approval as Modified by this Public Comment.

Replace proposal as follows:

<u>**R302.7 Floor separation**. Floor assemblies within dwelling units shall have a minimum of ½ inch (12.7 mm) gypsum board applied to the underside of the framing members in accordance with R702.3, when not required elsewhere in this code. This provision shall not supersede Sections R302.3, R302.4 or R302.5 where fire resistance ratings or greater thicknesses of gypsum board are required. Penetrations through the gypsum board shall be allowed for stairways, ducting, piping, and electrical and telecommunications outlet boxes, wiring and conduits.</u>

<u>**Exceptions:**</u>

1. <u>Floor assemblies located over crawl spaces, where the crawl space does not contain mechanical equipment or water heater(s).</u>
2. <u>Dwellings protected with an automatic sprinkler system designed and installed in accordance with NFPA 13D or in accordance with Section P2904.</u>

(Renumber remaining sections)

Commenter's Reason: We propose to modify the original proposal with a product and provision neutral approach to code enforcement. At the 2009 code hearings there were five (5) proposals on the same subject. Each had their own spin on the approach to a design which would accomplish the goal of providing the fire service with some separation of spaces from spaces where framing members that are normally exposed in dwellings today. In this case that separation is gypsum board, not unlike the protection outlined in IRC Section R302.6. Unfortunately, it was the number of variations and subsequent opinions of preference which convinced the code development committee to recommend disapproval for all five of those proposals (e.g. RB31, RB85, RB86, RB87, and RB88).

The modification acts on the following aspects:

Title:
The title chosen is "floor separation" which more appropriately describes the intent.

Neutral Approach:
The modification before you attempts to neutralize those original opinions by focusing on the basic applications necessary for that separation. The modification is product neutral, meaning it applies to all light frame constructions without exception. In addition, the provision is proposed for inclusion into Chapter 3 which further retains that neutrality.

Coordination:
The modification coordinates the other provisions which require gypsum board by referencing the specific sections and the priority, in the second sentence.

Penetrations:
The modification also addresses the impact of stairs, ducting, piping and electrical wiring and conduit penetrating the gypsum board ceiling, in the third sentence.

Exceptions
The modification includes only those exceptions that were found to be a common theme amongst the five original proposals, and practical for this application.

Final Action: AS AM AMPC____ D

RB91-09/10
R202 (New), R502.1.8 (New), R602.1.4 (New), R802.1.6 (New), Chapter 44 (New)

Proposed Change as Submitted

Proponent: Edward L. Keith, PE, APA-The Engineered Wood Association

1. Add new definition as follows:

STRUCTURAL COMPOSITE LUMBER. Structural members manufactured using wood elements bonded together with exterior adhesives. Examples of structural composite lumber are:

Laminated veneer lumber (LVL). A composite of wood veneer elements with wood fibers primarily oriented along the length of the member. Veneer thickness shall not exceed 0.25 in. (6.4 mm).

Parallel strand lumber (PSL). A composite of wood strand elements with wood fibers primarily oriented along the length of the member. The least dimension of the strands shall not exceed 0.25 in. (6.4 mm) and the average length shall be a minimum of 300 times the least dimension.

Laminated strand lumber (LSL). A composite of wood strand elements with wood fibers primarily oriented along the length of the member. The least dimension of the strands shall not exceed 0.10 in. (2.54 mm) and the average length shall be a minimum of 150 times the least dimension.

Oriented strand lumber (OSL). A composite of wood strand elements with wood fibers primarily oriented along the length of the member. The least dimension of the strands shall not exceed 0.10 in. (2.54 mm) and the average length shall be a minimum of 75 times the least dimension.

2. Add new text as follows:

R502.1.8 Structural composite lumber. Structural capacities for structural composite lumber shall be established and monitored in accordance with ASTM D5456.

R602.1.4 Structural composite lumber. Structural capacities for structural composite lumber shall be established and monitored in accordance with ASTM D5456.

R802.1.6 Structural composite lumber. Structural capacities for structural composite lumber shall be established and monitored in accordance with ASTM D5456.

3. Add new standard to Chapter 44 as follows:

ASTM
D5456-09 Standard Specification for Evaluation of Structural Composite Lumber Products

Reason: ASTM Standard D5456 09 is the standard by which structural composite lumber is evaluated. Structural composite lumber and this standard are already recognized in the 2006 IBC. Products manufactured to this standard are increasingly available in the market place and being used in residential construction even though not specifically recognized by the IRC. These products are being used as beams, headers, long length studs, floor and roof framing; and other applications where high strength, long length, and/or dimensional stability make sawn lumber unacceptable.

Recognition of the appropriate code-recognized standard on the identification marks required by the IRC will provide the designer, builder, plans examiner and building inspector with the assurance that structural composite lumber products are being manufactured with the appropriate quality control systems in place and that the design properties of the product are properly derived and maintained during production.

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: The proposed new standard, ASTM D 5456, is currently referenced in the *International Building Code*.

ICCFILENAME: KEITH-RB-6-R202-R502.1.8-CH 44

Public Hearing Results

Analysis: Review of the proposed new standard indicated that, in the opinion of ICC staff, the standard did comply with ICC standards criteria.

Committee Action: Approved as Submitted

Committee Reason: This change adds a much needed definition and standard for structural composite lumber as stated in the proponent's published reason.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Edward L. Keith, APA – The Engineered Wood Association, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

STRUCTURAL COMPOSITE LUMBER. Structural members manufactured using wood elements bonded together with exterior adhesives. Examples of structural composite lumber are:

Laminated veneer lumber (LVL). A composite of wood veneer elements with wood fibers primarily oriented along the length of the member~~.~~, where the veneer element ~~Veneer~~ thicknesses are ~~shall not exceed~~ 0.25 inches (6.4 mm) or less.

Parallel strand lumber (PSL). A composite of wood strand elements with wood fibers primarily oriented along the length of the member~~. The~~, where the least dimension of the wood strand~~s shall not exceed~~ elements is 0.25 in. (6.4 mm) or less and ~~the~~ their average lengths ~~shall be a minimum~~ are a minimum of 300 times the least dimension of the wood strand elements.

Laminated strand lumber (LSL). A composite of wood strand elements with wood fibers primarily oriented along the length of the member~~. The~~, where the least dimension of the wood strand~~s shall not exceed~~ elements is 0.10 in. (2.54 mm) or less and ~~the~~ their average lengths ~~shall be a minimum~~ are a minimum of 150 times the least dimension of the wood strand elements.

Oriented strand lumber (OSL). A composite of wood strand elements with wood fibers primarily oriented along the length of the member~~. The~~, where the least dimension of the wood strand~~s shall not exceed~~ elements is 0.10 in. (2.54 mm) or less and ~~the~~ their average lengths ~~shall be a minimum~~ are a minimum of 75 times and less than 150 times the least dimension ~~or more~~ of the wood strand elements.

(Portions of proposal not shown remain unchanged)

Commenter's Reason: While these provisions were approved by the Committee as proposed, it was suggested by the Committee that the Public Comment process be used to eliminate mandatory language from the definitions for consistency with the format of other definitions in the code. The above modification does so. With one exception the changes above in this Public Comment are non-technical. In the definition for OSL the further limitation "and less than 150 times" was returned to the definition. It was inadvertently left out of the original proposal but is a part of the definition in the standard. It is a necessary part of the definition to distinguish OSL from LSL.

Final Action: AS AM AMPC____ D

RB93-09/10
R502.2.2.1.1

Proposed Change as Submitted

Proponent: Dennis Pitts, American Forest & Paper Association

Revise as follows:

R502.2.2.1.1 Placement of lag screws or bolts in deck ledgers. The lag screws or bolts shall be placed not less than 2 inches (51 mm)in from the top of the deck ledger, ¾ inches (19 mm) from the bottom of the deck ledger, 2 inches (51 mm) from the bottom of rimboard, bottom or top of the deck ledgers and between 2 and 5 inches (51 and 127 mm) in from the ends of the deck ledger. The lag screws or bolts shall be staggered from the top to the bottom along the horizontal run of the deck ledger.

Reason: Placement provisions for lag screws and bolts in deck ledgers were added to the IRC last cycle; however, questions arose when designers compared the placement requirements with 2005 *National Design Specification*® (*NDS*®) *for Wood Construction* requirements for similar connections. The proposed changes bring the placement requirements into agreement with the minimum requirements in the 2005 *NDS*.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: PITTS-RB4-R502.2.2.1.1

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee feels the placement description is too confusing and should be presented in tabular form.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Dennis Pitts, representing American Wood Council and American Forest & Paper Association, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R502.2.2.1.1 Placement of lag screws or bolts in deck ledgers and band joists. The lag screws or bolts in deck ledgers and band joists shall be placed ~~not less than 2 inches (51 mm)in from the top of the deck ledger, ¾ inches (19 mm) from the bottom of the deck ledger, 2 inches (51 mm) from the bottom of rimboard, bottom or top of the deck ledgers and between 2 and 5 inches (51 and 127 mm) in from the ends of the deck ledger. The lag screws or bolts shall be staggered from the top to the bottom along the horizontal run of the deck ledger~~ in accordance with Table R502.2.1.1 and Figures R502.2.2.1.(1) and R502.2.2.1.(2).

TABLE R502.2.2.1.1
PLACEMENT OF LAG SCREWS AND BOLTS IN DECK LEDGERS AND BAND JOISTS

MINIMUM END AND EDGE DISTANCES AND SPACING BETWEEN ROWS				
	TOP EDGE	BOTTOM EDGE	ENDS	ROW SPACING
Ledger [1]	2 inches [4]	¾ inch	2 inches [2]	1-5/8 inch [2]
Band Joist [3]	¾ inch	2 inches	2 inches [2]	1-5/8 inch [2]

For SI: 1 inch = 2.54 mm
Notes:

1. Lag screws or bolts shall be staggered from the top to the bottom along the horizontal run of the deck ledger in accordance with Fig. R502.2.2.1.(1).
2. Maximum 5 inches (127 mm).
3. For engineered rim joists, the manufacturer's recommendations shall govern.
4. The minimum distance from bottom row of lag screws or bolts to the top edge of the ledger shall be in accordance with Fig. R502.2.2.1.(1).

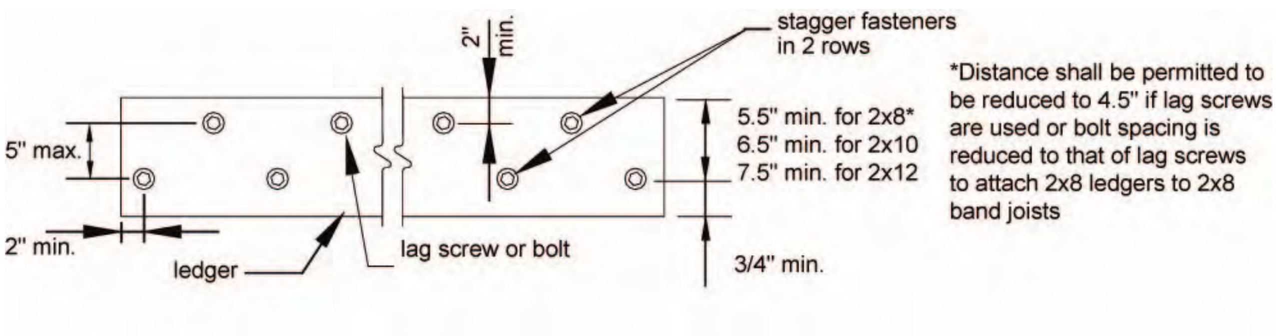

Fig. 502.2.2.1(1)
PLACEMENT OF LAG SCREWS AND BOLTS IN LEDGERS

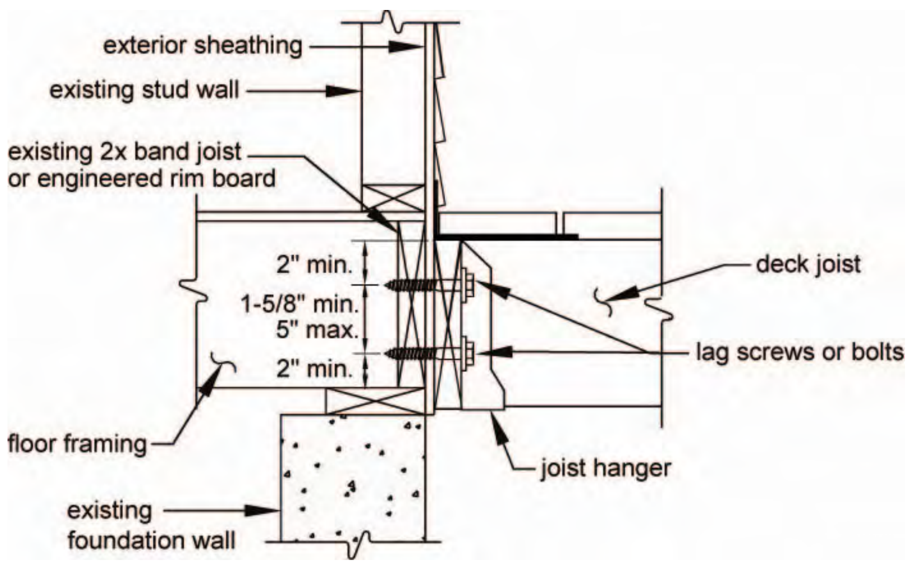

FIG.R502.2.2.1(2)
PLACEMENT OF LAG SCREWS AND BOLTS IN BAND JOISTS

Commenter's Reason: RB93-09/10 was intended to bring the requirements for the placement of screws or bolts in deck ledgers into agreement with the minimum requirements of the NDS®. The IRC B&E Committee members felt that "…the placement description is too confusing and should be presented in tabular form." This public comment puts the existing and the proposed requirements into a table and also provides illustrations to make those provisions clearer.

Final Action: AS AM AMPC____ D

RB94-09/10
R502.2.2.3, Figure R502.2.2.3

Proposed Change as Submitted

Proponent: Diana M. Hanson, representing North American Deck and Railing Association, Inc. (NADRA)

Delete without substitution:

~~**R502.2.2.3 Deck lateral load connection.** The lateral load connection required by Section R502.2.2 shall be permitted to be in accordance with FigureR502.2.2.3. Hold-down tension devices shall be installed in not less than two~~

~~locations per deck, and each device shall have an allowable stress design capacity of not less than 1500 pounds (6672 N).~~

~~FIGURE R502.2.2.3~~
~~DECK ATTACHMENT FOR LATERAL LOADS~~

Reason: The language of R502.2.2.3 is ambiguous resulting in potential misinterpretation by builders of decks and code officials. The phrasing “may be permitted to be” when coupled with the referenced Figure R502.2.2.3, results in a misunderstanding that this *example* of how to meet the lateral load requirement of R502.2.2, is a requirement, when in fact it is not.

This section has been the cause of much confusion and misunderstanding since its adoption in 2007. The language of 502.2.2.3 and the related figure is merely a suggestion, not a prescription for the only way to achieve a compliant lateral connection, yet NADRA has had to field inquiries and hold discussions with many builders and code officials who understandably misinterpret this code section and figure.

R502.2.2.3 and related Figure R502.2.2.3 add needless complexity to the code, its enforcement, and application and is potentially prone to misinterpretation. Experience shows such figures have a propensity for taking precedent over actual code language, resulting in commonly accepted construction practices being overlooked, and onerous methods being mistakenly understood to be required by both the builder and the code official, raising the likelihood of increased costs to both materials and labor.

IRC 2009, R101.3 Purpose, states “The purpose of this code is to provide *minimum requirements* to safeguard the public safety…” [emphasis added]. The Figure 502.2.2.3 is taken directly from the FEMA 2007 publication which is specifically for seismic areas. Suggesting that good building practices should meet seismic area requirements is not in line with R101.3.

Further, the language of 502.2.2.3 stating “not less than two” hold-down tension devices makes little sense when the size of the deck being attached is not taken into account.

For the above stated reasons, we propose that Figure 502.2.2.3 and the language of R502.2.2.3 suggesting its use, be removed from the IRC.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: HANSON-RB-2-R502.2.2.3-F. R502.2.2.3

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee feels that a prescriptive method should not be removed from the code but alternate methods should be added. The proponent should work with industry and bring back a solution using other methods.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Diana Hanson, North American Deck and Railing Association, Inc. (NADRA), requests Approval as Submitted.

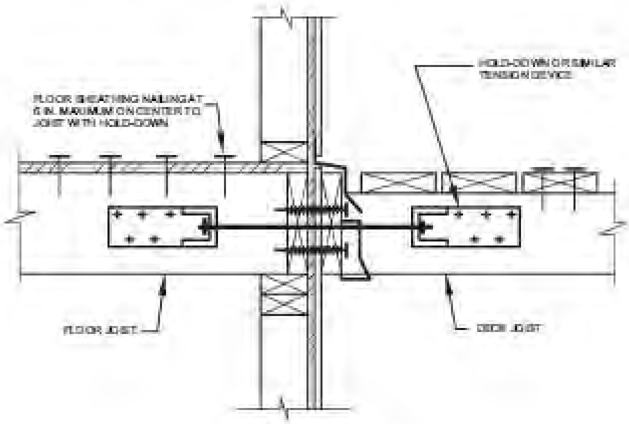
Commenter’s Reason: This public comment is for approval of RB94 As Submitted.

When the committee disapproved RB94 it gave as its reason that a prescriptive method should not be removed from the code, but that a solution providing other methods should be brought back.

We disagree in part, and agree in part.

We agree that carefully developed code that addresses the lateral load should be worked out and included in the IRC, and that industry should work together to achieve it.

However, we do not believe that to be a good enough reason to leave something in the code that is simply bad.



For SI: 1 inch = 25.4 mm

FIGURE 502.2.2.3
DECK ATTACHMENT FOR LATERAL LOADS

R502.2.2.3 Deck lateral load connection. The lateral load connection required by Section R502.2.2 shall be permitted to be in accordance with Figure R502.2.2.3. Hold-down tension devices shall be installed in not less than two locations per deck, and each device shall have an allowable stress design capacity of not less than 1500 pounds (6672 N).

The above Figure 502.2.2.3 was borrowed from Figure 7-10 of the *2006 Homebuilders' Guide to Earthquake-Resistant Design and Construction* (FEMA 232), with stricter requirements added:

1. Where FEMA 232 requires attachment at 12" on center (per R602.3(1)), R502.2.2.3 indicates a fastener pattern of 6" on center; and
2. The FEMA 232 design does not designate a load requirement for its tension devices, however R502.2.2.3 requires that each tension device meet a load requirement of 1500 lbs.

What is in the code now is greater in specification than what FEMA suggested for earthquake prone areas!

Further, while the tension devices of R502.2.2.3 do provide some means to resist lateral loads applied to the ledger connection, lateral load resistance is actually not completely solved by this connection detail. To imply that it does, is misleading since it does nothing to secure the deck from swaying. Swaying can deform the plane of the deck and weaken the connections throughout the deck, as well as compromise the integrity of the supporting posts.

Moreoever, no conditions are given for the use of R502.2.2.3. Multi-level decks, decks that wrap around a corner and decks that jog in and out with creative angles or curves make it impossible to use the generic requirement for "tension devices in two locations" without reference to where those locations are. It is much too simplistic to require two such devices without considering the lateral load resistance of the specific deck.

Clearly, the method of R502.2.2.3 and the related figure is not a cure all for any and all decks. Yet, it is being misunderstood as such and is therefore dangerous. We are already seeing misguided interpretations beginning to affect our industry. As awareness of this figure grows, it is our expectation that that confusion will grow exponentially.

We hope you will vote to remove R502.2.2.3 and the related Figure 502.2.2.3 by approving RB94 as submitted.

Final Action: AS AM AMPC____ D

RB102-09/10
R202 (New), R602.3

Proposed Change as Submitted

Proponent: Jay H. Crandell, PE, d/b/a ARES Consulting, representing the Foam Sheathing Coalition

1. Add new definition as follows:

EXTERIOR WALL COVERING. A material or assembly of materials applied on the exterior side of exterior walls for the purpose of providing a weather-resistive barrier, insulation or for aesthetics, including but not limited to, veneers, siding, exterior insulation and finish systems, architectural trim and embellishments such as cornices, soffits, fascias, gutters and leaders.

2. Revise as follows:

R602.3 Design and construction. Exterior walls of wood-frame construction shall be designed and constructed in accordance with the provisions of this chapter and Figures R602.3(1) and R602.3.(2) or in accordance with AF&PA's NDS. Components of exterior walls shall be fastened in accordance with Tables R602.3(1) through R602.3(4). When used as wall bracing in accordance with Section R602.10 or other structural framing purposes in accordance with this chapter, ~~Structural~~ wall sheathing shall be fastened directly to ~~structural~~ framing members~~. Exterior wall coverings~~ and, when placed on the exterior side of an exterior wall, shall be capable of resisting the wind pressures listed in Table R301.2(2) adjusted for height and exposure using Table R301.2(3). ~~Wood structural panel sheathing used for exterior walls shall conform to the requirements of Table R602.3(3).~~ Wall sheathing used only for exterior wall covering purposes shall comply with Section R703.

Studs shall be continuous from support at the sole plate to a support at the top plate to resist loads perpendicular to the wall. The support shall be a foundation or floor, ceiling or roof diaphragm or shall be designed in accordance with accepted engineering practice.

> **Exception:** Jack studs, trimmer studs and cripple studs at openings in walls that comply with Tables R502.5(1) and R502.5(2).

Reason: The definition of "exterior wall covering" from IBC Chapter 14 is introduced to the IRC for appropriate and consistent usage regardless of building type or occupancy. The proposed revision to section R602.3 then applies this definition and, as an editorial proposal, helps to clarify requirements for sheathing installation on exterior walls. Wall sheathing that is used for structural purposes (e.g., bracing) is addressed in Chapter 6 Wall Framing while wall sheathing that is used solely for exterior wall covering purposes is appropriately addressed in Chapter 7 Wall Covering. The special reference to wood structural panels at the exclusion of listing specific requirements for other sheathing types is deleted because the requirements for applicable wall sheathing materials, including wood structural panels, are adequately addressed by reference to Tables R602.3(1) through R602.3(4). This change will help ensure consistent use of the terms "exterior wall covering" and "wall sheathing" in the IRC and better organize the code to address distinct requirements depending on the application or function of wall sheathing.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: CRANDELL-RB-1-R202-R602.3

Public Hearing Results

Committee Action: **Approved as Modified**

Modify the proposal as follows:

EXTERIOR WALL COVERING. A material or assembly of materials applied on the exterior side of exterior walls for the purpose of providing a weather-resistive barrier, insulation or for aesthetics, including but not limited to, veneers, siding, exterior insulation and finish systems, architectural trim and embellishments such as cornices, soffits, and fascias~~, gutters and leaders~~.

(Portions of proposal not shown remain unchanged)
Committee Reason: The committee feels this new language will be an added improvement and will distinguish between structural wall covering and exterior wall covering. The modification deletes gutters and leaders from the definition since they are not external wall coverings.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Dennis Pitts, American Wood Council & American Forest & Paper Association, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R602.3 Design and construction. Exterior walls of wood-frame construction shall be designed and constructed in accordance with the provisions of this chapter and Figures R602.3(1) and R602.3.(2) or in accordance with AF&PA's NDS. Components of exterior walls shall be fastened in accordance with Tables R602.3(1) through R602.3(4). ~~When used as wall bracing in accordance with Section R602.10 or other structural framing purposes in accordance with this chapter,~~ <u>W</u>~~w~~all sheathing shall be fastened directly to framing members and, when placed on the exterior side of an exterior wall, shall be capable of resisting the wind pressures listed in Table R301.2(2) adjusted for height and exposure using Table R301.2(3). <u>Wood structural panel sheathing used for exterior walls shall conform to the requirements of Table R602.3(3).</u> Wall sheathing used only for exterior wall covering purposes shall comply with Section R703.

Studs shall be continuous from support at the sole plate to a support at the top plate to resist loads perpendicular to the wall. The support shall be a foundation or floor ceiling or roof diaphragm or shall be designed in accordance with accepted engineering practice.

Exception: Jack studs, trimmer studs and cripple studs at openings in walls that comply with Tables R502.5(1).

(Portions of proposal not shown remain unchanged)

Commenter's Reason: The proposed modifications further modify the change recommended for approval as modified by the IRC Committee. The proposal added a clause that limits the minimum fastening and resistance requirements for wall sheathing to only cases where the wall sheathing is being used as part of the wall bracing system per Section R602.10 or other undefined structural framing purposes in Chapter 6. Resisting out of plane wind forces is a major structural requirement on exterior sheathing. While the previous change did clarify some of the language in this section, it confused the issue of whether resistance of out-of-plane wind forces even need to be resisted by the exterior wall sheathing. This change clarifies that requirement while deleting an unnecessary reference to R602.10 in this section.

In addition, the previous change deleted a reference to the out-of-plane resistances provided in Table R602.3(3). This change proposed to re-insert that language while leaving the proposed language that permits exterior wall coverings to be designed per R703.

Public Comment 2:

Edward L. Keith, APA, The Engineered Wood Association, requests Disapproval.

Commenter's Reason: This code change requires only those areas of the wall that are used as bracing to be "capable of resisting wind pressures…" shown on the tables in Section R301.2.1.

The IRC bracing provisions permit distances of up to 21 feet between braced wall panels. That means that the same wind loads that are causing the lateral load on the structure and necessitating the use of braced wall panels may be ignored on these areas of the wall between the braced wall panels. This proposal provides a loop hole around the requirements of Section R301.2.1, reproduced below (important provisions are underlined for clarity):

R301.2.1 Wind limitations. *Buildings and portions thereof shall be limited by wind speed, as defined in Table R301.2(1) and construction methods in accordance with this code. Basic wind speeds shall be determined from Figure R301.2(4). Where different construction methods and structural materials are used for various portions of a building, the applicable requirements of this section for each portion shall apply.* <u>*Where loads for wall coverings*</u>*, curtain walls, roof coverings, exterior windows, skylights, garage doors and exterior doors* <u>*are not otherwise specified, the loads listed in Table R301.2(2) adjusted for height and exposure using Table R301.2(3) shall be used to determine design load performance requirements for wall coverings*</u>*, curtain walls, roof coverings, exterior windows, skylights, garage doors and exterior doors…*

The code, as quoted above, requires that all exterior surfaces of a structure be able to resist these wind loads – including windows, doors and roof coverings. This proposal will provide an exception for the walls of the structure *if they do not contain bracing panels* by prescriptively permitting the use of non-structural sheathing such as foam insulation board. It is unreasonable to assume that the wind will act only on the braced wall panel locations! Note that the wall may use let-in bracing in some situations. In such a situation <u>no</u> area of the opaque wall has to be designed for wind as the proposed provision limits such inconveniences to areas of wall sheathing used as bracing. This proposal is seriously flawed by ignoring the life-safety consideration mandated by the IRC, not to mentioned the increased risk for property damage.

Section R301.1 contains the statement:

Buildings and structures constructed as prescribed by this code are deemed to comply with the requirements of this section.

The intent of this Section 301.1 is to permit methods with a proven <u>history</u> of adequate performance not to be required to meet the engineering requirements of the code. It is disingenuous to use these provisions to permit systems with known performance issues to be exempt from the structural requirements of the code. This is exactly what the proposed code change tries to do and what we hope to persuade you to block with this Public Comment.

Recent thunder storms in the Midwest (Evansville, Indiana and Southwest Missouri, areas of nominal 85 mph wind speed) have left countless houses stripped of siding and foam wall sheathing. In most cases the actual winds were well below the maximum design wind speeds. In some cases, only those walls sections containing the wall bracing panels provided any weather protection for the inside of the house (see photos below). Additional photos are available in the Spring and Summer issues of the 2008 Wood Design Focus.

Figure 1. – Foam and vinyl wall covering failure.
(Storm damage – Southern IN, 2005)

Figure 2. – Foam and vinyl wall covering failure while wall bracing panel remains.
(Storm damage, Springfield, MO, 2006)

Please note that the legacy codes, the ICC, as well as their corresponding product evaluation organizations have long required all structural products to meet all 3 of the following requirements:

1. They must be manufactured to proprietary or consensus based structural standards. These standards describe the minimum physical properties, testing criteria, and durability requirements that must be met by the material for its intended end use.
2. An established quality control program must be in place and supported by the manufacturer to insure that the minimum standards are being met by the production facility.
3. An approved third-party quality assurance inspection agency must be under contract to monitor the manufacturer's QC program and issue trademark stamps.

These requirements are designed to protect the public from unsafe construction. While foam insulation boards are manufactured to insulation standards, they meet none of the structural requirements specified for all other structural products. Unlike wood structural panels or structural fiberboard, foam insulation is not manufactured to any consensus-based structural product manufacturing standards. As such, the structural performance of foam sheathing is undefined and uncontrolled. Furthermore, the quality control and quality assurance programs adopted by the foam insulation manufacturers are limited to the control of insulation characteristics of the products, but not the structural performance. The use of non-structural sheathing for structural applications is a serious life-safety issue.

Sections R612.5 and R612.6 require the same level of protection for windows and doors as is required for wood structural panels and structural fiberboard products:

R612.5 Performance. *Exterior windows and doors shall be designed to resist the design wind loads specified in Table R301.2(2) adjusted for height and exposure per Table R301.2(3).*

R612.6 Testing and labeling. *Exterior windows and sliding doors shall be tested by an approved independent laboratory, and bear a label identifying manufacturer, performance characteristics and approved inspection agency to indicate compliance with AMA/WDMA/CSA 101/I.S.2/A440…*

It is interesting to note that these requirements for windows and doors will be maintained in place while the walls are prescriptively permitted to be protected only by non-structural foam insulation that has none of the historic manufacturing safeguards in place. We used to hope that our windows and doors were as strong as our walls in a storm; this proposal effectively reverses this expectation!

We understand the rush to meet the up and coming energy requirements, however the building codes cannot sacrifice the health and safety of our families and friends to do so. The only solution that we can morally and ethically support is one that provides for both the safety and energy efficiency.

We urge overturning of the committee due to the serious flaw of the proposal in ignoring the important life-safety issue.

Public Comment 3:

T. Eric Stafford, representing Institute for Business and Home Safety, requests Disapproval.

Commenter's Reason: We are requesting disapproval of RB102-09/10 due to several problems with the proposed language. The proposed language adds a new definition of exterior wall covering and attempts to discern a difference between "wall coverings" and coverings used for "structural" purposes. For wind design, all parts of the building are considered structural elements as the exterior wall covering are defined as components and cladding and have to be capable of transferring the external wind loads to the Main Wind-Force Resisting System (MWFRS). Accordingly, exterior wall coverings have to be designed for component and cladding loads.

Additionally, this table deletes the specific reference to Table R602.3(3) for attachment of wood structural panel sheathing in favor of referencing Section R703. Table R602.3(3) was added during the last code cycle to provide a prescriptive method for attaching wood structural panel sheathing to resist out-of-plane wind loads. This table was submitted by APA based on calculations of the panel and the attachment's ability to resist the applicable out-of-plane wind loads. Table R602.3(3) takes into account the panel span rating, wall stud spacing, panel nail spacing, wind speed, and exposure category – none of which is specifically considered in Table R703.4.

The proposed language is also inconsistent and will result in numerous misinterpretations. The new language states that when wall sheathing is used as bracing or other structural framing purposes, and placed on the exterior side of the wall, it has to be capable of resisting the wind pressures from Table R301.2(2) (component and cladding loads). However, if it qualifies as an exterior wall covering as proposed in the new language, attachment in accordance with Section R703 is permitted. This language is particularly inconsistent. If wall sheathing is placed on the exterior side of a wall, it should be capable of resisting the applicable wind pressures regardless of whether the sheathing is used as bracing or not. The proposed language is inconsistent and conflicting with itself. As written it could result in misinterpretations and confusion.

Final Action: AS AM AMPC____ D

R602.7, R602.7.1 (New), Table R602.7.1 (New), Figures R602.7.1(1)-(2) (New)

Proposed Change as Submitted

Proponent: Joseph Lstiburek, Building Science Corporation

1. Revise as follows:

R602.7 Headers. For header spans see Tables R502.5(1) and R502.5(2). Alternative header applications in accordance with this section shall be permitted.

2. Add new text, table and figures as follows:

R602.7.1 Single member headers in exterior bearing walls. Single member headers in exterior bearing walls shall be permitted in accordance with Table R602.7.1. Single headers shall be framed top and bottom with a flat-wise 2x member. To make up the remaining space, cripples shall be installed above the header. See Figure R602.7.1(1). Alternatively, the header can be sized to fill the space between the wall top plate and a flat-wise 2x member. See Figure R602.7.1(2). The header assembly shall bear on a minimum of one jack stud at each end.

For SI: 1 inch=25.4 mm, 1 pound per square foot = 0.0479 kPa.

a. Spans are given in feet and inches.
b. Table is based on a maximum roof-ceiling dead load of 15 psf.
c. The header is permitted to be supported by an approved framing anchor attached to the full-height wall stud and to the header in lieu of the required jack stud.
d. The 20 psf ground snow load condition shall apply only when the roof pitch is 9:12 or greater. In conditions where the ground snow load is 30 psf or less and the roof pitch is less than 9:12, use the 30 psf ground snow load condition.

e. Building width is measured perpendicular to the ridge. For widths between those shown, spans are permitted to be interpolated.

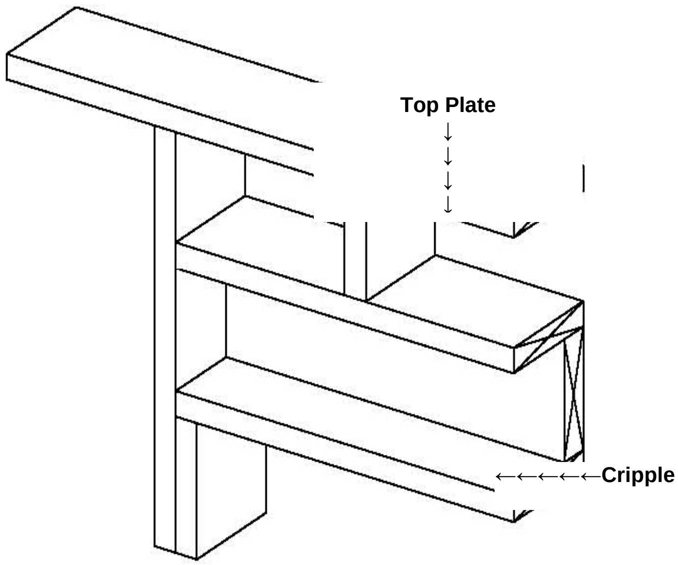

FIGURE R602.7.1(1)
SINGLE MEMBER HEADER IN EXTERIOR BEARING WALL

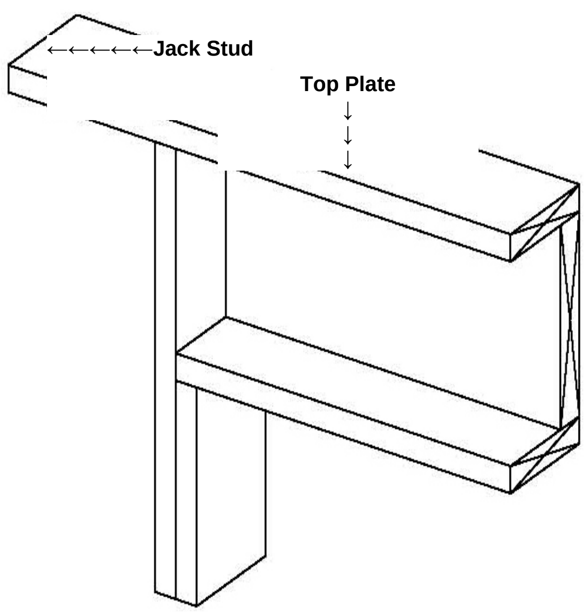

FIGURE R602.7.1(2)
ALTERNATE SINGLE MEMBER HEADER WITHOUT CRIPPLE

Reason: This proposal provides a means of implementing advanced, ←←←←←←**Jack Stud** ction practices for limited conditions where single headers can be used. Thus, insulation can be placed together with the single header to prevent heat loss through headers which otherwise create a thermal short-circuit in exterior walls. The table is evaluated in accordance with the NDS-2005 and ASCE 7-05 building loads. For ease-of-use, the table format is consistent with the principle header tables found in Chapter 5 of the code. The single header practice has been used successfully in thousands of homes since originally developed under the optimal value engineering "OVE" banner by the NAHB and HUD in the 1960's and more recently under the HUD/PATH and DOE Build America programs.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: LSTIBUREK-RB-1-R602.7

Public Hearing Results

Committee Action: **Approved as Modified**

Modify the proposal as follows:

R602.7 Headers. For header spans see Tables R502.5(1) and R502.5(2) and 602.7.1~~. Alternative header applications in accordance with this section shall be permitted.~~

R602.7.1 Single member headers. ~~**in exterior bearing walls.**~~ ~~Single member headers in exterior bearing walls shall be permitted in accordance with Table R602.7.1. Single headers shall be framed top and bottom with a flat-wise 2x member. To make up the remaining space, cripples shall be installed above the header. See Figure R602.7.1(1). Alternatively, the header can be sized to fill the space between the wall top plate and a flat-wise 2x member. See Figure R602.7.1(2). The header assembly shall bear on a minimum of one jack stud at each end.~~ Single headers shall be framed with a single flat 2-inch nominal member or wall plate not less in width than the wall studs on the top and bottom of the header in accordance with Figures R602.7.1(1) and R602.7.1(2).

TABLE R602.7.1
SPANS FOR MINIMUM No.2 GRADE SINGLE HEADER
~~**FOR EXTERIOR BEARING WALLS**~~[a,b,c,f]

f. The header shall bear on a minimum of one jack stud at each end.

(Portion of proposal not shown remains unchanged)

Committee Reason: The committee feels this is a good change that provides value engineering of the framing and provides additional energy savings. The detail has been in use and has been tested. The modification simplifies the language and puts it into code format and adds a clarifying note to the table.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Homer Maiel, City of San Jose, CA, representing ICC Tri-Chapter (Peninsula, East Bay, Monterey Bay Chapters), requests Disapproval.

Commenter's Reason: The Tri-Chapter recommends that this code proposal be denied until further structural analysis and evaluation can be performed. The lack of a solid header over wider window and door openings creates significant concerns over excessively "flexibility" around openings in exterior walls. This problem is much more significant when the exterior siding materials are rigid exterior building materials, such as exterior stucco plaster, where the recommended deflection criteria for stucco is limited to a maximum of l/360 (ASTM C926). For example, a single 2x12 header over a large window or door opening with up to an 8'-1" span would appear to fail to meet the deflection limitations for an exterior stucco wall when evaluating the potential bending in the header due to wind loading. As indicated, these "single headers" are only designed for vertical/gravity loading and are oriented in the "weak axis" for out-of-plane wind loading. Further, the allowance of a framing anchor attached to the full-height wall stud in lieu of the required jack stud results in additional problems of out-of-plane bending of the adjacent "single" king studs. For example, a single 2x4 king stud will fail to meet the maximum deflection criteria for out-of-plane bending when evaluating an 8'-0" opening and maximum wind speed and exposure as allowed in the IRC. The jack stud is no longer available to brace the king stud for out-of-plane wind forces. In addition to the out-of-plane bending problems identified above, the additional "flexibility and eccentricity" introduced by the use of "single headers" over wider window and door openings has not been evaluated. Even in minor earthquake and wind events, the additional flexibility around the wider window and door openings allowed in the proposed Table R602.7.1 are likely to result in more building damage due to excessive building movement.

We believe that whatever minimal energy savings is gained by the use of these single headers is more than offset by window failures and water intrusion issues that may result from excessive exterior wall deflection and building movement. We have seen examples of double pane window seals being broken, failure of window and door frames and seals, and water infiltration at door and window openings caused by excessive exterior wall deflection and building movement. The observed damages caused by excessive exterior wall deflection and building movement far exceeded the energy or materials savings that may otherwise result from this proposal.

Final Action: AS AM AMPC____ D

RB105-09/10

Table R602.3(1), R602.3.5 (new), Section R602.10 (including figures and tables), Table R802.11

Proposed Change as Submitted

Proponent: Chuck Bajnai, Chesterfield County, VA, Chairman, ICC Ad-Hoc Committee on Wall Bracing

1. Revise Table R602.3(1) as follows:

TABLE R602.3(1)
FASTENER SCHEDULE FOR STRUCTURAL MEMBERS

ITEM	DESCRIPTION OF BUILDING ELEMENTS	NUMBER AND TYPE OF FASTENER a,b,c	SPACING OF FASTENERS
	Roof		
1	Blocking between joists or rafters to top plate, toe nail	3-8d (2 ½" x 0.113")	--
2	Ceiling joists to plate, toe nail	3-8d (2 ½" x 0.113")	--
3	Ceiling joist not attached to parallel rafter, laps over partitions, face nail	3-10d	--
4	Collar tie to rafter, face nail, or 1-1/4” x 20 gage ridge strap	3-10d (3" x 0.128")	--
5	Rafter to plate, toe nail	2-16d (3 ½ "x 0.135")	--
6	Roof rafters to ridge, valley or hip rafters: toe nail face nail	 4-16d (3 ½" x 0.135") 3-16d (3 ½" x 0.135")	 -- --
	Wall		
7	Built-up ~~corner~~ studs –face nail	10d (3" x 0.128")	24" o.c.
8	Abutting studs at intersecting wall corners, face nail	16d (3 ½" x 0.135")	12”oc
~~8~~ 9	Built-up header, two pieces with ½”spacer	16d (3½” × 0.135")	16” o.c. along each edge
~~9~~ 10	Continued header, two pieces	16d (3½” × 0.135")	16” o.c. along each edge
~~10~~ 11	Continuous header to stud, toe nail	4-8d (2 ½" x 0.113")	-
~~11~~ 12	Double studs, face nail	10d (3" x 0.128")	24" o.c.
~~12~~ 13	Double top plates, face nail	10d (3" x 0.128")	24" o.c.
~~13~~ 14	Double top plates, minimum 24-inch offset of end joints, face nail in lapped area	8-16d (3½” × 0.135")	-
~~14~~ 15	Sole plate to joist or blocking, face nail	16d (3½” × 0.135")	16” o.c.
~~15~~ 16	Sole plate to joist or blocking at braced wall panels	3-16d (3½” × 0.135")	16” o.c.
~~16~~ 17	Stud to sole plate, toe nail	3-8d (2 ½" x 0.113") or 2-16d (3½” × 0.135")	- -
~~17~~ 18	Top or sole plate to stud, end nail	2-16d (3½” × 0.135")	-
~~18~~ 19	Top plates, laps at corners and intersections, face nail	2-10d (3" x 0.128")	-
~~19~~ 20	1” brace to each stud and plate, face nail	2-8d (2 ½" x 0.113") 2 staples 1¾”	- -
~~20~~ 21	1” × 6” sheathing to each bearing, face nail	2-8d (2 ½" x 0.113") 2 staples 1¾”	- -
~~21~~ 22	1” × 8” sheathing to each bearing, face nail	2-8d (2 ½" x 0.113") 3 staples 1¾”	- -
~~22~~ 23	Wider than 1” × 8” sheathing to each bearing, face nail	3-8d (2 ½" x 0.113") 4 staples 1¾”	- -
	Floor		
~~23~~ 24	Joist to sill or girder, toe nail	3-8d (2 ½" x 0.113")	-
~~26~~ 25	Rim joist to top plate, toe nail (roof applications also)	8d (2 ½" x 0.113")	6” o.c.
26	Rim joist or blocking to sill plate, toe nail	8d (2 ½" x 0.113")	6” o.c.
~~24~~ 27	1” × 6” subfloor or less to each joist, face nail	2-8d (2 ½" x 0.113") 2 staples 1¾”	- -
~~25~~ 28	2” subfloor to joist or girder, blind and face nail	2-16d (3½” × 0.135")	-
~~27~~ 29	2” planks (plank & beam – floor & roof)	2-16d (3½” × 0.135")	at each bearing
~~28~~ 30	Built up girders and beams, 2-inch lumber layers	10d (3" x 0.128")	Nail each layer as follows: 32”o.c. at top and bottom and staggered. Two nails at ends and at each splice.
~~29~~ 31	Ledger strip supporting joists or rafters	3-16d (3½” × 0.135")	At each joist or rafter

(Remainder of table unchanged except item numbers)

2. Move existing Section R602.10.1.2.1 to new Section R602.3.5 and revise as follows:

R602.3.5 ~~**R602.10.1.2.1**~~ **Braced wall panel uplift load path.** Braced wall panels located at exterior walls that support roof rafters or trusses (including stories below top story) shall have the framing members connected in accordance with one of the following:

1. Fastening in accordance with Table R602.3(1) where:
   1.1. The basic wind speed does not exceed 90 mph (40 m/s), the wind exposure category is B, the roof pitch is 5:12 or greater, and the roof span is 32 feet (9754 mm) or less, or
   1.2. The net uplift value at the top of a wall does not exceed 100 plf (146 N/mm). The net uplift value shall be determined in accordance with Section R802.11 and shall be permitted to be reduced by 40 plf (57 N/mm) for each full wall above and 40 plf (57 N/mm) for each floor platform above.
2. Where the net uplift value at the top of a wall exceeds 100 plf (146 N/mm), installing approved uplift framing connectors to provide a continuous load path from the top of the wall to the foundation or to a point where the uplift force is 100 plf (146 N/mm) or less. The net uplift value shall be as determined in Item 1.2 above.
3. Wall sheathing and fasteners designed in accordance with accepted engineering practice to resist combined uplift and shear forces.

3. Delete footnote "f" as follows:

TABLE R802.11
REQUIRED STRENGTH OF TRUSS OR RAFTER CONNECTIONS TO RESIST WIND UPLIFT FORCES[a, b, c, e, ~~f~~]
(Pounds per connection)
(No change to table values)

a. through e. *(No change)*
~~f. For wall-to-wall and wall-to-foundation connections, the capacity of the uplift connector is permitted to be reduced by 100 pounds for each full wall above. (For example, if a 600-pound rated connector is used on the roof framing, a 500-pound rated connector is permitted at the next floor level down).~~

4. Delete Section R602.10 and replace with the following:

R602.10 Wall bracing. Buildings shall be braced in accordance with this section. Where a building, or portion thereof, does not comply with one or more of the bracing requirements in this section, those portions shall be designed and constructed in accordance with Section R301.1.

R602.10.1 Braced wall lines. For the purpose of determining the amount and location of bracing required in each story level of a building, braced wall lines shall be designated as straight lines on the building plan placed in accordance with this section.

R602.10.1.1 Length of a braced wall line. The length of a braced wall line shall be the distance between its ends. The end of a braced wall line shall be the intersection with a perpendicular braced wall line or an angled braced wall line as permitted in Section R602.10.1.4. In the absence of an intersecting braced wall line, the end shall be the farthest exterior wall of the building as shown in Figure R602.10.1.1.

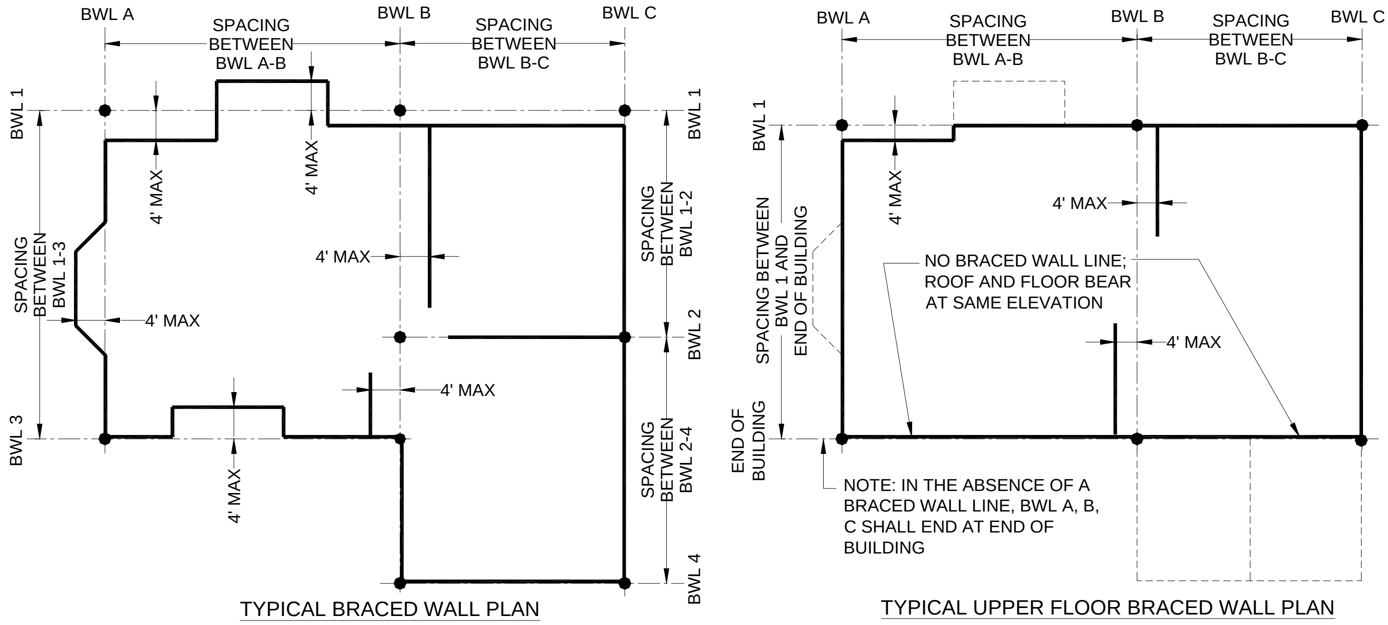

FIGURE R602.10.1.1
BRACED WALL LINES

R602.10.1.2 Offsets along a braced wall line. All exterior walls parallel to a braced wall line shall be permitted to offset up to 4 feet (1219 mm) from the designated braced wall line location as shown Figure R602.10.1.1. Interior walls used as bracing shall be permitted to offset up to 4 feet (1219 mm) from a braced wall line through the interior of the building as shown in Figure R602.10.1.1.

R602.10.1.3 Spacing of braced wall lines. There shall be a minimum of two braced wall lines in both the longitudinal and transverse direction as shown in Figure R602.10.1.1. Intermediate braced wall lines through the interior of the building shall be permitted. The spacing between parallel braced wall lines shall be in accordance with Table R602.10.1.3.

TABLE R602.10.1.3
BRACED WALL LINE SPACING

APPLICATION	**CONDITION**	**BUILDING TYPE**	**BRACED WALL LINE SPACING CRITERIA**	
			Maximum Spacing	**Exception to Maximum Spacing**
Wind bracing	85 mph to <110 mph	Detached, townhouse	60 feet	None
Seismic bracing	SDC A - C	Detached	Use wind bracing	
	SDC A – B	Townhouse	Use wind bracing	
	SDC C	Townhouse	35 feet	Up to 50 feet with adjustment of required length of bracing per Table R602.10.3(4)
	SDC D_0, D_1, D_2	Detached, townhouses, one- and two-story only	25 feet	Up to 35 feet to allow for a single room not to exceed 900 sq ft. Spacing of all other braced wall lines shall not exceed 25 feet.
	SDC D_0, D_1, D_2	Detached, townhouse	25 feet	Up to 35 feet when length of required bracing per Table R602.10.3(3) is adjusted in accordance with Table R602.10.3(4).

For SI: 1 foot = 304.8 mm

R602.10.1.4 Angled walls. Any portion of a wall along a braced wall line shall be permitted to angle out of plane for a maximum diagonal length of 8 feet (2438 mm). Where the angled wall occurs at a corner, the length of the braced wall line shall be measured from the projected corner as shown in Figure R602.10.1.4. Where the diagonal length is greater than 8 feet (2438 mm), it shall be considered a separate braced wall line and shall be braced in accordance with Section R602.10.1.

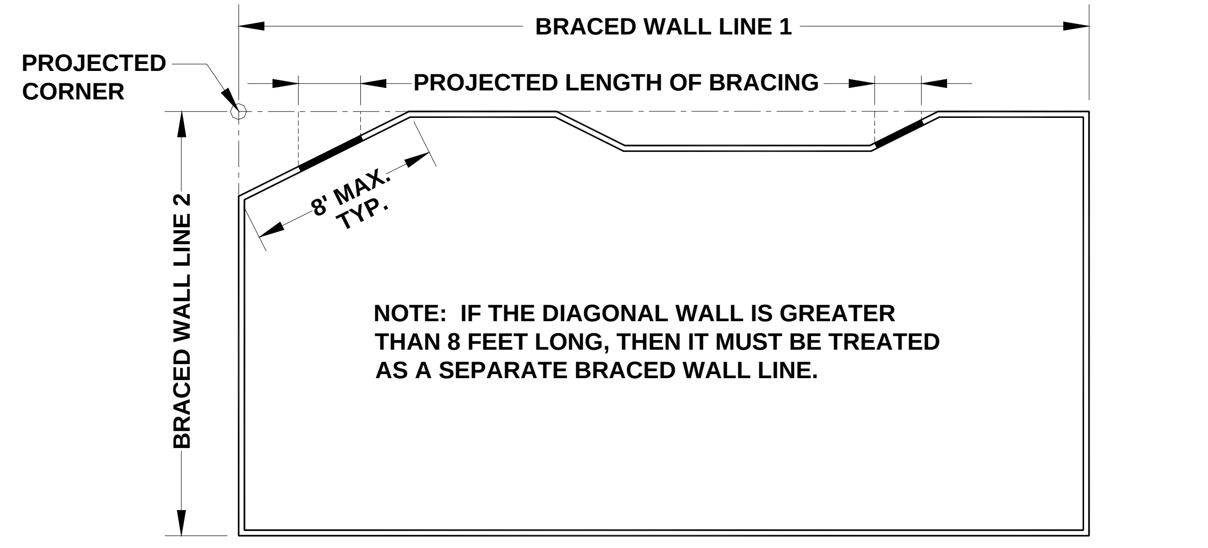

FIGURE R602.10.1.4
ANGLED WALLS

R602.10.2 Braced wall panels. Braced wall panels shall be full-height sections of wall that shall be continuous in the same plane. Braced wall panels shall be constructed and placed along a braced wall line in accordance with this section and the bracing methods specified in Section R602.10.4.

R602.10.2.1 Braced wall panel uplift load path. The bracing lengths in Table R602.10.3(1) apply only when uplift loads are resisted per Section R602.3.5.

R602.10.2.2 Locations of braced wall panels. A braced wall panel shall begin within 10 feet (3810 mm) from each end of a braced wall line as determined in Section R602.10.1.1. The distance between adjacent edges of two braced wall panels shall be no greater than 20 feet (6096 mm) as shown in Figure R602.10.2.2

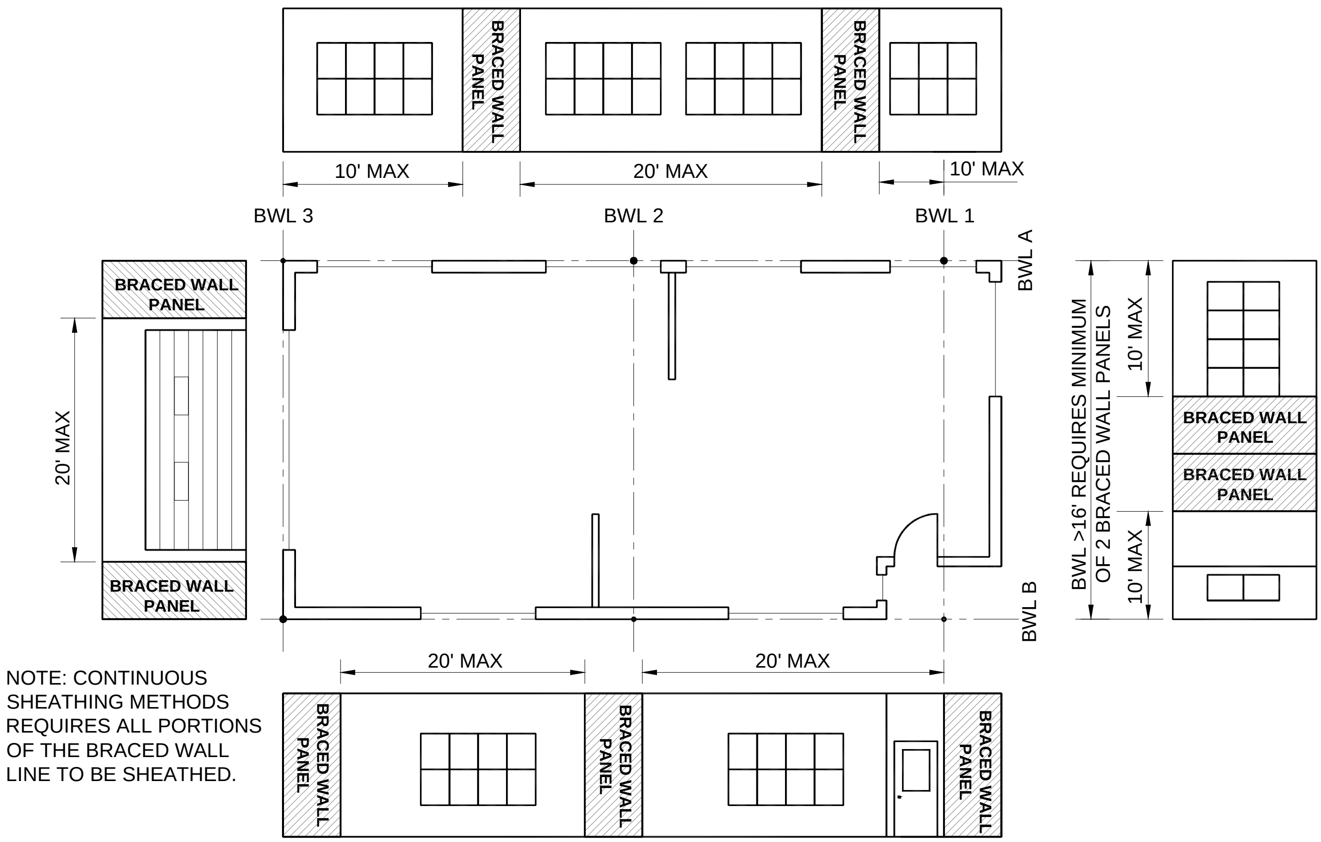

FIGURE R602.10.2.2
LOCATION OF BRACED WALL PANELS

R602.10.2.2.1 Location of braced wall panels in Seismic Design Categories D_0, D_1 and D_2. Braced wall panels shall be located at each end of a braced wall line.

Exception: Braced wall panels constructed of Methods WSP and continuous sheathing methods as specified in Section R602.10.4 shall be permitted to begin no more than 10 feet (3048 mm) from each end of a braced wall line provided each end complies with the following.

1. A minimum 24 in. wide (610 mm) panel for Methods WSP, CS-WSP, CS-G, CS-PF and 32 in. (813 mm) wide panel for Method CS-SFB is applied to each side of the building corner as shown in Condition 4 of Figure R602.10.7.
2. The end of each braced wall panel closest to the end of the braced wall line shall have an 1,800 lb (8 kN) hold-down device fastened to the stud at the edge of the braced wall panel closest to the corner and to the foundation or framing below as shown in Condition 5 of Figure R602.10.7.

R602.10.2.3 Minimum number of braced wall panels. Braced wall lines with a length of 16 feet (4877 mm) or less shall have a minimum of one braced wall panel. Braced wall lines greater than 16 feet (4877 mm) shall have a minimum of two braced wall panels.

R602.10.3 Required length of bracing. The required length of bracing along each braced wall line shall be determined as follows.

1. All buildings in Seismic Design Categories A and B shall use Table R602.10.3(1) and the applicable adjustment factors in Table R602.10.3(2).
2. Detached buildings in Seismic Design Category C shall use Table R602.10.3(1) and the applicable adjustment factors in Table R602.10.3(2).
3. Townhouses in Seismic Design Category C shall use the greater value determined from Table R602.10.3(1) or R602.10.3(3) and the applicable adjustment factors in Table R602.10.3(2) or R602.10.3(4) respectively.
4. All buildings in Seismic Design Categories D_0, D_1 and D_2 shall use the greater value determined from Table R602.10.3(1) or R602.10.3(3) and the applicable adjustment factors in Table R602.10.3(2) or R602.10.3(4) respectively.

Only braced wall panels parallel to the braced wall line shall contribute towards the required length of bracing of that braced wall line. Braced wall panels along an angled wall meeting the minimum length requirements of Tables R602.10.5 and R602.10.5.2 shall be permitted to contribute its projected length to the braced wall line as shown in Figure R602.10.1.4. Any braced wall panel on an angled wall at the end of a braced wall line shall contribute its projected length for only one of the braced wall lines at the projected corner. In no case shall the required length of bracing along a braced wall line after adjustments be less than 48 inches (1219 mm) total.

		60	27.5	27.5	15.5	13.5
		10	10.5	10.5	6.0	5.0
		20	19.0	19.0	11.0	9.5
		30	27.5	27.5	16.0	13.5
		40	36.0	36.0	20.5	17.5
		50	44.0	44.0	25.5	21.5
		60	52.5	52.5	30.0	25.5
		10	NP	15.5	9.0	7.5
		20	NP	28.5	16.5	14.0
		30	NP	41.0	23.5	20.0
		40	NP	53.0	30.5	26.0
		50	NP	65.5	37.5	32.0
		60	NP	77.5	44.5	37.5

For SI: 1 inch = 25.4 mm, 1 foot = 305 mm.

a. Linear interpolation shall be permitted.

b. Method LIB shall have gypsum board fastened to at least one side with nails or screws per Table R602.3(1) for exterior sheathing or Table R702.3.5 for interior gypsum board. Spacing of fasteners at panel edges shall not exceed 8 inches (203 mm).

c. The length of bracing for Method GB is based on a double sided application. Where GB is used in a one sided application (or in combination of single sided and double sided application), the single sided GB shall only contribute half as much as the double sided GB towards the minimum required length of bracing in this table.

d. Method CS-SFB does not apply where the wind speed is greater than 100 mph.

TABLE R602.10.3(2)
WIND ADJUSTMENT FACTORS TO THE REQUIRED LENGTH OF WALL BRACING

ADJUSTMENT BASED ON	STORY/ SUPPORTING	CONDITION	ADJUSTMENT FACTOR [a,b] (multiply length from Table R602.10.3(1) by this factor)	APPLICABLE METHODS
Exposure category	One story structure	B	1.00	All methods
		C	1.20	
		D	1.50	
	Two-story structure	B	1.00	
		C	1.30	
		D	1.60	
	Three-story structure	B	1.00	
		C	1.40	
		D	1.70	
Roof eave-to-ridge height	Roof only	≤5 ft	0.70	
		10 ft	1.00	
		15 ft	1.30	
		20 ft	1.60	
	Roof + 1 floor	≤5 ft	0.85	
		10 ft	1.00	
		15 ft	1.15	
		20 ft	1.30	
	Roof + 2 floors	≤5 ft	0.90	
		10 ft	1.00	
		15 ft	1.10	
		20 ft	Not permitted	
Wall height adjustment	Any story	8 ft	0.90	
		9 ft	0.95	
		10 ft	1.00	
		11 ft	1.05	
		12 ft	1.10	
Number of braced wall lines (per plan direction)	Any story	3	1.30	
		4	1.45	
		≥5	1.60	
Additional 800 lb hold-down device	Top story only	Fastened to the end studs of each braced wall panel and to the foundation or framing below	0.80	DWB, WSP, SFB, PBS, PCP, HPS
Interior gypsum board finish (or equivalent)	Any story	Omitted from inside face of braced wall panels	1.40	DWB, WSP, SFB,PBS, PCP, HPS, CS-WSP, CS-G, CS-SFB
Gypsum board fastening	Any story	4 in. o.c.at panel edges, including top and bottom plates, and all horizontal joints blocked	0.7	GB

For SI: 1 foot = 305 mm, 1 lb = 4.48 N.

a. Linear Interpolation shall be permitted.
b. The total adjustment factor is the product of all applicable adjustment factors.

TABLE R602.10.3(3)
BRACING REQUIREMENTS BASED ON SEISMIC DESIGN CATEGORY

- SOIL CLASS D [b]
- WALL HEIGHT = 10 FT
- 10 PSF FLOOR DEAD LOAD
- 15 PSF ROOF/CEILING DEAD LOAD

		50	NP	NP	NP	NP	NP

For SI: 1 foot 305 mm

a. Linear interpolation shall be permitted.
b. Wall bracing lengths are based on a soil site class "D." Interpolation of bracing length between the S_{ds} values associated with the Seismic Design Categories shall be permitted when a site-specific S_{ds} value is determined in accordance with Section 1613.5 of the International Building Code.
c. Method LIB shall have gypsum board fastened to at least one side with nails or screws per Table R602.3(1) for exterior sheathing or Table R702.3.5 for interior gypsum board. Spacing of fasteners at panel edges shall not exceed 8 inches (203 mm).
d. The length of bracing for Method GB is based on a double sided application. Where GB is used in a one sided application (or in combination of single sided and double sided application), the single sided GB shall only contribute half as much as the double sided GB towards the minimum required length of bracing in this table.
e. Method CS-SFB applies in SDC C only.

TABLE R602.10.3(4)
SEISMIC ADJUSTMENT FACTORS TO THE REQUIRED LENGTH OF WALL BRACING

ADJUSTMENT BASED ON:	STORY/ SUPPORTING	CONDITION	ADJUSTMENT FACTOR [a,b] (Multiply length from Table R602.10.3(1) by this factor)	APPLICABLE METHODS
Story height (Section 301.3)	Any story	≤10 ft	1.0	All methods
		>10 ft ≤ 12 ft	1.2	
Braced wall line spacing, townhouses in SDC C	Any story	≤35 ft	1.0	
		>35 ft ≤ 50 ft	1.43	
Braced wall line spacing, in SDC D_0, D_1, D_2 [c]	Any story	<25 ft ≤30 ft	1.2	
		>30 ft ≤ 35 ft	1.4	
Wall dead load	Any story	> 8 ft < 15 ft	1.0	
		<8 psf	0.85	
Roof/ceiling dead load for wall supporting	Roof only or roof plus one or two stories	<15 psf	1.0	
	Roof only	>15 psf ≤ 25 psf	1.2	
	Roof plus one or two stories	>15 psf ≤ 25 psf	1.1	
Walls with stone or masonry veneer	Any story	See Section R703.7		
Interior gypsum board finish (or equivalent)	Any story	Omitted from inside face of braced wall panels	1.5	DWB, WSP, SFB, PBS, PCP, HPS, CS-WSP, CS-G, CS-SFB

For SI: 1 psf = 47,8 N/m^2.

a. Linear interpolation shall be permitted.
b. The total length of bracing required for a given wall line is the product of all applicable adjustment factors.
c. The length-to-width ratio for the floor/roof *diaphragm* shall not exceed 3:1. The top plate lap splice nailing shall be a minimum of 12-16d nails on each side of the splice.

R602.10.4 Construction methods for braced wall panels. Intermittent and continuously sheathed braced wall panels shall be constructed in accordance with this section and the methods listed in Table R602.10.4.

TABLE R602.10.4
BRACING METHODS

METHODS, MATERIAL		MINIMUM THICKNESS	FIGURE	CONNECTION CRITERIA [a]	
				Fasteners	Spacing
Intermittent Bracing Methods	**LIB** Let-in-bracing	1x4 wood or approved metal straps at 45° to 60° angles for maximum 16" stud spacing		Wood: 2-8d common nails or 3-8d (2 ½" x 0.113") nails Metal strap: per manufacturer	Wood: per stud and top and bottom plates Metal: per manufacturer
	DWB Diagonal wood boards	¾" (1" nominal) for maximum 24" stud spacing		2-8d (2½" x 0.113") nails or 2 - 1¾" staples	Per stud
	WSP Wood structural panel (See Section R604)	$^{3}/_{8}$"		Exterior sheathing per Table R602.3(3) Interior sheathing per Table R602.3(1) or R602.3(2)	6" edges 12" field Varies by fastener
	SFB Structural fiberboard sheathing	$^{1}/_{2}$" or $^{25}/_{32}$" for maximum 16" stud spacing		1½" long x 0.12" dia. (for ½ " thick sheathing) 1$^{3}/_{4}$" long x 0.12" dia. (for $^{25}/_{32}$" thick sheathing) galvanized roofing nails or 8d common (2½"x0.131) nails	3" edges 6" field
	GB [d] Gypsum board (double sided)	$^{1}/_{2}$"		Nails or screws per Table R602.3(1) for exterior locations Nails or screws per Table R702.3.5 for interior locations	For all braced wall panel locations: 7" edges (including top and bottom plates) 7" field
	PBS Particleboard sheathing (See Section R605)	$^{3}/_{8}$" or $^{1}/_{2}$" for maximum16" stud spacing		For 3/8", 6d common (2"x0.113) nails For ½", 8d common (2½"x0.131) nails	3" edges 6" field
	PCP Portland cement plaster	See Section R703.6 for maximum 16" stud spacing		1½", 11 gage, $^{7}/_{16}$" head nails or $^{7}/_{16}$", 16 gage staples	6" o.c. on all framing members
	HPS Hardboard panel siding	$^{7}/_{16}$" for maximum 16" stud spacing		0.092" dia., 0.225" head nails with length to accommodate 1½" penetration into studs	4" edges 8" field
	ABW Alternate braced wall	$^{3}/_{8}$"		See Section R602.10.6.1	See Section R602.10.6.1
	PFH Portal frame with hold-downs	$^{3}/_{8}$		See Section R602.10.6.2	See Section R602.10.6.2
	PFG Portal frame at garage	$^{7}/_{16}$"		See Section R602.10.6.3	See Section R602.10.6.3
Continuous Sheathing Methods	**CS-WSP** Continuously sheathed wood structural panel	$^{3}/_{8}$"		Exterior sheathing per Table R602.3(3) Interior sheathing per Table R602.3(1) or R602.3(2)	6" edges 12" field Varies by fastener
	CS-G [b,c] Continuously sheathed wood structural panel adjacent to garage	$^{3}/_{8}$"		See Method CS-WSP	See Method CS-WSP

METHODS, MATERIAL	MINIMUM THICKNESS	FIGURE	CONNECTION CRITERIA [a]	
			Fasteners	Spacing
openings				
CS-PF Continuously sheathed portal frame	$^{7}/_{16}$"		See Section R602.10.6.4	See Section R602.10.6.4
CS-SFB Continuously sheathed structural fiberboard	$^{1}/_{2}$" or $^{25}/_{32}$" for maximum 16" stud spacing		1½" long x 0.12" dia. (for ½ " thick sheathing) $1^{3}/_{4}$" long x 0.12" dia. (for $^{25}/_{32}$" thick sheathing) galvanized roofing nails or 8d common (2½"x0.131) nails	3" edges 6" field

For SI: 1 inch = 25.4 mm, 1 foot = 305 mm.

a. Adhesive attachment of wall sheathing, including Method GB, shall not be permitted in Seismic Design Categories C, D_0, D_1 and D_2.
b. Applies to panels next to garage door opening when supporting gable end wall or roof load only. May only be used on one wall of the garage. In Seismic Design Categories D_0, D_1, and D_2, roof covering dead load may not exceed 3 psf (0.14 kN/m^2).
c. Garage openings adjacent to a Method CS-G panel shall be provided with a header in accordance with Table R502.5(1). A full height clear opening shall not be permitted adjacent to a Method CS-G panel.
d. "Double sided" GB shall mean that a full length/full height panel of GB sheathing is applied to both sides of the stud wall. GB bracing panels are not required to be aligned back to back – they may be offset from each other so long as their length's comply with Table R602.10.5. Where all of the GB is on one side of the studs or where there is a combination of "double sided" GB and "single sided" GB, the single sided GB shall contribute half of its actual length towards the minimum required length (i.e. 96" of single sided GB is equivalent to 48" of double sided GB).

R602.10.4.1 Mixing methods. Mixing of bracing methods shall be permitted as follows:

1. Mixing intermittent bracing and continuous sheathing methods from story to story shall be permitted.
2. Mixing intermittent bracing methods from braced wall line to braced wall line within a story shall be permitted. Within Seismic Design Categories A, B and C or in regions where the basic wind speed is less than or equal to 100 mph, mixing of intermittent bracing and continuous sheathing methods from braced wall line to braced wall line within a story shall be permitted.
3. Mixing intermittent bracing methods along a braced wall line shall be permitted in Seismic Design Categories A and B, and detached dwellings in Seismic Design Category C provided the length of required bracing in accordance with Table R602.10.3(1) or R602.10.3(3) is the highest value of all intermittent bracing methods used.
4. Mixing of continuous sheathing methods CS-WSP, CS-G and CS-PF along a braced wall line shall be permitted.
5. In Seismic Design Categories A and B, and for detached one- and two-family dwellings in Seismic Design Category C, mixing of intermittent bracing methods along the interior portion of a braced wall line with continuous sheathing methods CS-WSP, CS-G and CS-PF along the exterior portion of the same braced wall line shall be permitted. The length of required bracing shall be the highest value of all intermittent bracing methods used in accordance with Table R602.10.3(1) or R602.10.3(3). The requirements of Section R602.10.7 shall apply to each end of the continuously sheathed portion of the braced wall line.

R602.10.4.2 Continuous sheathing methods. Continuous sheathing methods require structural panel sheathing to be used on all sheathable surfaces on one side of a braced wall line including areas above and below openings and gable end walls and shall meet the requirements of Section R602.10.7.

R602.10.4.3 Braced wall panel interior finish material. Braced wall panels shall have gypsum wall board installed on the side of the wall opposite the bracing material. Gypsum wall board shall be not less than ½ inch (12.7 mm) in thickness and be fastened with nails or screws in accordance with Table R602.3(1) for exterior sheathing or Table R702.3.5 for interior gypsum wall board. Spacing of fasteners at panel edges for gypsum wall board opposite Method LIB bracing shall not exceed 8 inches (203 mm). Interior finish material shall not be glued in Seismic Design Categories D_0, D_1 and D_2.

Exceptions:

1. Interior finish material is not required opposite wall panels that are braced in accordance with Method GB, ABW, PFH, PFG and CS-PF, unless otherwise required by Section R302.6.
2. An approved interior finish material with an in-plane shear resistance equivalent to gypsum board shall be permitted to be substituted, unless otherwise required by Section R302.6.
3. Except for Method LIB, gypsum wall board is permitted to be omitted provided the required length of bracing in Tables R602.10.3(1) and R602.10.3(3) is multiplied by the appropriate adjustment factor in Tables R602.10.3(2) and R602.10.3(4) respectively, unless otherwise required by Section R302.6.

R602.10.5 Minimum length of a braced wall panel. The minimum length of a braced wall panel shall comply with Table R602.10.5. For Methods CS-WSP and CS-SFB, the minimum panel length shall be based on the adjacent clear opening height in accordance with Table R602.10.5 and Figure R602.10.5. When a panel has an opening on either side of differing heights, the taller opening height shall be used to determine the panel length.

R602.10.5.1 Contributing length. For purposes of computing the required length of bracing in Table R602.10.3(1) and R602.10.3(3), the contributing length of each braced wall panel shall be as specified in Table R602.10.5.

TABLE R602.10.5
MINIMUM LENGTH OF BRACED WALL PANELS

METHOD		MINIMUM LENGTH [a] (in) Wall Height 8 ft	9 ft	10 ft	11 ft	12 ft	CONTRIBUTING LENGTH (in)
DWG, WSP, SFB, PBS, PCP, HPS, GB [d]		48	48	48	53	58	Actual [b]
LIB		55	62	69	NP		Actual [b]
ABW	SDC A, B and C, wind speed < 110 mph	28	32	34	38	42	48
	SDC D_0, D_1 and D_2, wind speed < 110 mph	32	32	34	NP	NP	
PFH	Supporting roof only	16	16	16	18 [d]	20 [d]	48
	Supporting one story and roof	24	24	24	27 [d]	29 [d]	48
PFG		24	27	30	33 [e]	36 [e]	1.5 x Actual [b]

	108		54	46	43	41	
	112			50	45	43	
	116			55	48	45	
	120			60	52	48	
	124				56	51	
	128				61	54	
	132				66	58	
	136					62	
	140					66	
	144					72	

For SI: 1 inch = 25.4 mm
NP = Not permitted

a. Linear interpolation shall be permitted.
b. Use the actual length when it is greater than or equal to the minimum length.
c. As specified in Table R602.10.4, Method GB is intended to be double sided. Where all of the GB is on one side of the studs or where there is a combination of "double sided" GB and "single sided" GB, the single sided GB shall contribute half of its actual length towards the minimum required length (i.e. 96" of single sided GB is equivalent to 48" of double sided GB).
d. Maximum header height for PFH is 10' per Figure R602.10.6.2, but wall height may be increased to 12' with pony wall.
e. Maximum opening height for PFG is 10' per Figure R602.10.6.3, but wall height may be increased to 12' with pony wall.
f. Maximum opening height for CS-PF is 10' per Figure R602.10.6.4, but wall height may be increased to 12' with pony wall

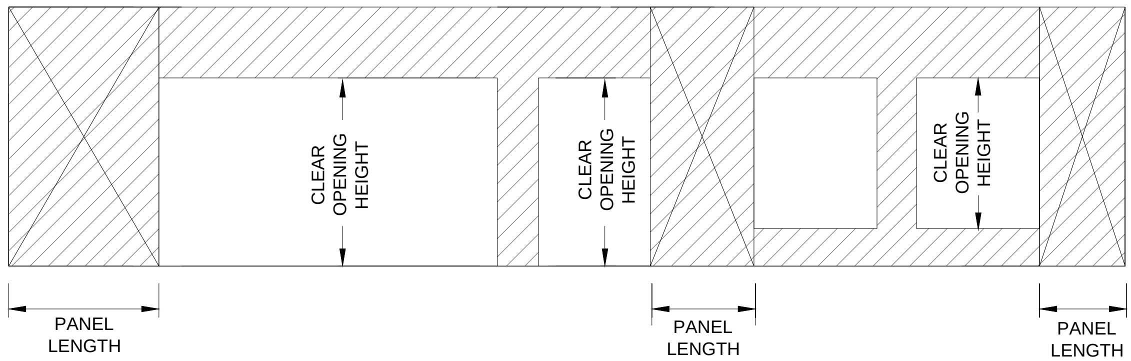

FIGURE R602.10.5
BRACED WALL PANELS WITH CONTINUOUS SHEATHING

R602.10.5.2 Partial credit. For Methods DWB, WSP, SFB, PBS, PCP and HPS in Seismic Design Categories A, B and C, panels between 36 inches and 48 inches in length shall be considered a braced wall panel and shall be permitted to partially contribute towards the required length of bracing in Table R602.10.3(1) and R602.10.3(3), and the contributing length shall be determined from Table R602.10.5.2.

TABLE R602.10.5.2
PARTIAL CREDIT FOR BRACED WALL PANELS LESS THAN 48 INCHES IN ACTUAL LENGTH

Actual Length of Braced Wall Panel (in)	Contributing Length of Braced Wall Panel (in) [a]	
	8 ft Wall Height	9 ft Wall Height
48	48	48
42	36	36
36	27	N/A

For SI: 1 inch = 25.4mm

a. Linear interpolation shall be permitted.

R602.10.6 Construction of Methods ABW, PFH, PFG and CS-PF. Methods ABW, PFH, PFG and CS-PF shall be constructed as specified in Sections R602.10.6.1 through R602.10.6.4.

R602.10.6.1 Method ABW: Alternate braced wall panels. Method ABW braced wall panels shall be constructed in accordance with Figure R602.10.6.1. The hold-down force shall be in accordance with Table R602.10.6.1.

TABLE R602.10.6.1
MINIMUM HOLD-DOWN FORCES FOR METHOD ABW BRACED WALL PANELS

SEISMIC DESIGN CATEGORY AND WIND SPEED	SUPPORTING/STORY	HOLD DOWN FORCE (lb)				
		Height of Braced Wall Panel				
		8 ft	9 ft	10 ft	11 ft	12 ft
SDC A, B and C Wind speed < 110 mph	One story	1800	1800	1800	2000	2200
	First of two story	3000	3000	3000	3300	3600
SDC D_o, D_1 and D_2 Wind speed < 110 mph	One story	1800	1800	1800	NP [a]	NP [a]
	First of two story	3000	3000	3000	NP [a]	NP [a]

For SI: 1 inch = 25.4 mm, 1 foot = 305 mm, 1 lb = 4.45 N
NP = Not Permitted.

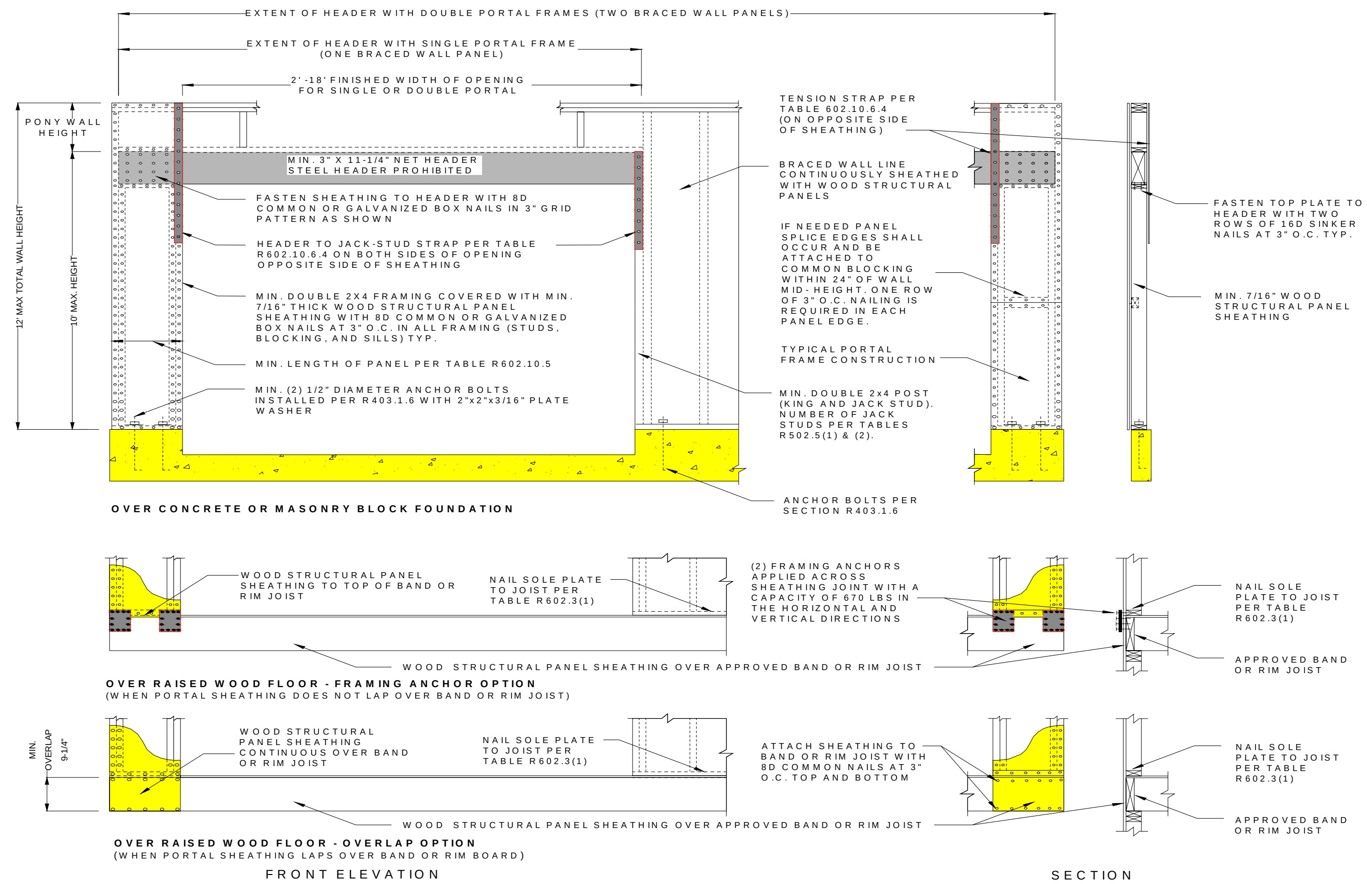
For SI: 1 inch = 25.4 mm, 1 foot = 305 mm, 1 lb = 4.45 N
a. DR = design required

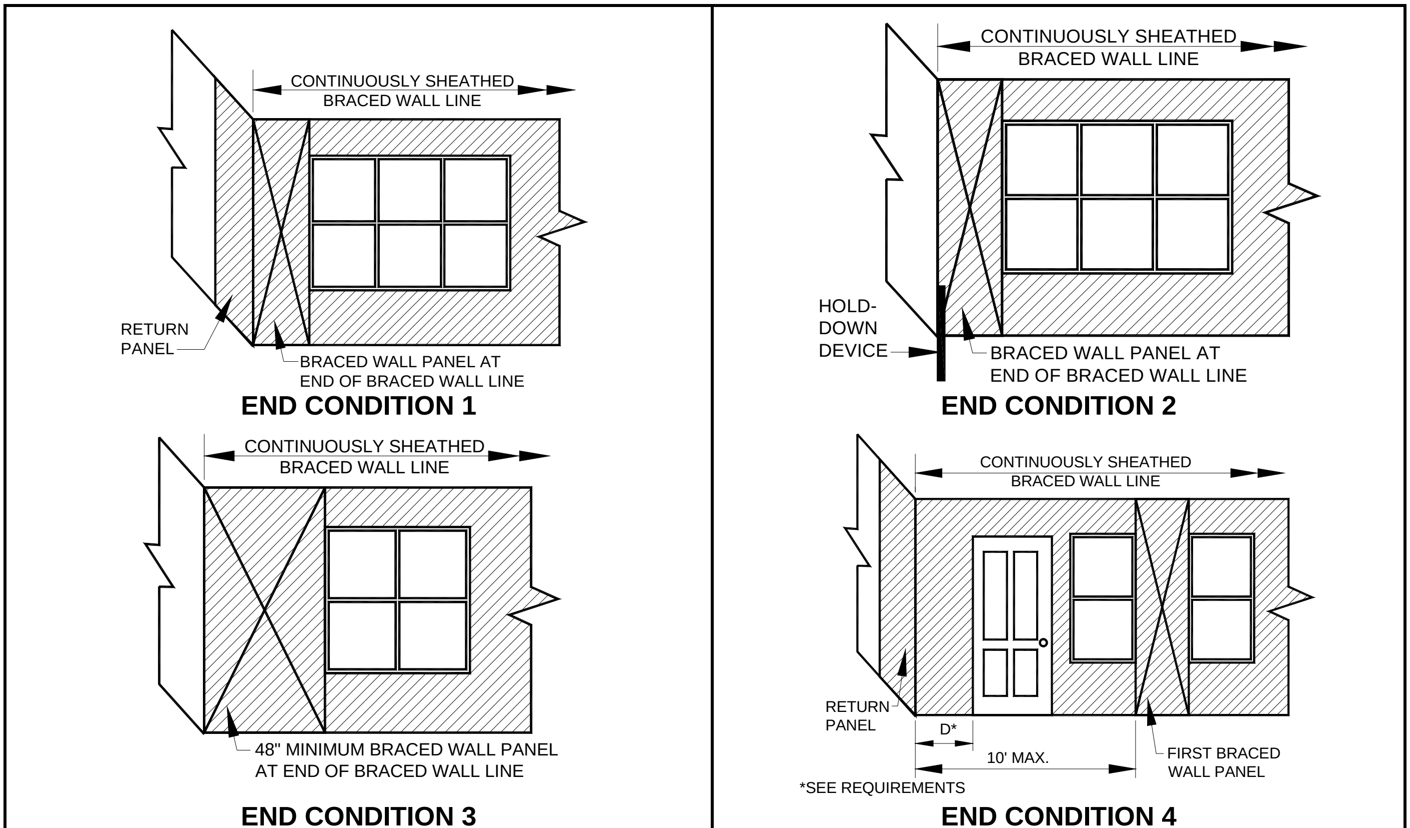
b. Strap shall be installed in accordance with manufacturer's recommendations.

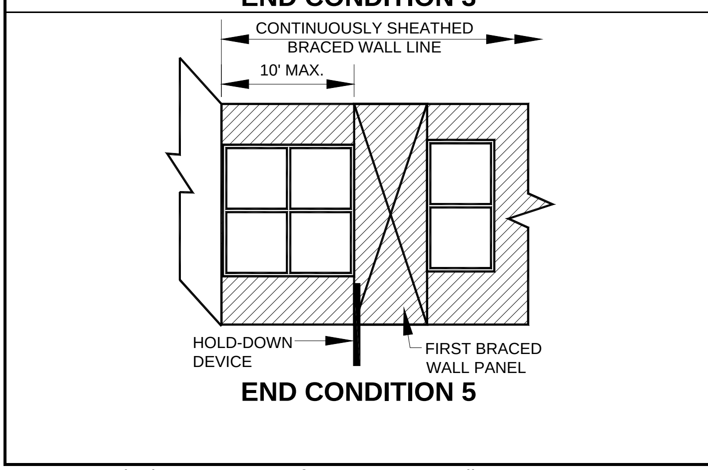


For SI: 1 inch = 25.4 mm, 1 foot = 305 mm, 1 lb = 4.45 N

FIGURE R602.10.6.4
METHOD CS-PF: CONTINUOUSLY SHEATHED PORTAL FRAME PANEL CONSTRUCTION

R602.10.7 Ends of braced wall lines with continuous sheathing. Each end of a braced wall line with continuous sheathing shall have one of the conditions shown in Figure R602.10.7.





REQUIREMENTS

Return panel: 24" for braced wall lines sheathed with wood structural panels
32" for braced wall lines sheathed with structural fiberboard

Distance D: 24" for braced wall lines sheathed with wood structural panels
32" for braced wall lines sheathed with structural fiberboard

Hold-down device: 800 lbs capacity fastened to the edge of the braced wall panel closest to the corner and to the foundation or floor framing below

For SI: 1 inch = 25.4 mm, 1 foot = 305 mm, 1 lb = 4.45 N

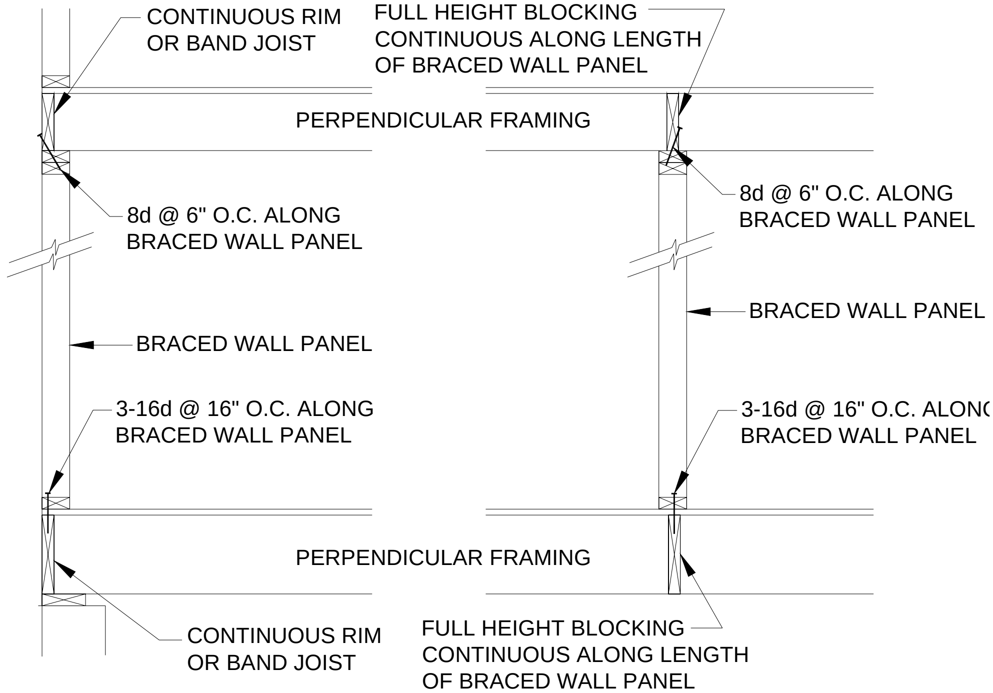
FIGURE R602.10.7
END CONDITIONS FOR BRACED WALL LINES WITH CONTINUOUS SHEATHING

R602.10.8 Braced wall panel connections. Braced wall panels shall be connected to floor framing or foundations as follows:

1. Where joists are perpendicular to a braced wall panel above or below, a rim joist, band joist or blocking shall be provided along the entire length of the braced wall panel in accordance with Figure R602.10.8(1). Fastening of top and bottom wall plates to framing, rim joist, band joist and/or blocking shall be in accordance with Table R602.3(1).
2. Where joists are parallel to a braced wall panel above or below, a rim joist, end joist or other parallel framing member shall be provided directly above and below the braced wall panel in accordance with Figure R602.10.8(2). Where a parallel framing member cannot be located directly above and below the panel, full-depth blocking at 16 inch (406 mm) spacing shall be provided between the parallel framing members to each

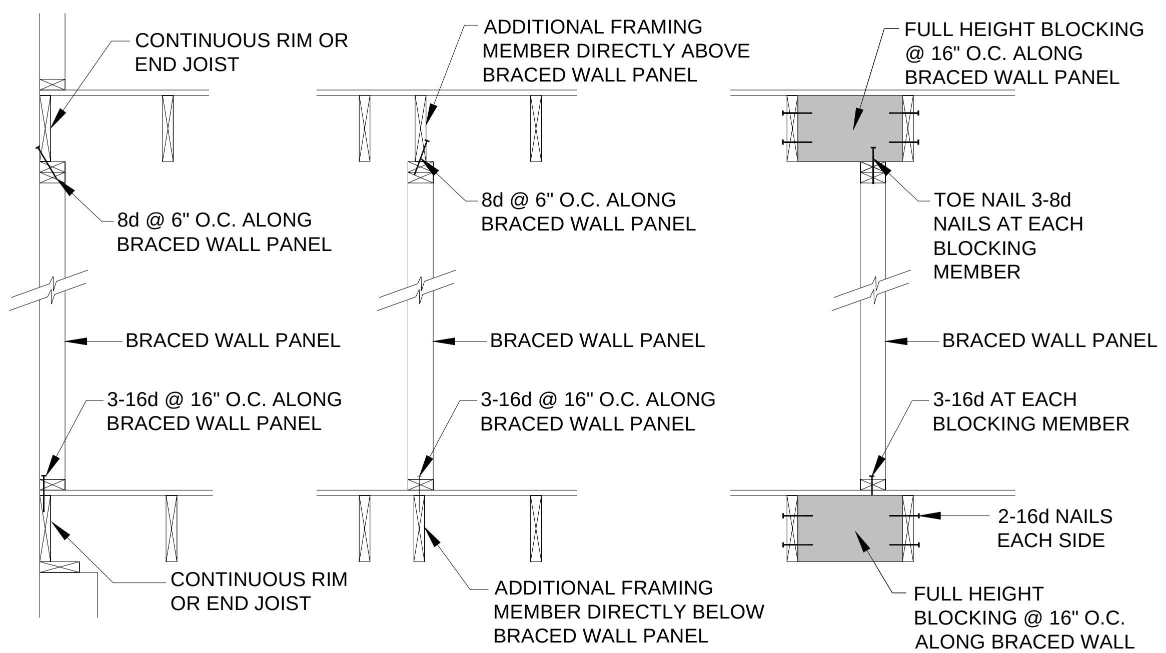
<u>side of the braced wall panel in accordance with Figure R602.10.8(2). Fastening of blocking and wall plates shall be in accordance with Table R602.3(1) and Figure R602.10.8(2).</u>

3. <u>Connections of braced wall panels to concrete or masonry shall be in accordance with Section R403.1.6.</u>



<u>For SI: 1 inch = 25.4 mm</u>

<u>FIGURE R602.10.8(1)</u>
<u>BRACED WALL PANEL CONNECTION WHEN PERPENDICULAR TO FLOOR/CEILING FRAMING</u>



<u>For SI: 1 inch = 25.4 mm</u>

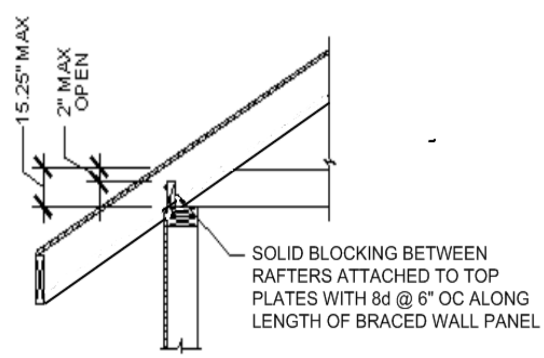
<u>FIGURE R602.10.8(2)</u>
<u>BRACED WALL PANEL CONNECTION WHEN</u>

PARALLEL TO FLOOR/CEILING FRAMING

R602.10.8.1 Braced wall panel connections for Seismic Design Categories D_0, D_1 and D_2. Braced wall panels shall be fastened to required foundations in accordance with Section R602.11.1, and top plate lap splices shall be face-nailed with at least eight 16d nails on each side of the splice.

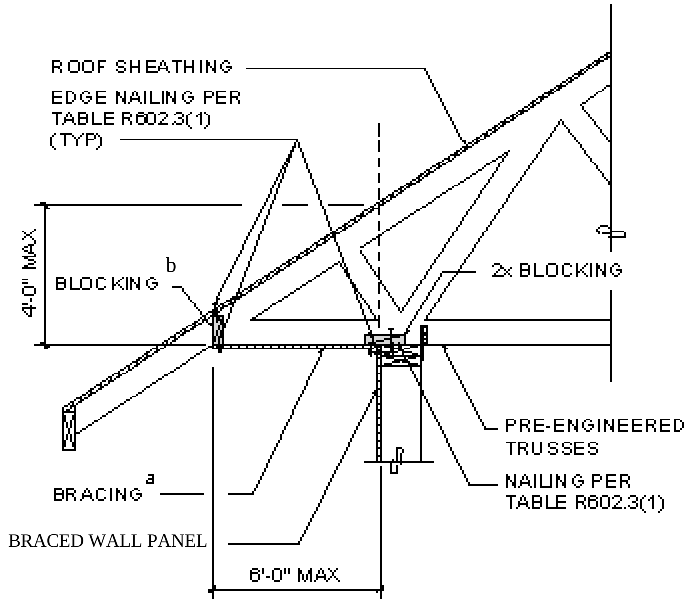
R602.10.8.2 Connections to roof framing. Exterior braced wall panels shall be connected to roof framing as follows.

1. Parallel rafters or roof trusses shall be attached to the top plates of braced wall panels in accordance with Table R602.3(1).
2. For Seismic Design Categories A, B and C and wind speeds less than 100 mph (45 m/s):
   2.1. Where the distance from the top of the rafters or roof trusses and perpendicular top plates is 9.25 inches (235 mm) or less, the rafters or roof trusses shall be connected to the top plates of braced wall panels in accordance with Table R602.3(1) and blocking need not be installed.
   2.2. Where the distance from the top of the rafters and perpendicular top plates is between 9.25 inches (235 mm) and 15.25 inches (387 mm) the rafters shall be connected to the top plates of braced wall panels with blocking in accordance with Figure R602.10.8.2(1) and attached in accordance with Table R602.3(1).
   2.3. Where the distance from the top of the roof trusses and perpendicular top plates is between 9.25 inches (235 mm) and 15.25 inches (387 mm) the roof trusses shall be connected to the top plates of braced wall panels with blocking in accordance with Table R602.3(1).
3. For Seismic Design Categories D_0, D_1 and D_2 or wind speeds of 100 mph (45 m/s) or greater, where the distance between the top of rafters or roof trusses and perpendicular top plates is 15.25 inches (387 mm) or less, rafters or roof trusses shall be connected to the top plates of braced wall panels with blocking in accordance with Figure R602.10.8.2(1) and attached in accordance with Table R602.3(1).
4. For all Seismic Design Categories and wind speeds, where the distance between the top of rafters or roof trusses and perpendicular top plates exceeds 15.25 inches (387 mm), perpendicular rafters or roof trusses shall be connected to the top plates of braced wall panels in accordance with one of the following methods
   4.1. In accordance with Figure R602.10.8.2(2),
   4.2. In accordance with Figure R602.10.8.2(3),
   4.3. With full height engineered blocking panels designed for values listed in American Forest and Paper Association (AF&PA) Wood Frame Construction Manual for One- and Two-Family Dwellings (WFCM). Both the roof and floor sheathing shall be attached to the blocking panels in accordance with Table R602.3(1).
   4.4. Designed in accordance with accepted engineering methods.
5. Lateral support for the rafters and ceiling joists shall be provided in accordance with Section R802.8.
6. Lateral support for trusses shall be provided in accordance with Section R802.10.3.



For SI: 1 inch = 25.4 mm

FIGURE R602.10.8.2(1)
BRACED WALL PANEL CONNECTION TO PERPENDICULAR RAFTERS

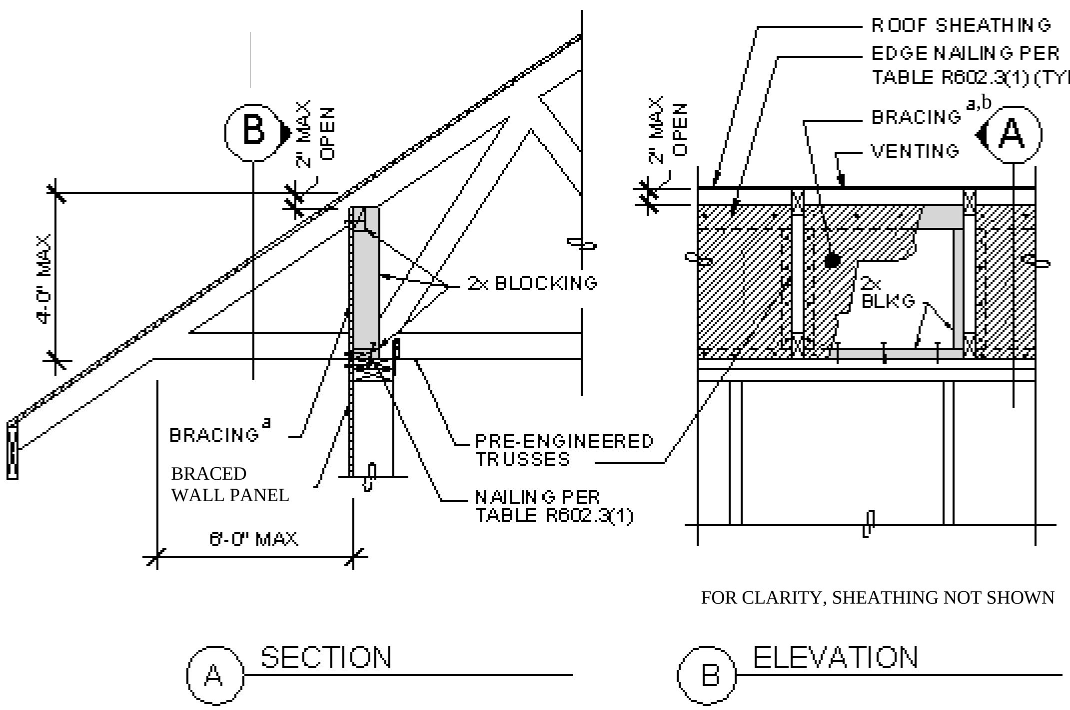


For SI: 1 inch = 25.4 mm

a. Methods of bracing shall be as described in Section R602.10.2 method DWB, WSP, SFB, GB, PBS, PCP OR HPS

b. Provide ventilation (not shown) per Section R806.

FIGURE R602.10.8.2(2)
BRACED WALL PANEL CONNECTION OPTION TO PERPENDICULAR RAFTERS OR ROOF TRUSSES



For SI: 1 inch = 25.4 mm

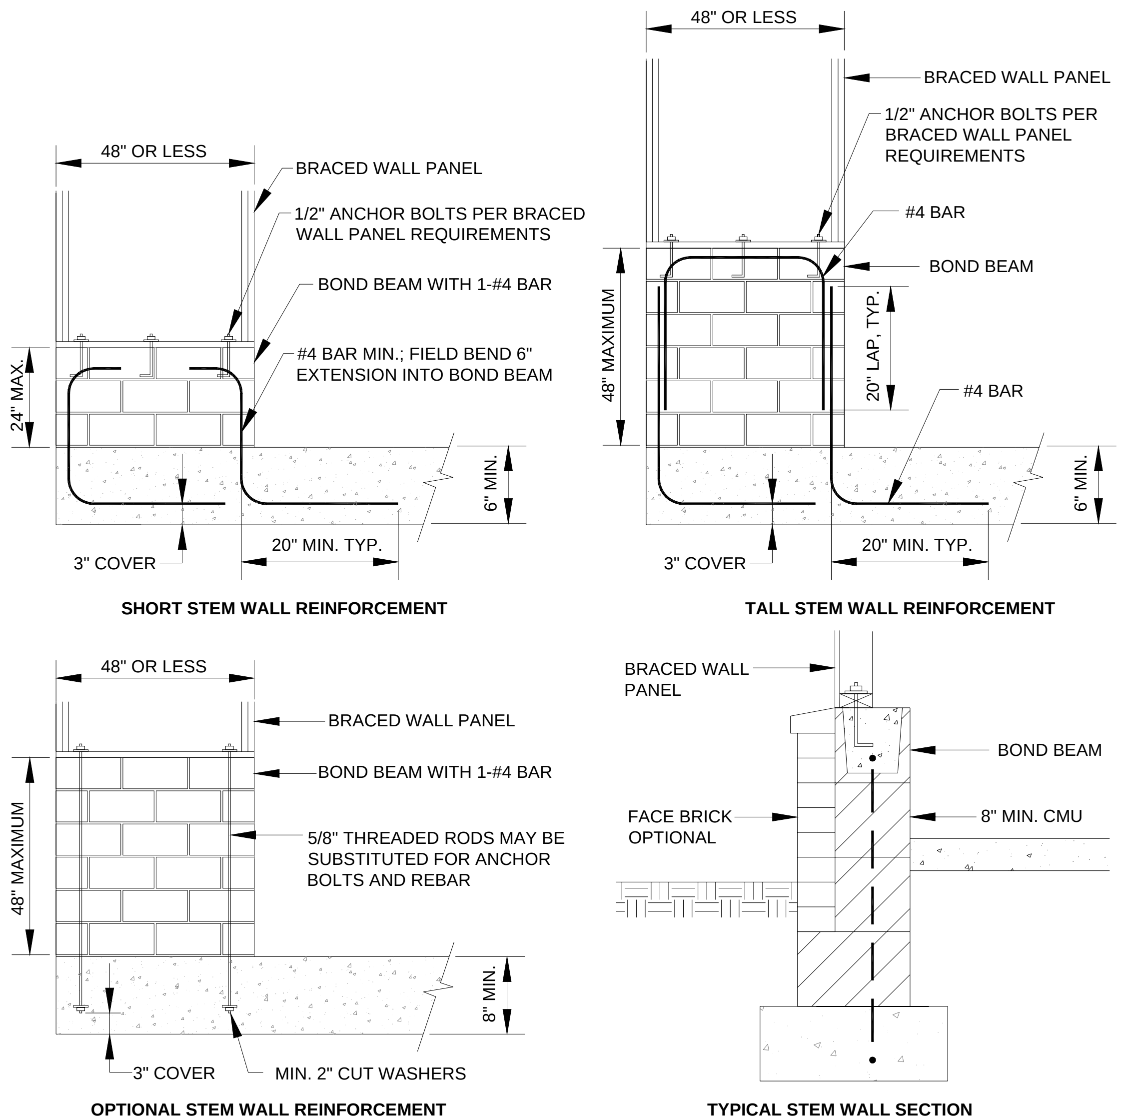
a. Methods of bracing shall be as described in Section R602.10.2 method DWB, WSP, SFB, GB, PBS, PCP OR HPS

b. Provide ventilation (not shown) per Section R608.

FIGURE R602.10.8.2(3)
BRACED WALL PANEL CONNECTION OPTION TO PERPENDICULAR RAFTERS OR ROOF TRUSSES

R602.10.9 Braced wall panel support. Braced wall panel support shall be provided as follows:

1. Cantilevered floor joists complying with Section R502.3.3 shall be permitted to support braced wall panels.
2. Elevated post or pier foundations supporting braced wall panels shall be designed in accordance with accepted engineering practice.
3. Masonry stem walls with a length of 48 inches (1220 mm) or less supporting braced wall panels shall be reinforced in accordance with Figure R602.10.9. Masonry stem walls with a length greater than 48 inches (1220 mm) supporting braced wall panels shall be constructed in accordance with Section R403.1 Methods ABW and PFH shall not be permitted to attach to masonry stem walls.
4. Concrete stem walls with a length of 48” or less, greater than 12 inches tall and less than 6 inches thick shall have reinforcement sized and located in accordance with Figure R602.10.9.



NOTE: GROUT BOND BEAMS AND ALL CELLS WHICH CONTAIN REBAR, THREADED RODS AND ANCHOR BOLTS.

For SI: 1 in=305 mm

FIGURE R602.10.9

MASONRY STEM WALLS SUPPORTING BRACED WALL PANELS

R602.10.9.1 Braced wall panel support for Seismic Design Category D_2. In one-story buildings located in Seismic Design Category D_2, braced wall panels shall be supported on continuous foundations at intervals not exceeding 50 feet (15 240 mm). In two story buildings located in Seismic Design Category D_2, all braced wall panels shall be supported on continuous foundations.

Exception: Two-story buildings shall be permitted to have interior braced wall panels supported on continuous foundations at intervals not exceeding 50 feet (15 240 mm) provided that:

1. The height of cripple walls does not exceed 4 feet (1219 mm).
2. First-floor braced wall panels are supported on doubled floor joists, continuous blocking or floor beams.
3. The distance between bracing lines does not exceed twice the building width measured parallel to the braced wall line.

R602.10.10 Panel joints. All vertical joints of panel sheathing shall occur over, and be fastened to common studs. Horizontal joints in braced wall panels shall occur over, and be fastened to common blocking of a minimum 1-1/2 inch (38 mm) thickness.

Exceptions:

1. Blocking at horizontal joints shall not be required in wall segments that are not counted as braced wall panels.
2. Where the length of bracing provided is at least twice the required length of bracing from Tables R602.10.3(1) and R602.10.3(3) blocking at horizontal joints shall not be required in braced wall panels constructed using Methods WSP, SFB, GB, PBS or HPS.
3. When Method GB panels are installed horizontally, blocking of horizontal joints is not required.

R602.10.11 Cripple wall bracing. In Seismic Design Categories other than D_2, cripple walls shall be braced with a length and type of bracing as required for the wall above in accordance with Tables R602.10.3(1) and R602.10.3(3) with the following modifications for cripple wall bracing:

1. The length of bracing as determined from Tables R602.10.3(1) and R602.10.3(3) shall be multiplied by a factor of 1.15, and
2. The wall panel spacing shall be decreased to 18 feet (5486 mm) instead of 25 feet (7620 mm).

R602.10.11.1 Cripple wall bracing in Seismic Design Categories D_0, D_1 and D_2. In addition to the requirements of Section R602.10.11, where braced wall lines at interior walls occur without a continuous foundation below, the length of parallel exterior cripple wall bracing shall be one and one-half times the length required by Table R602.10.3(3). Where cripple walls braced using Method WSP cannot provide this additional length, the capacity of the sheathing shall be increased by reducing the spacing of fasteners along the perimeter of each piece of sheathing to 4 inches (102 mm) on center.

In Seismic Design Category D_2, cripple walls shall be braced in accordance with Tables R602.10.3(3) and R602.10.3(4).

R602.10.11.2 Redesignation of cripple walls. In any Seismic Design Category, cripple walls shall be permitted to be redesignated as the first story walls for purposes of determining wall bracing requirements. If the cripple walls are redesignated, the stories above the redesignated story shall be counted as the second and third stories respectively.

Reason: As the wall bracing section evolved, it has become more universal and flexible, but, as a result, it has grown in size and complexity. After the Ad Hoc committee's "engineering" work was complete and integrated into the 2009 IRC, we heard back from end users that this section of the code was extremely challenging. The committee therefore wanted to focus on making the 2012 IRC easier to read, easier to understand and easier to use.

The *BIG BANG*: To accommodate over 30 separate editorial and technical "simplification" proposals, the Ad Hoc Committee agreed to delete Section R602.10 in its entirety, and replace it with one single change - rather than try to strikeout and insert individual tables, code sections and figures. The decision to integrate all the individual code changes into a single change was due in part to the complexity and interconnectivity of the pieces, and the necessity to "visualize" the final product in its totality. **Everything in this single change had unanimous support among committee members and was deemed to be non-controversial in nature**.

There are several other changes being proposed by committee members that are being submitted independent of this integrated change because of their scope and nature. Some have the unanimous backing of the committee, but may generate discussion from the floor, and others are being offered separately by individual members of the committee because of their content.

Non-technical changes:

Many of the code changes are reorganizational in nature from the 2009 IRC; we moved similar ideas and concepts together to read more smoothly, we merged or deleted unnecessary or duplicated pieces, and made editorial clarifications and improvements.

Technical changes:

The significant technical changes incorporated into this new section are listed below.

Table R602.3(1):

A new row was added to the table that incorporates the nailing requirements of 2009 IRC Figure R602.10.4.4(1) thus eliminating the large and complex figure. All other requirements of the eliminated figure are already covered elsewhere in the IRC. A new requirement for fastening the rim board to sill plate was added to complete the load path from braced wall panels to the foundation.

Section R602.10.1.1:

- o A new figure was added to replace several less effective figures: it clarifies offsets, BWL spacing, and explains how to handle the situation when an intersecting braced wall line is not present to define the length of BWL – it now explains that the end of the building will determine its length.

Section R602.10.2.2 and R602.10.2.3:

- o For consistency, the distance from the end of a BWL to the first BWP was unified at 10 feet for all SDCs and wind speeds.
- o The required summation of end distances was eliminated (2009 IRC Section R602.10.1.4); in its place, braced wall lines up to 16 feet in length may have only one braced wall panel.
- o BWP spacing was changed from 25' o.c.to a 20' edge-to-edge spacing to make it easier to measure.
- o Another new figure was introduced to better demonstrate how BWPs may be located along the walls of the house.

Section R602.10.3:

- o The contribution from BWP on an angled wall was clarified.

Tables R602.10.3(1) and (3):

- o Method GB was redefined as a <u>one sided, 4' application only</u>, because of the problem with interpreting what "double sided GB" meant. To compensate, the required length of bracing for a braced wall line with Method GB was doubled in these two tables.
- o Method CS-SFB was integrated into the tables as well.

Section R602.10.5:

- o Section R602.10.5 was deleted and the provisions for the use of Continuous Sheathing- Structural Fiberboard Sheathing were placed in the appropriate sections
- o

Section R602.10.4.1, Item 5:

- o The option to mix intermittent and continuous methods on a single braced wall line was provided. When a braced wall line begins on the exterior of the building and continues through the interior, the designer can brace the interior portions with intermittent methods and utilize the advantages of continuous sheathing on the exterior portions.

Figure R602.10.6.2:

- o The option for a pony wall atop a PFH portal frame was added so that all portal frames (including PFG and CS-PF) allow the pony wall extension above the header.

Figure R602.10.7:

- o A new end condition was added. Condition 3 allows no return panels or hold-downs if a 4 foot braced wall panel is located at the end of the braced wall line.

The uplift load path section, previously R602.10.1.2.1, was clarified, strengthened and moved to become Section R602.3.5.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: LSTIBUREK-RB-1-R602.7

<u>Public Hearing Results</u>

Committee Action: Approved as Modified

Modify the proposal as follows:

R602.3.5 Braced wall panel uplift load path. Braced wall panels located at exterior walls that support roof rafters or trusses (including stories below top story) shall have the framing members connected in accordance with one of the following:

1. Fastening in accordance with Table R602.3(1) where:
   1.1 The basic wind speed does not exceed 90 mph (40 m/s), the wind exposure category is B, the roof pitch is 5:12 or greater, and the roof span is 32 feet (9754 mm) or less, or
   1.2 The net uplift value at the top of a wall does not exceed 100 plf (146 N/mm). The net uplift value shall be determined in accordance with Section R802.11 and shall be permitted to be reduced by ~~40~~ <u>60</u> plf (~~57~~ <u>86</u> N/mm) for each full wall above ~~and 40 plf (57 N/mm) for each floor platform above~~.
2. Where the net uplift value at the top of a wall exceeds 100 plf (146 N/mm), installing approved uplift framing connectors to provide a continuous load path from the top of the wall to the foundation or to a point where the uplift force is 100 plf (146 N/mm) or less. The net uplift value shall be as determined in Item 1.2 above.
3. Wall sheathing and fasteners designed in accordance with accepted engineering practice to resist combined uplift and shear forces.

TABLE R802.11
REQUIRED STRENGTH OF TRUSS OR RAFTER CONNECTIONS
TO RESIST WIND UPLIFT FORCES[a, b, c, e, f]
(Pounds per connection)
(No change to table values)

a. through e. *(No change)*
f. For wall-to-wall and wall-to-foundation connections, the capacity of the uplift connector is permitted to be reduced by 100 pounds for each full wall above. (For example, if a 600-pound rated connector is used on the roof framing, a 500-pound rated connector is permitted at the next floor level down).

TABLE R602.10.3(4)
SEISMIC ADJUSTMENT FACTORS TO THE REQUIRED LENGTH OF WALL BRACING

ADJUSTMENT BASED ON:	**STORY/ SUPPORTING**	**CONDITION**	**ADJUSTMENT FACTOR [a,b] (Multiply length from Table R602.10.3(1) by this factor)**	**APPLICABLE METHODS**
Story height (Section 301.3)	Any story	≤10 ft	1.0	All methods
		>10 ft ≤ 12 ft	1.2	
Braced wall line spacing, townhouses in SDC C	Any story	≤35 ft	1.0	
		>35 ft ≤ 50 ft	1.43	
Braced wall line spacing, in SDC D_0, D_1, D_2[c]	Any story	≥25 ft ≤30 ft	1.2	
		>30 ft ≤ 35 ft	1.4	
Wall dead load	Any story	> 8 ft < 15 ft	1.0	
		<8 psf	0.85	
Roof/ceiling dead load for wall supporting	Roof only or roof plus one or two stories	<15 psf	1.0	
	Roof only	>15 psf ≤ 25 psf	1.2	
	Roof plus one or two stories	>15 psf ≤ 25 psf	1.1	
Walls with stone or masonry veneer	Any story	See Section R703.7		
Interior gypsum board finish (or equivalent)	Any story	Omitted from inside face of braced wall panels	1.5	DWB, WSP, SFB, PBS, PCP, HPS, CS-WSP, CS-G, CS-SFB

R602.10.11 Cripple wall bracing. In Seismic Design Categories other than D_2, cripple walls shall be braced with a length and type of bracing as required for the wall above in accordance with Tables R602.10.3(1) and R602.10.3(3) with the following modifications for cripple wall bracing:

1. The length of bracing as determined from Tables R602.10.3(1) and R602.10.3(3) shall be multiplied by a factor of 1.15, and
2. The wall panel spacing shall be decreased to 18 feet (5486 mm) instead of ~~25~~ 20 feet (~~7620~~ mm).

(Portion of proposal not shown remains unchanged)

Committee Reason: The committee feels this is a much needed improvement and adds considerable clarification to the wall bracing provisions while reducing the number of pages from 25 to 23. The modifications corrects for the proper wall load in R602.3.5, item 1.1.2, adds a deleted footnote to Table R802.11, corrects an inequality sign (<25 ft should be >25 ft) in Table R602.10.3(4) and corrects the 25 ft to 20 ft in Section R602.10.11 to comport with Section R602.10.2.2.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Charles S. Bajnai, VBCOA and Chesterfield County, VA, representing ICC Ad-Hoc Committee on Wall Bracing, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R602.10 Wall bracing. Buildings shall be braced in accordance with this section. Where a building, or portion thereof, does not comply with one or more of the bracing requirements in this section, those portions shall be designed and constructed in accordance with Section R301.1.

R602.10.1 Braced wall lines. For the purpose of determining the amount and location of bracing required in each story level of a building, braced wall lines shall be designated as straight lines ~~on~~ in the building plan placed in accordance with this section.

R602.10.1.1 Length of a braced wall line. The length of a braced wall line shall be the distance between its ends. The end of a braced wall line shall be the intersection with a perpendicular braced wall line, ~~or~~ an angled braced wall line as permitted in Section R602.10.1.4 or an exterior wall~~.~~ ~~In the absence of an intersecting braced wall line, the end shall be the farthest exterior wall of the building~~ as shown in Figure R602.10.1.1.

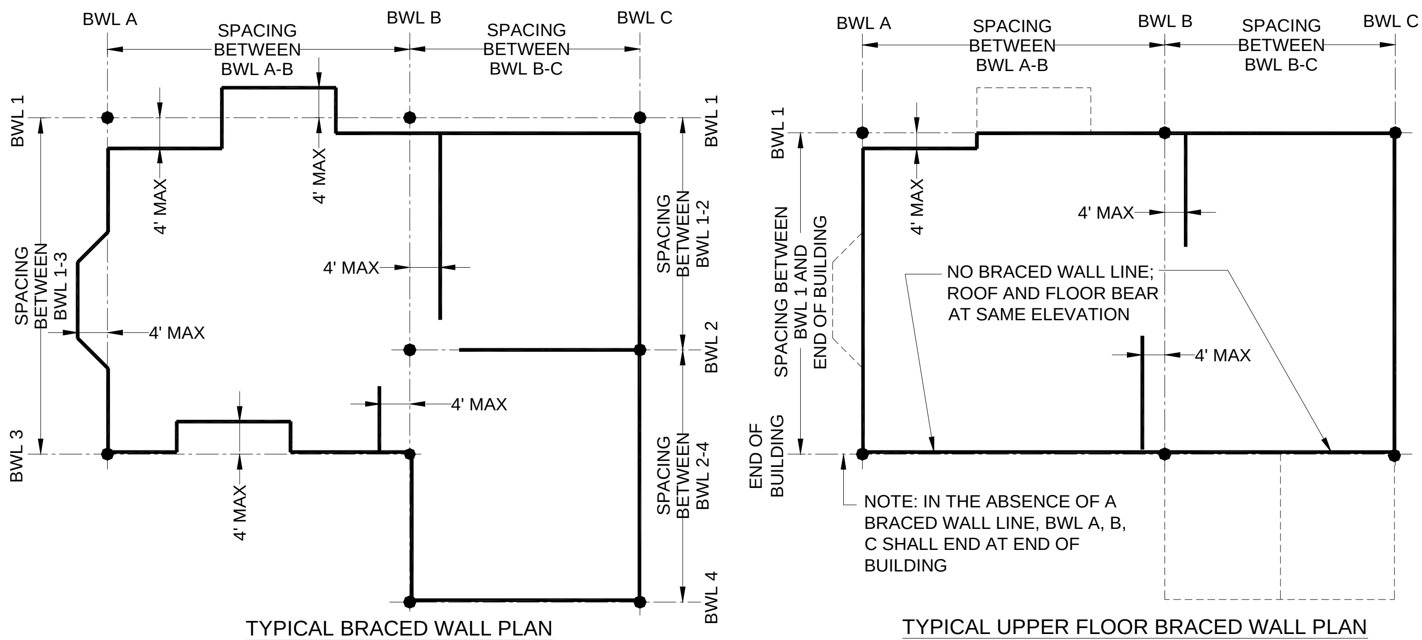


FIGURE R602.10.1.1
BRACED WALL LINES

R602.10.1.2 Offsets along a braced wall line. All exterior walls parallel to a braced wall line shall be permitted to offset up to 4 feet (1219 mm) from the designated braced wall line location as shown Figure R602.10.1.1. Interior walls used as bracing shall be permitted to offset up to 4 feet (1219 mm) from a braced wall line through the interior of the building as shown in Figure R602.10.1.1.

R602.10.1.3 Spacing of braced wall lines. There shall be a minimum of two braced wall lines in both the longitudinal and transverse direction as shown in Figure R602.10.1.1. Intermediate braced wall lines through the interior of the building shall be permitted. The spacing between parallel braced wall lines shall be in accordance with Table R602.10.1.3.

TABLE R602.10.1.3
BRACED WALL LINE SPACING

APPLICATION	CONDITION	BUILDING TYPE	BRACED WALL LINE SPACING CRITERIA	
			Maximum Spacing	Exception to Maximum Spacing
Wind bracing	85 mph to <110 mph	Detached, townhouse	60 feet	None
Seismic bracing	SDC A - C	Detached	Use wind bracing	
	SDC A – B	Townhouse	Use wind bracing	
	SDC C	Townhouse	35 feet	Up to 50 feet ~~with adjustment of required length of bracing per~~ when length of required bracing per Table R602.10.3(3) is adjusted in accordance with Table R602.10.3(4)
	SDC D_0, D_1, D_2	Detached, townhouses, one- and two-story only	25 feet	Up to 35 feet to allow for a single room not to exceed 900 sq ft. Spacing of all other braced wall lines shall not exceed 25 feet.
	SDC D_0, D_1, D_2	Detached, townhouse	25 feet	Up to 35 feet when length of required bracing per Table R602.10.3(3) is adjusted in accordance with Table R602.10.3(4).

For SI: 1 foot = 304.8 mm

R602.10.1.4 Angled walls. Any portion of a wall along a braced wall line shall be permitted to angle out of plane for a maximum diagonal length of 8 feet (2438 mm). Where the angled wall occurs at a corner, the length of the braced wall line shall be measured from the projected corner as shown in Figure R602.10.1.4. Where the diagonal length is greater than 8 feet (2438 mm), it shall be considered a separate braced wall line and shall be braced in accordance with Section R602.10.1.

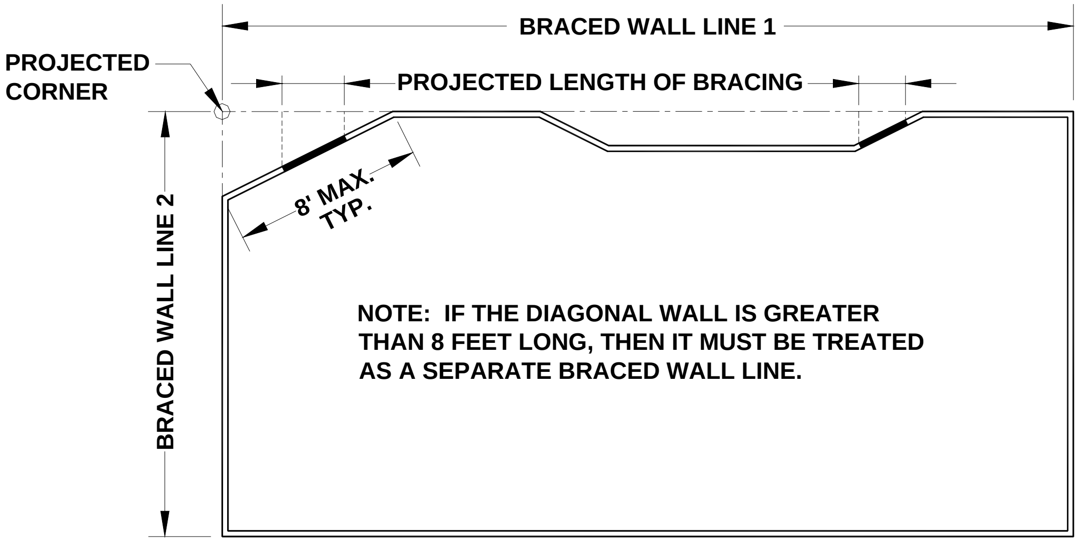

FIGURE R602.10.1.4
ANGLED WALLS

R602.10.2 Braced wall panels. Braced wall panels shall be full-height sections of wall that shall <u>have no vertical or horizontal offsets</u> ~~be continuous in the same plane~~. Braced wall panels shall be constructed and placed along a braced wall line in accordance with this section and the bracing methods specified in Section R602.10.4.

R602.10.2.1 Braced wall panel uplift load path. The bracing lengths in Table R602.10.3(1) apply only when uplift loads are resisted per Section R602.3.5.

R602.10.2.2 Locations of braced wall panels. A braced wall panel shall begin within 10 feet (3810 mm) from each end of a braced wall line as determined in Section R602.10.1.1. The distance between adjacent edges of ~~two~~ braced wall panels <u>along a braced wall line</u> shall be no greater than 20 feet (6096 mm) as shown in Figure R602.10.2.2.

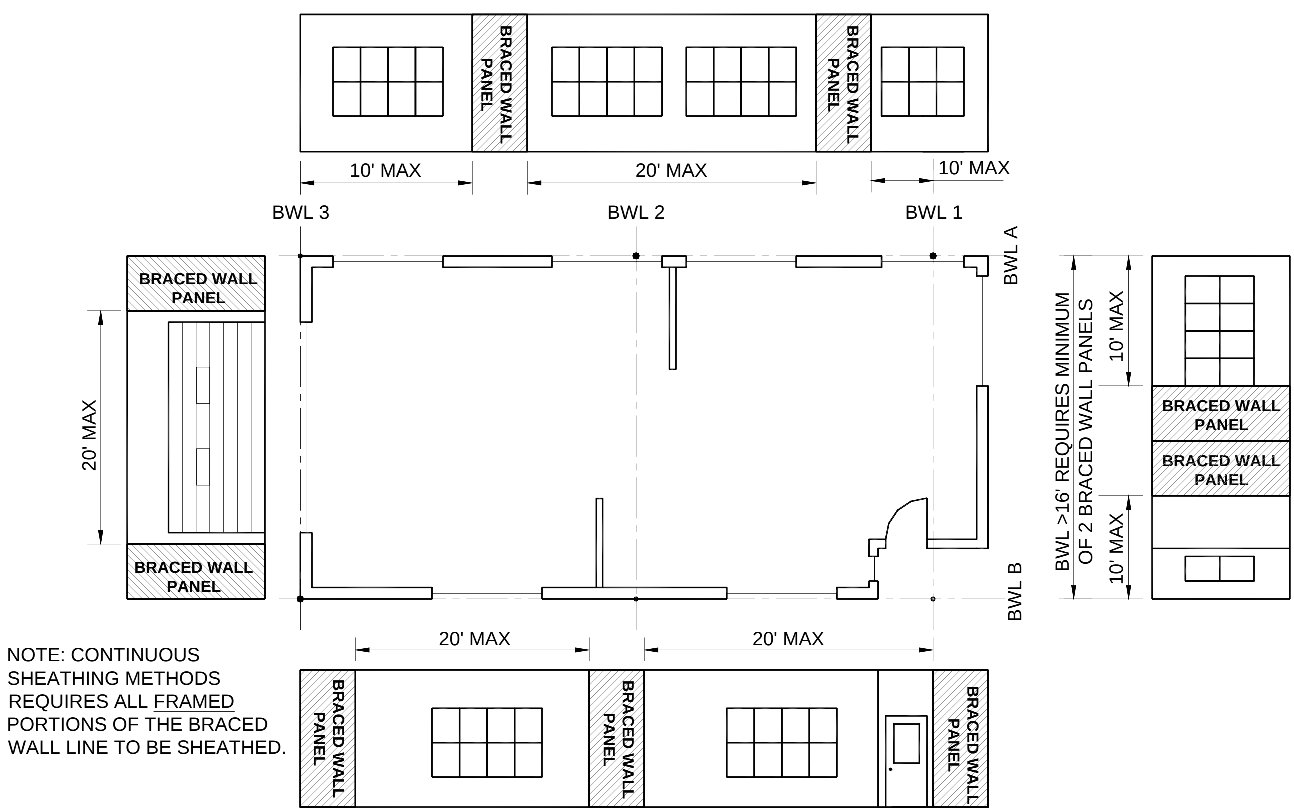

FIGURE R602.10.2.2
LOCATION OF BRACED WALL PANELS

R602.10.2.2.1 Location of braced wall panels in Seismic Design Categories D_0, D_1 and D_2. Braced wall panels shall be located at each end of a braced wall line.

Exception: Braced wall panels constructed of Methods WSP and continuous sheathing methods as specified in Section R602.10.4 shall be permitted to begin no more than 10 feet (3048 mm) from each end of a braced wall line provided each end complies with one of the following.

1. A minimum 24 in. wide (610 mm) panel for Methods WSP, CS-WSP, CS-G, CS-PF and 32 in. (813 mm) wide panel for Method CS-SFB is applied to each side of the building corner as shown in Condition 4 of Figure R602.10.7.
2. The end of each braced wall panel closest to the end of the braced wall line shall have an 1,800 lb (8 kN) hold-down device fastened to the stud at the edge of the braced wall panel closest to the corner and to the foundation or framing below as shown in Condition 5 of Figure R602.10.7.

R602.10.2.3 Minimum number of braced wall panels. Braced wall lines with a length of 16 feet (4877 mm) or less shall have a minimum of ~~one~~ two braced wall panels of any length or one braced wall panel equal to 48 inches (1219 mm) or more. Braced wall lines greater than 16 feet (4877 mm) shall have a minimum of two braced wall panels.

R602.10.3 Required length of bracing. The required length of bracing along each braced wall line shall be determined as follows.

1. All buildings in Seismic Design Categories A and B shall use Table R602.10.3(1) and the applicable adjustment factors in Table R602.10.3(2).
2. Detached buildings in Seismic Design Category C shall use Table R602.10.3(1) and the applicable adjustment factors in Table R602.10.3(2).
3. Townhouses in Seismic Design Category C shall use the greater value determined from Table R602.10.3(1) or R602.10.3(3) and the applicable adjustment factors in Table R602.10.3(2) or R602.10.3(4) respectively.
4. All buildings in Seismic Design Categories D_0, D_1 and D_2 shall use the greater value determined from Table R602.10.3(1) or R602.10.3(3) and the applicable adjustment factors in Table R602.10.3(2) or R602.10.3(4) respectively.

Only braced wall panels parallel to the braced wall line shall contribute towards the required length of bracing of that braced wall line. Braced wall panels along an angled wall meeting the minimum length requirements of Tables R602.10.5 and R602.10.5.2 shall be permitted to contribute its projected length towards the minimum required length of bracing for ~~to~~ the braced wall line as shown in Figure R602.10.1.4. Any braced wall panel on an angled wall at the end of a braced wall line shall contribute its projected length for only one of the braced wall lines at the projected corner. ~~In no case shall the required length of bracing along a braced wall line after adjustments be less than 48 inches (1219 mm) total.~~

		50	NP	65.5	37.5	32.0
		60	NP	77.5	44.5	37.5

For SI: 1 inch = 25.4 mm, 1 foot = 305 mm.

a. Linear interpolation shall be permitted.

b. Method LIB shall have gypsum board fastened to at least one side with nails or screws per Table R602.3(1) for exterior sheathing or Table R702.3.5 for interior gypsum board. Spacing of fasteners at panel edges shall not exceed 8 inches (203 mm).

~~c. The length of bracing for Method GB is based on a double sided application. Where GB is used in a one sided application (or in combination of single sided and double sided application), the single sided GB shall only contribute half as much as the double sided GB towards the minimum required length of bracing in this table.~~

c~~d~~. Method CS-SFB does not apply where the wind speed is greater than 100 mph.

Table R602.10.3(2)
WIND ADJUSTMENT FACTORS TO THE REQUIRED LENGTH OF WALL BRACING

ADJUSTMENT BASED ON	STORY/ SUPPORTING	CONDITION	ADJUSTMENT FACTOR[a,b] (multiply length from Table R602.10.3(1) by this factor)	APPLICABLE METHODS
Exposure category	One story structure	B	1.00	All methods
		C	1.20	
		D	1.50	
	Two-story structure	B	1.00	
		C	1.30	
		D	1.60	
	Three-story structure	B	1.00	
		C	1.40	
		D	1.70	
Roof eave-to-ridge height	Roof only	≤5 ft	0.70	
		10 ft	1.00	
		15 ft	1.30	
		20 ft	1.60	
	Roof + 1 floor	≤5 ft	0.85	
		10 ft	1.00	
		15 ft	1.15	
		20 ft	1.30	
	Roof + 2 floors	≤5 ft	0.90	
		10 ft	1.00	
		15 ft	1.10	
		20 ft	Not permitted	
Wall height adjustment	Any story	8 ft	0.90	
		9 ft	0.95	
		10 ft	1.00	
		11 ft	1.05	
		12 ft	1.10	
Number of braced wall lines (per plan direction)[c]	Any story	2	1.00	
		3	1.30	
		4	1.45	
		≥5	1.60	
Additional 800 lb hold-down device	Top story only	Fastened to the end studs of each braced wall panel and to the foundation or framing below	0.80	DWB, WSP, SFB, PBS, PCP, HPS
Interior gypsum board finish (or equivalent)	Any story	Omitted from inside face of braced wall panels	1.40	DWB, WSP, SFB,PBS, PCP, HPS, CS-WSP, CS-G, CS-SFB
Gypsum board fastening	Any story	4 in. o.c. at panel edges, including top and bottom plates, and all horizontal joints blocked	0.7	GB

For SI: 1 foot = 305 mm, 1 lb = 4.48 N.

a. Linear Interpolation shall be permitted.

b. The total adjustment factor is the product of all applicable adjustment factors.

c. The adjustment factor is permitted to be 1.0 when determining bracing amounts for intermediate braced wall lines provided the bracing mounts on adjacent braced wall lines are based on a spacing and number that neglects the intermediate braced wall line.

		50	NP	NP	NP	NP	NP

For SI: 1 foot 305 mm

a. Linear interpolation shall be permitted.

b. Wall bracing lengths are based on a soil site class "D." Interpolation of bracing length between the S_{ds} values associated with the Seismic Design Categories shall be permitted when a site-specific S_{ds} value is determined in accordance with Section 1613.5 of the International Building Code.

c. Method LIB shall have gypsum board fastened to at least one side with nails or screws per Table R602.3(1) for exterior sheathing or Table R702.3.5 for interior gypsum board. Spacing of fasteners at panel edges shall not exceed 8 inches (203 mm).

~~d. The length of bracing for Method GB is based on a double sided application. Where GB is used in a one sided application (or in combination of single sided and double sided application), the single sided GB shall only contribute half as much as the double sided GB towards the minimum required length of bracing in this table.~~

d~~e~~. Method CS-SFB applies in SDC C only.

TABLE R602.10.3(4)
SEISMIC ADJUSTMENT FACTORS TO THE REQUIRED LENGTH OF WALL BRACING

ADJUSTMENT BASED ON:	**STORY/SUPPORTING**	**CONDITION**	**ADJUSTMENT FACTOR [a,b] (Multiply length from Table R602.10.3(1) by this factor)**	**APPLICABLE METHODS**
Story height (Section 301.3)	Any story	≤10 ft	1.0	All methods
		>10 ft ≤ 12 ft	1.2	
Braced wall line spacing, townhouses in SDC C	Any story	≤35 ft	1.0	
		>35 ft ≤ 50 ft	1.43	
Braced wall line spacing, in SDC D_0, D_1, D_2 [c]	Any story	> 25 ft ≤30 ft	1.2	
		>30 ft ≤ 35 ft	1.4	
Wall dead load	Any story	> 8 ft < 15 ft	1.0	
		<8 psf	0.85	
Roof/ceiling dead load for wall supporting	Roof only or roof plus one or two stories	~~<~~ ≤15 psf	1.0	
	~~Roof only~~	~~>15 psf ≤ 25 psf~~	~~1.2~~	
	Roof plus one or two stories	>15 psf ≤ 25 psf	1.1	
	Roof only	>15 psf ≤ 25 psf	1.2	
Walls with stone or masonry veneer	Any story	See Section R703.7		
Interior gypsum board finish (or equivalent)	Any story	Omitted from inside face of braced wall panels	1.5	DWB, WSP, SFB, PBS, PCP, HPS, CS-WSP, CS-G, CS-SFB

For SI: 1 psf = 47,8 N/m^2.

a. Linear interpolation shall be permitted.

b. The total length of bracing required for a given wall line is the product of all applicable adjustment factors.

c. The length-to-width ratio for the floor/roof diaphragm shall not exceed 3:1. The top plate lap splice nailing shall be a minimum of 12-16d nails on each side of the splice.

R602.10.4 Construction methods for braced wall panels. Intermittent and continuously sheathed braced wall panels shall be constructed in accordance with this section and the methods listed in Table R602.10.4.

TABLE R602.10.4
BRACING METHODS

	METHODS, MATERIAL	MINIMUM THICKNESS	FIGURE	CONNECTION CRITERIA [a] Fasteners	CONNECTION CRITERIA [a] Spacing
Intermittent Bracing Methods	**LIB** Let-in-bracing	1x4 wood or approved metal straps at 45° to 60° angles for maximum 16” stud spacing		Wood: 2-8d common nails or 3-8d (2 ½” long x 0.113” dia.) nails Metal strap: per manufacturer	Wood: per stud and top and bottom plates Metal: per manufacturer
Intermittent Bracing Methods	**DWB** Diagonal wood boards	¾” (1” nominal) for maximum 24” stud spacing		2-8d (2½" long x 0.113" dia.) nails or 2 - 1¾" long staples	Per stud
Intermittent Bracing Methods	**WSP** Wood structural panel (See Section R604)	$^{3}/_{8}$"		Exterior sheathing per Table R602.3(3) Interior sheathing per Table R602.3(1) or R602.3(2)	6" edges 12" field Varies by fastener
Intermittent Bracing Methods	**SFB** Structural fiberboard sheathing	$^{1}/_{2}$" or $^{25}/_{32}$" for maximum 16" stud spacing		1½" long x 0.12" dia. (for ½ “ thick sheathing) 1$^{3}/_{4}$” long x 0.12” dia. (for $^{25}/_{32}$” thick sheathing) galvanized roofing nails or 8d common (2½" long x0.131" dia.) nails	3" edges 6" field
Intermittent Bracing Methods	**GB** [d] Gypsum board ~~(double sided)~~	$^{1}/_{2}$"		Nails or screws per Table R602.3(1) for exterior locations Nails or screws per Table R702.3.5 for interior locations	For all braced wall panel locations: 7" edges (including top and bottom plates) 7" field
Intermittent Bracing Methods	**PBS** Particleboard sheathing (See Section R605)	$^{3}/_{8}$" or $^{1}/_{2}$" for maximum16" stud spacing		For 3/8”, 6d common (2” long x0.113" dia.) nails For ½”, 8d common (2½" long x0.131" dia.) nails	3" edges 6" field
Intermittent Bracing Methods	**PCP** Portland cement plaster	See Section R703.6 for maximum 16” stud spacing		1½" long, 11 gage, $^{7}/_{16}$" dia. head nails or $^{7}/_{\cancel{16}8}$" long, 16 gage staples	6" o.c. on all framing members
Intermittent Bracing Methods	**HPS** Hardboard panel siding	$^{7}/_{16}$" for maximum 16” stud spacing		0.092" dia., 0.225" dia. head nails with length to accommodate 1½" penetration into studs	4" edges 8" field
Intermittent Bracing Methods	**ABW** Alternate braced wall	$^{3}/_{8}$"		See Section R602.10.6.1	See Section R602.10.6.1
Intermittent Bracing Methods	**PFH** Portal frame with hold-downs	$^{3}/_{8}$		See Section R602.10.6.2	See Section R602.10.6.2
Intermittent Bracing Methods	**PFG** Portal frame at garage	$^{7}/_{16}$"		See Section R602.10.6.3	See Section R602.10.6.3
Continuous Sheathing	**CS-WSP** Continuously sheathed wood structural panel	$^{3}/_{8}$"		Exterior sheathing per Table R602.3(3) Interior sheathing per Table R602.3(1) or R602.3(2)	6" edges 12" field Varies by fastener

	CS-G [b,c] Continuously sheathed wood structural panel adjacent to garage openings	$^{3}/_{8}$"		See Method CS-WSP	See Method CS-WSP
	CS-PF Continuously sheathed portal frame	$^{7}/_{16}$"		See Section R602.10.6.4	See Section R602.10.6.4
	CS-SFB [d] Continuously sheathed structural fiberboard	$^{1}/_{2}$" or $^{25}/_{32}$" for maximum 16" stud spacing		1½" long x 0.12" dia. (for ½ " thick sheathing) $1^{3}/_{4}$" long x 0.12" dia. (for $^{25}/_{32}$" thick sheathing) galvanized roofing nails or 8d common (2½" long x0.131" dia.) nails	3" edges 6" field

For SI: 1 inch = 25.4 mm, 1 foot = 305 mm.

a. Adhesive attachment of wall sheathing, including Method GB, shall not be permitted in Seismic Design Categories C, D_0, D_1 and D_2.

b. Applies to panels next to garage door opening when supporting gable end wall or roof load only. May only be used on one wall of the garage. In Seismic Design Categories D_0, D_1, and D_2, roof covering dead load may not exceed 3 psf (0.14 kN/m^2).

c. Garage openings adjacent to a Method CS-G panel shall be provided with a header in accordance with Table R502.5(1). A full height clear opening shall not be permitted adjacent to a Method CS-G panel.

~~d. "Double sided" GB shall mean that a full length/full height panel of GB sheathing is applied to both sides of the stud wall. GB bracing panels are not required to be aligned back to back – they may be offset from each other so long as their length's comply with Table R602.10.5. Where all of the GB is on one side of the studs or where there is a combination of "double sided" GB and "single sided" GB, the single sided GB shall contribute half of its actual length towards the minimum required length (i.e. 96" of single sided GB is equivalent to 48" of double sided GB).~~

d. Method CS-SFB does not apply in Seismic Design Categories D_0, D_1 and D_2 and in areas where the wind speed exceeds 100 mph.

R602.10.4.1 Mixing methods. Mixing of bracing methods shall be permitted as follows:

1. Mixing intermittent bracing and continuous sheathing methods from story to story shall be permitted.
2. Mixing intermittent bracing methods from braced wall line to braced wall line within a story shall be permitted. Within Seismic Design Categories A, B and C or in regions where the basic wind speed is less than or equal to 100 mph, mixing of intermittent bracing and continuous sheathing methods from braced wall line to braced wall line within a story shall be permitted.
3. Mixing intermittent bracing methods along a braced wall line shall be permitted in Seismic Design Categories A and B, and detached dwellings in Seismic Design Category C provided the length of required bracing in accordance with Table R602.10.3(1) or R602.10.3(3) is the highest value of all intermittent bracing methods used.
4. Mixing of continuous sheathing methods CS-WSP, CS-G and CS-PF along a braced wall line shall be permitted.
5. In Seismic Design Categories A and B, and for detached one- and two-family dwellings in Seismic Design Category C, mixing of intermittent bracing methods along the interior portion of a braced wall line with continuous sheathing methods CS-WSP, CS-G and CS-PF along the exterior portion of the same braced wall line shall be permitted. The length of required bracing shall be the highest value of all intermittent bracing methods used in accordance with Table R602.10.3(1) or R602.10.3(3) as adjusted by Tables R602.10.3(2) and R602.10.3(4), respectively. The requirements of Section R602.10.7 shall apply to each end of the continuously sheathed portion of the braced wall line.

R602.10.4.2 Continuous sheathing methods. Continuous sheathing methods require structural panel sheathing to be used on all sheathable surfaces on one side of a braced wall line including areas above and below openings and gable end walls and shall meet the requirements of Section R602.10.7.

R602.10.4.3 Braced wall panel interior finish material. Braced wall panels shall have gypsum wall board installed on the side of the wall opposite the bracing material. Gypsum wall board shall be not less than ½ inch (12.7 mm) in thickness and be fastened with nails or screws in accordance with Table R602.3(1) for exterior sheathing or Table R702.3.5 for interior gypsum wall board. Spacing of fasteners at panel edges for gypsum wall board opposite Method LIB bracing shall not exceed 8 inches (203 mm). Interior finish material shall not be glued in Seismic Design Categories D_0, D_1 and D_2.

Exceptions:

1. Interior finish material is not required opposite wall panels that are braced in accordance with Method GB, ABW, PFH, PFG and CS-PF, unless otherwise required by Section R302.6.
2. An approved interior finish material with an in-plane shear resistance equivalent to gypsum board shall be permitted to be substituted, unless otherwise required by Section R302.6.
3. Except for Method LIB, gypsum wall board is permitted to be omitted provided the required length of bracing in Tables R602.10.3(1) and R602.10.3(3) is multiplied by the appropriate adjustment factor in Tables R602.10.3(2) and R602.10.3(4) respectively, unless otherwise required by Section R302.6.

R602.10.5 Minimum length of a braced wall panel. The minimum length of a braced wall panel shall comply with Table R602.10.5. For Methods CS-WSP and CS-SFB, the minimum panel length shall be based on the adjacent clear opening height in accordance with Table R602.10.5 and Figure R602.10.5. When a panel has an opening on either side of differing heights, the taller opening height shall be used to determine the panel length.

R602.10.5.1 Contributing length. For purposes of computing the required length of bracing in Table R602.10.3(1) and R602.10.3(3), the contributing length of each braced wall panel shall be as specified in Table R602.10.5.

TABLE R602.10.5
MINIMUM LENGTH OF BRACED WALL PANELS

METHOD (See Table R602.10.4)		**MINIMUM LENGTH [a] (in)**					**CONTRIBUTING LENGTH (in)**

	136					62	
	140					66	
	144					72	

For SI: 1 inch = 25.4 mm
NP = Not permitted

a. Linear interpolation shall be permitted.
b. Use the actual length when it is greater than or equal to the minimum length.
~~c. As specified in Table R602.10.4, Method GB is intended to be double sided. Where all of the GB is on one side of the studs or where there is a combination of "double sided" GB and "single sided" GB, the single sided GB shall contribute half of its actual length towards the minimum required length (i.e. 96" of single sided GB is equivalent to 48" of double sided GB).~~
~~d~~c. Maximum header height for PFH is 10' per Figure R602.10.6.2, but wall height may be increased to 12' with pony wall.
~~e~~d. Maximum opening height for PFG is 10' per Figure R602.10.6.3, but wall height may be increased to 12' with pony wall.
~~f~~e. Maximum opening height for CS-PF is 10' per Figure R602.10.6.4, but wall height may be increased to 12' with pony wall

For SI: 1 inch = 25.4 mm, 1 foot = 305 mm, 1 lb = 4.45 N
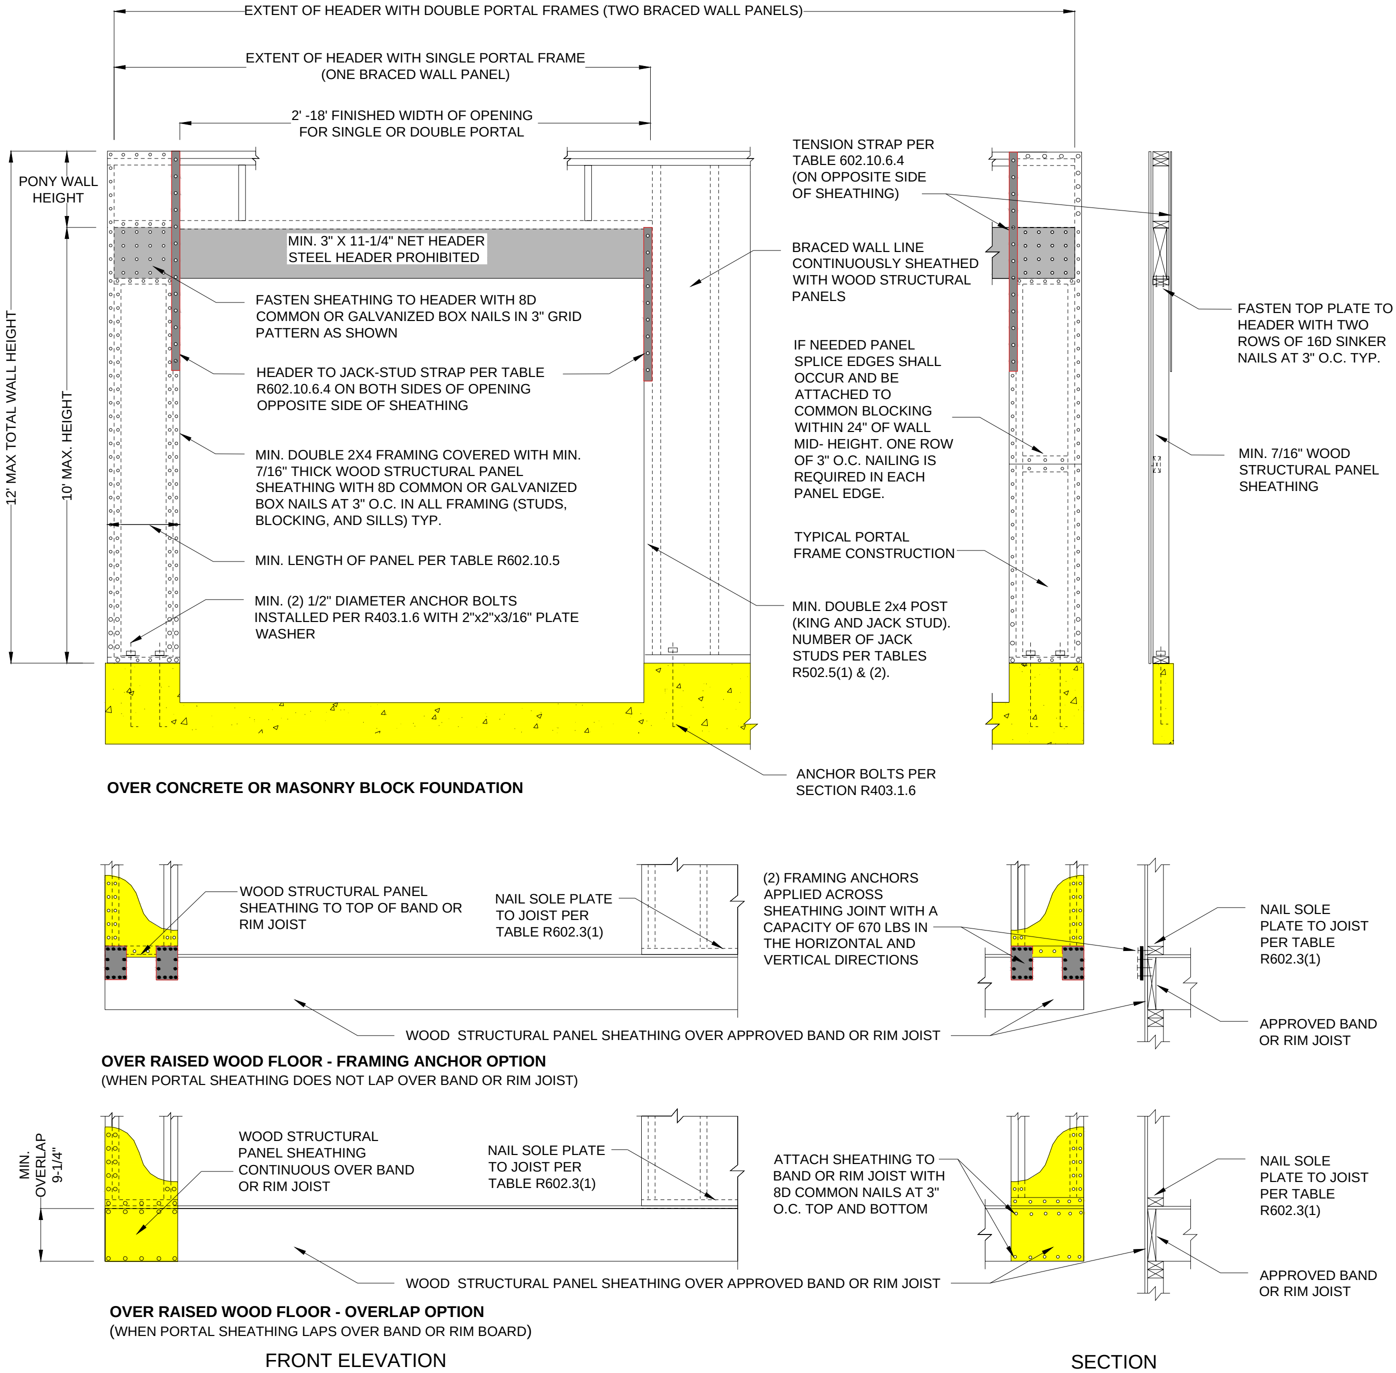
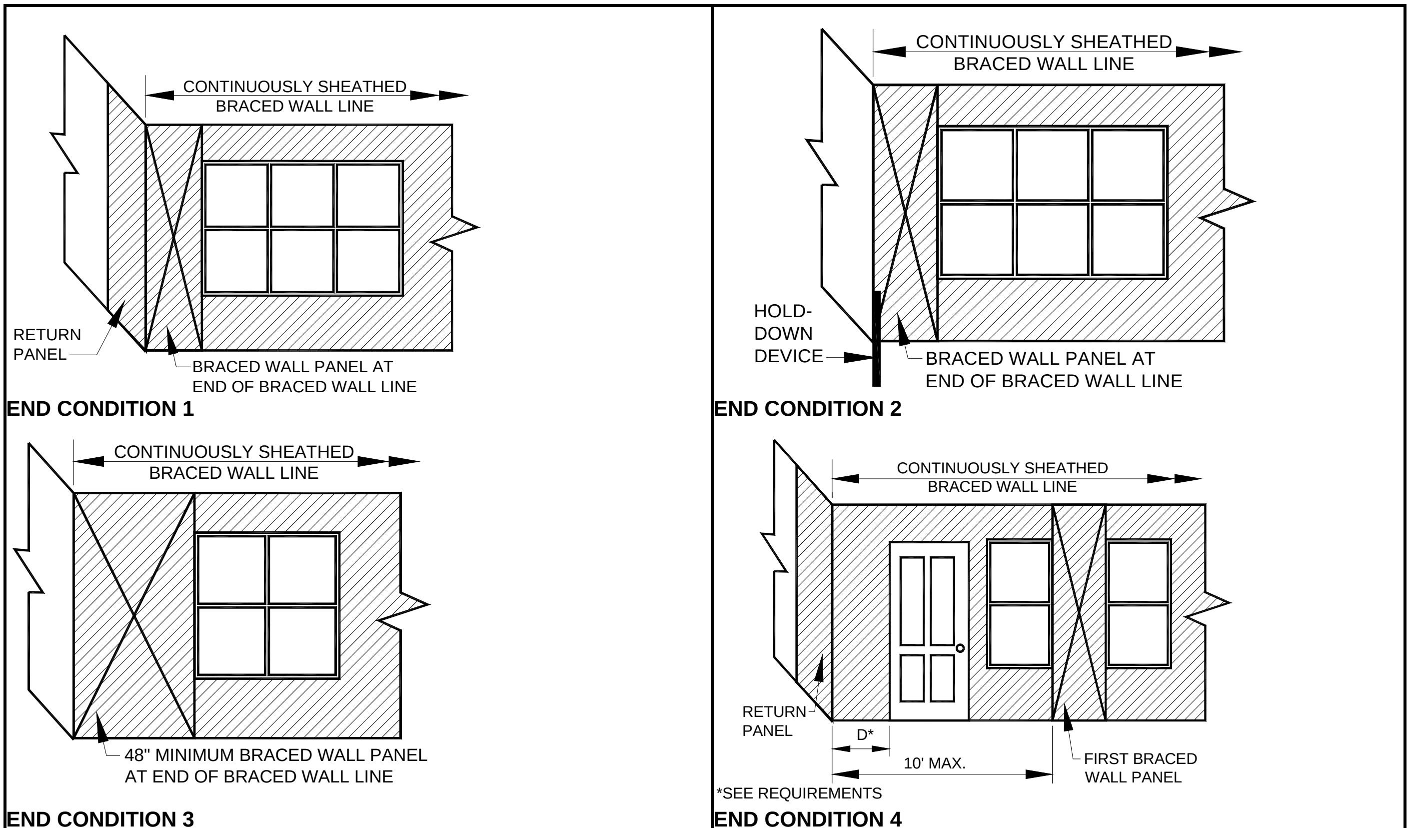
a. DR = design required
b. Strap shall be installed in accordance with manufacturer's recommendations.

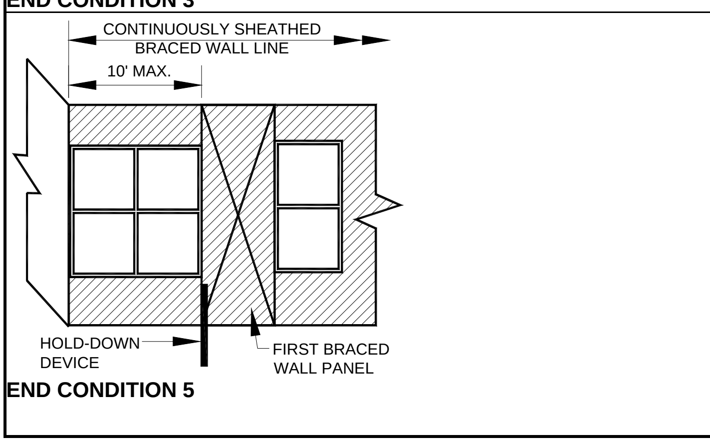


For SI: 1 inch = 25.4 mm, 1 foot = 305 mm, 1 lb = 4.45 N

FIGURE R602.10.6.4
METHOD CS-PF: CONTINUOUSLY SHEATHED PORTAL FRAME PANEL CONSTRUCTION

R602.10.7 Ends of braced wall lines with continuous sheathing. Each end of a braced wall line with continuous sheathing shall have one of the conditions shown in Figure R602.10.7.





REQUIREMENTS

Return panel: 24" for braced wall lines sheathed with wood structural panels
32" for braced wall lines sheathed with structural fiberboard

Distance D: 24" for braced wall lines sheathed with wood structural panels
32" for braced wall lines sheathed with structural fiberboard

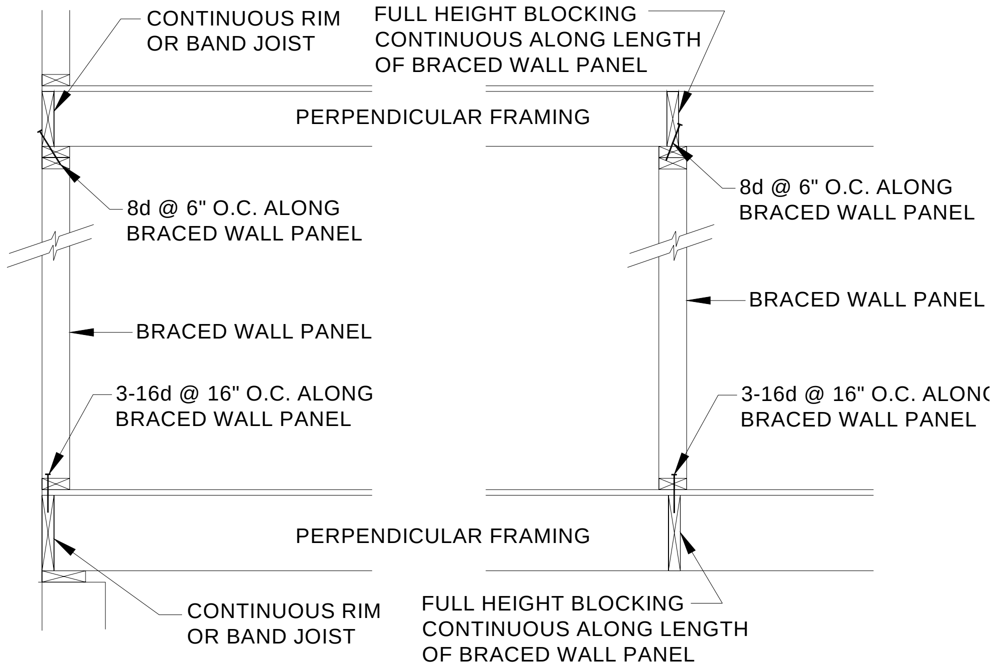
Hold-down device: 800 lbs capacity fastened to the edge of the braced wall panel closest to the corner and to the foundation or floor framing below

For SI: 1 inch = 25.4 mm, 1 foot = 305 mm, 1 lb = 4.45 N

FIGURE R602.10.7
END CONDITIONS FOR BRACED WALL LINES WITH CONTINUOUS SHEATHING

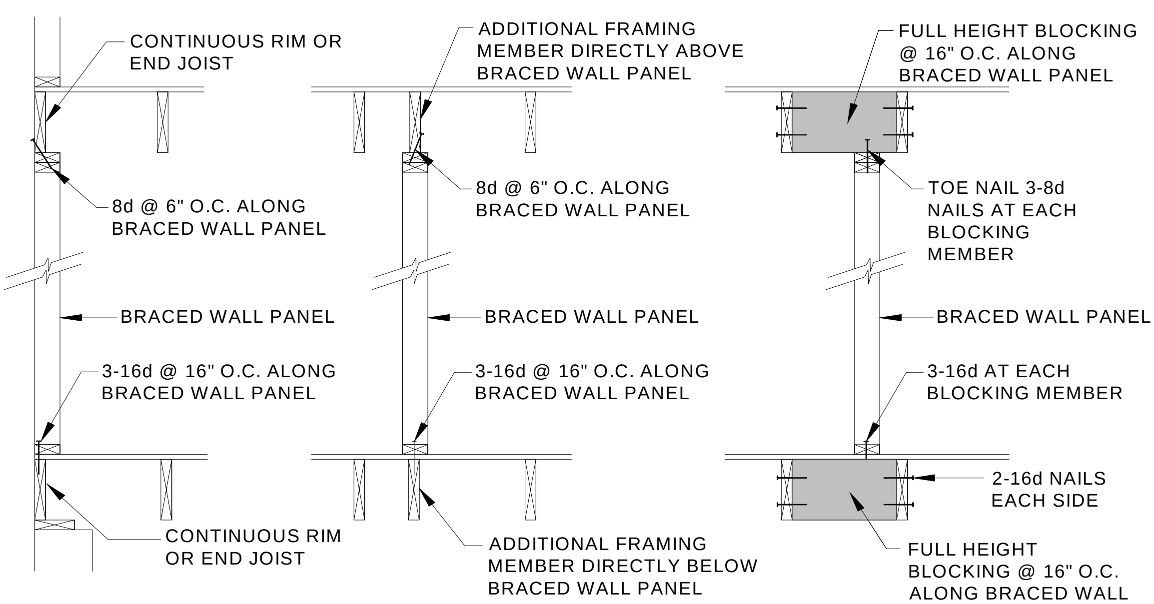
R602.10.8 Braced wall panel connections. Braced wall panels shall be connected to floor framing or foundations as follows:

1. Where joists are perpendicular to a braced wall panel above or below, a rim joist, band joist or blocking shall be provided along the entire length of the braced wall panel in accordance with Figure R602.10.8(1). Fastening of top and bottom wall plates to framing, rim joist, band joist and/or blocking shall be in accordance with Table R602.3(1).
2. Where joists are parallel to a braced wall panel above or below, a rim joist, end joist or other parallel framing member shall be provided directly above and below the braced wall panel in accordance with Figure R602.10.8(2). Where a parallel framing member cannot be located directly above and below the panel, full-depth blocking at 16 inch (406 mm) spacing shall be provided between the parallel framing members to each side of the braced wall panel in accordance with Figure R602.10.8(2). Fastening of blocking and wall plates shall be in accordance with Table R602.3(1) and Figure R602.10.8(2).
3. Connections of braced wall panels to concrete or masonry shall be in accordance with Section R403.1.6.



For SI: 1 inch = 25.4 mm

FIGURE R602.10.8(1)
BRACED WALL PANEL CONNECTION WHEN
PERPENDICULAR TO FLOOR/CEILING FRAMING



For SI: 1 inch = 25.4 mm

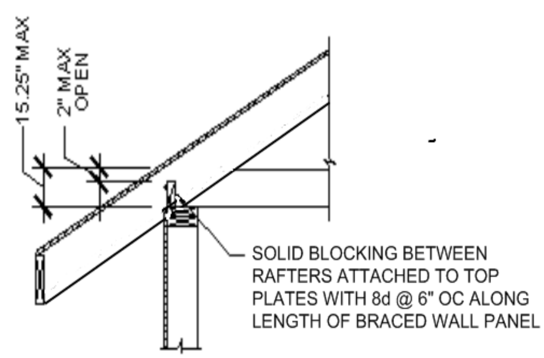
FIGURE R602.10.8(2)
BRACED WALL PANEL CONNECTION WHEN

PARALLEL TO FLOOR/CEILING FRAMING

R602.10.8.1 Braced wall panel connections for Seismic Design Categories D_0, D_1 and D_2. Braced wall panels shall be fastened to required foundations in accordance with Section R602.11.1, and top plate lap splices shall be face-nailed with at least eight 16d nails on each side of the splice.

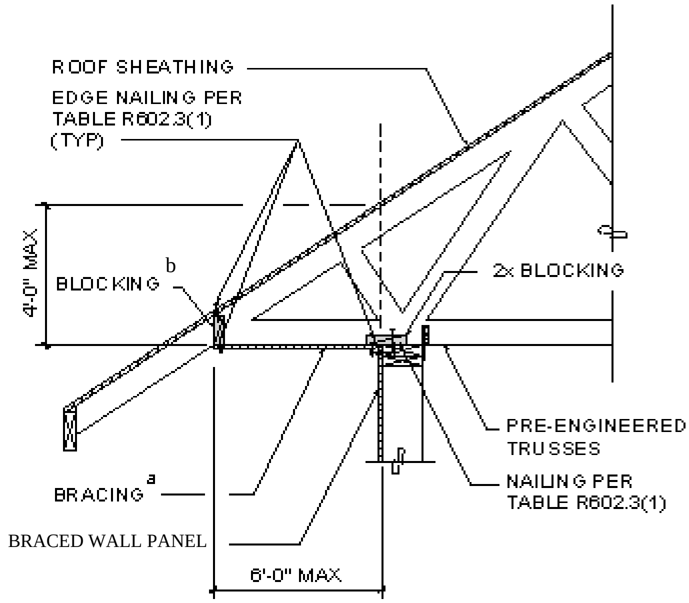
R602.10.8.2 Connections to roof framing. Exterior braced wall panels shall be connected to roof framing as follows.

1. Parallel rafters or roof trusses shall be attached to the top plates of braced wall panels in accordance with Table R602.3(1).
2. For Seismic Design Categories A, B and C and wind speeds less than 100 mph (45 m/s):
   2.1 Where the distance from the top of the rafters or roof trusses and perpendicular top plates is 9.25 inches (235 mm) or less, the rafters or roof trusses shall be connected to the top plates of braced wall panels in accordance with Table R602.3(1) and blocking need not be installed.
   2.2 Where the distance from the top of the rafters and perpendicular top plates is between 9.25 inches (235 mm) and 15.25 inches (387 mm) the rafters shall be connected to the top plates of braced wall panels with blocking in accordance with Figure R602.10.8.2(1) and attached in accordance with Table R602.3(1).
   2.3 Where the distance from the top of the roof trusses and perpendicular top plates is between 9.25 inches (235 mm) and 15.25 inches (387 mm) the roof trusses shall be connected to the top plates of braced wall panels with blocking in accordance with Table R602.3(1).
3. For Seismic Design Categories D_0, D_1 and D_2 or wind speeds of 100 mph (45 m/s) or greater, where the distance between the top of rafters or roof trusses and perpendicular top plates is 15.25 inches (387 mm) or less, rafters or roof trusses shall be connected to the top plates of braced wall panels with blocking in accordance with Figure R602.10.8.2(1) and attached in accordance with Table R602.3(1).
4. For all Seismic Design Categories and wind speeds, where the distance between the top of rafters or roof trusses and perpendicular top plates exceeds 15.25 inches (387 mm), perpendicular rafters or roof trusses shall be connected to the top plates of braced wall panels in accordance with one of the following methods
   4.1. In accordance with Figure R602.10.8.2(2),
   4.2. In accordance with Figure R602.10.8.2(3),
   4.3. With full height engineered blocking panels designed for values listed in American Forest and Paper Association (AF&PA) Wood Frame Construction Manual for One- and Two-Family Dwellings (WFCM). Both the roof and floor sheathing shall be attached to the blocking panels in accordance with Table R602.3(1).
   4.4. Designed in accordance with accepted engineering methods.
5. Lateral support for the rafters and ceiling joists shall be provided in accordance with Section R802.8. 6. Lateral support for trusses shall be provided in accordance with Section R802.10.3.



For SI: 1 inch = 25.4 mm

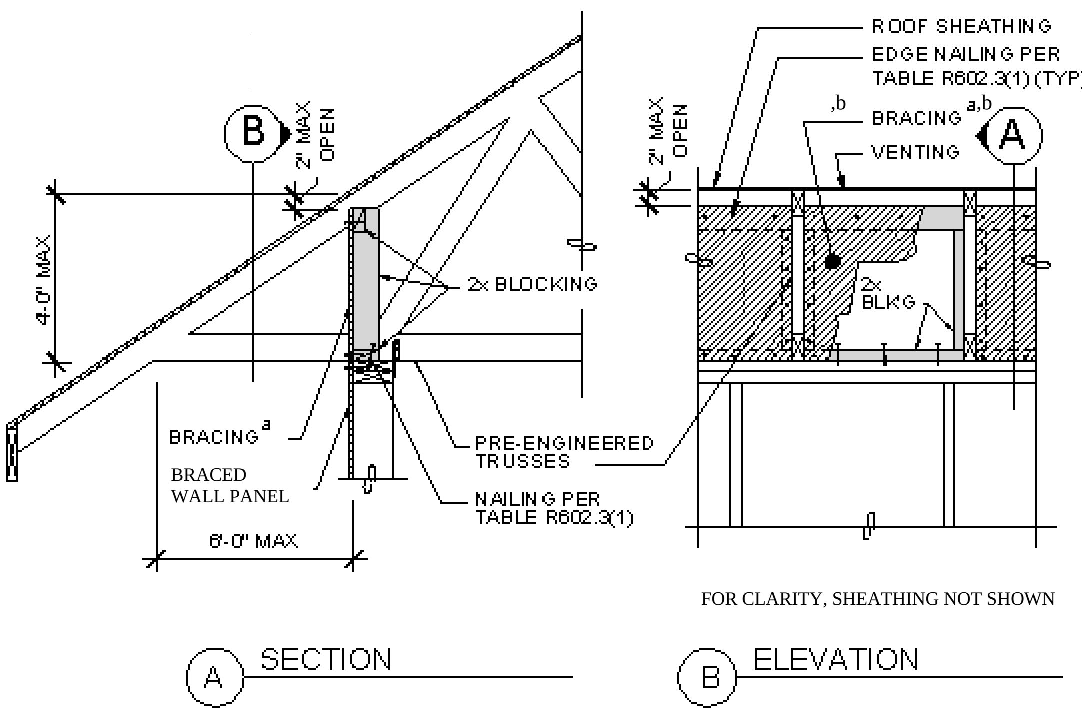
FIGURE R602.10.8.2(1)
BRACED WALL PANEL CONNECTION TO PERPENDICULAR RAFTERS



For SI: 1 inch = 25.4 mm

a. Methods of bracing shall be as described in Section R602.10.2 method DWB, WSP, SFB, GB, PBS, PCP OR HPS
b. Provide ventilation (not shown) per Section R806.

FIGURE R602.10.8.2(2)
BRACED WALL PANEL CONNECTION OPTION TO PERPENDICULAR RAFTERS OR ROOF TRUSSES



For SI: 1 inch = 25.4 mm

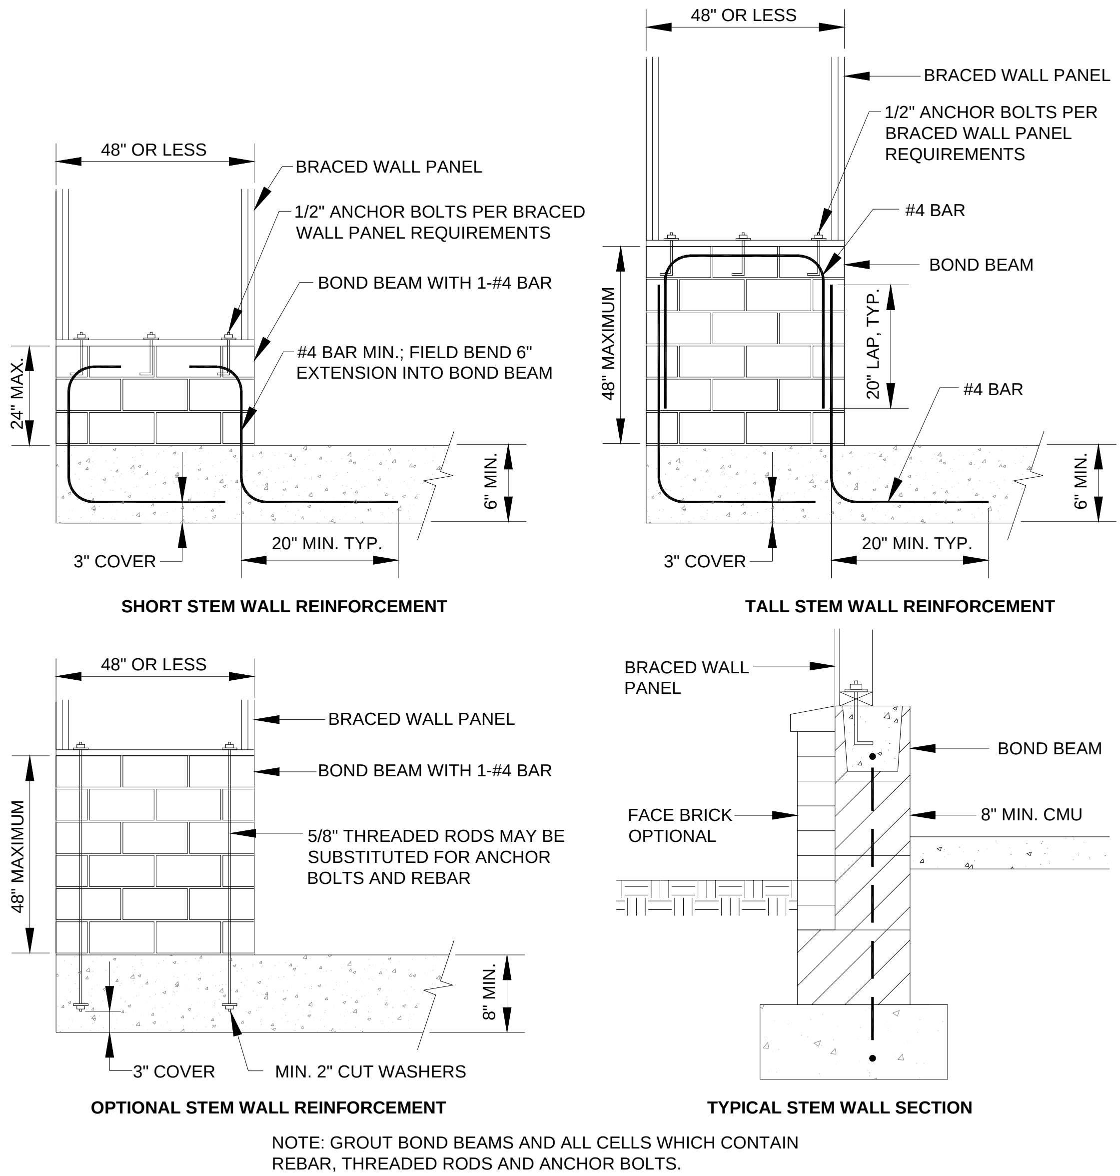
a. Methods of bracing shall be as described in Section R602.10.2 method DWB, WSP, SFB, GB, PBS, PCP OR HPS
b. Provide ventilation (not shown) per Section R806.

FIGURE R602.10.8.2(3)
BRACED WALL PANEL CONNECTION OPTION TO PERPENDICULAR RAFTERS OR ROOF TRUSSES

R602.10.9 Braced wall panel support. Braced wall panel support shall be provided as follows:

1. Cantilevered floor joists complying with Section R502.3.3 shall be permitted to support braced wall panels.
2. Elevated post or pier foundations supporting braced wall panels shall be designed in accordance with accepted engineering practice.

3. Masonry stem walls with a length of 48 inches (1220 mm) or less supporting braced wall panels shall be reinforced in accordance with Figure R602.10.9. Masonry stem walls with a length greater than 48 inches (1220 mm) supporting braced wall panels shall be constructed in accordance with Section R403.1 Methods ABW and PFH shall not be permitted to attach to masonry stem walls.
4. Concrete stem walls with a length of 48" or less, greater than 12 inches tall and less than 6 inches thick shall have reinforcement sized and located in accordance with Figure R602.10.9.



For SI: 1 in=305 mm

FIGURE R602.10.9
MASONRY STEM WALLS SUPPORTING BRACED WALL PANELS

R602.10.9.1 Braced wall panel support for Seismic Design Category D_2. In one-story buildings located in Seismic Design Category D_2, braced wall panels shall be supported on continuous foundations at intervals not exceeding 50 feet (15 240 mm). In two story buildings located in Seismic Design Category $D_{2,}$ all braced wall panels shall be supported on continuous foundations.

Exception: Two-story buildings shall be permitted to have interior braced wall panels supported on continuous foundations at intervals not exceeding 50 feet (15 240 mm) provided that:

1. The height of cripple walls does not exceed 4 feet (1219 mm).
2. First-floor braced wall panels are supported on doubled floor joists, continuous blocking or floor beams.
3. The distance between bracing lines does not exceed twice the building width measured parallel to the braced wall line.

R602.10.10 Panel joints. All vertical joints of panel sheathing shall occur over, and be fastened to common studs. Horizontal joints in braced wall panels shall occur over, and be fastened to common blocking of a minimum 1-1/2 inch (38 mm) thickness.

Exceptions:

1. Blocking at horizontal joints shall not be required in wall segments that are not counted as braced wall panels.
2. Where the length of bracing provided is at least twice the required length of bracing from Tables R602.10.3(1) and R602.10.3(3) blocking at horizontal joints shall not be required in braced wall panels constructed using Methods WSP, SFB, GB, PBS or HPS.
3. When Method GB panels are installed horizontally, blocking of horizontal joints is not required.

R602.10.11 Cripple wall bracing. In Seismic Design Categories other than D_2, cripple walls shall be braced with a length and type of bracing as required for the wall above in accordance with Tables R602.10.3(1) and R602.10.3(3) with the following modifications for cripple wall bracing:

1. The length of bracing as determined from Tables R602.10.3(1) and R602.10.3(3) shall be multiplied by a factor of 1.15, and
2. ~~The wall panel spacing shall be decreased to 18 feet (5486 mm) instead of 20 feet (7620 mm)~~ The distance between adjacent edges of braced wall panels shall be reduced from 20 feet (6096 mm) to 14 feet (4267 mm).

R602.10.11.1 Cripple wall bracing in Seismic Design Categories D_0, D_1 and D_2. In addition to the requirements of Section R602.10.11, where braced wall lines at interior walls occur without a continuous foundation below, the length of parallel exterior cripple wall bracing shall be one and one-half times the length required by Table R602.10.3(3). Where cripple walls braced using Method WSP cannot provide this additional length, the capacity of the sheathing shall be increased by reducing the spacing of fasteners along the perimeter of each piece of sheathing to 4 inches (102 mm) on center.

In Seismic Design Category D_2, cripple walls shall be braced in accordance with Tables R602.10.3(3) and R602.10.3(4).

R602.10.11.2 Redesignation of cripple walls. In any Seismic Design Category, cripple walls shall be permitted to be redesignated as the first story walls for purposes of determining wall bracing requirements. If the cripple walls are redesignated, the stories above the redesignated story shall be counted as the second and third stories respectively.

Commenter's Reason: The proposed amendments sharpen and clarify the intent of the original RB105 by moving provisions to more accessible sections and strengthening language to avoid misinterpretations. Other housekeeping included replacing story location figures, moving a requirement in footnotes to a more prominently location providing, clarifying nail/staple lengths and diameters and correcting typographical errors.

Public Comment 2:

Randall Shackelford, Simpson Strong-Tie Company requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R602.10.1.2 Offsets along a braced wall line. All exterior walls parallel to a braced wall line shall be ~~permitted to~~ offset ~~up to~~ not more than 4 feet (1219 mm) from the designated braced wall line location as shown Figure R602.10.1.1. Interior walls used as bracing shall be ~~permitted to~~ offset ~~up to~~ not more than 4 feet (1219 mm) from a braced wall line through the interior of the building as shown in Figure R602.10.1.1.

R602.10.1.3 Spacing of braced wall lines. ~~There shall be a minimum of two braced wall lines in both the longitudinal and transverse direction as shown in Figure R602.10.1.1.~~ ~~Intermediate braced wall lines through the interior of the building shall be permitted.~~ The spacing between parallel braced wall lines shall be in accordance with Table R602.10.1.3. Intermediate braced wall lines through the interior of the building shall be permitted.

(Portions of proposal not shown remain unchanged)

Commenter's Reason: This Public Comment clarifies that all exterior walls must be part of, or within 4 feet of, a braced wall line. This is to carry on the traditional wall bracing requirement that all exterior walls must be braced. The language is cleaned up to remove "permitted" language in favor of mandatory language.

When the first section is clarified to require all exterior walls to be part of a braced wall line, the first sentence of R602.10.1.3 is unnecessary, so it is deleted.

The text regarding braced wall lines at building interior is relocated to the last part of the paragraph because the primary purpose of this paragraph is to provide spacing requirements, so that should come first.

Public Comment 3:

Randall Shackelford, Simpson Strong-Tie Company, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R602.10 Wall bracing. Buildings shall be braced in accordance with this section. Where a building, or portion thereof, does not comply with one or more of the bracing requirements in this section, those portions shall be designed and constructed in accordance with Section R301.1.

R602.10.1 Braced wall lines. For the purpose of determining the amount and location of bracing required in each story level of a building, braced wall lines shall be designated as straight lines ~~on~~ in the building plan placed in accordance with this section. All exterior walls of a building shall be part of a braced wall line.

R602.10.1.1 Length of a braced wall line. The length of a braced wall line shall be the distance between its ends. The end of a braced wall line shall be the intersection with a perpendicular braced wall line, ~~or~~ an angled braced wall line as permitted in Section R602.10.1.4 or an exterior wall. ~~In the absence of an intersecting braced wall line, the end shall be the farthest exterior wall of the building~~ as shown in Figure R602.10.1.1. The end of the braced wall line shall be chosen so that the maximum length results.

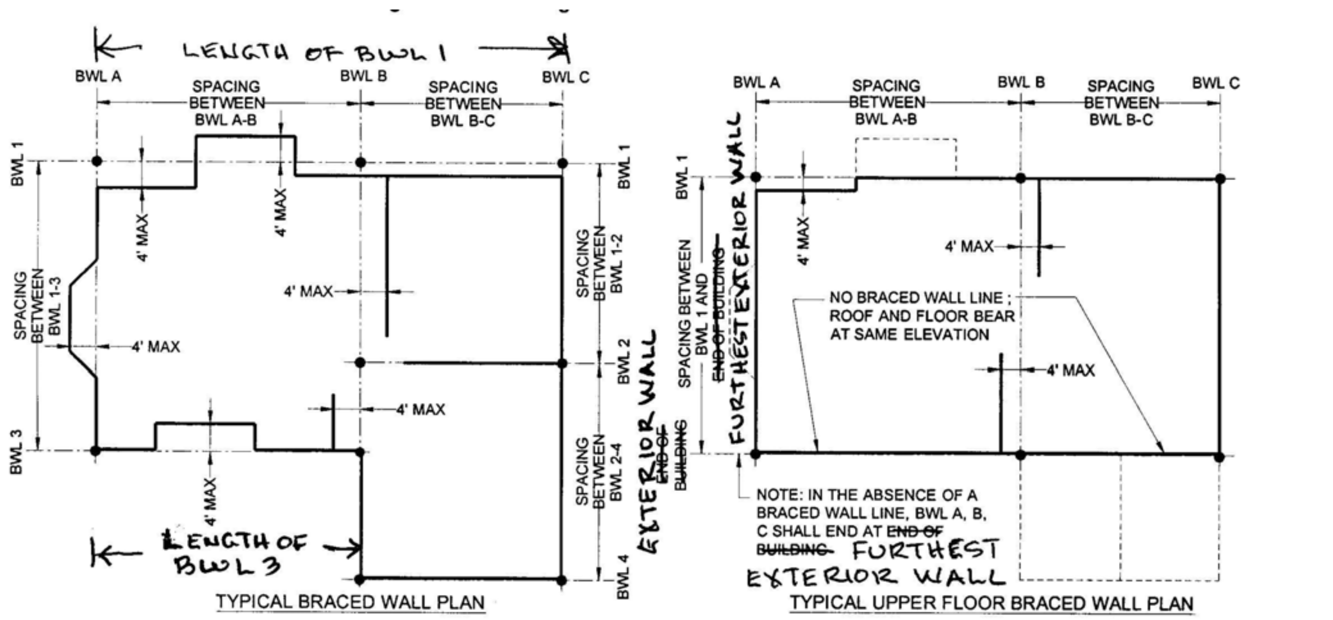


FIGURE R602.10.1.1
BRACED WALL LINES

R602.10.1.2 Offsets along a braced wall line. All exterior walls parallel to a braced wall line shall be permitted to offset up to 4 feet (1219 mm) from the designated braced wall line location as shown Figure R602.10.1.1. Interior walls used as bracing shall be permitted to offset up to 4 feet (1219 mm) from a braced wall line through the interior of the building as shown in Figure R602.10.1.1. <u>Walls that are offset in accordance with this section are permitted to count as a single braced wall line.</u>

(Portions of proposal not shown remain unchanged)

Commenter's Reason: This Public Comment achieves 4 things.

1. It maintains the requirements from past wall bracing provisions that all exterior walls shall be braces. Somehow in the drafting of the new provisions, this explicit requirement has been lost. While it may be argued that R602.10.1.2 implies that exterior walls have to have a braced wall line within 4 feet, it does not come out and say that directly. This will clarify the wall bracing provisions.
2. It clarifies that the length of the braced wall line has to be chosen so that the maximum length results. The amount of seismic bracing is still based on the length of the braced wall line, so the length of the braced wall line has to be chosen correctly. This wording ensures that the user will not choose the length of an exterior braced wall line as the intersection with in interior braced wall line when the line actually continues to the end of the wall.
3. Figure R602.10.1.1 is clarified in several ways. First, this figure supposedly goes with Section R602.10.1.1, which describes the length of braced wall lines, but the figure does not say anything about the length of braced wall lines. Two dimensions are added to illustrate choosing the length of braced wall lines. Second, the wording "End of building" is changed to "Exterior Wall" and "Furthest Exterior Wall" to be consistent with the wording in the Section.
4. Language is added to the offset section to clarify that walls that meet the offset requirement are permitted to count as one wall. Otherwise, the user could count two walls with an offset of less than 8 feet as two single walls, when the intent is to count them as one wall.

Public Comment 4:

Maureen Traxler, City of Seattle Department of Planning & Development, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

<u>TABLE R602.10.3(4)</u>
<u>SEISMIC ADJUSTMENT FACTORS TO THE REQUIRED LENGTH OF WALL BRACING</u>

ADJUSTMENT BASED ON:	STORY/ SUPPORTING	CONDITION	ADJUSTMENT FACTOR a,b (Multiply length from Table R602.10.3(1) by this factor)	APPLICABLE METHODS
Story height (Section 301.3)	Any story	≤ 10 ft	1.0	All methods
		>10 ft <u>and</u> ≤ 12 ft	1.2	
Braced wall line spacing, townhouses in SDC C	Any story	≤ 35 ft	1	
		>35 ft <u>and</u> ≤ 50 ft	1.43	

Braced wall line spacing, in SDC D0, D1, D2[c]	Any story	>25 ft and ≤ 30 ft	1.2	
		>30 ft and ≤ 35 ft	1.4	
Wall dead load	Any story	> 8 ft and < 15 ft	1	
		<8 psf	0.85	
Roof/ceiling dead load for wall supporting	Roof only or roof plus one or two stories	<15 psf	1.0	
	Roof only	>15 psf and ≤ 25 psf	1.2	
	Roof plus one or two stories	>15 psf and ≤ 25 psf	1.1	
Walls with stone or masonry veneer	Any story	See Section R703.7		
Interior gypsum board finish (or equivalent)	Any story	Omitted from inside face of braced wall panels	1.5	DWB, WSP, SFB, PBS, PCP, HPS, CS-WSP, CS-G, CS-SFB

(Portions of proposal not shown remain unchanged)

Commenter's Reason: Editorial clarification to show lower and upper limits must both be satisfied.

Final Action: AS AM AMPC____ D

RB106-09/10

R602.9, Table R602.10.1.2(2), R602.10.9, R602.10.9.1, R602.10.9.2, R602.10.9.3, R602.11.2

Proposed Change as Submitted

Proponent: Chuck Bajnai, Chesterfield County, VA, Chairman, ICC Ad-Hoc Committee on Wall Bracing

1. Revise as follows:

R602.9 Cripple walls. Foundation cripple walls shall be framed of studs not smaller than the studding above. When exceeding 4 feet (1219 mm) in height, such walls shall be framed of studs having the size required for an additional *story*.

Cripple walls with a stud height less than 14 inches (356 mm) shall be continuously sheathed on ~~at least~~ one side with ~~a~~ wood structural panels ~~that is~~ fastened to both the top and bottom plates in accordance with Table R602.3(1), or the cripple walls shall be constructed of solid blocking.

All cripple walls shall be supported on continuous foundations.

TABLE R602.10.1.2(2)[a, b, c]

(Portions of table not shown remain unchanged)

R602.10.9 Cripple wall bracing. ~~In Seismic Design Categories other than D2, cripple walls shall be braced with a length and type of bracing as required for the wall above in accordance with Tables R602.10.1.2(1) and R602.10.1.2(2) with the following modifications for cripple wall bracing:~~ Cripple walls shall be constructed in accordance with Section R602.9 and braced in accordance with this section. Cripple walls shall be braced with the length and method of bracing used for the wall above in accordance with Tables R602.10.1.2(1) and R602.10.1.2(2), except that the length of cripple wall bracing shall be multiplied by a factor of 1.15.

1. ~~The length of bracing as determined from Tables R602.10.1.2(1) and R602.10.1.2(2) shall be multiplied by a factor of 1.15, and~~
2. ~~The wall panel spacing shall be decreased to 18 feet (5486 mm) instead of 25 feet (7620 mm).~~

2. Delete and substitute as follows:

~~**R602.10.9.1 Cripple wall bracing in Seismic Design Categories D0, D1 and D2.** In addition to the requirements of Section R602.10.9, where *braced wall lines* at interior walls occur without a continuous foundation below, the length of parallel exterior cripple wall bracing shall be 11/2 times the length required by Tables R602.10.1.2(1) and R602.10.1.2(2). Where cripple walls braced using Method WSP of Section R602.10.2 cannot provide this additional length, the capacity of the sheathing shall be increased by reducing the spacing of fasteners along the perimeter of each piece of sheathing to 4 inches (102 mm) on center. In Seismic Design Category D2, cripple walls shall be braced in accordance with Tables R602.10.1.2(1) and R602.10.1.2(2).~~

R602.10.9.1 Cripple wall bracing for Seismic Design Categories D_0, D_1 and townhouses in Seismic Design Category C. In addition to the requirements in Section R602.10.9, braced wall panels for cripple walls shall be located no more than 18 feet (5486 mm) on center along a braced wall line.

Where braced wall lines at interior walls are not supported on a continuous foundation below, the adjacent parallel cripple walls, where provided, shall be braced with Method WSP per Section R602.10.2 or Method CS-WSP per Section R602.10.4. The length of bracing required per Table R602.10.1.2(2) for the cripple walls shall be multiplied by 1.5. Where the cripple walls do not have sufficient length to provide the required bracing, the spacing of panel edge fasteners shall be reduced to 4 inches (102 mm) on center and the required bracing length adjusted by 0.7. If the required length can still not be provided, the cripple wall shall be designed in accordance with accepted engineering practice.

R602.10.9.2 Cripple wall bracing for Seismic Design Category D_2. In Seismic Design Category D_2, cripple walls shall be braced in accordance with Tables R602.10.1.2(1) and R602.10.1.2(2).

3. Revise as follows:

R602.10.9.~~2~~3 Redesignation of cripple walls. ~~In any Seismic Design Category,~~ Where all cripple wall segments along a braced wall line do not exceed 48 inches in height, the cripple walls shall be permitted to be redesignated as ~~the~~ a first *story* wall~~s~~ for purposes of determining wall bracing requirements. Where any cripple wall segment in a braced wall line exceeds 48 inches in height, the entire cripple wall shall be counted as an additional story. If the cripple walls are redesignated, the stories above the redesignated *story* shall be counted as the second and third stories, respectively.

R602.11.2 Stepped foundations in Seismic Design Categories D_0, D_1 and D_2. In all buildings located in Seismic Design Categories D_0, D_1 or D_2, where the height of a required *braced wall line* that extends from foundation to floor above varies more than 4 feet (1219 mm), the *braced wall line* shall be constructed in accordance with the following:

1. Where the lowest floor framing rests directly on a sill bolted to a foundation not less than 8 feet (2440 mm) in length along a line of bracing, the line shall be considered as braced. The double plate of the cripple stud wall beyond the segment of footing that extends to the lowest framed floor shall be spliced by extending the upper top plate a minimum of 4 feet (1219 mm) along the foundation. Anchor bolts shall be located a maximum of 1 foot and 3 feet (305 and 914 mm) from the step in the foundation. See Figure R602.11.2.
2. Where cripple walls occur between the top of the foundation and the lowest floor framing, the bracing requirements of Sections R602.10.9, ~~and~~ R602.10.9.1 and R602.10.9.2 shall apply.
3. Where only the bottom of the foundation is stepped and the lowest floor framing rests directly on a sill bolted to the foundations, the requirements of Sections R403.1.6 and R602.11.1 shall apply.

Reason: This proposal clarifies and coordinates the basic cripple wall provisions in Section R602.9 and the cripple wall bracing provisions in Section R602.10.9.

The changes to Section R602.9 are largely editorial. The apparent intent of the provisions for cripple walls shorter than 14" is to require solid blocking or continuous sheathing. However, the current language calls for "a structural panel". Taken literally, that calls for one single sheet of plywood or OSB to be placed on the wall. The language is revised to clarify the apparent intent. Also, the continuous foundation requirement is moved to its own paragraph, as it clearly is intended to apply to all cripple walls, not just 14" and shorter ones.

The 75% minimum WSP bracing requirement for cripple walls in SDC D2 was mistakenly deleted from the reformatted seismic bracing table and is restored to Table R602.10.1.2(2). Consistent with the revisions last cycle, the percentage is converted into a foot length. The 15% reduction for continuous sheathing is also applied.

Section R602.10.9 and R609.10.9.1 are revised to divide the requirements into low-seismic (i.e. governed by wind) and high-seismic sections. The same calculation method and spreadsheet the ICC Ad-Hoc Wall Bracing Committee used to define the wind bracing table, was used to verify that the 1.15x multiplier is accurate for the wind bracing case as well as the seismic bracing case. The 18 foot braced wall panel spacing limit is applied only for high-seismic. There is no documentation of cripple wall failures in wind events, as there is for seismic events. Thus there is no technical justification to apply the additional limit for wind bracing.

The provisions regarding braced wall lines on interior walls not supported on continuous foundations are clarified. The 50% increase in bracing is applied to the adjacent cripple walls. It is noted these walls could potentially be either exterior or interior walls. Also, a complex house plan may have exterior cripple walls that are not adjacent to the unsupported wall (e.g. on an attached garage, den, or other feature) and do not inherit seismic loads from the unsupported wall. It would not then make sense to increase the bracing for those walls. Furthermore, it is clarified that the bracing for the adjacent cripple walls can be either Method WSP or Method CS-WSP. Finally, a specific factor is provided for the increased strength provided by the reduction to 4" edge nailing. Of course, for some plans, the reduction may still result in a required bracing length that exceeds the total length of the cripple wall. Obviously, an engineered solution would be required in that case,

The provision on re-designation of cripple walls is amended to require exterior cripple walls exceeding 48" in height to be considered a story. This is consistent with the calculation performed above to verify the 1.15 multiplier. The increase in bracing for taller cripple walls would begin to approach, and finally equal, the difference in bottom-floor bracing from the addition of a story. Thus, it would make sense to automatically re-designate these taller cripple walls as a story. This will also help clarify the determination of bracing for houses on sloped sites, where figuring out the bracing for the cripple walls occurring on the walls parallel to the slope has been an issue.

Finally, the section references in R602.11.2 are revised to include R602.10.9.2.

Cost Impact: The code change proposal may increase the cost of construction for houses with cripple walls exceeding 48" in height..

ICCFILENAME: BAJNAI-AHWB-RB-3-R602.9-R602.10-R602.11

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: This change adds needed changes and adds clarifying changes to the cripple wall bracing section and into the table for bracing requirements based on Seismic Design Categories.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Charles S. Bajnai, VBCOA and Chesterfield County, VA, representing ICC Ad-Hoc Committee on Wall Bracing, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R602.10.9.1 Cripple wall bracing for Seismic Design Categories D_0, D_1 and townhouses in Seismic Design Category C. In addition to the requirements in Section R602.10.9, the distance between adjacent edges of braced wall panels for cripple walls along a braced wall line shall be 14 feet (4267 mm) maximum ~~located no more than 18 feet (5486 mm) on center along a braced wall line~~.

(Portions of proposal not shown remain unchanged)

Commenter's Reason: The ICC Ad-Hoc Wall Bracing Committee determined that using a maximum distance between adjacent edges of braced wall panels on a braced wall line as the controlling limit for braced wall panel spacing is easier to apply and enforce than using a maximum center-to-center distance. Using the distance between adjacent edges better accommodates braced wall segments greater than 48" in length. The revised language above mirrors the language in Section R602.10.2.2 of RB105-09/10 that was approved at the Baltimore hearings.

Final Action: AS AM AMPC____ D

RB109-09/10

R602.10.6.2, Figure R602.10.6.2(2), Figure R602.10.6.2(3)

Proposed Change as Submitted

Proponent: Gary Ehrlich, National Association of Home Builders (NAHB)

1. Revise as follows:

R602.10.6.2 Connections to roof framing. ~~Exterior *braced wall panels* shall be connected to roof framing as follows.~~

~~1.~~ ~~Parallel rafters or roof trusses shall be attached to the top~~ Top plates of exterior *braced wall panels* shall be attached to rafters or roof trusses above in accordance with Table R602.3(1) and this section. Where required by this section, blocking between rafters or roof trusses shall be attached to top plates of *braced wall panels* and to rafters and roof trusses in accordance with Table R602.3(1). A continuous band, rim, or header joist or roof truss parallel to the *braced wall panels* shall be permitted to replace the blocking required by this section.

Blocking shall not be required over openings in continuously-sheathed *braced wall lines*. In addition to the requirements of this section, lateral support shall be provided for rafters and ceiling joists in accordance with Section R802.8 and for trusses in accordance with Section R802.10.3. Roof ventilation shall be provided in accordance with R806.1. .

~~2~~ 1. For SDC A, B and C and wind speeds less than 100 miles per hour (45 m/s), where the distance from the top of the *braced wall panel* to the top of the rafters or roof trusses above ~~and perpendicular top plates~~ is 91/4 inches (235 mm) or less, ~~the rafters or roof trusses shall be connected to the top plates of *braced wall lines* in accordance with Table R602.3(1) and~~ blocking between rafters or roof trusses shall ~~need~~ not be ~~installed~~ required. Where the distance from the top of the *braced wall panel* to the top of the rafters above ~~and perpendicular top plates~~ is between 91/4 inches (235 mm) and 151/4 inches (387 mm) ~~the rafters shall be connected to the top plates of *braced wall panels* with~~ blocking between rafters shall be provided above the *braced wall panel* in accordance with Figure R602.10.6.2(1) ~~and attached in accordance with Table R602.3(1)~~. Where the distance from the top of the *braced wall panel* to the top of the roof trusses ~~and perpendicular top plates~~ above is between 91/4 inches (235 mm) and 151/4 inches (387 mm) ~~the roof trusses shall be connected to the top plates of *braced wall panels* with blocking in accordance with Table R602.3(1)~~ lateral load transfer shall be provided in accordance with Section R802.10.3.

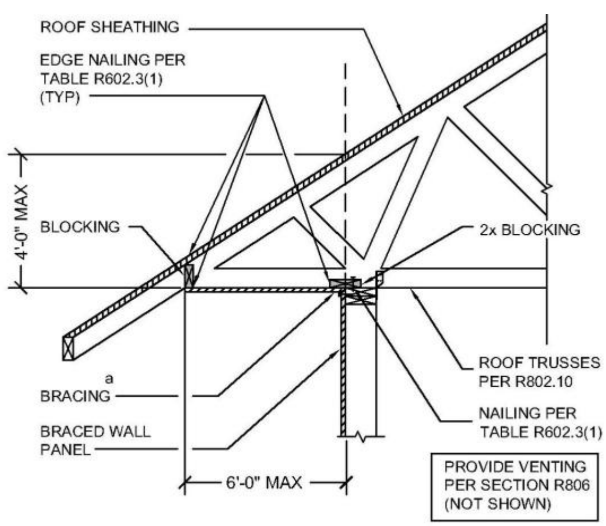
~~3~~ 2. For SDC D_0, D_1 and D_2 or wind speeds of 100 miles per hour (45 m/s) or greater, where the distance ~~between~~ from the top of the *braced wall panel* to the top of the rafters or roof trusses ~~and perpendicular top plates~~ is 151/4 inches (387 mm) or less, ~~rafters or roof trusses shall be connected to the top plates of *braced wall panels* with~~ blocking between rafters or roof trusses shall be provided above the *braced wall panel* in accordance with Figure R602.10.6.2(1) ~~and attached in accordance with Table R602.3(1)~~.

~~4~~ 3. ~~For all seismic design categories and wind speeds,~~ Where the distance ~~between~~ from the top of the *braced wall panel* to the top of the rafters or roof trusses ~~and perpendicular top plates~~ exceeds 151/4 inches (387 mm), ~~perpendicular rafters or roof trusses shall be connected to~~ the top plates of the *braced wall panels* shall be connected to perpendicular rafters or roof trusses above in accordance with one or more of the following methods:

- ~~4~~ 3.1. Soffit blocking panels constructed in accordance with Figure R602.10.6.2(2),
- ~~4~~ 3.2. Vertical blocking panels constructed in accordance with Figure R602.10.6.2(3),
- ~~4~~ 3.3. ~~With f~~Full -height engineered blocking panels designed ~~for values listed in~~ per the AF&PA WFCM ~~American Forest and Paper Association (AF&PA) Wood Frame Construction Manual for One- and Two-Family Dwellings (WFCM). Both the roof and floor sheathing shall be attached to the blocking panels in accordance with Table R602.3(1)~~.
- ~~4~~ 3.4. Blocking, blocking panels, or other methods of lateral load transfer ~~Designed~~ designed in accordance with accepted engineering ~~methods~~ practice.

~~Lateral support for the rafters and ceiling joists shall be provided in accordance with Section R802.8. Lateral support for trusses shall be provided in accordance with Section R802.10.3. Ventilation shall be provided in accordance with Section R806.1.~~

Replace Figure R602.10.6.2(2) with the following:



a. Methods of bracing shall be as described in Section R602.10.1.1~~R602.10.2 method DWB, WSP, SFB, GB, PBS, PCP OR HPS~~
For SI: 1 inch = 25.4 mm.

FIGURE R602.10.6.2(2)

BRACED WALL PANEL CONNECTION OPTION TO PERPENDICULAR RAFTERS OR ROOF TRUSSES

3. Replace Figure R602.10.6.2(3) with the following:

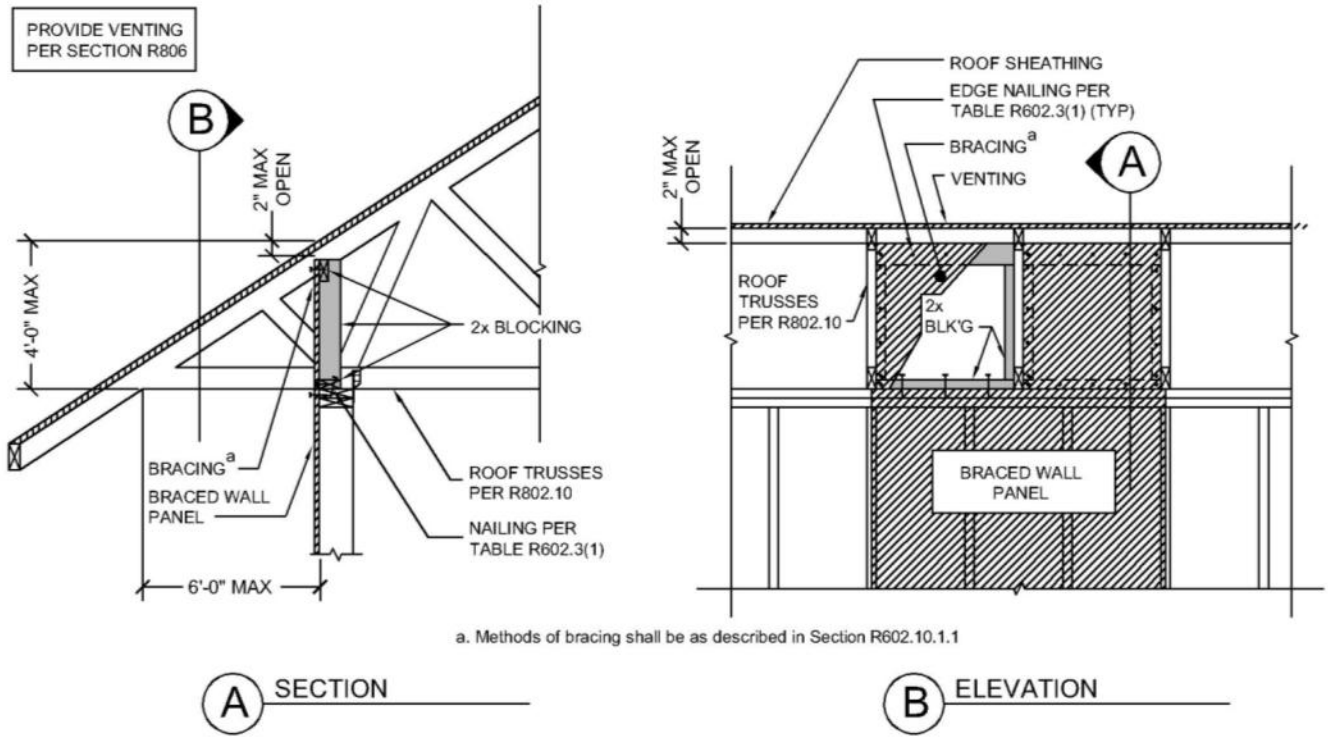


FIGURE R602.10.6.2(3)
BRACED WALL PANEL CONNECTION OPTION TO PERPENDICULAR RAFTERS OR ROOF TRUSSES

Reason: The purpose of this proposal is to amend and simplify the language for blocking between roof rafters and trusses over braced wall panels added during the 2007-2008 Code Development Cycle. The 2009 IRC language is incomprehensible and will create an enforcement nightmare. The change is primarily editorial, although minor technical changes have been introduced.

The terminology in the original code change is often unclear. Terms such as "parallel rafters or roof trusses" and "perpendicular top plates" leave it unclear as to what the framing members or top plates are parallel or perpendicular to. The statement that "blocking need not be installed" is permissive language. The text can even be taken to read that the BLOCKING is what's used to connect the rafter/truss to the top plate. To simplify the requirements, all of the references to "parallel" or "perpendicular" are removed, and the multiple references to Table R602.3(1) replaced with one comprehensive reference in the opening paragraph. Further, since this is the wall section, the blocking requirements and triggers are flipped so the braced wall panel is the point of reference, not the roof framing.

Language allowing a continuous rim board, rim joist, or truss in lieu of the blocking is added. This allows the distinction between "parallel" and "perpendicular" to be removed throughout the proposal, since providing a continuous member over the braced wall panels will be the obvious solution where roof framing direction is parallel to the panels and the framing depth is deep enough to require blocking.

Figures R602.10.6.2(2) and R602.10.6.2(3) are extensively revised. The details are clarified to indicate the blocking panel is only required at the braced wall panels, not along the entire braced wall line. The list of allowable methods is revised to point to Section R602.10.1.1, which includes all the allowable intermittent and continuous bracing methods, including the various alternate narrow wall panels and portal frames. Finally, the reference to "pre-engineered trusses" is replaced with a reference to R802.10, since roof trusses under the IRC are not required to be designed by an engineer.

NAHB asks for your support of this proposal.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: EHRLICH-RB-12-R602.10.6.2

Public Hearing Results

Committee Action: **Approved as Modified**

Modify the proposal as follows:

R602.10.6.2 Connections to roof framing. Top plates of exterior *braced wall panels* shall be attached to rafters or roof trusses above in accordance with Table R602.3(1) and this section. Where required by this section, blocking between rafters or roof trusses shall be attached to top plates of *braced wall panels* and to rafters and roof trusses in accordance with Table R602.3(1). A continuous band, rim, or header joist or roof truss parallel to the *braced wall panels* shall be permitted to replace the blocking required by this section. Blocking shall not be required over openings in continuously-sheathed *braced wall lines*. In addition to the requirements of this section, lateral support shall be provided for rafters and ceiling joists in accordance with Section R802.8 and for trusses in accordance with Section R802.10.3. Roof ventilation shall be provided in accordance with R806.1.

1. For SDC A, B and C and wind speeds less than 100 miles per hour (45 m/s), where the distance from the top of the *braced wall panel* to the top of the rafters or roof trusses above is 91/4 inches (235 mm) or less, blocking between rafters or roof trusses shall not be required. Where the distance from the top of the *braced wall panel* to the top of the rafters or roof trusses above is between 91/4 inches (235 mm) and 151/4 inches (387 mm) blocking between rafters or roof trusses shall be provided above the *braced wall panel* in accordance with Figure R602.10.6.2(1). ~~Where the distance from the top of the braced wall panel to the top of the roof trusses above is between 9 1/4 inches and 15 1/4 inches lateral load transfer shall be provided in accordance with Section R802.10.3.~~
2. For SDC D_0, D_1 and D_2 or wind speeds of 100 miles per hour (45 m/s) or greater, where the distance from the top of the *braced wall panel* to the top of the rafters or roof trusses is 151/4 inches (387 mm) or less, blocking between rafters or roof trusses shall be provided above the *braced wall panel* in accordance with Figure R602.10.6.2(1).
3. Where the distance from the top of the *braced wall panel* to the top of the rafters or roof trusses exceeds 151/4 inches (387 mm), the top plates of the *braced wall panel~~s~~* shall be connected to perpendicular rafters or roof trusses above in accordance with one or more of the following methods:
   3.1. Soffit blocking panels constructed in accordance with Figure R602.10.6.2(2),
   3.2. Vertical blocking panels constructed in accordance with Figure R602.10.6.2(3),
   3.3. Full -height engineered blocking panels designed in accordance with the AF&PA WFCM.
   3.4. Blocking, blocking panels, or other methods of lateral load transfer designed in accordance with accepted engineering practice.

(Portions of proposal not shown remain unchanged)

Committee Reason: The committee feels this change simplifies the language and addresses the requirements for rafters and trusses. The modification aligns the blocking requirements for trusses with the blocking requirement for rafters.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Steven Winkel, FAIA, P.E., and Kelly Cobeen, P.E., S.E., Building Seismic Safety Council of the National Institute of Building Sciences, representing Federal Emergency Management Agency/Building Seismic Safety Council Code Resource Support Committee (FEMA/BSSC CRSC), request Approval as Modified by this Public Comment.

Further modify the proposal as follows:

R602.10.6.2 Connections to roof framing. Top plates of exterior braced wall panels shall be attached to rafters or roof trusses above in accordance with Table R602.3(1) and this section. Where required by this section, blocking between rafters or roof trusses shall be attached to top plates of braced wall panels and to rafters and roof trusses in accordance with Table R602.3(1). A continuous band, rim, or header joist or roof truss parallel to the braced wall panels shall be permitted to replace the blocking required by this section.
Blocking shall not be required over openings in continuously-sheathed braced wall lines. In addition to the requirements of this section, lateral support shall be provided for rafters and ceiling joists in accordance with Section R802.8 and for trusses in accordance with Section R802.10.3. Roof ventilation shall be provided in accordance with R806.1.

1. For SDC A, B and C and wind speeds less than 100 miles per hour (45 m/s), where the distance from the top of the braced wall panel to the top of the rafters or roof trusses above is 91/4 inches (235 mm) or less, blocking between rafters or roof trusses shall not be required. Where the distance from the top of the braced wall panel to the top of the rafters or roof trusses above is between 91/4 inches (235 mm) and 151/4 inches (387 mm) blocking between rafters or roof trusses shall be provided above the braced wall panel in accordance with Figure R602.10.6.2(1)
2. For SDC D0, D1 and D2 or wind speeds of 100 miles per hour (45 m/s) or greater, where the distance from the top of the braced wall panel to the top of the rafters or roof trusses is 151/4 inches (387 mm) or less, blocking between rafters or roof trusses shall be provided over the full length of the braced wall line ~~above the braced wall panel~~ in accordance with Figure R602.10.6.2(1).
3. Where the distance from the top of the braced wall panel to the top of the rafters or roof trusses exceeds 151/4 inches (387 mm), the top plates of the braced wall panels shall be connected to perpendicular rafters or roof trusses over the full length of the braced wall line ~~above~~ in accordance with one or more of the following methods:
   3.1. Soffit blocking panels constructed in accordance with Figure R602.10.6.2(2),
   3.2. Vertical blocking panels constructed in accordance with Figure R602.10.6.2(3),
   3.3. Full -height engineered blocking panels designed in accordance with the AF&PA WFCM.
   3.4. Blocking, blocking panels, or other methods of lateral load transfer designed in accordance with accepted engineering practice.

(Portion of proposal not shown remain unchanged)

Commenter's Reason: The purpose of these blocking panels is to transfer seismic and wind loads from the roof to the wall below. The addition of a 2-inch gap between the top of blocking and the roof sheathing above reduces the strength and capacity of the roof system and the connection. There is not adequate research available to demonstrate that the reduced strength and stiffness are sufficient when blocking is limited to the length of the braced wall panel. Extension of the blocking over the full wall line length replicates common existing construction that has a history of adequate performance.

Final Action: AS AM AMPC____ D

RB111-09/10
R602.10, R602.12 (New)

Proposed Change as Submitted

Proponent: Chuck Bajnai, Chesterfield County, VA, Chairman, ICC Ad-Hoc Committee on Wall Bracing

1. Revise as follows:

R602.10 Wall bracing. Buildings shall be braced in accordance with this section or, when applicable, Section R602.12. Where a building, or portion thereof, does not comply with one or more of the bracing requirements in this section, those portions shall be designed and constructed in accordance with Section R301.1.

> **Exception:** Detached one- and two-family *dwellings* located in Seismic Design Category C are exempt from the seismic bracing requirements of this section. Wind speed provisions for bracing shall be applicable to detached one- and two-family *dwellings*.

2. Add new section as follows:

R602.12 Simplified wall bracing. Buildings meeting all of the conditions listed below shall be permitted to be braced in accordance with this section as an alternate to the requirements of Section R602.10.

1. A rectangle circumscribing the entire enclosed building, as shown in Figure R602.12.3, shall have no side longer than 60 feet (18 288 mm), and the ratio between the long side and short side shall be a maximum of 3:1.
2. There shall be no more than two stories above the top of a concrete or masonry foundation or basement wall. Permanent wood foundations shall not be permitted.
3. Floors shall not cantilever more than 24 inches (607 mm) beyond the foundation or bearing wall below.
4. Wall height shall not be greater than 10 feet (2743 mm).
5. Interior walls shall not contribute toward bracing required in this section.
6. The building shall have a roof eave-to-ridge height of 15 feet (4572 mm) or less.
7. All exterior walls shall have gypsum board with a minimum thickness of 1/2 inches (12.7 mm) installed on the interior side fastened in accordance with Table R702.3.5.
8. The structure shall be located where the basic wind speed is less than or equal to 90 mph (40 m/s), and the Exposure Category is A or B.
9. The structure shall be located in Seismic Design Category of A, B or C for detached one- and two-family dwellings or Seismic Design Category A or B for townhouses.
10. Cripple walls shall not be permitted in two-story buildings.

When the bracing described in this section is used, the use of other bracing provisions of R602.10, except as specified herein, shall not be permitted.

R602.12.1 Sheathing materials. The following sheathing materials installed on the exterior side of exterior walls shall be used to construct a bracing unit as defined in Section R602.12.2. Mixing materials is prohibited.

1. Wood structural panels with a minimum thickness of 3/8 inch (9.5 mm) fastened in accordance with Table R602.3(3).
2. Structural fiberboard sheathing with a minimum thickness of 1/2 inch (12.7 mm) fastened in accordance with Table R602.3(1).

R602.12.2 Bracing unit. A bracing unit shall be a full-height sheathed segment of the exterior wall with no openings and a minimum length as specified below.

1. When all framed portions of all exterior walls are continuously sheathed in accordance with Section R602.12.1, Including areas between bracing units, above and below openings and on gable end walls, the minimum length of a bracing unit shall be 3 feet (914 mm).
2. When the exterior walls are braced with intermittent sheathing in accordance with Section R602.12.1 and infilled with other materials, the minimum length of a bracing unit shall be 4 feet (1219 mm).

R602.12.2.1 Multiple bracing units. Segments of wall compliant with Section R602.12.2 and longer than the minimum bracing unit length shall be considered as multiple bracing units. The number of bracing units shall be determined by dividing the wall segment length by the minimum bracing unit length. The number of bracing units provided by one or more compliant wall segments shall be added together and rounded down to the nearest whole number. Full-height sheathed segments of wall shorter than the minimum bracing unit length shall not contribute toward a bracing unit except as specified in Section R602.12.6.1.

R602.12.3 Number of bracing units. The number of bracing units required along each side of a building shall be determined by circumscribing a rectangle around the entire enclosed building for each story level as shown in Figure R602.12.3. Each side of the rectangle shall have, at a minimum, the number of bracing units per Table R602.12.3 placed on the parallel exterior walls facing the side of the rectangle. Bracing units shall then be placed using the distribution requirements specified in Section R602.12.4. Mixing intermittent and continuous sheathing shall not be permitted.

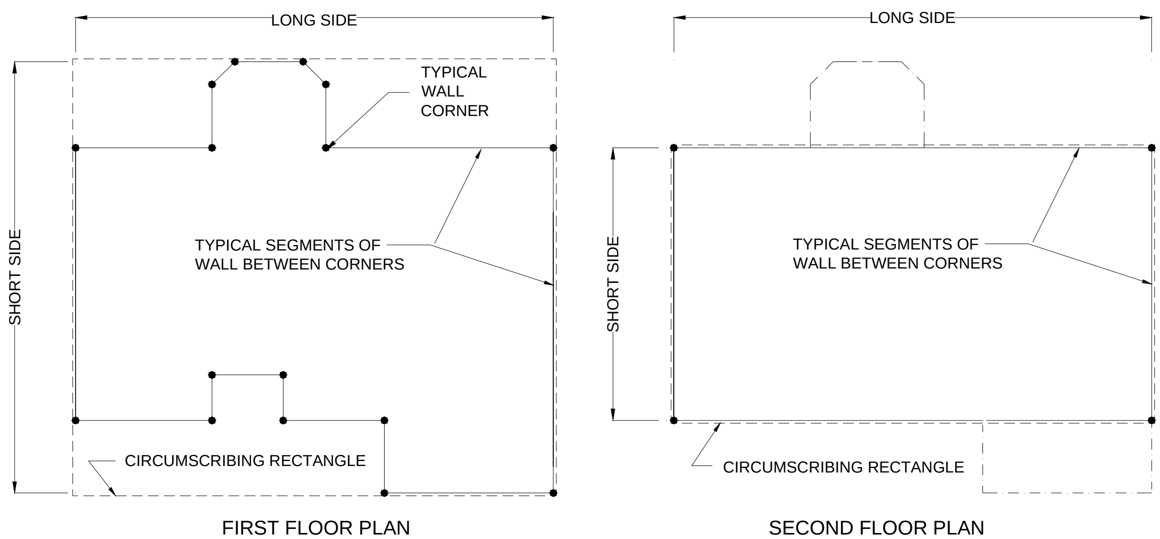

FIGURE R602.12.3

MINIMUM NUMBER OF BRACING UNITS ON
EACH SIDE OF A CIRCUMSCRIBED RECTANGLE

STORY LEVEL		EAVE-TO RIDGE HEIGHT (FEET)	MINIMUM NUMBER OF BRACING UNITS ON EACH LONG SIDE [a,b]						MINIMUM NUMBER OF BRACING UNITS ON EACH SHORT SIDE [a,b]					
			Length of short side (ft) [c]						Length of long side (ft) [c]					
			10	20	30	40	50	60	10	20	30	40	50	60
	One-story house or second floor of a two-story	10	1	2	2	2	3	3	1	2	2	2	3	3
	First floor of a two-story house	10	2	3	3	4	5	6	2	3	3	4	5	6
	One-story house or second floor of a two-story	15	1	2	3	3	4	4	1	2	3	3	4	4
	First floor of a two-story house	15	2	3	4	5	6	7	2	3	4	5	6	7

For SI: 1 ft = 304.8 mm
a. Interpolation shall not be permitted.
b. Cripple walls or wood-framed basement walls in a walk-out condition of a one-story structure shall be designed as the first floor of a two-story house.
c. Actual lengths of the sides of the circumscribed rectangle shall be rounded to the next highest unit of 10 when using this table.

R602.12.4 Distribution of bracing units. The placement of bracing units on exterior walls shall meet all of the following requirements as shown in Figure R602.12.4.

1. A bracing unit shall begin no more than 12 feet (3658 mm) from any wall corner.
2. The distance between adjacent edges of two bracing units shall be no greater than 20 feet (6096 mm).
3. Segments of wall greater than 8 feet (2438 mm) in length shall have a minimum of one bracing unit.

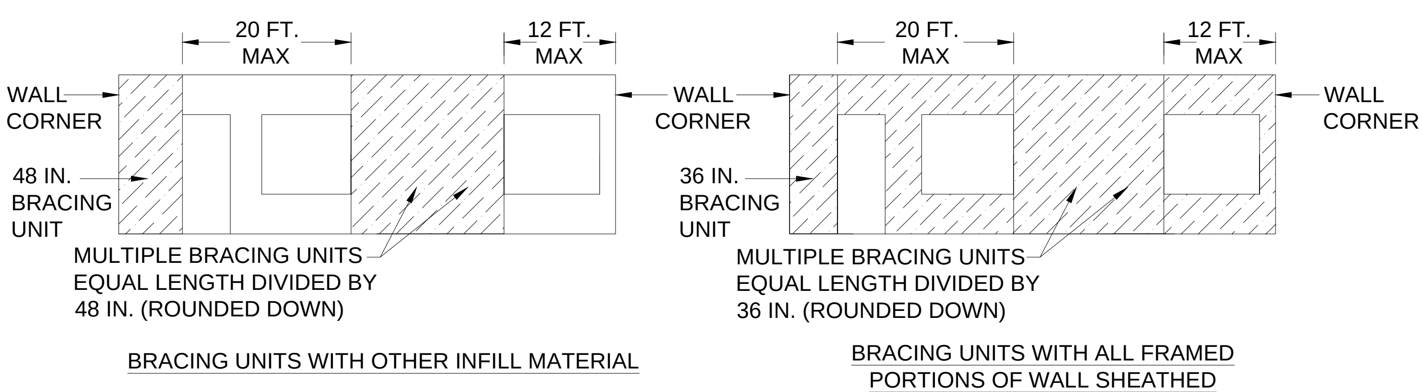

FIGURE R602.12.4
BRACING UNIT DISTRIBUTION

R602.12.5 Narrow panels. The bracing methods referenced in Section R602.10 and specified in Sections R602.12.5.1 through R602.12.5.3 shall be permitted when using simplified wall bracing.

R602.12.5.1 Method CS-G. Braced wall panels constructed as Method CS-G in accordance with Tables R602.10.4.1. and R602.10.4.2 shall be permitted for single story garages when all framed portions of all exterior walls are sheathed with wood structural panels. Each CS-G panel shall be equivalent to 0.5 of a bracing unit. Segments of wall which include a Method CS-G panel shall meet the requirements of Section R602.10.4.4.

R602.12.5.2 Method CS-PF. Braced wall panels constructed as Method CS-PF in accordance with Section R602.10.4.1.1 shall be permitted when all framed portions of all exterior walls are sheathed with wood structural panels. Each CS-PF panel shall equal 0.5 bracing units. A maximum of four CS-PF panels shall be permitted on all the segments of walls parallel to each side of the circumscribed rectangle. Segments of wall which include a Method CS-PF panel shall meet the requirements of Section R602.10.4.4.

R602.12.5.3 Methods PFH and PFG. Braced wall panels constructed as Method PFH and PFG shall be permitted when bracing units are constructed using wood structural panels. Each PFH and panel shall equal one bracing unit, and each PFG shall be equal to 0.75 bracing units.

R602.12.6 Lateral support. For bracing units located along the eaves, the vertical distance from the outside edge of the top wall plate to the roof sheathing above shall not exceed 9.25 inches (235 mm) at the location of a bracing unit unless lateral support is provided in accordance with Section R602.10.6.2.

R602.12.7 Stem walls. Masonry stem walls with a height and length of 48 inches (1219 mm) or less supporting a bracing unit or a Method CS-G, CS-PF or PFG braced wall panel shall be constructed in accordance with Figure R602.10.7. Concrete stem walls with a length of 48" or less, greater than 12 inches tall and less than 6 inches thick shall be reinforced sized and located in accordance with Figure R602.10.7

Reason: As the wall bracing section evolved, it has become more universal and flexible, but, as a result, it has grown in size and complexity. After the Ad Hoc committee's "engineering" work was complete and integrated into the 2009 IRC, we heard back from end users that this section of the code was extremely challenging. The committee therefore wanted to focus on making the 2012 IRC easier to read, easier to understand and easier to use.

The Ad Hoc committee strove to provide an easy, prescriptive procedure that would serve most users throughout the country. We defined the "majority of the country" as users in the 90 mph and SDC A and B areas.

The Committee developed a quick, prescriptive approach for those homes that fall within certain limitations. This simplified approach:

1. Eliminated all of the extra text provisions required for high seismic areas,
2. Eliminated the requirement for braced wall lines,
3. Quantified the amount of bracing using a simple table, and
4. Eliminated from the text the less-often utilized (and frequently the most verbose) bracing methods and concentrated on the most common bracing materials.

Simplified wall bracing incorporates intermittent and continuous sheathing methods (wood structural panels and structural fiberboard), but defines a braced wall panel and its minimum length as a "bracing unit." The minimum number of bracing units is determined by first drawing a rectangle around the building and then using its dimensions to select the total bracing from Table R602.12.3. Bracing units are also required to be placed per the distribution requirements in Section R602.12.4

This simplified method is intended as one easier to use option. Where homes do not qualify because they are located in higher wind or seismic zones, or are more complex in structure, or if the builder simply prefers it, the traditional "long" approach can still be used.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: BAJNAI-AHWB-RB-2-R602.10-R602.12

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: The committee feels this is a much needed simplified wall bracing method for structures in low seismic areas and as stated in the proponent's published reason..

Assembly Action: **None**

<u>*Individual Consideration Agenda*</u>

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Charles S. Bajnai, VBCOA and Chesterfield County, VA, representing ICC Ad-Hoc Committee on Wall Bracing, requests Approval as Modified by this Public Comment.

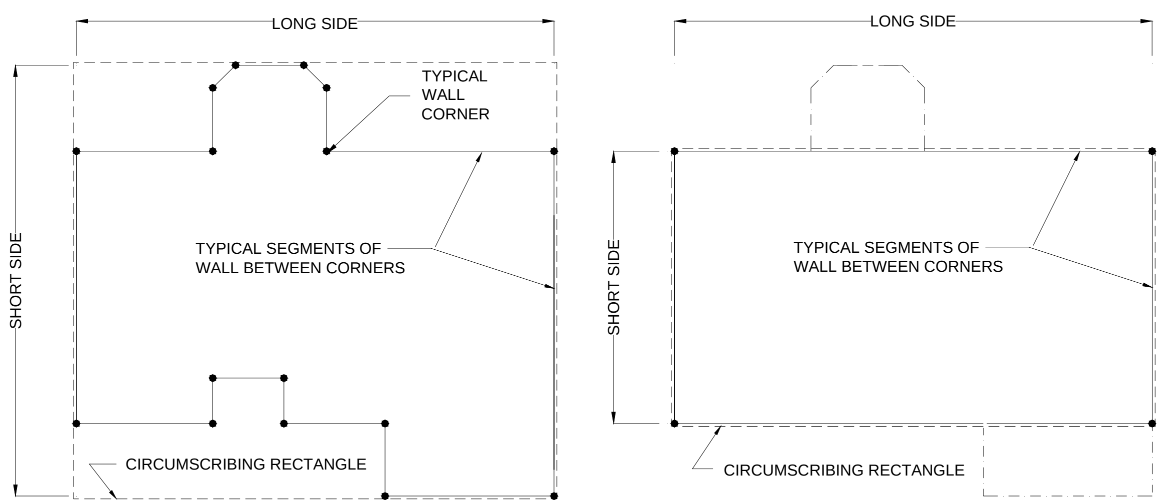
Modify the proposal as follows:

R602.12 Simplified wall bracing. Buildings meeting all of the conditions listed below shall be permitted to be braced in accordance with this section as an alternate to the requirements of Section R602.10. <u>The entire building shall be braced in accordance with this section; the use of other bracing provisions of R602.10, except as specified herein, shall not be permitted.</u>

- ~~1.~~ ~~A rectangle circumscribing the entire enclosed building, as shown in Figure R602.12.3, shall have no side longer than 60 feet (18 288 mm), and the ratio between the long side and short side shall be a maximum of 3:1.~~
- 1~~2~~. There shall be no more than two stories above the top of a concrete or masonry foundation or basement wall. Permanent wood foundations shall not be permitted.
- 2~~3~~. Floors shall not cantilever more then 24 inches (607 mm) beyond the foundation or bearing wall below.
- 3~~4~~. Wall height shall not be greater than 10 feet (2743 mm).
- ~~5.~~ ~~Interior walls shall not contribute toward bracing required in this section.~~
- 4~~6~~. The building shall have a roof eave-to-ridge height of 15 feet (4572 mm) or less.
- 5~~7~~. All exterior walls shall have gypsum board with a minimum thickness of $^1/_2$ inches (12.7 mm) installed on the interior side fastened in accordance with Table R702.3.5.
- 6~~8~~. The structure shall be located where the basic wind speed is less than or equal to 90 mph (40 m/s), and the Exposure Category is A or B.
- 7~~9~~. The structure shall be located in Seismic Design Category of A, B or C for detached one- and two-family dwellings or Seismic Design Category A or B for townhouses.
- 8~~10~~. Cripple walls shall not be permitted in two-story buildings.

~~When the bracing described in this section is used, the use of other bracing provisions of R602.10, except as specified herein, shall not be permitted.~~

<u>**R602.12.1 Circumscribed rectangle.** The bracing required for each building shall be determined by circumscribing a rectangle around the entire building on each floor as shown in Figure R602.12.1. The rectangle shall surround all enclosed offsets and projections such as sunrooms and attached garages. Open structures, such as carports and decks shall be permitted to be excluded. The rectangle shall have no side greater than 60 feet (18 288 mm), and the ratio between the long side and short side shall be a maximum of 3:1.</u>



<u>**FIGURE R602.12.1**</u>
<u>**RECTANGLE CIRCUMSCRIBING AN ENCLOSED BUILDING**</u>

~~R602.12.1~~ <u>R602.12.2</u> Sheathing materials. The following sheathing materials installed on the exterior side of exterior walls shall be used to construct a bracing unit as defined in Section R602.12.3~~2~~. Mixing materials is prohibited.

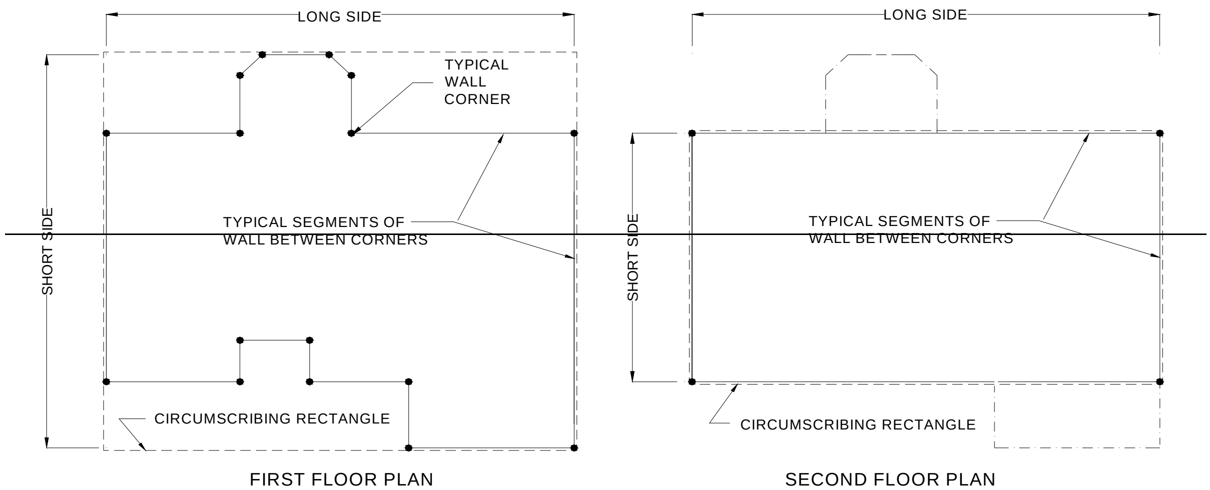
1. Wood structural panels with a minimum thickness of $^3/_8$ inch (9.5 mm) fastened in accordance with Table R602.3(3).
2. Structural fiberboard sheathing with a minimum thickness of $^1/_2$ inch (12.7 mm) fastened in accordance with Table R602.3(1).

~~R602.12.2~~ R602.12. 3Bracing unit. A bracing unit shall be a full-height sheathed segment of the exterior wall with no openings or vertical or horizontal offsets and a minimum length as specified below. Interior walls shall not contribute toward the amount of required bracing. Mixing of Items 1 and 2 below is prohibited on the same story.

1. ~~When~~Where all framed portions of all exterior walls are ~~continuously~~ sheathed in accordance with Section ~~R602.12.1~~, R602.12.2 ~~Including~~ including wall areas between bracing units, above and below openings and on gable end walls, the minimum length of a bracing unit shall be 3 feet (914 mm).
2. ~~When~~Where the exterior walls are braced with ~~intermittent~~ sheathing panels in accordance with Section ~~R602.12.1~~ R602.12.2 and areas between bracing units are ~~infilled~~covered with other materials, the minimum length of a bracing unit shall be 4 feet (1219 mm).

~~R602.12.2.1~~ R602.12.3.1 Multiple bracing units. Segments of wall compliant with Section R602.12.2 and longer than the minimum bracing unit length shall be considered as multiple bracing units. The number of bracing units shall be determined by dividing the wall segment length by the minimum bracing unit length. ~~The number of bracing units provided by one or more compliant wall segments shall be added together and rounded down to the nearest whole number.~~ Full-height sheathed segments of wall ~~shorter~~ narrower than the minimum bracing unit length shall not contribute toward a bracing unit except as specified in Section R602.12.6~~.1~~.

~~R602.12.3~~ R602.12.4 Number of bracing units. ~~The number of bracing units required along each side of a building shall be determined by circumscribing a rectangle around the entire enclosed building for each story level as shown in Figure R602.12.3.~~ Each side of the circumscribed rectangle, as shown in Figure R602.12.1, shall have, at a minimum, the number of bracing units per Table R602.12.4~~3~~ placed on the parallel exterior walls facing the side of the rectangle. Bracing units shall then be placed using the distribution requirements specified in Section R602.12.5~~4~~. ~~Mixing intermittent and continuous sheathing shall not be permitted.~~



~~FIGURE R602.12.3~~
~~RECTANGLE CIRCUMSCRIBING AN ENCLOSED BUILDING~~

TABLE ~~R602.12.3~~ R602.12.4
MINIMUM NUMBER OF BRACING UNITS ON EACH SIDE OF ~~A~~ THE CIRCUMSCRIBED RECTANGLE

STORY LEVEL	EAVE-TO RIDGE HEIGHT (FEET)	MINIMUM NUMBER OF BRACING UNITS ON EACH LONG SIDE [a,b]						MINIMUM NUMBER OF BRACING UNITS ON EACH SHORT SIDE [a,b]

a Interpolation shall not be permitted.
b Cripple walls or wood-framed basement walls in a walk-out condition of a one-story structure shall be designed as the first floor of a two-story house.
c Actual lengths of the sides of the circumscribed rectangle shall be rounded to the next highest unit of 10 when using this table.

~~R602.12.4~~ R602.12.5 Distribution of bracing units. The placement of bracing units on exterior walls shall meet all of the following requirements as shown in Figure ~~R602.12.4~~ R602.12.5.

1. A bracing unit shall begin no more than 12 feet (3658 mm) from any wall corner.
2. The distance between adjacent edges of ~~two~~ bracing units shall be no greater than 20 feet (6096 mm).
3. Segments of wall greater than 8 feet (2438 mm) in length shall have a minimum of one bracing unit.

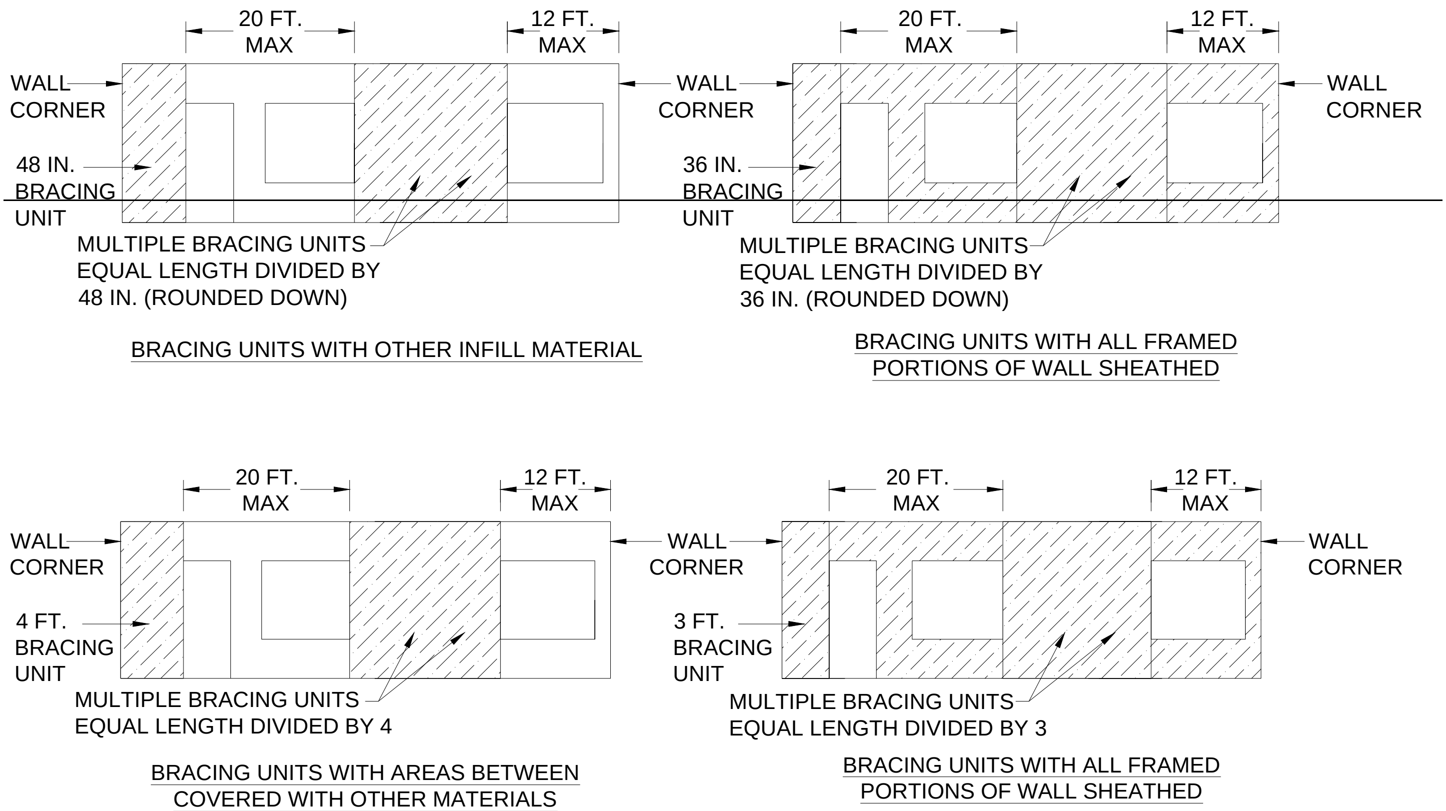

FIGURE ~~R602.12.4~~ R602.12.5
BRACING UNIT DISTRIBUTION

~~R602.12.5~~ R602.12.6 Narrow panels. The bracing methods referenced in Section R602.10 and specified in Sections R602.12.6.1 through R602.12.6.3 shall be permitted when using simplified wall bracing.

~~R602.12.5.1~~ R602.12.6.1 Method CS-G. Braced wall panels constructed as Method CS-G in accordance with Tables R602.10.4.1. and R602.10.4.2 shall be permitted for ~~single~~ one-story garages when all framed portions of all exterior walls are sheathed with wood structural panels. Each CS-G panel shall be equivalent to 0.5 of a bracing unit. Segments of wall which include a Method CS-G panel shall meet the requirements of Section R602.10.4.4.

~~R602.12.5.2~~ R602.12.6.2 Method CS-PF. Braced wall panels constructed as Method CS-PF in accordance with Section R602.10.4.1.1 shall be permitted when all framed portions of all exterior walls are sheathed with wood structural panels. Each CS-PF panel shall equal 0.5 bracing units. A maximum of four CS-PF panels shall be permitted on all the segments of walls parallel to each side of the circumscribed rectangle. Segments of wall which include a Method CS-PF panel shall meet the requirements of Section R602.10.4.4.

~~R602.12.5.3~~ R602.12.6.3 Methods PFH and PFG. Braced wall panels constructed as Method PFH and PFG shall be permitted when bracing units are constructed using wood structural panels. Each PFH and panel shall equal one bracing unit and each PFG shall be equal to 0.75 bracing units.

~~R602.12.6~~ R602.12.7 Lateral support. For bracing units located along the eaves, the vertical distance from the outside edge of the top wall plate to the roof sheathing above shall not exceed 9.25 inches (235 mm) at the location of a bracing unit unless lateral support is provided in accordance with Section R602.10.6.2.

~~R602.12.7~~ R602.12.8 Stem walls. Masonry stem walls with a height and length of 48 inches (1219 mm) or less supporting a bracing unit or a Method CS-G, CS-PF or PFG braced wall panel shall be constructed in accordance with Figure R602.10.7. Concrete stem walls with a length of 48 inches (1219 mm) or less, greater than 12 inches (305 mm) tall and less than 6 inches (152 mm) thick shall be reinforced sized and located in accordance with Figure R602.10.7.

Commenter's Reason: The proposed amendments, which are housekeeping in nature, clarify the simplified approach and further defines bracing units and their material requirements.

Final Action: AS AM AMPC____ D

RB112-09/10

R602.12, R603.12.1, R602.12.1.3, Table R602.12(1), Table R602.12(2), Figure R602.12, R703.7, Table R703.7(1), Table R703.7(2)

Proposed Change as Submitted

Proponent: Charles Clark, Brick Industry Association, representing the Masonry Alliance for Codes and Standards (MACS)

Revise as follows:

R602.12 Wall bracing and stone and masonry veneer. Where stone and masonry veneer is installed in accordance with Section R703.7, wall bracing on exterior *braced wall lines*, and *braced wall lines* on the interior of the building, shall comply with this section. In Seismic Design Categories D_0, D_1 and D_2, cripple walls shall not be permitted, and required *braced wall lines* on the interior of the building shall be supported on continuous foundations.

For all buildings in Seismic Design Categories A and~~,~~ B, ~~and~~ for townhouses in Seismic Design Category C, and for one- or two-family dwellings in Seismic Design Category D_0, wall bracing ~~at exterior and interior *braced wall lines*~~ shall be in accordance with Section R602.10 and the additional requirements of Table R602.12(1).

For townhouses in Seismic Design Category D_0 and detached one- or two-family *dwellings* in Seismic Design Categories D_0, D_1 and D_2, wall bracing and hold downs ~~at exterior and interior *braced wall lines*~~ shall be in accordance with Sections R602.10 and R602.11 and the additional requirements of Section R602.12.1, ~~and~~ Table R602.12(2) and Figure R602.12. ~~In Seismic Design Categories D_0, D_1 and D_2, cripple walls are not permitted, and required interior *braced wall lines* shall be supported on continuous foundations.~~

R602.12.1 Townhouses in Seismic Design Category D_0 and one- or two-family dwellings in Seismic Design Categories ~~D_0,~~ D_1 and D_2. Wall bracing where stone and masonry veneer exceeds the first story height for townhouses in Seismic Design Category D_0 and one- or two-family dwellings in Seismic Design Categories ~~D_0,~~ D_1 and D_2 shall conform to the requirements of Sections R602.10 and R602.11 and ~~the following requirements~~ Sections R602.12.1.1 to R602.12.1.6.

R602.12.1.3 Braced wall panel construction. *Braced wall panels* shall be constructed of wood structural panel sheathing with a thickness of not less than 7/16 inch (11 mm) nailed with 8d common nails spaced 4 inches (102 mm) on center at all panel edges and 12 inches (305 mm) on center at intermediate supports. The end of each *braced wall panel* shall have a hold down device in accordance with Table R602.12(2) installed at each end. Size, height and spacing of wood studs shall be in accordance with Table R602.3(5).

TABLE R602.12(1)

a. Cripple walls ~~are~~ shall not be permitted in Seismic Design Categories D_0, D_1 or D_2.

b. Applies to exterior ~~and interior~~ braced wall lines~~,~~ and braced wall lines on the interior of the building. Required braced wall lines on the interior of the building shall be supported on a continuous foundation.

c. Comply with Figure R602.12. Hold down force is minimum allowable stress load for connector providing uplift tie from wall framing at end of braced wall panel at the noted story to wall framing at end of braced wall panel at the story below, or to foundation or foundation wall. Use single story hold down force where edges of braced wall panels do not align; a continuous load path to the foundation shall be maintained. ~~[See Figure R602.12].~~

d. Comply with Figure R602.12. Where hold down connectors from stories above align with stories below, use cumulative hold down force size middle and bottom story hold down connectors. ~~(See Figure R602.12)~~

FIGURE R602.12
~~HOLD DOWNS AT EXTERIOR AND INTERIOR BRACED WALL PANELS~~
STONE OR MASONRY VENEER WALL BRACING HOLD-DOWN REQUIREMENTS FOR SEISMIC DESIGN

(No change to figure)

R703.7 Stone and masonry veneer, general. Stone and masonry veneer shall be installed in accordance with this chapter, Table R703.4 and Figure R703.7. These veneers installed over a backing of wood or cold-formed steel shall be limited to the first *story* above-grade and shall not exceed 5 inches (127 mm) in thickness. See Section R602.12 for wall bracing requirements for masonry veneer for wood framed construction and Section R603.9.5 for wall bracing requirements for masonry veneer for cold-formed steel construction.

Exceptions:

1. For all buildings in Seismic Design Categories A, B and C, exterior stone or masonry veneer, as specified in Table R703.7(1), with a backing of wood or steel framing shall be permitted to the height specified in Table R703.7(1) above a noncombustible foundation.
2. For all buildings in Seismic Design Category D_0 and for detached one- or two-family *dwellings* in Seismic Design Categories ~~D_0,~~ D_1 and D_2, exterior stone or masonry veneer, as specified in Table R703.7(2), with a backing of wood framing shall be permitted to the height specified in Table R703.7(2) above a noncombustible foundation.

TABLE R703.7(1)
STONE OR MASONRY VENEER LIMITATIONS AND REQUIREMENTS, WOOD OR STEEL FRAMING, SEISMIC DESIGN CATEGORIES A, B AND C

SEISMIC DESIGN CATEGORY	NUMBER OF WOOD OR STEEL FRAMED STORIES	MAXIMUM HEIGHT OF VENEER ABOVE NONCOMBUSTIBLE FOUNDATION OR FOUNDATION WALL[a] (feet)	MAXIMUM NOMINAL THICKNESS OF VENEER (inches)	MAXIMUM WEIGHT OF VENEER (psf)[b]	~~WOOD OR STEEL FRAMED STORY~~
A or B	Steel: 1 or 2 Wood: 1, 2 or 3	30	5	50	~~All~~
C	1	30	5	50	~~1 only~~
	2	30	5	50	~~top~~
					~~bottom~~
	Wood only: 3	30	5	50	~~top~~
					~~middle~~
					~~bottom~~

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.479 kPa.

a. An additional 8 feet ~~is~~ shall be permitted for gable end walls. ~~See also~~ Comply with story height limitations of Section R301.3.

b. Maximum weight ~~is~~ shall be installed weight and shall include~~s~~ weight of mortar, grout, lath and other materials used for installation. Where veneer is placed on both faces of a wall, the combined weight shall not exceed that specified in this table.

TABLE R703.7(2)
STONE OR MASONRY VENEER LIMITATIONS AND REQUIREMENTS, ~~ONE- AND TWO-FAMILY DETACHED DWELLINGS,~~ WOOD FRAMING, SEISMIC DESIGN CATEGORIES D_0, D_1 AND D_2

STRUCTURE TYPE AND SEISMIC DESIGN CATEGORY	NUMBER OF WOOD FRAMED STORIES	MAXIMUM HEIGHT OF VENEER ABOVE NONCOMBUSTIBLE FOUNDATION OR FOUNDATION WALL (feet)	MAXIMUM NOMINAL THICKNESS OF VENEER (inches)	MAXIMUM WEIGHT OF VENEER (psf)
All buildings in SDC D_0	1	20[c]	4	40
	2	20[c]	4	40
	3	30[d]	4	40
One- and two-family dwellings in SDC D_1	1	20[c]	4	40
	2	20[c]	4	40
	3	20[c]	4	40
One- and two-family dwellings in SDC D_2	1	20[c]	3	30
	2	20[c]	3	30

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.479 kPa, 1 pound-force = 4.448 N.

a. Cripple walls ~~are~~ shall not be permitted in Seismic Design Categories D_0, D_1 and D_2.

b. Maximum weight ~~is~~ shall be installed weight and shall include~~s~~ weight of mortar, grout and lath, and other materials used for installation.

c. The veneer shall not exceed 20 feet in height above a noncombustible foundation, with an additional 8 feet permitted for gable end walls, or 30 feet in height with an additional 8 feet for gable end walls where the lower 10 feet has a backing of concrete or masonry wall. ~~See also~~ Comply with story height limitations of Section R301.3.

d. The veneer shall not exceed 30 feet in height above a noncombustible foundation, with an additional 8 feet permitted for gable end walls. ~~See also~~ Comply with story height limitations of Section R301.3.

Reason: This code change adjusts the overly conservative special wall bracing requirements for houses with masonry veneer in moderate to high-seismic regions. This adjustment is based on full-scale whole-building shake-table testing that has demonstrated that the in-plane shear performance of anchored masonry veneer can resist a portion its own seismically-induced load. It showed that the shear capacity of the veneer is significant and can effectively carry a portion of its load directly to the foundation. (Bibliography References 3 & 4 below)

This testing is substantiated by other full-scale tests on whole-houses in the United States, Australia, England, Japan and New Zealand. One study in the United States reported that a two-story split foyer dwelling had a maximum deflection of 0.04 inches (1 mm) at a uniform wind pressure of 25 psf. This deflection was significantly less than that predicted by conventional analysis. Numerous whole-house tests have also been conducted in Australia. These tests demonstrated that conventional residential construction (only slightly different than that in the United States) withstood 2.4 times to 4.75 times its intended design load without failure. In England, researchers have determined that shear loads transferred from veneer to wood-framed shear walls in a full brick-veneered building were reduced by as much as 45% for wind loads. In New Zealand, tests demonstrated that for masonry veneer on conventional wood-stud framing, the veneer can take up to 50% of the lateral in-plane load.

This code change effectively reduces the special wall bracing requirements for wood-stud framing behind masonry veneer in recognition that the veneer carries a significant portion of its own load in-plane.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: CLARK-RB-5-R602.12

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee agrees with the intent and this is a needed addition, however the Final Report or the full-scale shake-table test is needed in order to further evaluate this issue.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Charles Clark, Brick Industry Association, representing Masonry Alliance for Codes and Standards (MACS), requests Approval as Modified by this Public Comment.

Modify proposal as follows:

602.12 Wall bracing and stone and masonry veneer. Where stone and masonry veneer is installed in accordance with Section R703.7, wall bracing on exterior *braced wall lines*, and *braced wall lines* on the interior of the building, shall comply with this section. In Seismic Design Categories D_0, D_1 and D_2, cripple walls shall not be permitted, and required *braced wall lines* on the interior of the building shall be supported on continuous foundations.

For all buildings in Seismic Design Categories A ~~and~~ , B, ~~for townhouses in Seismic Design Category~~ and C, and for detached one- or two-family dwellings in Seismic Design Category D_0, wall bracing shall be in accordance with Section R602.10 and the additional requirements of Table R602.12(1).

For townhouses in Seismic Design Category D_0 and detached one- or two-family *dwellings* in Seismic Design Categories D_0, D_1 and D_2, wall bracing and hold downs shall be in accordance with Sections R602.10 and R602.11 and the additional requirements of Section R602.12.1, Table R602.12(2) and Figure R602.12.

TABLE R602.12(2)
STONE OR MASONRY VENEER WALL BRACING REQUIREMENTS USING 7/16 INCH WOOD STRUCTURAL PANEL SHEATHING

STRUCTURE TYPE AND SEISMIC DESIGN CATEGORY	NUMBER OF STORIES [a]	STORY	MINIMUM BRACED WALL PANEL (percent of braced wall line length) [b]	MINIMUM BRACED WALL PANEL SHEATHING THICKNESS AND FASTENING	SINGLE STORY HOLD DOWN FORCE (lb) [c]	CUMULATIVE HOLD DOWN FORCE (lb) [d]
Townhouses in SDC D_0	1	1 only	35	7/16-inch wood structural panel sheathing with 8d common nails spaced at 4 inches on center at panel edges, 12 inches on center at intermediate supports; 8d common nails at 4 inches on center at braced wall panel end posts with hold down attached	N/A	---
	2	top	35		1900	---

a. Cripple walls are shall not be permitted in Seismic Design Categories D_0, D_1 or D_2.
b. Applies to exterior and interior braced wall lines, and braced wall lines on the interior of the building. Required braced wall lines on the interior of the building shall be supported on a continuous foundation.
c. Comply with Figure R602.12. Hold down force is minimum allowable stress load for connector providing uplift tie from wall framing at end of braced wall panel at the noted story to wall framing at end of braced wall panel at the story below, or to foundation or foundation wall. Use single story hold down force where edges of braced wall panels do not align; a continuous load path to the foundation shall be maintained. [See Figure R602.12].
d. Comply with Figure R602.12. Where hold down connectors from stories above align with stories below, use cumulative hold down force size middle and bottom story hold down connectors. (See Figure R602.12)

TABLE R703.7(2)
STONE OR MASONRY VENEER LIMITATIONS AND REQUIREMENTS, WOOD FRAMING, SEISMIC DESIGN CATEGORIES D_0, D_1 AND D_2

STRUCTURE TYPE AND SEISMIC DESIGN CATEGORY	NUMBER OF WOOD FRAMED STORIES	MAXIMUM HEIGHT OF VENEER ABOVE NONCOMBUSTIBLE FOUNDATION OR FOUNDATION WALL (feet)	MAXIMUM NOMINAL THICKNESS OF VENEER (inches)	MAXIMUM WEIGHT OF VENEER (psf)
All buildings in SDC D_0	1	20[c]	4	40
	2	20[c]	4	40
	3	30[d]	4	40
Detached One- and two-family dwellings in SDC D_1	1	20[c]	4	40
	2	20[c]	4	40
	3	20[c]	4	40
Detached One- and two-family dwellings in SDC D_2	1	20[c]	3	30
	2	20[c]	3	30

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 pound per square foot = 0.479 kPa, 1 pound-force = 4.448 N.
a. Cripple walls are shall not be permitted in Seismic Design Categories D_0, D_1 and D_2.
b. Maximum weight is shall be installed weight and shall includes weight of mortar, grout and lath, and other materials used for installation.
c. The veneer shall not exceed 20 feet in height above a noncombustible foundation, with an additional 8 feet permitted for gable end walls, or 30 feet in height with an additional 8 feet for gable end walls where the lower 10 feet has a backing of concrete or masonry wall. See also Comply with story height limitations of Section R301.3.
d. The veneer shall not exceed 30 feet in height above a noncombustible foundation, with an additional 8 feet permitted for gable end walls. See also Comply with story height limitations of Section R301.3.

Commenter's Reason: This public comment is filed anticipating the release of a report documenting the full-scale whole-building shaking-table tests conducted as a part of the NFS NEES Small-Group Project on masonry veneer. Preliminary reports from the testing show that the in-plane shear performance of anchored masonry veneer can resist a portion its own seismically-induced load. It shows that the shear capacity of the veneer is significant and can effectively carry a portion of its load directly to the foundation.

This code change adjusts the overly conservative special wall bracing requirements for houses with masonry veneer in moderate to high seismic regions. This code change effectively reduces the special wall bracing requirements for wood-stud framing behind masonry veneer in recognition that the veneer carries a significant portion of its own load in-plane.

The test results from the NFS NEES Small-Group Project are substantiated by other full-scale tests on whole-houses in the United States, Australia, England, Japan and New Zealand. One study in the United States reported that a two-story split foyer dwelling had a maximum deflection of 0.04 inches (1 mm) at a uniform wind pressure of 25 psf. This deflection was significantly less than that predicted by conventional analysis. Numerous whole-house tests have also been conducted in Australia. These tests demonstrated that conventional residential construction (only slightly different than that in the United States) withstood 2.4 times to 4.75 times its intended design load without failure. In England, researchers have determined that shear loads transferred from veneer to wood-framed shear walls in a full brick-veneered building were reduced by as much as 45% for wind loads. In New Zealand, tests demonstrated that for masonry veneer on conventional wood-stud framing, the veneer can take up to 50% of the lateral in-plane load.

FIGURE R602.12
~~HOLD DOWNS AT EXTERIOR AND INTERIOR BRACED WALL PANELS~~
STONE OR MASONRY VENEER WALL BRACING HOLD-DOWN REQUIREMENTS, ONE- AND TWO-FAMILY DETACHED DWELLINGS, SEISMIC DESIGN CATEGORIES D_0, D_1 AND D_2

(No change to figure)

Reason: The purpose of this proposal is to revise the overly conservative special wall bracing requirements for dwellings with stone or masonry veneer in moderate and high-seismic regions. A common application is for only the front wall of a dwelling to be provided with stone or masonry veneer. However, the provisions as currently stated require the specified bracing length to be increased for every braced wall in the dwelling (both exterior and on the interior), and in high-seismic conditions for hold-downs to be provided on every segment of every braced wall panel in the dwelling.

In recent testing at the University of Texas and UC San Diego, masonry veneer on individual wood-framed wall segments and on a full wood-framed building did not fail until subjected to peak ground accelerations well above the ground motions characteristic of Seismic Design Category D2. Thus, failure did not occur until well beyond the seismic limits of the IRC. Additionally, the major failure mode is veneer falling off the segments and building, rather than any damage to the wood framing back-up.

Additionally, testing at BRANZ in New Zealand of conventionally-braced structure with masonry veneer has shown that the masonry itself is capable of taking as much as 50% of the lateral load delivered in-plane to the wall. Further, the veneer showed good performance up to deflections of an inch. The allowable design capacities for bracing in the IRC result in deflections of around ½-inch, well within the range of good performance seen in the BRANZ tests.

There are no documented racking failures of a properly-braced house with stone or masonry veneer due to a seismic event. (Obviously, lack of veneer reinforcing and ties is an entirely different issue). Based on that fact and the UT, UCSD and BRANZ testing, the current requirement is not technically justified and clearly an onerous burden on masonry veneer construction. The proposed revisions will limit the increases in bracing and vertical load-path connections to just those walls that need to resist the seismic loads imparted to the structure by the masonry veneer.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: EHRLICH-RB-8-R602.12

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee feels that a truly quantified result is not available that would allow this change, based on the previous action on RB112-09/10.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Gary J. Ehrlich, National Association of Home Builders, requests Approval as Modified by this Public Comment.

Modify the proposal as:

R602.12 Wall bracing and stone and masonry veneer. Where stone and masonry veneer is installed in accordance with Section R703.7, wall bracing on exterior *braced wall lines*, and *braced wall lines* on the interior of the building, backing or perpendicular to and laterally supporting veneered walls shall comply with this section.

For all buildings in Seismic Design Categories A, B and C, wall bracing shall be in accordance with Section R602.10 and the additional requirements of Table R602.12(1).

For detached one- or two-family *dwellings* in Seismic Design Categories D0, D1 and D2, wall bracing and hold downs shall be in accordance with Sections R602.10 and R602.11 and the additional requirements of Section R602.12.1 and Table R602.12(2). In Seismic Design Categories D0, D1 and D2, cripple walls shall not be permitted, and required *braced wall lines* on the interior of the building shall be supported on continuous foundations.

TABLE R602.12(1)
STONE OR MASONRY VENEER WALL BRACING REQUIREMENTS, WOOD FRAMING, SEISMIC DESIGN CATEGORIES A, B AND C

SEISMIC DESIGN CATEGORY	NUMBER OFWOOD FRAMED STORIES	WOOD FRAMED STORY	MINIMUM SHEATHING AMOUNT
A or B	1, 2 or 3	all	Table R602.10.1.2(2)
~~C (detached one- and two-family dwellings)~~	~~1, 2 or 3~~	~~all~~	~~Table R602.10.1.2(2)~~

	2	top	Table R602.10.1.(2)
		bottom	1.5 times length required by Table R602.10.1.2(2)
	3	top	Table R602.10.1(1)
		middle	1.5 times length required by Table R602.10.1.2(2)
		bottom	1.5 times length required by Table R602.10.1.2(2)

a. Applies to exterior braced wall lines, and braced wall lines on the interior of the building, backing or perpendicular to and laterally supporting veneered walls.

TABLE R602.12(2)
STONE OR MASONRY VENEER WALL BRACING REQUIREMENTS,
ONE- AND TWO-FAMILY DETACHED DWELLINGS, SEISMIC DESIGN CATEGORIES D0, D1 AND D2

b. Applies to exterior braced wall lines, and braced wall lines on the interior of the building, backing or perpendicular to and laterally supporting veneered walls.

(Remainder of table and footnotes remain unchanged)

(Portions of proposal not shown remain unchanged)

Commenter's Reason: The purpose of this public comment is to incorporate the modification that was ruled out-of-order during the Public Hearings in Baltimore. This modification accomplishes two things. First, by adding the phrase "backing or", the requirement for a wood-framed wall providing backup for masonry veneer to be braced using these special seismic bracing provisions is maintained. Second, by adding the phrase "laterally supporting", the intent of the proposal to remove the bracing requirement from walls not seeing load from the veneer is maintained. An example of a wall meeting this provision would be the outermost wall of a one-story garage constructed without masonry veneer but attached to a veneered or partially-veneered two-story house.

This proposal does not reduce the required amount of bracing on any wall backing masonry veneer, or on any wall perpendicular to and laterally supporting a masonry veneer wall. These are the walls that will see seismic loads imposed on them due to the masonry and need the additional bracing. What this proposal is trying to address is walls such as the back wall of a house with masonry only on the front wall that will see little, if any, additional force due to the presence of the veneer. These walls should not have to be transformed into fully-restrained shear walls with hold-downs or subject to increased bracing lengths simply because there is masonry veneer on the opposite side of the house.

For SDC D0, D1 and D2, the walls that are exempted from the special bracing provisions by this change still need to be braced using one of the eight standard intermittent bracing methods, with the standard 48" minimum braced wall panel length required. This is consistent with the rules which forbid mixing of intermittent and continuous bracing methods on the same story in high-seismic regions. Similarly, the "partial-credit" provision for intermittent panels between 36" and 48" is also prohibited in high-seismic regions. Thus, the total amount of bracing which would be provided on the walls not subject to the special increases will likely be greater than the total amount which would be provided if the dwelling had no veneer. Therefore, concerns about potential torsional effects or deformation compatibility do not apply. The performance of the bracing will be equivalent regardless of whether the braced wall panels have veneer and/or hold-downs on them or not.

Final Action: AS AM AMPC____ D

RB116-09/10
R606.6.1

Proposed Change as Submitted

Proponent: Gary Ehrlich, PE, National Association of Home Builders (NAHB)

Revise as follows:

R606.6.1 Pier cap. Hollow piers shall be capped with 4 inches (102 mm) of *solid masonry* or concrete, a masonry cap block, or shall have cavities of the top course filled with concrete or grout, unless a sill plate of 2-inch (51 mm) minimum nominal thickness and bearing on two face shells is provided. The sill plate shall provide a minimum nominal bearing area of 48 square inches (30 865 square mm). ~~or other *approved* methods.~~

Reason: The purpose of this proposal is to provide additional options for providing bearing at the top of masonry piers. No guidance is currently provided in the code for the common condition where the top of a masonry pier does not match the bottom of the floor framing. Even if the pier has been properly constructed with solid masonry or grouted cells, the code does not clearly require direct bearing, and this gap is often filled with shims or small blocks that are not adequate to transfer the reaction from the beam or girder to the pier. Language previously included in Section 1804.6.4 of the 1999 SBC requiring a nominal section of sill plate is added to R606.6.1. Also, a reference to a masonry cap block (or "FHA block") is added. These blocks have a solid top surface over hollow cores and are intended to be used at the top courses of masonry piers or walls. However, the "cap" is not 4" thick, hence the need for a separate reference.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: EHRLICH-RB-9-R606.6.1

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: Based on the committee's previous action on RB80-09/10 and the proponent's request for disapproval with intent to rework and bring back to Final Action.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Gary J. Ehrlich, PE, National Association of Home Builders, request Approval as Modified by this Public Comment

Modify the proposal as:

R502.6 Bearing. The ends of each joist, beam or girder shall have not less than 1.5 inches (38 mm) of bearing on wood or metal and not less than 3 inches (76 mm) on masonry or concrete except where supported on a 1-inch-by-4-inch (25.4 mm by 102 mm) ribbon strip and nailed to the adjacent stud or by the use of *approved* joist hangers. The bearing on masonry or concrete shall be direct, or a sill plate of 2-inch (51 mm) minimum nominal thickness shall be provided under the joist, beam or girder. The sill plate shall provide a minimum nominal bearing area of 48 square inches (30 865 square mm).

R606.6.1 Pier cap. Hollow piers shall be capped with 4 inches (102 mm) of *solid masonry* or concrete, a masonry cap block, or shall have cavities of the top course filled with concrete or grout~~, unless a sill plate of 2-inch (51 mm) minimum nominal thickness and bearing on two face shells is provided. The sill plate shall provide a minimum nominal bearing area of 48 square inches (30 865 square mm)~~.

R802.6 Bearing. The ends of each rafter or ceiling joist shall have not less than 1 1/2 inches (38 mm) of bearing on wood or metal and not less than 3 inches (76 mm) on masonry or concrete. <u>The bearing on masonry or concrete shall be direct, or a sill plate of 2-inch (51 mm) minimum nominal thickness shall be provided under the rafter or ceiling joist. The sill plate shall provide a minimum nominal bearing area of 48 square inches (30 865 square mm).</u>

Commenter's Reason: The purpose of this public comment is to address concerns raised during testimony regarding the ability of the sill plate to provide sufficient bearing and load transfer across a hollow cell. While this is not an issue for many typical spans and load conditions, it could be for long spans, three-story dwellings and dwellings in areas of high snow loads. In recognition of these possible conditions, and to keep the code as simple as possible, we have agreed to delete the hollow-cell option.

The need still exists to address the condition where a gap does occur, for whatever reason, between the top of a pier and the floor or roof framing. For this reason, the sill plate language must be retained. Otherwise, a dowel or pile of shims filling the gap would be acceptable as long as the dowel or shims are at least three inches long. A sill plate segment will provide stronger and more stable bearing. The sill plate requirement is removed from R606.6.1 and moved to the end of Sections R502.6 and R802.6 where it is more appropriate.

Final Action: AS AM AMPC____ D

RB119-09/10

R612.1, R703.8

<u>Proposed Change as Submitted</u>

Proponent: Jeff Lowinski, representing the Window and Door Manufacturers Association (WDMA)

Revise as follows:

R612.1 General. This section prescribes performance and construction requirements for exterior window and door <u>assemblies</u> installed in wall<u>s</u>. Windows and doors shall be installed ~~and flashed~~ in accordance with the fenestration manufacturer's written installation instructions. Window and door openings shall be flashed in accordance with Section R703.8. Written installation instructions shall be provided by the fenestration manufacturer for each window or door.

R703.8 Flashing. ~~*Approved* corrosion-resistant flashing shall be applied shingle-fashion in a manner to prevent entry of water into the wall cavity or penetration of water to the building structural framing components. Self-adhered membranes used as flashing shall comply with AAMA 711. The flashing shall extend to the surface of the exterior wall finish. *Approved* corrosion-resistant flashings shall be installed at all of the following locations:~~ <u>Penetrations and openings in exterior walls shall be flashed or sealed in such a manner that will inhibit entry of water into the wall cavity or penetration of water to the building structural framing components. Flashing components shall be applied shingle fashion and shall direct water to the surface of the exterior wall finish. Material and components used to flash penetrations and openings shall be water-resistant and corrosion-resistant. Self-adhered membranes used as flashing shall comply with AAMA 711. The following locations shall be flashed:</u>

1. Exterior window and door openings. Flashing at exterior window and door openings shall extend to the surface of the exterior wall finish or to the water-resistive barrier for subsequent drainage.
2. At the intersection of chimneys or other masonry construction with frame or stucco walls, with projecting lips on both sides under stucco copings.
3. Under and at the ends of masonry, wood or metal copings and sills.
4. Continuously above all projecting wood trim.
5. Where exterior porches, decks or stairs attach to a wall or floor assembly of wood-frame construction.
6. At wall and roof intersections.
7. At built-in gutters.

<u>Exterior wall plumbing penetrations shall be in accordance with Section P2606.</u>

Reason: The revisions proposed for Chapter 6 clarify that it is window and door assemblies that are installed in walls, and removes the inappropriate flashing text in this chapter since flashing requirements for windows and doors are explicit in Chapter 7.

In Chapter 7, the proposed is intended to be editorial and improves the charging language for flashing. The proposal also directs the reader to the requirements in Section P2606 for exterior wall plumbing penetrations.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: LOWINSKI-RB-4-R612.1-R703.8

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee feels that this change does not clearly define who is responsible for the instructions, the manufacturer or the code. ASTM E 2112 needs to be brought into compliance and brought into the code and that would resolve these issues. It is not clear that this is adequate for all openings.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jeff Inks, Window and Door Manufacturer's Association, requests Approval as Modified by this Public Comment.

Replace proposal as follows:

R612.1 General. This section prescribes performance and construction requirements for exterior window<u>s</u> and door<u>s</u> installed in wall<u>s</u>. Windows and doors shall be installed in accordance with the fenestration manufacturer's written installation instructions. Window and door openings shall be flashed in accordance with Section R703.8. Written installation instructions shall be provided by the fenestration manufacturer. ~~for each window or door~~.

R703.8 Flashing. *Approved* corrosion-resistant flashing shall be applied shingle-fashion in a manner to prevent entry of water into the wall cavity or penetration of water to the building structural framing components. Self-adhered membranes used as flashing shall comply with AAMA 711. The flashing shall extend to the surface of the exterior wall finish. *Approved* corrosion-resistant flashings shall be installed at all of the following locations:

1. Exterior window and door openings. Flashing at exterior window and door openings shall extend to the surface of the exterior wall finish or to the water-resistive barrier for subsequent drainage. <u>Flashing at exterior window and door openings shall be installed in accordance with one or more of the following:</u>
   <u>1.1.</u> <u>The fenestration manufacturer's written flashing instructions.</u>
   <u>1.2.</u> <u>For applications not addressed in the fenestration manufacturer's written instructions, in accordance with the flashing manufacturer's written instructions.</u>
   <u>1.3</u> <u>In accordance with the flashing method of a registered design professional.</u>
2. At the intersection of chimneys or other masonry construction with frame or stucco walls, with projecting lips on both sides under stucco copings.
3. Under and at the ends of masonry, wood or metal copings and sills.
4. Continuously above all projecting wood trim.
5. Where exterior porches, decks or stairs attach to a wall or floor assembly of wood-frame construction.
6. At wall and roof intersections.
7. At built-in gutters.

Exterior wall plumbing penetrations shall be in accordance with Section P2606.

Commenter's Reason: The intent of the original proposal is to clarify that the installation of windows is part of the design and construction of walls and partitions as provided for in Chapter 6, and that flashing is part of the design and construction of the exterior wall covering as provided for in Chapter 7, which is not disputed. In addition the intent was to clarify the respective Chapter 7 language accordingly.

The modification proposed for 703.8 by this public comment addresses the Committee's reason for rejecting the original proposal by clearly defining who is responsible for the (flashing) instructions, while also clarifying that door and window installation is to be in accordance with manufacturer's instructions as part of the design and construction of walls and partitions provided for in Chapter 6, and window and door flashing in accordance with 703.8 as part of the design and construction of the exterior wall covering which is already explicitly provided for in Chapter 7. Amending the sections in this way will help to avoid any confusion over how the IRC window and door installation and flashing requirements are to apply to doors and windows.

The requirement that instructions be provided for every single window and door is deleted from the last sentence in Section 612.1 because it is simply not necessary. Manufacturers are required to provide written instructions and they do, but there is no reason why the same set of printed instructions needs to be provided with every window and door when the products are identical. Duplicative copies are not needed, not used, and simply wasted at the jobsite. Complete manufacturer's instructions are readily available to builders, designers and installers in many ways. Requiring a separate set for every window and door is an unnecessary waste of resources.

This modification also addresses the Committee's other comment noting ASTM E 2112 as one way of providing a comprehensive set of installation and flashing instructions that the IRC could rely upon. At this time, E 2112 is undergoing significant revision and does not currently fully meet ICC criteria for referenced standards and therefore cannot be referenced by the IRC until revised. The above modification provides an acceptable alternative and one that the Committee agreed with in their consideration of RB-145.

While a window and door manufacturer's installation and flashing instructions do cover a wide variety of wall and project conditions, they simply cannot account for every conceivable project specific condition that may need to be considered given the virtually limitless set of conditions that are possible in residential construction, or for when a builder or design professional wants to employ a proven flashing method that may not be covered by a particular manufacturer's instructions. The IRC therefore needs to provide some flexibility at the local level to allow for flashing alternatives that are compliant with the performance requirements of 703.8, but may not be expressly provided for in the manufacturer's instructions. This modification serves that purpose while still maintaining the requirement that manufacturer's must provide instructions in accordance with Section 612.1, but also provides the noted flexibility that is needed by builders and design professionals.

Final Action: AS AM AMPC____ D

RB122-09/10, Part I
R612.2

Proposed Change as Submitted

Proponent: Paul K. Heilstedt, PE, FAIA, Chair, representing ICC Code Technology Committee (CTC)

PART I – IRC BUILDING/ENERGY

Revise as follows:

R612.2 Window sills. In *dwelling* units, where the opening of an operable window is located more than 72 inches (1829 mm) above the finished *grade* or surface below, the lowest part of the clear opening of the window shall be a minimum of ~~24~~ 36 inches (610 mm) above the finished floor of the room in which the window is located. Operable sections of windows shall not permit openings that allow passage of a 4 inch (102 mm) diameter sphere where such openings are located within ~~24~~ 36 inches (610 mm) of the finished floor.

Exceptions:

1. Windows whose openings will not allow a 4-inch diameter(102 mm) sphere to pass through the opening when the opening is in its largest opened position.
2. Openings that are provided with window fall prevention devices that comply with Section R612.3.
3. Openings that are provided with fall prevention devices that comply with ASTM F 2090.
4. Windows that are provided with opening limiting devices that comply with Section R612.4.

Reason: The ICC Board established the ICC Code Technology Committee (CTC) as the venue to discuss contemporary code issues in a committee setting which provides the necessary time and flexibility to allow for full participation and input by any interested party. The code issues are assigned to the CTC by the ICC Board as "areas of study". Information on the CTC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CTC effort can be downloaded from the following website: http://www.iccsafe.org/cs/cc/ctc/index.html. Since its inception in April/2005, the CTC has held seventeen meetings - all open to the public.

This proposed change is a result of the CTC's investigation of the area of study entitled "Child Window Safety". The scope of the activity is noted as:

> Study the incidence and mechanisms of falls from open windows by children and to investigate the necessity and suitability of potential safeguards and/or revisions to the current codes.

The intent of IBC Section 1405.13.2 and IRC Section R612.2 is clearly to provide safety mechanisms to reduce the possibility of children falling through a window. The CTC has determined that this can be realized in the code in three ways: window fall prevention devices; window opening control devices; or reducing the possibility of accessing the window by increasing the minimum sill height. The purpose of this code change is to reduce the potential hazard by increasing the sill height from 24 inches to 36 inches.

In response to the CTC studying the Climbability of Guards, the National Ornamental & Miscellaneous Metals Association (NOMMA) commissioned a paper entitled "Review of Fall Safety of Children Between the Ages of 18 months and 4 Years in Relation to Guards and Climbing in the Built Environment", referred to in this code change as "NOMMA paper". This paper is posted on the CTC website as noted below. The paper provides a summary of the building code requirements, a critical review of relevant per-reviewed scientific literature on guard research and injury data and includes a section entitled "Children's Interaction with the Built Environment". Included in this section is an analysis of falls from windows where it is noted that "Falls from windows are among the most common types of unintended injuries to children and they are a major health concern" (NOMMA paper page 30). The study efficiently places within a few pages the data on window fall incidents and the means of reducing the number of incidents.

U.S. Fall Injury Data

NOMMA report page 7: The 1,421,137 injuries reported by NEISS between 2002 and 2005, inclusive, correspond to a national average of 51,217,603 based on weighting data included with the record data. The average over the four years is 12,804,401. The weighted estimate of 1,117,278 incidents on average annually for children between the ages of 18 months and 4 years represents 8.7 percent of these incidents. For all the incidents to children between the ages of 18 months and 4 years, 5.6 percent involved stairs, 1.22 percent involved windows, and 0.87 percent involved porches, balconies, open-sided floors, and floor openings.

NOMMA paper page 30 – 33. The paper further cites reports which have been compiled in the table below:

Study	Location	Falls	% fatalities
Vish et al. (2005)	**Chicago**	**11/yr**	
Istre et al. (2003)	**Dallas county**	**17/yr**	
Benoit et al. (2002)	**L.A. county**	**12/yr (11%)**	**4% (4 yrs old or less)**
Stone et al. (2000)	**Cincinnati**	**12/yr (6.3%)**	**4.7%**
Benoit et al. (2000)	**Northern Virginia**	**11/yr (11%)**	

Center of Gravity
NOMMA paper page 11, Table 2: The standing center of gravity of children aged 2 to 3.5 years is 24.1 inches (50th percentile is 22.2 inches) and of children aged 3.5 to 4.5 is 25.2 (50th percentile is 23.6).

A reasonable expectation for the Code is that, absent any fall protection in the window opening, a minimum sill height will be required to reduce the ability of a child to climb onto the sill enabling the fall through the opening. Using a child target age of up to 4 years of age and the associated center of gravity, the code mandated height of 24" is not adequate. A child need only extend themselves on their toes, stand on modest stack of books or blocks or hoist themselves a matter of a few inches with their arms to be able to flop onto the sill and expose themselves to the window opening and the associated risk of falling.

The hazards associated with child window falls cannot be understated as evidenced by the following CPSC Press release dated May 15, 2008:

NEWS from CPSC
U.S. Consumer Product Safety Commission
Office of Information and Public Affairs Washington, DC 20207

FOR IMMEDIATE RELEASE
May 15, 2008
Release #08-270

CPSC Hotline: (800) 638-2772
CPSC Media Contact: (301) 504-7908

Window Falls Prompts CPSC to Issue Warning
WASHINGTON, D.C. - With the arrival of the warmer spring weather, families across the nation are opening their windows to let the fresh air in. This pleasant feeling can quickly turn tragic in households with small children. In recent weeks, several children have fallen from windows. The U.S. Consumer Product Safety Commission is warning parents and caregivers to take precautions to keep children from falling from windows.
"CPSC staff is aware of at least 18 falls from windows through media reports, including two deaths, involving small children since April," said CPSC Acting Chairman Nancy Nord. "We are issuing this warning so parents will take the necessary steps to prevent these incidents from happening."

These deaths and injuries frequently occur when kids push themselves against window screens or climb onto furniture located next to an open window.

From 2002-2004, CPSC staff received an average of 25 reports a year of fatalities associated with falls from windows. Children younger than five years of age account for approximately one-third of these reported fatalities. For all age categories, more males died from window falls than females.

To help prevent injuries and tragedies, CPSC recommends the following safety tips:
* Safeguard your children by using window guards or window stops.
* Install window guards to prevent children from falling out of windows. (For windows on the 6th floor and below, install window guards that adults and older children can open easily in case of fire.)
* Install window stops so that windows open no more than 4 inches.
* Never depend on screens to keep children from falling out of windows.
* Whenever possible, open windows from the top -- not the bottom.
* Keep furniture away from windows, to discourage children from climbing near windows.

To see this release on CPSC's web site, please go to:
http://www.cpsc.gov/cpscpub/prerel/prhtml08/08270.html

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: HEILSTEDT-RB-2-R612-IBC 1405.13.2

Public Hearing Results

PART I – IRC

Committee Action: Disapproved

Committee Reason: The committee feels the 24 inch height has not been in use long enough to accumulate needed data to justify a change to 36 inches.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Paul K. Heilstedt, P.E., Hon. AIA, Chair, ICC Code Technology Committee (CTC), requests Approval as Submitted.

Commenter's Reason: This code change proposal included two parts, one to the IRC (part 1) and one to the IBC (part 2), to increase the minimum sill height for windows from 24" to 36". Part 2 to the IBC was approved. In approving the code change to the IBC, the committee noted "…increasing the current 24 inch sill height requirement to 36 inches was justified by the data submitted by the proponent."

This public comment coordinates the requirements between the IRC and the IBC. The focus of this change is to provide for the safety of children that are accidentally injured and killed each year due to falls through windows. The window industry has illustrated its ability to provide the type of barrier that can easily offer the level of protection needed to prevent such accidents. CTC does not pretend that this will prevent children from falling from windows that are higher than this 36" threshold because they or others provide opportunities to climb. This doesn't mean we shouldn't establish rational thresholds that would avoid the accidental fall from windows as we have with guards.

Public Comment 2:

Gregory R. Istre, M.D., Injury Prevention Center of Greater Dallas, requests Approval as Submitted.

Commenter's Reason: I am writing in support of the proposal to change "RB 122" to set a minimum height of 36" for window sills in dwelling units. Our organization (the Injury Prevention Center of Greater Dallas), in collaboration with the Texas Department of Health, undertook a three-year study of children who had fallen from heights, in Dallas, Texas, and the data from that study support a mandate for a minimum height of window sills[1]. We found that 89% of the children who fell from a window had fallen directly out of a window whose sill was within 3 feet of the floor. In each case the windows were open and most had a screen, but the screens did not prevent the fall. Also, in almost every case, we found that a parent had been supervising the child but they could not prevent the fall. Our study concludes that most of the falls could have been prevented if either the window sills had been higher off the floor or if the windows had been manufactured to not open far enough to allow a child to pass through the opening.

I am aware that the current number in the code since 2006 is 24", which will go a long way toward decreasing window fall-related injuries to children. By our calculations from our data, ~75% of these falls may be prevented by having minimum sill height of 24", which is the current building standard, and an additional ~15% of falls could be prevented by raising the minimum sill height requirement to 36".

I am aware of Mr. Sealy's work for the past several years and have studied his current proposal, and am convinced that implementation of this code change will go a long way in preventing window fall-related injuries to children.-Gregory Istre, M.D.2/8/2010

Bibliography:

1) Istre, et al. "Childhood injuries due to falls from apartment windows and balconies" *Injury Prevention* 2003;9:349-352.

Public Comment 3:

Jim. W. Sealy, FAIA representing self, requests Approval as Submitted.

Commenter's Reason: This process began for me in early 2000 when I became involved in a legal action involving a toddler falling from an open window in his third floor apartment. During the course of my work I did a lot of research in window placement and falls from windows involving children. As a result of my work, I submitted a proposed change to both the IBC and IRC whereby windowsills would be required to be a minimum distance (36") above the finished floor of the room in which the window is located.

All of the technical requirements in my proposals were based on existing code language and none of it was arbitrary or contrived. My first proposals were submitted in 2002 and both failed because of objections from the window industry and homebuilders and building designers; with the 36" sill height being the major concern on their part. In the following cycle, I resubmitted both proposals and ultimately made concessions to the opposition and I accepted a sill height of 24". However, that height had no logical basis and had not been researched or studied – it was merely a concession on my part.

Both committees approved the section with the 24" height in the first part of the cycle and they were also approved in the final hearings held in Overland Park, Kansas. HOWEVER, in order t delay the section from going into the 2003 edition of the codes, one of the opponents filed a “formal challenge”. I continued my mission and I ultimately received approval of the modified section and it was printed in the 2006 edition of he codes.

Subsequently the ICC Code Technology Committee (CTC) began to study the sections dealing with this issue and they submitted code changes to resurrect my original proposals on the windowsills being positioned at 36” above the floor. They concluded that logic and outside studies confirmed my original premise and they have been successful in getting the 36” height passed by the IBC committee at the hearings in Baltimore. However, the IRC committee is still reluctant to accept logic and stated that the 24” height has not been in the codes long enough to determine its effectiveness.

The 24” dimension was purely arbitrary and was nothing more than a concession made to get something in the code. The 36” dimension, on the other hand, was and still is based on logic and has been proven in the codes for decades. In summary, the 36” height is justifiable and no lengthy study or research is necessary. It has been in the codes for decades and has not been challenged. In my opinion, this is proof that the 24” height is unacceptable in addressing the problem of children falling from windows and further proof that Approval As Submitted is the correct action for RB 122 09/10 Part 1.

Final Action: AS AM AMPC____ D

RB122-09/10, Part II
IBC 1405.13.2

Proposed Change as Submitted

Proponent: Paul K. Heilstedt, PE, FAIA, Chair, representing ICC Code Technology Committee (CTC)

PART II – IBC FIRE SAFETY

Revise as follows:

1405.13.2 Window sills. In Occupancy Groups R-2 and R-3, one- and two-family and multiple-family dwellings, where the opening of the sill portion of an operable window is located more than 72 inches (1829 mm) above the finished grade or other surface below, the lowest part of the clear opening of the window shall be at a height not less than ~~24~~ 36 inches (610 mm) above the finished floor surface of the room in which the window is located. Glazing between the floor and a height of ~~24~~ 36 inches (610 mm) shall be fixed or have openings through which a 4-inch (102 mm) diameter sphere cannot pass.

Exception: Openings that are provided with window guards that comply with ASTM F 2006 or F 2090.

Reason: The ICC Board established the ICC Code Technology Committee (CTC) as the venue to discuss contemporary code issues in a committee setting which provides the necessary time and flexibility to allow for full participation and input by any interested party. The code issues are assigned to the CTC by the ICC Board as “areas of study”. Information on the CTC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CTC effort can be downloaded from the following website: http://www.iccsafe.org/cs/cc/ctc/index.html. Since its inception in April/2005, the CTC has held seventeen meetings - all open to the public.

This proposed change is a result of the CTC’s investigation of the area of study entitled “Child Window Safety”. The scope of the activity is noted as:

> Study the incidence and mechanisms of falls from open windows by children and to investigate the necessity and suitability of potential safeguards and/or revisions to the current codes.

The intent of IBC Section 1405.13.2 and IRC Section R612.2 is clearly to provide safety mechanisms to reduce the possibility of children falling through a window. The CTC has determined that this can be realized in the code in three ways: window fall prevention devices; window opening control devices; or reducing the possibility of accessing the window by increasing the minimum sill height. The purpose of this code change is to reduce the potential hazard by increasing the sill height from 24 inches to 36 inches.

In response to the CTC studying the Climbability of Guards, the National Ornamental & Miscellaneous Metals Association (NOMMA) commissioned a paper entitled “Review of Fall Safety of Children Between the Ages of 18 months and 4 Years in Relation to Guards and Climbing in the Built Environment”, referred to in this code change as “NOMMA paper”. This paper is posted on the CTC website as noted below. The paper provides a summary of the building code requirements, a critical review of relevant per-reviewed scientific literature on guard research and injury data and includes a section entitled “Children’s Interaction with the Built Environment”. Included in this section is an analysis of falls from windows where it is noted that “Falls from windows are among the most common types of unintended injuries to children and they are a major health concern” (NOMMA paper page 30). The study efficiently places within a few pages the data on window fall incidents and the means of reducing the number of incidents.

U.S. Fall Injury Data

NOMMA report page 7: The 1,421,137 injuries reported by NEISS between 2002 and 2005, inclusive, correspond to a national average of 51,217,603 based on weighting data included with the record data. The average over the four years is 12,804,401. The weighted estimate of 1,117,278 incidents on average annually for children between the ages of 18 months and 4 years represents 8.7 percent of these incidents. For all the incidents to children between the ages of 18 months and 4 years, 5.6 percent involved stairs, 1.22 percent involved windows, and 0.87 percent involved porches, balconies, open-sided floors, and floor openings.

NOMMA paper page 30 – 33. The paper further cites reports which have been compiled in the table below:

Study	Location	Falls	% fatalities
Vish et al. (2005)	**Chicago**	**11/yr**	
Istre et al. (2003)	**Dallas county**	**17/yr**	
Benoit et al. (2002)	**L.A. county**	**12/yr (11%)**	**4% (4 yrs old or less)**
Stone et al. (2000)	**Cincinnati**	**12/yr (6.3%)**	**4.7%**
Benoit et al. (2000)	**Northern Virginia**	**11/yr (11%)**	

Center of Gravity
NOMMA paper page 11, Table 2: The standing center of gravity of children aged 2 to 3.5 years is 24.1 inches (50^{th} percentile is 22.2 inches) and of children aged 3.5 to 4.5 is 25.2 (50^{th} percentile is 23.6).

A reasonable expectation for the Code is that, absent any fall protection in the window opening, a minimum sill height will be required to reduce the ability of a child to climb onto the sill enabling the fall through the opening. Using a child target age of up to 4 years of age and the associated center of gravity, the code mandated height of 24" is not adequate. A child need only extend themselves on their toes, stand on modest stack of books or blocks or hoist themselves a matter of a few inches with their arms to be able to flop onto the sill and expose themselves to the window opening and the associated risk of falling.

The hazards associated with child window falls cannot be understated as evidenced by the following CPSC Press release dated May 15, 2008:

PART II - IBC Fire Safety

Committee Action: Approved as Submitted

Committee Reason: The committee agreed that increasing the current 24 inch sill height requirement to 36 inches was justified by the data submitted by the proponent.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Jeff Inks, Window and Door Manufacturer's Association, requests Disapproval.

Commenter's Reason: First, the ICC CTC has determined that the intent of 1405.13.2 can be met in three ways: window fall prevention devices; window opening control devices; or reducing the possibility of accessing the window by increasing the minimum sill height.

All three of those ways are already provided for in the current code as a result of the long debate that lead to the inclusion of the 24" requirement in the 2006 edition of the IBC. There is no adequate justification to further increase the height of the sills other than what we believe is a subjective determination by the CTC based upon a paper – not actual research -- that did not focus on window sill heights, but rather on climbable guards.

The "NOMMA paper" cited as the justification for proposing a minimum 36" sill height is in fact just a review which is clearly declare by its authors in the abstract that the paper who state that the paper, "*provides a summary of the building code requirements, a critical review of relevant peer-reviewed scientific literature on guard research and injury data related to children's climbing, and an analysis of the latest injury statistics*."

The paper was not commissioned nor is it intended to serve as the bases for building code requirements and there is nothing to suggest that it should. This too is clearly declared by the authors who expressly stated in the Executive Summary that the "*Results from either the research studies or the injury data are neither specific enough nor consistent enough to constitute a solid basis for building code requirements*."

The authors go even further with respect to the injury data in the report by stating that "*Caution should be used in applying the NEISS data to assign causation of an event. The designations provided in the NEISS reporting system focus on "product codes" and not on the mechanism or physical environment surrounding the injury.*" A copy of the report is available at http://www.iccsafe.org/cs/CTC/Documents/guards/resource/NOMMA_Final_Report_20080506R_May_08.pdf

If the authors of the report that is being used as the basis for approving this code change are adding such caveats for their own work, we believe that makes it clear that the report is not intended to serve as the basis for establishing building code requirements.

Second, the proponents reason statement goes on to state that with respect to the current 24" requirement "*a child need only extend themselves on their toes, stand on modest stack of books or blocks or hoist themselves a matter of a few inches with their arms to be able to flop onto the sill and expose themselves to the window opening and the associated risk of falling*." All of the factors cited in that statement as contributing to falls are factors that don't go away by raising the sill height, and there is no sound data to substantiate that raising the sill height further than 24" will result in a reduction of child falls. Equally concerning is the lack of consideration given to the potential for higher sill heights to actually encourage the placement of climbable/stepable objects or furniture near or under the window making the sill even more accessible. One can equally conclude from intuitive reasoning that there is a greater likelihood of this occurring the higher the sill height is. In fact, this could also encourage a child to climb to see out the window regardless of whether there are climbable/stepable objects available.

Regardless, those factors are precisely why most child safety advocacy organizations focus their fall prevention guidance on things such as keeping windows closed in rooms where children play, ensuring appropriate supervision, opening windows from the top, avoiding the placement of furniture and other climbable objects near the window, etc.

All of those factors are outside the control of the building code. We therefore do not believe that increasing the sill height to 36" will have a meaningful impact on reducing child falls. Promoting window safety awareness does however have a proven, meaningful impact versus a minimum 36" sill height and we therefore urge disapproval of it.

Public Comment 2:

Tim Pate, representing, City & County of Broomfield, CO, representing Colorado Chapter of ICC, requests Disapproval.

Commenter's Reason: This public comment is asking for the membership to overturn the IBC Fire Safety Committee and disapprove this code change. The IRC-Building/Energy Committee disapproved this same code change due to lack of any substantial data to show that the requirement for this sill height at 24" minimum which was put into the 2006 IBC and IRC has been effective in stopping child falls out of windows.

We need to wait until there is sufficient data to show that the 24" is not working (or even helping) before raising the number any higher. The original proponent himself stated that a child need only extend themselves on their toes, stand on modest stack of books or blocks or hoist themselves a matter of a few inches with their arms to be able to flop onto the sill and expose themselves to the window opening and the associated risk of falling.

Raising the window sill to 36" will only require the same child to stack up a higher stack of books or blocks and potentially fall out. There would even be a potentially higher risk of having an end table pushed up to the exterior wall in these locations and therefore make it even easier for child to get on top of and potentially fall out. Nowhere in the CPSC list of recommendations that the proponent has shown in original reason statement does it say to have a higher window sill. It does say to keep furniture away and use window stops and guards.

Public Comment 3:

Julie Ruth, JRuth Code Consulting, representing American Architectural Manufacturer's Association, requests Disapproval.

Commenter's Reason: RB122, Part II raises the minimum height required to the lowest part of the clear opening of an operable window from 24 inches to 36 inches in the IBC. The stated intent of doing so, by the proponent, is to reduce the risk of children falling through the open window. AAMA opposes this increase in the minimum sill height requirements of the IBC for the following reasons:

1. No evidence has been presented that establishing any minimum sill height, or raising that height, will prevent or reduce the number of **children who fall through windows each year.** The proponent of RB122 points to a study that was conducted by the National Ornamental and Miscellaneous Metals Association (NOMMA) regarding the ability of children to climb over guard rails as evidence of the need to raise the minimum sill height. The results of that study, which was conducted for NOMMA by the National Association of Home Builders Research Center, were published in a paper entitled ""Review of Fall Safety of Children Between the Ages of 18 months and 4 Years in Relation to Guards and Climbing in the Built Environment".

The study itself does not make any recommendations regarding an effective barrier height for young children. In fact, the Executive Summary includes the following statement. "Results from either the research studies or the injury data are neither specific enough nor consistent enough to constitute a solid basis for building code requirements."

Another result from the study, however, was consistent with a viewpoint that the fenestration industry has expressed many times as the dialog regarding the establishment of minimum sill heights has continued. That view is that children climb. The specific statement from the Executive Summary of the NOMMA report is: "Research shows that climbing plays an important role in the physical, cognitive, and social development of the young child, and that this is encouraged in many situations, such as playgrounds and school gymnasia."

Within the body of the report, the topic of children's climbing abilities is further expanded. "Children begin to practice climbing skills early in life. Many children learn rudimentary climbing before they begin to walk and climbing has been observed as early as 8 months of age (McGraw, 1935, cited in Readdick and Park, 1998). By around one year a child is able to pull himself up onto a ledge or table. By the age of 13 months many children have started walking unaided. By 14 months 25 percent of children are climbing, and this rises to 50 percent by 17 months (Readdick and Park, 1998). At 21 months 75 percent of children are climbing and 90 percent or more are climbing by 22 months of age (ibid.). By 4 years of age boys have started to develop greater upper body strength than girls. By the age of 6 years many children can begin to climb in a manner similar to an adult (van Herrewegen, Molenbroek and Goossens, 2004). As a consequence of these developmental processes, the acquisition of climbing skills mostly occurs between 3 and 6 years of age (van Herrewegen et al., 2004)."

Given children's documented ability to climb, it would not be realistic to expect a barrier of any height to be sufficient to prevent a child from going over it, unless the establishment of such a barrier were accompanied by a ban on the placement of any object adjacent to that barrier that might facilitate climbing, at any time during the occupancy of the building. This of course would be unenforceable. A previous review of window fall reports received from the Consumer Product Safety Commission indicates that in some instances children move objects, such as toys, Styrofoam coolers, pillows and small pieces of furniture, to enable themselves to climb to the sill height. It then becomes obvious that the establishment of a barrier of any height could still be overcome by a child who wishes to satisfy their own curiosity about what is going on outside the room they are in.

2. Raising the sill height could have the effect of raising the height from which children fall. Since we understand that children can and will climb, if we raise the height of the sill we are in essence raising the height they need to climb to if their objective is to see outside the window. By doing so, we also raise the height from which they may fall, both to the exterior of the building, and to the interior. This obviously increases the risk of injury to the child, rather than reducing it.

3. Raising the sill height would definitely make it more difficult for other occupants of the building to egress from the building through an open window. Although children can climb over barriers of great height, relative to their own, other occupants of the building may have difficulty doing so. This is particularly true of elderly, or the disabled. The likelihood of this, and the percentage of the population who could not overcome a barrier, increases as the height of the barrier does. Therefore, establishing any minimum sill height merely puts in place a barrier that may not reduce the number of children that fall through the window while increasing the likelihood that other occupants of the building will not be able to egress the building through that opening. Raising the height makes that situation worse – it does not improve it.

Final Action: AS AM AMPC____ D

RB123-09/10-PART II
IBC 1405.13.2, 1405.13.2.1 (New)

NOTE: PART I DID NOT RECEIVE A PUBLIC COMMENT AND IS ON THE CONSENT AGENDA. PART I IS REPRODUCED ONLY FOR INFORMATIONAL PURPOSES ONLY FOLLOWING ALL OF PART II.

Proposed Change as Submitted

Proponent: Paul K. Heilstedt, PE, FAIA, Chair, representing ICC Code Technology Committee (CTC)

PART II – IBC FIRE SAFETY

1. Revise as follows:

1405.13.2 Window sills. In Occupancy Groups R-2 and R-3, one- and two-family and multiple-family dwellings, where the opening of the sill portion of an operable window is located more than 72 inches (1829 mm) above the finished grade or other surface below, the lowest part of the clear opening of the window shall be a minimum of 24 inches

(610 mm) above the finished floor surface of the room in which the window is located. ~~Glazing between the floor and a height of 24 inches (610 mm) shall be fixed or have openings such that a 4-inch (102 mm) diameter sphere cannot pass through.~~ Operable sections of windows shall not permit openings that allow passage of a 4 inch diameter sphere where such openings are located within 24 inches of the finished floor.

Exceptions:

~~Openings that are provided with window guards that comply with ASTM F 2006 or F 2090.~~

1. Windows whose openings will not allow a 4-inch-diameter (102 mm) sphere to pass through the opening when the opening is in its largest opened position.
2. Openings that are provided with window fall prevention devices that comply with ASTM F 2090.
3. Windows that are provided with window opening control devices that comply with Section 1405.13.2.1..

2. Add new text as follows:

1405.13.2.1 Window opening control devices. When required elsewhere in this code, window opening control devices shall comply with ASTM F 2090. The window opening control device, after operation to release the control device allowing the window to fully open, shall not reduce the minimum net clear opening area of the window unit to less than the area required by Section 1029.2. The device or any portion thereof shall not project more than 1 inch into the required net clear opening for a length not exceeding 3 inches when the window is in the fully open position.

Reason: The ICC Board established the ICC Code Technology Committee (CTC) as the venue to discuss contemporary code issues in a committee setting which provides the necessary time and flexibility to allow for full participation and input by any interested party. The code issues are assigned to the CTC by the ICC Board as "areas of study". Information on the CTC, including: meeting agendas; minutes; reports; resource documents; presentations; and all other materials developed in conjunction with the CTC effort can be downloaded from the following website: http://www.iccsafe.org/cs/cc/ctc/index.html. Since its inception in April/2005, the CTC has held seventeen meetings - all open to the public. This proposed change is a result of the CTC's investigation of the area of study entitled "Child Window Safety". The scope of the activity is noted as:

> Study the incidence and mechanisms of falls from open windows by children and to investigate the necessity and suitability of potential safeguards and/or revisions to the current codes.

This code change is a follow-up to code change RB173-07/08 last cycle. At the Final Action Hearings in Minneapolis, the membership approved RB 173-07/08 Part 1 (Public Comment 2) to the IRC to include prescriptive provisions for window opening limiting devices but failed to approve the corresponding and identical provisions to the IBC. The proposal corrects this inconsistent action as well as replaces the prescriptive provisions with a reference to a consensus standard which has been updated to specifically address these devices.

IRC/IBC coordination: The result of this two part code change will be consistency between the IBC and IRC in terms of requirements.
Updated standard ASTM F2090 – 08: Both the IBC and IRC currently reference the 2007 edition of the standard entitled "Specification for Window Fall Prevention Devices with Emergency Escape (Egress Release Mechanisms". This standard was updated in 2008 to address window opening control devices. However, it was not updated in time to be included by reference in the 2009 IBC and IRC. This standard includes the necessary window operational criteria which results in the window not being able to be opened beyond the 4 inch performance threshold which is currently found in IRC Section R612.4.1. This control device can be released to allow the window to be fully opened in order to comply with the emergency escape provisions in both the IBC (1029.2) and IRC (R310.1.1)

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: HEILSTEDT-RB-1-R612-IBC 1405.13.2

Public Hearing Results

PART II - IBC Fire Safety
Committee Action: **Approved as Modified**

Modify the proposal as follows:

1405.13.2.1 Window opening control devices. ~~When required elsewhere in this code, w~~Window opening control devices shall comply with ASTM F 2090. The window opening control device, after operation to release the control device allowing the window to fully open, shall not reduce the minimum net clear opening area of the window unit to less than the area required by Section 1029.2. ~~The device or any portion thereof shall not project more than 1 inch into the required net clear opening for a length not exceeding 3 inches when the window is in the fully open position.~~

(Portions of the proposal not shown remain unchanged)

Committee Reason: The committee agreed that it was appropriate to have consistency between the IRC and the IBC with respect to the provisions for window sills and window opening control devices. The modification appropriately removes projection requirements that have not been justified.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jeff Inks, Window and Door Manufacturer's Association, requests Approved as Modified by this public comment.

Modify the proposal as follows:

1405.13.2 Window sills. In Occupancy Groups R-2 and R-3, one- and two-family and multiple-family dwellings, where the opening of the sill portion of an operable window is located more than 72 inches (1829 mm) above the finished grade or other surface below, the lowest part of the clear opening of the window shall be a minimum of 24 inches (610 mm) above the finished floor surface of the room in which the window is located. Operable sections of windows shall not permit openings that allow passage of a 4 inch diameter sphere where such openings are located within 24 inches of the finished floor.

Exceptions:

1. Windows whose openings will not allow a 4-inch-diameter (102 mm) sphere to pass through the opening when the opening is in its largest opened position.
2. Openings that are provided with window fall prevention devices that comply with ASTM F 2090.
3. Windows that are provided with window opening control devices that comply with Section ~~1405.13.2.1~~ 1405.13.3.

~~1405.13.2.1~~ 1404.13.3 Window opening control devices. Window opening control devices shall comply with ASTM F 2090. The window opening control device, after operation to release the control device allowing the window to fully open, shall not reduce the minimum net clear opening area of the window unit to less than the area required by Section 1029.2.

Commenter's Reason: This change in the section number formatting is intended to ensure that all window opening control devices, regardless of whether or not they are used to serve as an exception to the sill height requirement, meet ASTM F2090.

Final Action: AS AM AMPC____ D

NOTE: PART I REPRODUCED FOR INFORMATIONAL PURPOSES ONLY – SEE ABOVE

PART I – IRC BUILDING/ENERGY

1. Revise as follows:

R612.2 Window sills. In dwelling units, where the opening of an operable window is located more than 72 inches (1829 mm) above the finished grade or surface below, the lowest part of the clear opening of the window shall be a minimum of 24 inches (610 mm) above the finished floor of the room in which the window is located. Operable sections of windows shall not permit openings that allow passage of a 4 inch diameter sphere where such openings are located within 24 inches of the finished floor.

Exceptions:

1. Windows whose openings will not allow a 4-inch-diameter (102 mm) sphere to pass through the opening when the opening is in its largest opened position.
2. ~~Openings that are provided with window fall prevention devices that comply with Section R612.3.~~
3. Openings that are provided with window fall prevention devices that comply with ASTM F 2090.
4. Windows that are provided with window opening ~~limiting~~ control devices that comply with ~~Section R612.4.~~ R612.3.

2. Delete without substitution:

~~**R612.3 Window fall prevention devices.** Window fall prevention devices and window guards, where provided, shall comply with the requirements of ASTM F 2090.~~

3. Renumber and revise Section R612.4 as follows:

~~R612.4~~ R612.3 Window opening ~~limiting~~ control devices. When required elsewhere in this code, window opening ~~limiting~~ control devices shall comply with ~~the provisions of this section.~~ ASTM F 2090. The window opening control device, after operation to release the control device allowing the window to fully open, shall not reduce the minimum net clear opening area of the window unit to less than the area required by Section R 310.1.1. The device or any portion thereof shall not project more than 1 inch into the required net clear opening for a length not exceeding 3 inches when the window is in the fully open position.

4. Delete without substitution:

~~**R612.4.1 General requirements**. Window opening limiting devices shall be self- acting and shall be positioned so as to prohibit the free passage of a 4.0-in. (102-mm) diameter rigid sphere through the window opening when the window opening limiting device is installed in accordance with the manufacturer's instructions.~~

~~**R612.4.2 Operation for Emergency Escape.** Window opening limiting devices shall be designed with release mechanisms to allow for emergency escape through the window opening without the need for keys, tools or special knowledge. Window opening limiting devices shall comply with all of the following:~~

1. ~~Release of the window opening-limiting device shall require no more than 15 lbf (66 N) of force.~~
2. ~~The window opening limiting device release mechanism shall operate properly in all types of weather.~~
3. ~~Window opening limiting devices shall have their release mechanisms clearly identified for proper use in an emergency.~~
4. ~~The window opening limiting device shall not reduce the minimum net clear opening area of the window unit below what is required by Section R310.1.1 of the code.~~

PART I - IRC
Committee Action: **Approved as Modified**

Modify the proposal as follows:

R612.3 Window opening control devices. ~~When required elsewhere in this code,~~ Window opening control devices shall comply with ASTM F 2090. The window opening control device, after operation to release the control device allowing the window to fully open, shall not reduce the minimum net clear opening area of the window unit to less than the area required by Section R 310.1.1. ~~The device or any portion thereof shall not project more than 1 inch into the required net clear opening for a length not exceeding 3 inches when the window is in the fully open position.~~

(Portions of proposal not shown remain unchanged)

Committee Reason: The committee feels this is a good change and the ICC CTC and industry has reached a consensus for a solution to the window opening control devices and achieves consistency with the IBC. The modification requires all window opening control devices to comply with the standard and eliminate the proposed language about hardware projection.

Assembly Action: **None**

RB127-09/10
R612.8, Chapter 44 (New)

Proposed Change as Submitted

Proponent: Jeff Burton, Director of Codes and Standards, representing Association of Millwork Distributors

1. Revise as follows:

R612.8 Other exterior window and door assemblies. Exterior windows and door assemblies not included within the scope of Section R612.6 or Section R612.7 shall be tested in accordance with ASTM E 330 or AMD SHEDS. Glass in assemblies covered by this exception shall comply with Section R308.5.

2. Add new standard to Chapter 44 as follows:

AMD Association of Millwork Distributors
10047 Robert Trent Jones Boulevard
Port Richey, FL 34655

SHEDS Side Hinged Exterior Door Standard

Reason: The code change proposal adds an additional requirement (option) to the code in that it includes a structural component interchangeability methodology that is prevalent in the side hinged exterior door (SHED) industry but is not addressed in the building codes or its current referenced standards. The addition of the AMD SHEDS (Side Hinged Exterior Door Standard), which is designed in accordance with the current industry ASTM E330 static pressure test, adds that needed structural component interchangeability option.

The current minimum code requirements for SHEDs adequately address concerns with public safety and protection of property, in that, to date, no empirical evidence or testimony has been provided to the ICC code development process proving that SHEDs are a significant failure relating to variable pressure from hurricanes force or high winds, in fact, the foremost leading post hurricane/building code experts provide no significant evidence of actual failures relating to SHEDs*. This lack of evidence supports current regulation and commonly used industry practices (component interchange) in place today. The current code is too restrictive in that it references SHED “system only” test standards and should allow for a SHEDs component interchange option similar to its allowances relating to fire rated doors.

Rainwater Management Performance of Newly Constructed Residential Building Enclosures During August and September 2004 by Dr. Joe Lstiburek of the Building Science Corp., the Home Builders Association of Metro Orlando and the Florida Home Builders Association

The Benefits of Modern Wind Resistant Building Codes on Hurricane Claim Frequency and Severity-A Summary Report by Dr. Timothy Reinhold at the Institute for Business and Home Safety

Post 2004 Hurricane Field Survey-an Evaluation of the Relative Performance of the Standard Building Code and the Florida Building Code by Dr. Kurt Gurley of the University of Florida.

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: A review of the standard proposed for inclusion in the code, AMD SHEDS, for compliance with ICC criteria for referenced standards given in Section 3.6 of Council Policy #CP 28 will be posted on the ICC website on or before September 24, 2009.

ICCFILENAME: BURTON-RB-1-R612.8

Public Hearing Results

Note: The following analysis was not in the Code Change Monograph:

Analysis: Review of proposed new standard indicated that, in the opinion of ICC Staff, the standard did not comply with ICC standards criteria, Section 3.6.3.1.

Committee Action: Approved as Submitted

Committee Reason: The committee feels this is a needed change and reflects industry practice as stated in the proponent's published reason. The new reference standard is in draft form and must be available by Final Action.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Jonathan Humble, ICC Reference Standards Committee, requests Disapproval.

Commenter's Reason: The ICC Reference Standards Committee is a committee that was organized "to support the codes development committees through the review of reference standards for the International Codes." We submit this code challenge to provide an opinion regarding code change.

It is the reference standards committee's view that the proposal currently lacks sufficient information concerning the promulgation process. We would preface this opinion that it is not our view to state that the proposed document is technically deficient or that the proposal does not have technical merit, but rather to state that the document development process and maintenance process do not comply with ICC Council Policy 28, specifically Section 3.6.3, which requires standards be completed and readily available.

We therefore request Disapproval.

Public Comment 2:

Jeff Inks, Window and Door Manufacturer's Association, requests Disapproval.

Commenter's Reason: The first and foremost reason we are requesting disapproval is because as of submission of this public comment, the document is still in drafting stages and has not yet undergone even an initial public review.

While component interchangeability is not new, it is complex and must be carefully considered. Although we appreciate the efforts of the proponent to include a standard that can address the issue, approval of a draft standard such as that proposed by RB127 is not justified and does not meet ICC criteria for referenced standards.

Public Comment 3:

Julie Ruth: JRuth Code Consulting, representing American Architectural Manufacturer's Association, requests Disapproval.

Commenter's Reason: RB127 adds a new standard to the IRC, Association of Millwork Distributor's *Side Hinged Exterior Door Standard (SHEDS)*, for the determination of the design pressure rating of exterior side hinged doors. The proposal would permit the use of the component interchangeability methodology provided in AMD SHEDs as an alternative to the current code requirement for full system testing of side hinged doors in accordance with ASTM E330.

AAMA seeks the disapproval of RB127 for several reasons:

1. The standard is not yet complete. The IRC Building and Energy Committee approved a draft of AMD SHEDs during the 2009 Code Development Hearings without knowledge of what the final content of the standard would be. For example, there were several instances in the draft edition of the standard that was approved where actual values had not yet been determined, and the value "x" or "xx" only was stated. Two such examples were Section 8.3.3, which stated "Determine change in length from original measurement and record percentage. The lineal shrinkage shall not exceed XX%" and Section 8.4.3, which stated "Determine change in height and record percentage. The change in functional height shall not exceed XX%."

Obviously, a document that contains such language is not enforceable, and should not be approved for reference in the IRC, or any other International Code.

Furthermore, although AMD indicated during the Code Development Hearing it was their intent to seek approval of AMD SHEDs from the American National Standards Institute, they had not yet begun the process to achieve such approval at that time. Although ICC procedures do not require standards to be approved by ANSI to be referenced in International Codes, it does require they be developed in an open, consensus process such as ANSI or ASTM. If approval of the standard by ANSI has not been received by the Final Action Hearings on RB proposals in May 2010, then compliance with the requirement for development of the standard through an open, consensus process should be demonstrated in some other manner. As of the date of this submittal, evidence of compliance with the requirements of the ICC procedures has not been provided.

2. The provisions of the standard are inadequate. The members of the American Architectural Manufacturers Association (AAMA) Door Council have been working towards the development of a component interchangeability methodology for the rating of exterior side hinged doors for several years now. What we have found is that even just rating these products for structural design pressure (not even including consideration of resistance to air infiltration or water penetration) is significantly complicated. Analysis of an exterior door subject to a uniform design pressure perpendicular to the door is the analysis of a flat plate subject to a uniform load. Such analysis is difficult even if the plate is uniform in composition and symmetrically supported within the opening. An exterior door is not uniform in composition in that some sections of the door consist of door skins over framing, some sections consist of door skins over insulation, some sections consist of glazing, with or without its own framing, and some sections include hardware. The door is also not uniformly supported. One long edge will typically be supported against design pressure perpendicular to the plane of the door by three or four hinges that are varying distances from the corner of the door. The other long edge is typically supported by one lock/latch that is located somewhere along the edge, but usually not quite centered on it, and which in some cases anchors into a door jamb, and in other cases, anchors into the long edge of another door. This may be coupled by bolts on the top or bottom of the door that anchor it further at those corners, or it may not.

Overall, the analysis of what happens to that door (both the slab itself, and the hardware securing it to the opening) when subjected to structural loads is extremely complex. AAMA has been certifying fenestration products for structural performance, as well as resistance to air and water infiltration, for almost 50 years. Drawing upon the experience gained through that, and in an attempt to begin to address this complexity, a series of preliminary tests were conducted. Significant, unexpected inconsistencies in overall design pressures (ranging from 2.5 to 45 psf) resulted during door system testing using doors of like panel, frame and glazing constructions that would have otherwise been anticipated to have consistent results.

The door systems tested were provided by three different manufacturers and were produced with the following commonalities: overall size, type and gauge of skin material, stile material, insulating material, glass make-up, and identical lock/deadbolt. Some variables included hinges, frame/stop design, density of insulating material, and IG sealants.

The test results demonstrated that even with predominately common elements in the construction of the door, variation of single components such as the hinges, the frame/stop design, the density of the insulation material, and the sealants on the Insulating Glass (IG) units could provide dramatically different results with regards to the doors ability to withstand uniform pressure.

The methodology provided by AMD in their SHED does not address this variation in the overall door assemblies' ability to withstand structural load.

3. Validation test data from proponents of AMD SHEDs has not been made available for review. Confirmation of the validity of a proposed new testing and rating method, either through peer review, round robin testing, or some other method of verifying the validity of the results, is the hallmark of meaningful standards development. The need for it should not be dismissed or lightly set aside.
AAMA intends to continue to conduct research, including both testing and structural analysis, to develop the appropriate method to be used for interchangeability of components in door systems. We believe it can be done, and we intend to draw upon our years of experience in testing and certification of fenestration products to do that. But we also know the approach taken by AMD in their SHEDs is not the correct approach. It is premature and inadequate. Its use will result in erroneously rated door systems that will not perform as anticipated, hoped or needed when subjected to high wind events.

4. Use of the proposed referenced standard would significantly weaken the current requirements of the IRC. During the committee discussion on RB127 there seemed to be some confusion with regards to the current requirements of the IRC. Some parties seemed to be of the impression that there currently are no requirements for side hinged doors in the IRC, and that adding reference to AMD SHEDs would "at least be better than nothing."

In actuality, the 2009 IRC does have requirements for determining the resistance of side hinged exterior doors to design wind pressure. It requires doors such as these, which are not within the scope of AAMA/WDMA/CSA 101/I.S.2/A440, to be tested in accordance with ASTM E330. ASTM E330 requires a full scale test of the entire assembly being evaluated. Testing individual components and then compiling those components into an assembly under the methodology presented in AMD SHEDs does not provide an equivalent amount of information with regards to the performance of the completed assembly as a full scale test conducted in accordance with ASTM E330 does. Whether or not AMD SHEDs is "better than nothing" could be argued one way or the other, but it is very clear that AMD SHEDs is not better than the current code requirement for full scale testing in accordance with ASTM E330, or even equivalent.

Public Comment 4:

Thomas Meyers, City of Central City, CO, representing Colorado Chapter of ICC, requests Disapproval.

Commenter's Reason: The IRC building and energy committee approved the SHEDS standards with the understanding that the standard would be finalized and published prior to the final action hearings. This proposal is intended to provide a means to disapprove the standard should the SHEDS standards body fail to have the document completed in time for testimony in Dallas, TX.

Analysis: The standard proposed for reference in the code, AMD SHEDS was not completed and readily available at the time of the Code Development Hearings in Baltimore. ICC Council Policy CP#28-05, Code Development, Section 3.6.3.1, required that the standard must be completed and readily available at the time of these Final Action Hearings in order to be considered for inclusion in the code.

Final Action: AS AM AMPC____ D

RB129-09/10
R613.7

Proposed Change as Submitted

Proponent: Edward L. Keith, representing APA – The Engineered Wood Association

Revise as follows:

R613.7 Drilling and notching. The maximum vertical chase penetration in SIPs shall have a maximum side dimension of 2 inches (51 mm) centered in the panel core. Vertical chases shall have a minimum spacing of 24-inches (610 mm) on center. Maximum of two horizontal chases shall be permitted in each wall panel - one at 14 inches (360 mm) from the bottom of the panel and one at mid-height of the wall panel. The maximum allowable penetration size in a wall panel shall be circular or rectangular with a maximum dimension of 12 inches (300 mm). <u>The minimum wall length for such a penetration shall be 20 feet (6100 mm) and only one such penetration shall be permitted in each full 20 foot (6100 mm) length of wall. Where multiple penetrations are to be located in a single wall line, they shall be placed no closer together than 20 feet (6100 mm) measured between adjacent edges of two penetrations.</u> Overcutting of holes in facing panels shall not be permitted.

Reason: The existing R613.7 provides no limitation on the field-placement of these holes up to 12" x 12" in size. As such, the proposed language is added to clarify the limitation proposed in the original code proposal in 2006. From an engineering perspective, a hole this size will have minimal impact on the capacity of the wall system as long as the wall or the spacing between holes is sufficiently long (20 feet or longer).

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: KEITH-RB-1-R613.7

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The SIP Panels are an engineered product and the code cannot provide a prescriptive requirement. The penetration will have to be approved by the manufacturer and will be shown on the engineered drawings.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Edward L. Keith, APA- The Engineered Wood Association, requests Approval as Submitted.

Commenter's Reason: I ask that the body overturn the Committee's recommendation and accept the proposal as submitted. While it is true that SIP panels are delivered with a set of construction documents that have window and door openings "engineered" on the drawings, it is not uncommon that, during construction, the need arises for small field-applied openings that are not shown on the drawings. Some typical examples would be plumbing penetrations, "wet" room vents, or through-wall vented zero-clearance fire places, etc.

This proposal was developed on behalf of the Structural Insulated Panel Association to provide for some guidance for the builder and/or inspector on what size and how often such small openings can be installed without an engineering analysis by the manufacturer. The prescriptive limits of this proposal were determined as being appropriate by the technical staffs of the SIP manufacturers.

Another purpose of this proposal is to provide guidance for building officials in the evaluation of remodeling permits in the future that require small through-wall penetrations. Note that the maximum 12-inch by 12-inch hole size was specified as this is the size of the through-wall vent (with thermal protection) most commonly specified for the installation of high-efficiency zero-clearance fire places.

Final Action: AS AM AMPC____ D

RB135-09/10
Table R703.4

Proposed Change as Submitted

Proponent: Jay H. Crandell, PE, d/b/a ARES Consulting, representing the Foam Sheathing Coalition

Revise table as follows:

TABLE R703.4
WEATHER–RESISTANT SIDING ATTACHMENT AND MINIMUM THICKNESS

				TYPE OF SUPPORTS FOR THE SIDING MATERIAL AND FASTENERS [b,c,d]					
SIDING MATERIAL	NOMINAL THICKNESS[a] (INCHES)	JOINT TREATMENT	WATER-RESISTIVE BARRIER REQUIRED	WOOD OR WOOD STRUCTURAL PANEL SHEATHING INTO STUD	FIBERBOARD SHEATHING INTO STUD	GYPSUM SHEATHING INTO STUD	FOAM PLASTIC SHEATHING INTO STUD	DIRECT TO STUDS	NUMBER OR SPACING OF FASTENERS

(Portions of table not shown remain unchanged)

a. through c. *(No change)*

d. Nails or staples shall be aluminum, galvanized, or rust-preventative coated and shall be driven into the studs where ~~for~~ fiberboard, ~~or~~ gypsum, or foam plastic sheathing backing is used. Where wood or wood structural panel sheathing is used, nails shall be driven into studs unless otherwise permitted to be driven into sheathing in accordance with the siding manufacturer's installation instructions.

e. through z. *(No change)*

Reason: For many cases with siding attached over wood or wood structural panel sheathing, insufficient fastener penetration is provided if siding nails required by Table R703.4 are driven only into the sheathing. Only in cases where specific fastening instructions are provided for use of sheathing as a nail base should such a practice be permitted. In general, this will require a closer fastener spacing than currently required in Table R703.4 to account for the reduced withdrawal resistance of the siding nails installed in sheathing only (which may be no thicker than 3/8"). The change to the column heading for 'wood or wood structural panel sheathing' and footnote 'd' in Table R703.4 is needed to address this issue and avoid a common source of confusion resulting in potentially inadequate siding installations.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: CRANDELL-RB-4-T. R703.4

Public Hearing Results

Committee Action: **Approved as Modified**

Modify the proposal as follows:

d. Nails or staples shall be aluminum, galvanized, or rust-preventative coated and shall be driven into the studs where fiberboard, gypsum, or foam plastic sheathing backing is used. Where wood or wood structural panel sheathing is used, ~~nails~~ fasteners shall be driven into studs unless otherwise permitted to be driven into sheathing in accordance with the siding manufacturer's installation instructions.

(Portions of proposal not shown remains unchanged)

Committee Reason: The committee feels this provides further clarity to the code and gives options where not nailed into studs. This helps to bring new products into the code. The modification changes the word "nails" to "fasteners" and will add flexibility to the code.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Dennis Pitts, American Wood Council, American Forest & Paper Association, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

TABLE R703.4

SIDING MATERIAL	**NOMINAL THICKNESS[a] (inches)**	**JOINT TREATMENT**	**WATER-RESISTIVE BARRIER REQUIRED**	**TYPE OF SUPPORTS FOR THE SIDING MATERIAL AND FASTENERS[b,c,d]**					
				Wood or wood structural panel sheathing ~~into stud~~	**Fiberboard sheathing into stud**	**Gypsum sheathing into stud**	**Foam plastic sheathing into stud**	**Direct to studs**	**Number of spacing of fasteners**
(Remainder of table unchanged)									

a. through c. *(No change)*

d. Nails or staples shall be aluminum, galvanized, or rust-preventative coated and shall be driven into the studs where fiberboard,gypsum, or foam plastic sheathing ~~backing~~ is used as backing material to support siding. Where wood or wood structural panel sheathing is used, fasteners shall be driven into studs ~~unless otherwise permitted to be driven into~~ or sheathing in accordance with the provisions of this code or in accordance with the siding manufacturer's installation instructions.

e. through z. *(No change)*

Commenter's Reason: The original change raised the point that some proprietary siding products have special provisions for attaching the siding material to wood structural panels in order to meet higher wind load ratings. The proposed solution eliminated the option of attaching siding to wood structural panels to avoid any misapplication. However, this solution only corrects the misapplication of proprietary siding while eliminating a common application permitted in the IRC such as wood shakes and shingles (703.5.3) and exterior plaster (R703.6.1). The proposed modifications recognizes that attachment of siding directly to wood structural panel sheathing is desirable and often recommended in the IRC while still highlighting the problem identified by the previous proposal.

Public Comment 2:

Edward L. Keith, APA-The Engineered Wood Association, request Disapproval.

Commenter's Reason: I request that the body overturn the Committee's recommendation for approval as submitted and disapprove the original code change proposal.

This code change reverses the way the IRC and legacy One and Two Family Dwelling Codes have dealt with nailable structural panel wall sheathing. Since 1995, the One and Two Family Dwelling Codes has recognized wood structural panels as a nailable sheathing in essentially the same table as Table R703.4 in the 2009 IRC. As such, the heading of the fifth column from the left ("Wood or Wood Structural Panel Sheathing") for the last 15 years has permitted nailing into wood or wood structural panel sheathing and not required nailing into the studs unless specifically recommended by the siding manufacturer.

Testimony was heard from the vinyl siding industry that they do currently have recommendations for nailing into studs as well as additional nailing into the wood structural panel sheathing for increased wind performance. This change makes the code's minimum recommendations more stringent than the manufacturer's!

Note also that "Wood Structural Panel Lap Siding" in this same table requires nailing into the nailable sheathing in that it requires nails along bottom edge at 8 inches on center. With the change as proposed, this lap siding could only be applied over studs at 8 inches on center, which is not only impractical, but is not supported by the good performance history of the current code provisions known to every jurisdiction in this country.

The proposed change will also eliminate the installation of siding products over structural insulated panels (SIPs) as recognized in Section R613.

Elimination of the recognition of wood or wood structural panel as a nailable sheathing may have numerous unintended consequences besides those mentioned above. Remember there are 17 different kinds of siding listed in the table and each with traditional attachment methods. Altering the code to not permit nailing into wood structural panel sheathing has the potential to make the accepted installation practices for numerous types of siding (in addition to vinyl siding and wood structural panel lap siding) no longer valid.

For over 15 years – it will be 17 years by the time the 2012 IRC is published – wood structural panels have been recognized as nailable sheathing. The current attachment provisions have performed adequately in the past and are the appropriate minimum attachment standard. For all these years, if a manufacturer has had more stringent attachment recommendations, these specific requirements have always controlled over the code minimum recommendations. This is not going to change in the 2012 IRC. This code change proposal reverses the way the code reads. It treats wood and wood structural panel sheathing like the non-structural sheathings and essentially sets a maximum attachment standard when wood structural panel sheathing is used.

The purpose of this code change proposal is not fire and life safety and was accompanied with no technical justification. This proposal ignores the 17 year history of good performance history by wood structural panels as nailable sheathing and will ignore significant advantages for components and cladding installed in conjunction with wood structural panels. Please reverse the Committee's decision by disapproving the proposed changes.

Final Action: AS AM AMPC____ D

RB137-09/10
R703.7

Proposed Change as Submitted

Proponent: Kimdolyn Boone, representing DuPont Building Innovations

Revise as follows:

R703.7 Stone and masonry veneer, general. Stone and masonry veneer shall be installed in accordance with this chapter, Table R703.4, ~~and~~ Figure R703.7, Section R703.6.3 and Sections 6.1 and 6.3 of ACI 530/ASCE 5/TMS-402. These veneers installed over a backing of wood or cold-formed steel shall be limited to the first *story* above-grade and shall not exceed 5 inches (127 mm) in thickness. See Section R602.12 for wall bracing requirements for masonry veneer for wood framed construction and Section R603.9.5 for wall bracing requirements for masonry veneer for cold-formed steel construction.

Exceptions:

1. For all buildings in Seismic Design Categories A, B and C, exterior stone or masonry veneer, as specified in Table R703.7(1), with a backing of wood or steel framing shall be permitted to the height specified in Table R703.7(1) above a noncombustible foundation.
2. For detached one- or two-family *dwellings* in Seismic Design Categories D0, D1 and D2, exterior stone or masonry veneer, as specified in Table R703.7(2), with a backing of wood framing shall be permitted to the height specified in Table R703.7(2) above a noncombustible foundation.

Reason: Clarification of current requirement of the code. The requirements are currently listed in the Table 703.4 and footnotes. Adding the reference to the text makes both the table & text agree.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: BOONE-RB-1-R703.7

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: Based on the proponent's request for disapproval. The committee feels the proponent should work with interested parties on a consensus of what is required for anchored and adhered veneer and bring this back to Final Action.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Kimdolyn Boone, DuPont Building Innovations, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R703.7 Stone and masonry veneer, general. Stone and masonry veneer shall be installed in accordance with this chapter, Table R703.4~~,~~ and Figure R703.7~~, Section R703.6.3 and Sections 6.1 and 6.3 of ACI 530/ASCE 5/TMS-402~~. These veneers installed over a backing of wood or cold-formed steel shall be limited to the first *story* above-grade and shall not exceed 5 inches (127 mm) in thickness. See Section R602.12 for wall bracing requirements for masonry veneer for wood framed construction and Section R603.9.5 for wall bracing requirements for masonry veneer for coldformed steel construction.

Exceptions:

1. For all buildings in Seismic Design Categories A, B and C, exterior stone or masonry veneer, as specified in Table R703.7(1), with a backing of wood or steel framing shall be permitted to the height specified in Table R703.7(1) above a noncombustible foundation.
2. For detached one- or two-family *dwellings* in Seismic Design Categories D_0, D_1 and D_2, exterior stone or masonry veneer, as specified in Table R703.7(2), with a backing of wood framing shall be permitted to the height specified in Table R703.7(2) above a noncombustible foundation.

R703.12 Adhered masonry veneer installation. Adhered masonry veneer shall be installed in accordance with the manufacturer's instructions, Section R703.6.3 and Sections 6.1 and 6.3 of ACI 530/ASCE 5/TMS-402.

Commenter's Reason: This modification was developed with interested parties within industry in response to the technical committee's direction to *"work with interested parties on a consensus of what is required for anchored and adhered veneer and bring this back to Final Action".*

The purpose of the original code change was to clarify and make explicitly clear the existing provisions to install adhered masonry veneer. Currently, these provisions reside in Table R703.4 under "adhered veneer", footnote "w" of Table R703.4 and Section R703.12 on adhered masonry veneer installation. Section R703.7 addresses anchored masonry veneer and is not appropriate for adhered masonry veneer.

This change adds footnote "w" of Table R703.4 to the adhered masonry veneer installation provisions found in Section R703.12. In this way, it is explicitly clear that adhered masonry veneer must not only comply with the manufacturer's instructions, but also that it be installed in accordance with Section R703.6.3 and the requirements of Sections 6.1 and 6.3 of ACI 530/ASCE 5/TMS 402. By not including this text in Section R703.12, the User may not install the water-resistive barrier required by Section R703.6.3 and may weigh more than 15 lb/ft^2 as required by Sections 6.1 and 6.3 of ACI 530/ASCE 5/TMS 402.

This change is necessary in order to ensure that adhered masonry veneer is installed correctly. It does this by having all the adhered masonry veneer requirements included in the code text.

Final Action: AS AM AMPC____ D

RB140-09/10
R703.7.4, R703.7.4.2, R703.7.4.3, Table R703.7.4 (New)

Proposed Change as Submitted

Proponent: Charles Clark, Brick Industry Association, representing the Masonry Alliance for Codes and Standards (MACS)

1. Revise as follows:

R703.7.4 Anchorage. Masonry veneer shall be anchored to the supporting wall with corrosion-resistant metal ties embedded in mortar or grout and extending into the veneer a minimum of 11/2 inches (38 mm), with not less than 5/8 inch (15.9 mm) mortar or grout cover to outside face. Masonry veneer shall conform to Table R703.7.4. ~~Where veneer is anchored to wood backings by corrugated sheet metal ties, the distance separating the veneer from the sheathing material shall be a maximum of a nominal 1 inch (25 mm). Where the veneer is anchored to wood backings using metal strand wire ties, the distance separating the veneer from the sheathing material shall be a maximum of 41/2 inches (114 mm). Where the veneer is anchored to cold-formed steel backings, adjustable metal strand wire ties shall be used. Where veneer is anchored to cold-formed steel backings, the distance separating the veneer from the sheathing material shall be a maximum of 41/2 inches (114 mm).~~

2. Delete without substitution:

~~**R703.7.4.2 Air space.** The veneer shall be separated from the sheathing by an air space of a minimum of a nominal 1 inch (25 mm) but not more than 41/2 inches (114 mm).~~

3. Revise as follows:

R703.7.4. 3 Mortar or grout fill. As an alternate to the air space required by ~~Section~~ ~~R703.7.4.2~~ Table R703.7.4, mortar or grout shall be permitted to fill the air space .When the air space is filled with mortar, a water-resistive barrier is required over studs or sheathing. When filling the air space, replacing the sheathing and water-resistive barrier with a wire mesh and *approved* water-resistive barrier or an *approved* water-resistive barrier-backed reinforcement attached directly to the studs is permitted.

4. Add new table as follows:

TABLE R703.7.4
TIE ATTACHMENT AND AIR SPACE REQUIREMENTS

BACKING AND TIE	MINIMUM TIE	MINIMUM TIE FASTENER [A]	MINIMUM AIR SPACE	MAXIMUM AIR SPACE
Wood Backing with Corrugated Sheet Metal	22 U.S. gage (0.0299 in.) x 7/8 in. wide	8d common nail [b]	Nominal 1 in. between sheathing and veneer	Nominal 1 in. between sheathing and veneer
Wood Backing with Metal Strand Wire	W1.7 (No. 9 U.S. gage; 0.148 in.) with hook embedded in mortar joint	8d common nail [b]	Nominal 1 in. between sheathing and veneer	4½ in. between backing and veneer
Cold-Formed Steel Backing with Adjustable Metal Strand Wire	W1.7 (No. 9 U.S. gage; 0.148 in.) with hook embedded in mortar joint	No. 10 screw	Nominal 1 in. between sheathing and veneer	4½ in. between backing and veneer

For SI: 1 inch = 25.4 mm.

a. In Seismic Design Category D_0, D_1 or D_2, the minimum tie fastener shall be an 8d ring-shank nail or a No. 10 screw, 2 ½ inches long.
b. All fasteners shall have rust inhibitive coating suitable for the installation in which they are being used, or be manufactured from material not susceptible to corrosion.

Reason: This code change adds a table to the anchored masonry veneer provisions that accomplishes the following:

1) Makes the code easier to use by having minimum requirements for tie and tie fastener in a tabular form. The table also includes minimum and maximum air space requirements.
2) Footnote a) adds a requirement that a ring-shank nail is to be used when the veneer is constructed in a Seismic Design Category D_0, D_1 or D_2. Recent full-scale building shaking-table testing conducted at the University of California San Diego found that “fasteners on one side of the specimen failed by extraction of nails under dynamic tensile loads, at levels of shaking less than the Design Basis Earthquake (DBE). This behavior is not consistent with performance objectives for veneer. Current IRC requirements for the attachment of connectors to wood-stud backing need improvement in Seismic Design Category D_0 and above. (See references in Bibliography below)
3) Footnote b) requires that the fasteners be able to resist corrosion. This text is very similar to existing text in Section R603.2.4 on fastening requirements.

Bibliography:

1. Klingner, Richard E., Shing, P. Benson, McGinley, Mark W., McLean, David I., Okail, Hussein, and Jo, Seongwoo, “NSF NEES Small-Group Project on Performance-based Design of Masonry and Masonry Veneer: Overview and Preliminary Results,” *TMS Journal*, The Masonry Society, Boulder, Colorado, December 2008 (date submitted for publication).
2. Klingner, Richard E., “Behavior of Anchored Masonry Veneer with Light Wood Stud-Framing or Masonry Backing in Full-Scale Whole-Building Shaking-Table Tests,” *TMS Journal*, The Masonry Society, Boulder, Colorado, June 2009 (date submitted for publication).

Cost Impact: The code change proposal may slightly increase the cost of anchored masonry veneer construction in Seismic Design Categories D_0, D_1 and D_2.

ICCFILENAME: CLARK-RB-4-R703.7.4

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: Based on the proponent's request for disapproval. The committee feels the proponent should work with interested parties on a consensus of what is required for anchored and adhered veneer and bring this back to Final Action.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Charles Clark, AIA, PE, of the Brick Industry Association, representing the Masonry Alliance for Codes and Standards (MACS); Steven Winkel, FAIA, PE, and J. Daniel Dolan, PhD, PE, representing the Federal Emergency Management Agency/Building Seismic Safety Council Code Resource Support Committee (FEMA/BSSCCRSC); Bonnie Manley, American Iron and Steel Institute (AISI), representing The Steel Framing Alliance (SFA), requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R703.7.4 Anchorage. Masonry veneer shall be anchored to the supporting wall studs with corrosion-resistant metal ties embedded in mortar or grout and extending into the veneer a minimum of 1 ½ inches (38 mm), with not less than 5/8 inch (15.9 mm) mortar or grout cover to outside face. Masonry veneer shall conform to Table R703.7.4.

TABLE R703.7.4
TIE ATTACHMENT AND AIR SPACE REQUIREMENTS

Backing and Tie	Minimum Tie	Minimum Tie Fastener [a]	~~Minimum Air Space~~	~~Maximum Air Space~~
			Air Space	
Wood Stud Backing with Corrugated Sheet Metal	22 U.S. gage (0.0299 in.) x 7/8 in. wide	8d common nail [b] (2 ½ in. x 0.131 in.)	~~Nominal 1 in. between sheathing and veneer~~ Nominal 1 in. between sheathing and veneer	~~Nominal 1 in. between sheathing and veneer~~
Wood Stud Backing with Metal Strand Wire	W1.7 (No. 9 U.S. gage; 0.148 in.) with hook embedded in mortar joint	8d common nail [b] (2 ½ in. x 0.131 in.)	Minimum ~~N~~nominal 1 in. between sheathing and ~~veneer~~	Maximum 4½ in. between backing and ~~veneer~~
Cold-Formed Steel Stud Backing with Adjustable Metal Strand Wire	W1.7 (No. 9 U.S. gage; 0.148 in.) with hook embedded in mortar joint	No. 10 screw extending through the steel framing a minimum of three exposed threads	Minimum ~~N~~nominal 1 in. between sheathing and veneer	Maximum 4½ in. between backing and veneer

For SI: 1 inch = 25.4 mm.

a. In Seismic Design Category D_0, D_1 or D_2, the minimum tie fastener shall be an 8d ring-shank nail (2 ½ in. x 0.131 in.) or a No. 10 screw~~, 2 ½ inches long.~~ extending through the steel framing a minimum of three exposed threads.
b. All fasteners shall have rust inhibitive coating suitable for the installation in which they are being used, or be manufactured from material not susceptible to corrosion.

(Portions of proposal not shown remain unchanged)

Commenter's' Reason: While the IRC Building/Energy Committee recommended that this code change be Approved as Submitted (AS), they also indicate in their Committee Reason statement that the change needs more work and the proponent should work with interested parties and bring back in a public comment the modification that was ruled out of order. The proposed modification submitted with this Public Comment complies with the committee's request and adds further clarity to the provisions.

Specifically, the modification accomplishes four things:

1) Clarifies that the air space requirements in the table are either minimums or maximums depending on the situation.
2) Includes the dimensions of the nails to be used for wood construction.
3) Specifies the minimum penetration for acceptable performance of screws used with steel framing.
4) Specifies that the ties are required to be attached to the studs and not the sheathing.

Final Action: AS AM AMPC____ D

RB145-09/10
R703.8

Proposed Change as Submitted

Proponent: Jeff Lowinski, representing the Window and Door Manufacturers Association (WDMA)

1. Add new definition as follows:

<u>**PAN FLASHING.** Corrosion-resistant flashing at the base of an opening that is integrated into the building exterior wall to direct water to the exterior and is pre-manufactured, fabricated, formed or applied at the job site.</u>

2. Revise as follows:

R703.8 Flashing. *Approved* corrosion-resistant flashing shall be applied shingle-fashion in a manner to prevent entry of water into the wall cavity or penetration of water to the building structural framing components. Self-adhered membranes used as flashing shall comply with AAMA 711. The flashing shall extend to the surface of the exterior wall finish. *Approved* corrosion-resistant flashings shall be installed at all of the following locations:

1. Exterior window and door openings. Flashing at exterior window and door openings shall extend to the surface of the exterior wall finish or to the water-resistive barrier for subsequent drainage. <u>Flashing at exterior window and door openings shall be installed in accordance with one or more of the following:</u>
    <u>1.1.</u> <u>The fenestration manufacturer's installation and flashing instructions, or for applications not addressed in the fenestration manufacturer's instructions, in accordance with the flashing manufacturer's instructions. Where flashing instructions or details are not provided, pan flashing shall be installed at the sill of exterior window and door openings. Pan flashing shall be sealed or sloped in such a manner as to direct water to the surface of the exterior wall finish or to the water-resistive barrier for subsequent drainage. Openings using pan flashing shall also incorporate flashing or protection at the head and sides.</u>
    <u>1.2.</u> <u>In accordance with the flashing design or method of a registered design professional.</u>
    <u>1.3.</u> <u>In accordance with other approved methods.</u>
2. At the intersection of chimneys or other masonry construction with frame or stucco walls, with projecting lips on both sides under stucco copings.
3. Under and at the ends of masonry, wood or metal copings and sills.
4. Continuously above all projecting wood trim.
5. Where exterior porches, decks or stairs attach to a wall or floor assembly of wood-frame construction.
6. At wall and roof intersections.
7. At built-in gutters.

Reason: This proposal identifies alternate flashing methods for windows and doors that complement the requirements of Section R703.8 and includes mandatory options for window and door flashing depending on the conditions of the project.

Window and door manufactures are required, by Section R613.1, to provide installation instructions for each window and door. Most window and door manufacturers require installation per their instructions and many window and door manufacturers are incorporate a pan flashing in their window and door installation instructions. Window and door manufacturers create installation and flashing instructions for a wide variety of wall conditions but are unable to create installation instructions for every conceivable wall condition. The 2nd and 3rd flashing methods identified in this proposal allows necessary flexibility while retaining the performance requirements of Section R703.8.

This proposal also introduces a definition of pan flashing into the code.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: LOWINSKI-RB-5-R703.8

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee feels this is close but needs more work. Item 1.1 is confusing and should be a list rather than text. Also, the term "other approved methods" needs to be defined.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jeff Inks, Window and Door Manufacturer's Association, requests Approval as Modified by this Public Comment.

Replace proposal as follows:

R703.8 Flashing. *Approved* corrosion-resistant flashing shall be applied shingle-fashion in a manner to prevent entry of water into the wall cavity or penetration of water to the building structural framing components. Self-adhered membranes used as flashing shall comply with AAMA 711. The flashing shall extend to the surface of the exterior wall finish. *Approved* corrosion-resistant flashings shall be installed at all of the following locations:

1. Exterior window and door openings. Flashing at exterior window and door openings shall extend to the surface of the exterior wall finish or to the water-resistive barrier for subsequent drainage. <u>Flashing at exterior window and door openings shall be installed in accordance with one or more of the following:</u>
   <u>1.1</u> <u>The fenestration manufacturer's installation and flashing instructions.</u>
   <u>1.2</u> <u>For applications not addressed in the fenestration written manufacturer's instructions, in accordance with the flashing manufacturer's written instructions, or flashing method of a registered design professional.</u>
2. At the intersection of chimneys or other masonry construction with frame or stucco walls, with projecting lips on both sides under stucco copings.
3. Under and at the ends of masonry, wood or metal copings and sills.
4. Continuously above all projecting wood trim.
5. Where exterior porches, decks or stairs attach to a wall or floor assembly of wood-frame construction.
6. At wall and roof intersections.
7. At built-in gutters.

Commenter's Reason: As noted by the Committee in their reason statement, they agreed with the intent of the original proposal which is to respond to the need for providing the flexibility to use alternative flashing methods that are compliant with the requirements in section R703.8, if there are project specific conditions that are not covered by the manufacturer's installation instructions. However, the Committee recommended that the provisions in item 1.1 in the original proposal be listed instead of combined in a single paragraph and that item 1.4 "Other approved methods" be defined if it was to be included.

The modification proposed by this comment addresses the Committee's concerns and actually further simplifies the section. Pan flashing language was removed because it can be covered by items 1.1 & 1.2 as proposed in this comment, and "Other approved methods" was removed because it is not necessary. Manufacturers are still required by Section 612.1 to provide written instructions, which they do. However, while a manufacturer's instructions do cover a wide variety of wall and project conditions, they simply cannot account for every conceivable project specific condition that may need to be considered given the virtually limitless set of conditions that are possible in residential construction. The IRC therefore needs to provide some flexibility at the local level to allow for flashing alternatives that are compliant with the performance requirements of 703.8, but may not be expressly provided for in the manufacturer's instructions. Item 1.2 covers that situation.

Final Action: AS AM AMPC____ D

RB146-09/10
R703.8

Proposed Change as Submitted

Proponent: Mike Rice, Maplewood, MN, representing the Association of Minnesota Building Officials

Revise as follows:

R703.8 Flashing. *Approved* corrosion-resistant flashing shall be applied shingle-fashion in a manner to prevent entry of water into the wall cavity or penetration of water to the building structural framing components. Self-adhered membranes used as flashing shall comply with AAMA 711. The flashing shall extend to the surface of the exterior wall finish. *Approved* corrosion-resistant flashings shall be installed at all of the following locations:

1. Exterior window and door openings. Flashing at exterior window and door openings shall extend to the surface of the exterior wall finish or to the water-resistive barrier for subsequent drainage.
2. At the intersection of chimneys or other masonry construction with frame or stucco walls, with projecting lips on both sides under stucco copings.
3. Under and at the ends of masonry, wood or metal copings and sills.
4. Continuously above all projecting wood trim.
5. Where exterior porches, decks or stairs attach to a wall or floor assembly of wood-frame construction.

6. At wall and roof intersections. Kick out flashing shall be installed where the lower portion of a sloped roof stops within the plane of an intersecting wall cladding in such a manner as to divert or kick out water away from the assembly.
7. At built-in gutters.

Reason: This change would complement the current code addressing wall and roof intersections and further prevent water from entering the wall cavity or penetrating to the structural building components. Step flashing at wall and roof intersections is incomplete without the kick out flashing, where the lower portion of a sloped roof stops within the plane of an intersecting wall. The water must be diverted away or it will find a way behind the water-resistive barrier and the siding or, in some cases, it will go through the siding. The benefit of adding the kick out flashing would far exceed the cost, as the cost would be little.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: RICE-RB-2-R703.8

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee feels this needs to be addressed but it belongs in Chapter 9. The proponent needs to rework and bring this back. This needs a detail or definition of "kick out flashing".

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Scott Dornfeld, City of Delano, requests Approval as Modified by this Public Comment.

Modify the proposal as:

R703.8 Flashing. Approved corrosion-resistant flashing shall be applied shingle-fashion in a manner to prevent entry of water into the wall cavity or penetration of water to the building structural framing components. Self-adhered membranes used as flashing shall comply with AAMA 711. The flashing shall extend to the surface of the exterior wall finish. Approved corrosion-resistant flashing shall be installed at all of the following locations:

1. Exterior window and openings. Flashing at exterior window openings shall extend to the surface of the wall finish or to the water-restive barrier for subsequent drainage.
2. At the intersection of chimneys or other masonry construction with frame or stucco walls, with projecting lips on both sides under stucco copings.
3. Under and at the ends of masonry, wood or metal copings and sills.
4. Continuously above all projecting wood trim.
5. Where exterior porches, decks or stairs attach to a wall or floor assembly of wood framed construction.
6. At wall and roof intersections. ~~Kick out~~ A flashing shall be installed to divert the water away from where the eave ~~lower portion~~ of a sloped roof ~~stops within the plane of an~~ ~~intersecting~~ intersects a vertical sidewall ~~wall cladding in such a manner as to divert or kick out water away from the assembly~~.
7. At built-in gutters.

Commenter's Reason: When this was brought forward at the Baltimore hearings, the idea was very good. The committee thought that there were some terms that needed work, in order to move forward I have been in contact with other concerned parties, I believe that this language will now make it clear on where the flashing at the eaves edge needs to be placed to prevent the water damage to the structure that we have been seeing for many years.

Final Action: AS AM AMPC____ D

Table R703.4, R703.11.2, R703.11.2.1,R703.11.2.2, R703.11.2.3, Table R703.11 (New)

Proposed Change as Submitted

Proponent: Dennis Pitts, American Forest & Paper Association

1. Revise as follows:

TABLE R703.4
WEATHER–RESISTANT SIDING ATTACHMENT AND MINIMUM THICKNESS

SIDING MATERIAL	NOMINAL THICKNESS[a] (INCHES)	JOINT TREATMENT	WATER-RESISTIVE BARRIER REQUIRED	TYPE OF SUPPORTS FOR THE SIDING MATERIAL AND FASTENERS b,c,d					
				WOOD OR WOOD STRUCTURAL PANEL SHEATHING	FIBERBOARD SHEATHING INTO STUD	GYPSUM SHEATHING INTO STUD	FOAM PLASTIC SHEATHING INTO STUD	DIRECT TO STUDS	NUMBER OR SPACING OF FASTENERS
VINYL SIDING[l]	0.035	LAP	Yes	0.120 NAIL (SHANK) WITH A .313 HEAD OR 16 GAGE STAPLE WITH 3/8 TO 1/2-IN. CROWN[y,z]	0.120 NAIL (SHANK) WITH A .313 HEAD OR 16 GAGE STAPLE WITH 3/8 TO 1/2-IN. CROWN[y]	0.120 NAIL (SHANK) WITH A .313 HEAD OR 16 GAGE STAPLE WITH 3/8 TO 1/2-IN. CROWN[y]	~~0.120 NAIL (SHANK) WITH A 0.313 HEAD PER~~ SEE SECTION R703.11.2	NOT ALLOWED	16 INCHES ON CENTER OR AS SPECIFIED BY THE MANUFACTURER INSTRUCTIONS OR TEST REPORT

(Portions of table and footnotes not shown remain unchanged)

2. Delete and substitute as follows:

~~**R703.11.2 Foam plastic sheathing.** Vinyl siding used with foam plastic sheathing shall be installed in accordance with Section R703.11.2.1, R703.11.2.2, or R703.11.2.3.~~

> ~~**Exception:** Where the foam plastic sheathing is applied directly over wood structural panels, fiberboard, gypsum sheathing or other *approved* backing capable of independently resisting the design wind pressure, the vinyl siding shall be installed in accordance with Section R703.11.1.~~

R703.11.2 Backing material. Vinyl siding certified per D 3679 is rated for use where the vinyl siding is directly applied over wood structural panels, structural fiberboard, exterior gypsum sheathing, or other approved backing material capable of independently resisting the design suction wind loads in Table R703.11, Case 1. For vinyl siding over foam plastic sheathing or other backing material not approved to independently resist the design wind loads, the vinyl siding must be rated for the design suction wind loads in Table R703.11, Case 2 or 3.

3. Delete without substitution:

~~**R703.11.2.1 Basic wind speed not exceeding 90 miles per hour and Exposure Category B.** Where the basic wind speed does not exceed 90 miles per hour (40 m/s), the Exposure Category is B and gypsum wall board or equivalent is installed on the side of the wall opposite the foam plastic sheathing, the minimum siding fastener penetration into wood framing shall be 11/4 inches (32 mm) using minimum 0.120-inch diameter nail (shank) with a minimum 0.313-inch diameter head, 16 inches on center. The foam plastic sheathing shall be minimum 1/2-inch-thick (12.7 mm) (nominal) extruded polystyrene per ASTM C578, 1/2-inch-thick (12.7 mm) (nominal) polyisocyanurate per ASTM C1289, or 1-inch-thick (25 mm)(nominal) expanded polystyrene perASTMC578.~~

~~**R703.11.2.2 Basic wind speed exceeding 90 miles per hour or Exposure Categories C and D.** Where the basic wind speed exceeds 90 miles per hour (40 m/s) or the Exposure Category is C or D, or all conditions of Section~~

~~R703.11.2.1 are not met, the adjusted design pressure rating for the assembly shall meet or exceed the loads listed in Tables R301.2(2) adjusted for height and exposure using Table R301.2(3). The design wind pressure rating of the vinyl siding for installation over solid sheathing as provided in the vinyl siding manufacturer's product specifications shall be adjusted for the following wall assembly conditions:~~

1. ~~For wall assemblies with foam plastic sheathing on the exterior side and gypsum wall board or equivalent on the interior side of the wall, the vinyl siding's design wind pressure rating shall be multiplied by 0.39.~~
2. ~~For wall assemblies with foam plastic sheathing on the exterior side and no gypsum wall board or equivalent on the interior side of wall, the vinyl siding's design wind pressure rating shall be multiplied by 0.27.~~

~~**R703.11.2.3 Manufacturer specification.** Where the vinyl siding manufacturer's product specifications provide an *approved* design wind pressure rating for installation over foam plastic sheathing, use of this design wind pressure rating shall be permitted and the siding shall be installed in accordance with the manufacturer's installation instructions.~~

4. Add new table as follows:

TABLE R703.11
REQUIRED NEGATIVE (SUCTION) WIND LOAD RATINGS (psf) FOR VINYL SIDING CERTIFIED PER ASTM D 3679[a,b]

Case	Backing Material	Wind Exposure	Basic Wind Speed (mph - 3 second gust)				
			85	90	100	105	110
1	Exterior Side: Wood structural panels, structural fiberboard, exterior gypsum sheathing, or other approved backing capable of independently resisting the design wind load. Infill materials are permitted between the vinyl siding and the backing material if the minimum fastener penetration is maintained.	B	17.4 [c]	19.5 [c]	24.1 [c]	26.6 [c]	29.1 [c]
		C	24.4 [c]	27.3 [c]	33.7	37.2	40.7
		D	28.9 [c]	32.4	40.0	44.2	48.3
2	Exterior Side: Foam plastic sheathing or other backing material not approved to independently resist the design wind loads. Interior Side: Gypsum wallboard or equivalent on interior side of wall.	B	45.1	50.6	62.5	69.0	75.4
		C	63.2	70.8	87.5	96.5	105.6
		D	74.9	83.9	103.7	114.5	125.2
3	Exterior Side: Foam plastic sheathing or other backing material not approved to independently resist the design wind loads. Interior Side: None	B	64.4	72.2	89.3	98.5	107.8
		C	90.2	101.1	125.0	137.9	150.9
		D	107.0	119.9	148.2	163.5	178.9

Reason: Vinyl siding is required to be certified per ASTM D3679 which includes negative (suction) wind testing to set a design wind rating. This wind rating is based on tests conducted with OSB or plywood used as backing material and assumes that the vinyl siding will be applied over similar backing material that can independently resist the negative wind loads. During the last cycle, provisions were added to IRC 703.11 to address the common condition where vinyl siding is installed over foam sheathing. Under this condition, the vinyl siding must resist the full wind load since the foam sheathing does not resist the negative wind loads.

At the final hearings, a new provision was added that provided a prescriptive solution for the case where the basic wind speed does not exceed 90 mph, the Exposure Category is B, and gypsum wallboard or equivalent is installed on the side of the wall opposite the foam plastic sheathing. In support, the following data was provided:

WIND PRESSURE TESTING OF WALL ASSEMBLIES
WITH FOAM SHEATHING AND VINYL SIDING PRODUCTS
(NAHB Research Center Report #4107003013108)

	Backing Material	Ult. Test Capacity (psf)	Wind Load resisted by Vinyl Siding	Safety Factor on Vinyl Siding	Wind Rating (psf)	Reference
Low Capacity Vinyl Siding	**CONTROL:** Vinyl Siding test (OSB backing material perforated per D 3679)					
	(none)	22.7	36%	1.50	42.1	D 3679
	Vinyl Siding + Foam Sheathing test (Solid foam sheathing backing material)					
	3/8" EPS	29.1	100%	2.00	14.6	2009 IRC
	1/2" ISO	41.1	100%	2.00	20.6	2009 IRC
	1/2" XPS	41.6	100%	2.00	20.8	2009 IRC
High Capacity Vinyl Siding	**CONTROL:** Vinyl Siding test (OSB backing material perforated per D 3679)					
	(none)	81.9	36%	1.50	151.6	D 3679
	Vinyl Siding + Foam Sheathing test (Solid foam sheathing backing material)					
	3/8" EPS	77.0	100%	2.00	38.5	2009 IRC
	1/2" ISO	86.1	100%	2.00	43.1	2009 IRC
	1/2" XPS	89.5	100%	2.00	44.7	2009 IRC

For the CONTROL case, the vinyl siding was wind rated at 42.1 psf using the procedures in D 3679. This rating was determined from the ultimate test capacity of the vinyl siding acting alone, divided by 0.36 in recognition that the backing material is resisting most of the wind load and by a safety factor of 1.5 since the vinyl siding is serving primarily as an exterior covering. The ultimate test capacity of the vinyl siding backed by solid foam sheathing was divided by 1.0 in recognition that the vinyl siding attachment must resist the wind load and by a safety factor of 2.0 since the vinyl siding is now acting as a structural sheathing to protect the building envelop. For the low capacity vinyl siding, the vinyl siding backed by 3/8" EPS was not capable of resisting the minimum wind loads in the IRC; however, ½" ISO and ½" XPS were capable of resisting the 19.5 psf negative wind loads associated with 90 mph, Exposure B. This case was selected as the basis of the current prescriptive provisions in R703.11.2.1.

Upon further study of the CONTROL case in the previous table, it can be seen that the low-capacity vinyl siding used in the tests would have a wind rating of 42.1 psf, not the minimum of 29.1 psf permitted by D 3679. A re-analysis was conducted to see what the result would be if minimum vinyl siding was used over foam sheathing:

	Backing Material	D 3679 min. Capacity (psf)	Wind Load resisted by Vinyl Siding	Safety Factor on Vinyl Siding	Wind Rating (psf)	Reference
D 3679 min. Vinyl Siding	OSB	15.7	36%	1.50	29.1	D 3679
	3/8" EPS	15.7	100%	2.00	7.9	2009 IRC
	1/2" ISO	15.7	100%	2.00	7.9	2009 IRC
	1/2" XPS	15.7	100%	2.00	7.9	2009 IRC

In order for the vinyl siding to resist the full wind load, this re-analysis suggests that it would take a medium grade of vinyl siding to meet the minimum negative wind loads and a high grade of vinyl siding and attachment to meet the moderate negative wind loads. For this reason, it is recommended that Section R703.11.2 and R703.11.2.1 be deleted and replaced with wind Table R703.11. Also, the prescriptive fastening in Table R703.4 should be replaced by a reference to the general section since the fastening schedule is linked to the wind rating.

Section R703.11.2.2 was previously added to provide an adjustment to the D 3679 wind ratings for cases where foam sheathing is used as the backing material. It requires the user to multiply the D 3679 wind ratings provided by the vinyl siding manufacturer in literature or an Evaluation Report, with a factor associated with the construction. In this proposed change, Section R703.11.2.2 was deleted and the adjustment factors were incorporated as increases in the required wind ratings in a new Table R703.11. Until D 3679 is modified to provide a means of determining wind ratings using the actual backing materials, this method should be used to prevent confusion and aid the user in selecting the proper vinyl siding.

Section R703.11.3 was added to provide guidance on the use of data for combined vinyl siding and foam sheathing tests. However, no standardized test procedure exists and any information developed by the vinyl siding manufacturer should be evaluated carefully prior to approval. This section is redundant with Section R104.11 and is, therefore, recommended for deletion.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: PITTS-RB-5-T. R703.4-R703.11

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee feels that the deleting of this section may unfairly penalize the use of vinyl siding. Section R703.11.2 contains permissive language. There is a conflict between Footnote b in the proposed new table and Table R703.4. Also, Footnote c requires contact with the manufacture for higher wind loads.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Dennis Pitts, American Wood Council, American Forest & Paper Association, requests Approval as Modified by this Public Comment.

Replace proposal as follows:

TABLE R703.4
WEATHER–RESISTANT SIDING ATTACHMENT AND MINIMUM THICKNESS

SIDING MATERIAL	NOMINAL THICKNESS[a] (inches)	JOINT TREATMENT	WATER-RESISTIVE BARRIER REQUIRED	TYPE OF SUPPORTS FOR THE SIDING MATERIAL AND FASTENERS[b,c,d]					
				Wood or wood structural panel sheathing	Fiberboard sheathing into stud	Gypsum sheathing into stud	Foam plastic sheathing into stud	Direct to studs	Number or spacing of fasteners
(remainder of table unchanged)									
Vinyl siding ~~[l]~~	0.035	Lap	Yes	0.120 nail (shank) with a .313 head or 16 gauge staple with 3/8 to ½-in crown [y, z]	0.120 nail (shank) with a .313 head or 16 gauge staple with 3/8 to ½-in crown [y]	0.120 nail (shank) with a .313 head or 16 gauge staple with 3/8 to ½-in crown [y]	~~.0120 nail (shank) with a 0.313 head per~~ <u>See</u> Section R703.11.2	Not allowed	16 inches on center or as specified by the manufacturer instructions or test report

(Footnotes remain unchanged)

R703.11 Vinyl siding. Vinyl siding shall be certified and labeled as conforming to the requirements of ASTM D 3679 by an *approved* quality control agency.

R703.11.1 Installation. Vinyl siding, soffit and accessories shall be installed in accordance with the manufacturer's installation instructions.

R703.11.1.1 Soffit panels shall be individually fastened to a supporting component such as a nailing strip, fascia, or subfascia component or as specified by the manufacturer's instructions.

R703.11.2 Foam plastic sheathing. Vinyl siding used with foam plastic sheathing shall be installed in accordance with R703.11.2.1, R703.11.2.2, or R703.11.2.3.

> **Exception:** Where the foam plastic sheathing is applied directly over wood structural panels, fiberboard, gypsum sheathing, or other *approved* backing capable of independently resisting the design wind pressure, the vinyl siding shall be installed in accordance with R703.11.1.

R703.11.2.1 Basic wind speed not exceeding 90 miles per hour and exposure Category B. Where the basic wind speed does not exceed 90 miles per hour (40 m/s), the Exposure Category is B and gypsum wallboard or equivalent is installed on the side of the wall opposite the foam plastic sheathing, <u>the vinyl siding shall be certified to a design wind pressure rating of at least 42 psf per ASTM D 3679 and</u> the minimum siding fastener penetration into wood framing shall be 1-1/4 inches (32 mm) using minimum 0.120-inch diameter nail (shank) with a minimum 0.313-inch diameter head, 16 inches on center. The foam plastic sheathing shall be minimum ½-inch-thick (12.7 mm) (nominal) extruded polystyrene per ASTM C578, ½-inch-thick (12.7 mm) (nominal) polyisocyanurate per ASTM C1289, or 1-inch-thick (25 mm) (nominal) expanded polystyrene per ASTM C578.

R703.11.2.2 Basic wind speed exceeding 90 miles per hour or exposure Categories C and D. Where the basic wind speed exceeds 90 miles per hour (40 m/s) or the Exposure Category is C or D, or all conditions of Section R703.11.2.1 are not met, the adjusted design pressure rating for the assembly shall meet or exceed the loads listed in Tables R301.2(2) adjusted for height and exposure using Section R301.2(3). The design wind pressure rating of the vinyl siding for installation over solid sheathing as provided in the vinyl siding manufacturer's product specifications shall be adjusted for the following wall assembly conditions:

1. For wall assemblies with foam plastic sheathing on the exterior side and gypsum wall board or equivalent on the interior side of the wall, the ~~vinyl siding's~~ <u>ASTM D 3679</u> design wind pressure rating <u>of the vinyl siding</u> shall be multiplied by 0.39.
2. For wall assemblies with foam plastic sheathing on the exterior side and no gypsum wall board or equivalent on the interior side of wall, the ~~vinyl siding's~~ <u>ASTM D 3679</u> design wind pressure rating <u>of the vinyl siding</u> shall be multiplied by 0.27.

R703.11.2.3 Manufacturer specification. Where the vinyl siding manufacturer's product specifications provide an *approved* design wind pressure rating for installation over foam plastic sheathing, use of this design wind pressure rating shall be permitted and the siding shall be installed in accordance with the manufacturer's installation instructions.

Commenter's Reason: Vinyl siding is required to be certified per ASTM D3679 which includes negative (suction) wind testing to set a design wind rating. This wind rating is based on tests conducted with OSB or plywood used as backing material and assumes that the vinyl siding will be applied over similar backing material that can independently resist the negative wind loads. During the last cycle, provisions were added to IRC 703.11 to address the common condition where vinyl siding is installed over foam sheathing. Under this condition, the vinyl siding must resist the full negative wind load since the foam sheathing does not resist the negative wind loads.

R703.11.2.1

At the final hearings during the last cycle, proposal RB195-07/08 added a new provision that provided a prescriptive solution for the case where the basic wind speed does not exceed 90 mph, the Exposure Category is B, and gypsum wallboard or equivalent is installed on the side of the wall opposite the foam plastic sheathing. In support of that proposal, the following data was provided:

WIND PRESSURE TESTING OF WALL ASSEMBLIES WITH FOAM SHEATHING AND VINYL SIDING PRODUCTS

(from NAHB Research Center Report #4107003013108)

	Backing Material	Ult. Test Capacity (psf)	Wind Load resisted by Vinyl Siding	Safety Factor on Vinyl Siding	Wind Rating (psf)	Reference
Low Capacity Vinyl Siding	**CONTROL:** Vinyl Siding test (OSB backing material perforated per D 3679)					
	(none)	22.7	36%	1.50	42.1	D 3679
	Vinyl Siding + Foam Sheathing test (Solid foam sheathing backing material)					
	3/8" EPS	29.1	100%	2.00	14.6	2009 IRC
	1/2" ISO	41.1	100%	2.00	20.6	2009 IRC
	1/2" XPS	41.6	100%	2.00	20.8	2009 IRC
High Capacity Vinyl Siding	**CONTROL:** Vinyl Siding test (OSB backing material perforated per D 3679)					
	(none)	81.9	36%	1.50	151.6	D 3679
	Vinyl Siding + Foam Sheathing test (Solid foam sheathing backing material)					
	3/8" EPS	77.0	100%	2.00	38.5	2009 IRC
	1/2" ISO	86.1	100%	2.00	43.1	2009 IRC
	1/2" XPS	89.5	100%	2.00	44.7	2009 IRC

For the CONTROL case, the vinyl siding was evaluated and found to resist 22.7 psf which equates to a wind rating of 42.1 psf using the procedures in D 3679. This rating was determined from the ultimate test capacity of the vinyl siding acting alone, divided by 0.36 in recognition that the backing material resists most of the wind load and by a safety factor of 1.5 since the vinyl siding is serving primarily as an exterior covering.

The ultimate test capacity of the vinyl siding was then backed by various types of solid foam sheathing was tested. An equivalent wind rating of the composite system was estimated per the requirements of the 2009 IRC R703.11.2 by dividing the ultimate test capacity by 1.0 in recognition that the vinyl siding attachment must resist the wind load and by a safety factor of 2.0 since the vinyl siding is now acting as a structural component necessary to protect the building envelop.

For the low capacity vinyl siding, the vinyl siding backed by 3/8" EPS was not capable of resisting the minimum wind loads in the IRC with the required safety factor; however, ½" ISO and ½" XPS were capable of providing a rated resistance of 20.6 and 20.8 psf, respectively, slightly higher than the 19.5 psf negative wind loads associated with 90 mph, Exposure B. This case was selected as the basis of the current prescriptive provisions in R703.11.2.1.

Upon further study of the CONTROL case in the previous table, it can be seen that the low-capacity vinyl siding used in the tests would have a wind rating of 42.1 psf, not the minimum of 29.1 psf permitted by D 3679. In order for the vinyl siding/foam sheathing composite described in R703.11.2.1 to resist the wind loads with the required safety factor, the test data clearly indicates that the vinyl siding needs to be rated per D 3679 for about 42 psf, not the minimum value of 29.1. This proposal states this limit explicitly in Section R703.11.2.1.

R703.11.2.2

This revision is simply editorial.

Table R703.4

The prescriptive fastening schedule for vinyl siding over foam sheathing in Table R703.4 has been replaced by a reference to R703.11.2. Use of products and systems in R703.11.2 can result in a wide variety of fastener types, sizes, and schedules. R703.11.2.1 already provides the prescriptive fastening schedule currently in Table R703.4 for the special case associated with R703.11.2.1. For other conditions covered in R703.11.2.2 and R703.11.2.3, different fastening schedules and detailing will likely be required to meet the higher wind loads. This change corrects this inconsistency.

Final Action: AS AM AMPC____ D

RB148-09/10
R202 (New), R703.13 (New), Chapter 44 (New)

Proposed Change as Submitted

Proponent: Marcelo M. Hirschler, GBH International, representing the American Fire Safety Council

1. Add new definition as follows:

POLYPROPYLENE SIDING. A shaped material, made principally from polypropylene homopolymer, or copolymer, which in some cases may contain fillers and/or reinforcements, that is used to clad exterior walls of buildings.

2. Add new text as follows:

R703.13 Polypropylene siding. Polypropylene siding shall be certified and labeled as conforming to the requirements of R703.13.1, of R703.13.2 or of R703.3 by an approved quality control agency. Polypropylene siding shall be installed in accordance with the manufacturer's installation instructions.

R703.13.1 Flame spread index. The polypropylene siding material shall comply with the requirements of ASTM D 7254. The certification shall be accompanied by a test report stating that all portions of the test specimen ahead of the flame front remained in position during the test in accordance with ASTM E 84 or UL 723.

R703.13.2 Heat release. The polypropylene siding material shall comply with the requirements of ASTM D 7254 and a 4 foot by 8 foot (1.22 x 2.44 m) section of the polypropylene siding material shall exhibit a peak rate of heat release not exceeding 100 kW when tested in accordance with NFPA 289 using the 20 kW ignition source at the thickness intended for use.

R703.13.3 Fire separation distance. The polypropylene siding shall comply with all the requirements of ASTM D 7254 and the fire separation distance between a building with polypropylene siding and the adjacent building shall be no less than 10 feet (3.05 m).

3. Add new standards to Chapter 44 as follows:

NFPA
289 Standard Method of Fire Test for Individual Fuel Packages (2009)

ASTM
D 7254 Standard specification for polypropylene (PP) siding

Reason: Polypropylene siding is being used in construction now although the IBC does not permit it. Therefore, it is important to regulate the use of polypropylene siding in a way that it can be used safely. The new sections are similar to the existing sections on vinyl siding, except for the fire testing. Vinyl siding is known to have adequate fire performance since the siding needs to be made of rigid (unplasticized) PVC in accordance with ASTM D 3679. Polypropylene is known not to have adequate fire performance unless properly fire retarded.

A new standard specification has been issued for polypropylene siding, ASTM D 7254. The specification addresses many of the key requirements for the material. Unfortunately the fire test requirement in ASTM D 7254 is not explicit enough. ASTM D 7254 does not require that, when fire testing is conducted in the ASTM E 84 (Steiner tunnel), the test specimen must remain in place during the test and flaming drips and falling test specimens are not allowed to happen. This requirement is critical for materials that are used exposed so that the flame spread index assesses actual surface flame spread on the material surface. The standards committee responsible for the ASTM E 84 fire test (ASTM E05) decided that this issue should be addressed in the code rather than in the standard itself. Polypropylene that has not been appropriately fire retarded will release abundant amount of heat, much more than other combustible sidings permitted by the code, such as wood siding or vinyl (PVC) siding, and spread fire through flaming drips. Such flaming drips will contribute to ignite mulch and debris found near the building and spread the fire. Table 1 shows such results.

Recent fire tests were also conducted in the Steiner tunnel, ASTM E 84, on a rigid PVC material 0.06 in. thick; it exhibited a flame spread index of 10. Under the same test conditions, a fire retarded polypropylene material 0.15 in. thick exhibited a flame spread index of 50. These are both very adequate values, in view of the fact that both the polypropylene material and the PVC material remained in place during the ASTM E 84 test and did not generate flaming drips.

Table 1: Results of Steiner Tunnel Tests (ASTM E 84)

Material	Flame Spread Index	Maximum Flame Front Advance (ft)	Time to Max. Flame Front Advance (min:s)	Flaming on Floor (Duration) (min:s)
PVC	10	4.6	7:48	None
FR Polypropylene	50	19.5	6:24	4:18

This shows that it is possible to use fire retarded polypropylene materials that give very adequate flame spread values and also very adequate heat release values, without flaming drips. Consequently, polypropylene siding should only be used when it is shown to exhibit the appropriate fire performance.

When polypropylene siding material (which does not have the appropriate fire performance) is tested in ASTM E 84 (Steiner tunnel) the test specimen will often fall ahead of the arrival of the flame giving incorrect results.

Table 2 shows new results of cone calorimeter heat release tests with polypropylene and PVC:

Table 2: Results of Cone Calorimeter (ASTM E 1354) Tests

Material	Peak Heat Release Rate	Total Heat Released	Time to Ignition	Effective Heat of Combustion	Fire Performance Index
	kW/m^2	MJ/m^2	s	MJ/kg	$s\ m^2/kW$
PVC	186.8	16.7	36	9.2	0.19
Non FR Polypropylene	768.3	47.2	23	40.3	0.03

Table 3 shows some earlier results with polypropylene, PVC and wood materials in the cone calorimeter:

Table 3 - Cone Calorimeter Data on Plastics and Douglas Fir

PVC Rigid, Custom Inj. Mold.	191	93.0	45	12.7	0.24
PVC Rigid, Extrusion	190	96.5	48	10.8	0.25
PP Non FR	2421	231.1	41	43.1	0.02
PE Non FR	2735	227.5	47	42.6	0.02
XLPE FR	268	129.2	35	24.7	0.13
Douglas Fir	196	50.0	12	13.5	0.06

Table 3 shows that, when tested in the cone calorimeter, ASTM E 1354, under the same conditions, it was found that non fire retarded polypropylene exhibits a peak heat release rate of 1509 kW/m^2, while a non fire retarded PVC material exhibits a peak heat release rate of 183 kW/m^2, and a Douglas fir material exhibits a peak heat release rate of 221 kW/m^2. Such a very high heat release rate is unacceptable for a siding material. Testing in the cone calorimeter, including the testing above, is normally conducted in the horizontal orientation with radiant heat exposing the test specimen from above, thus capturing any flaming drips and assessing their effects.

Table 4 shows that wood materials, when not fire retarded, will usually exhibit flame spread index values that are less than 200 and will correspond to Class B or Class C categories. At the same time rigid PVC (vinyl) materials will generally exhibit flame spread index values less than 25. Neither wood nor PVC materials will cause flaming drips or molten material burning on the ground.

Table 4. Steiner tunnel (ASTM E 84) Data for Wood and Vinyl Materials					
Material/Product	Flame Spread Index		Material/Product	Flame Spread Index	
	Low	High		Low	High
Cellulose fiberboard ceiling tile	70	80	Ponderosa pine B	105	170
Cottonwood	115		Poplar	170	185
Cypress	145	150	Red Gum	140	155
Douglas fir	70	100	Red oak flakeboard	70	190

Plywood paneling over gypsum	130	150	Western white pine	75	
Ponderosa pine A	170	230	Yellow birch	105	110

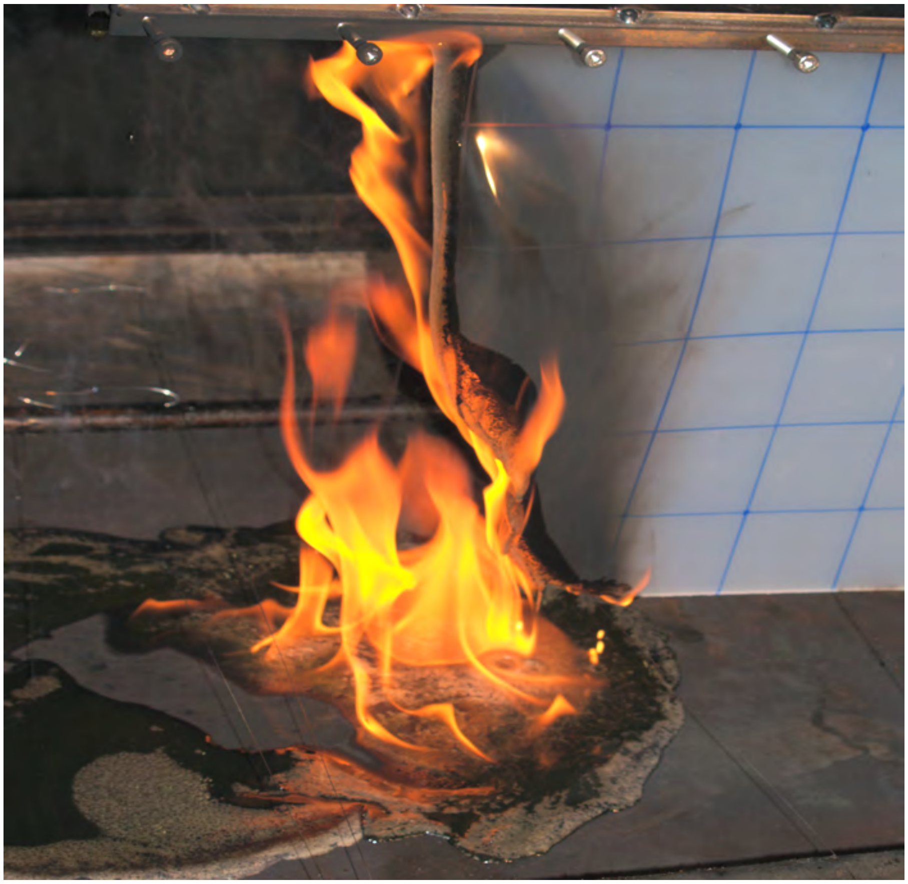
Figure 1 shows char from a PVC siding fire (no foam backing): the material softened, charred and burned but is still substantially intact. Figure 2 shows a vertical PP sheet melting and resulting in flaming drips on the floor.

The reason that heat release rate and floor flaming are important issues is because it has been shown that the heat radiated by siding is a major contributor to the ignition of neighboring houses, as is the spread of fire along the ground, particularly when there are loose combustibles present.

That is the reason that the third option allows polypropylene siding to be used, but with a larger separation distance, when the results of the ASTM E 84/UL 723 (Steiner tunnel) test are based on a test specimen that is not self supporting and falls to the floor of the tunnel during the test. The standard ASTM E 84 states: "1.4 Testing of materials that melt, drip, or delaminate to such a degree that the continuity of the flame front is destroyed, results in low flame spread indices that do not relate directly to indices obtained by testing materials that remain in place." Therefore valid test results require the test specimen to stay in place ahead of the exposing flame.

Figure 1 – Remains of vinyl siding fire

Figure 2 Polypropylene siding melting and flaming on the floor.



NFPA 289 was developed to test individual fuel packages and is similar in concept to UL 1975, already widely used in the ICC codes.

Cost Impact: The code does not at present allow the use of polypropylene siding. In order to safely use polypropylene siding construction costs would have to increase either by using materials that would meet test requirements for adequate fire safety or by increasing fire separation distances.

Analysis: A review of the standards proposed for inclusion in the code, NFPA 289 and ASTM D 7254, for compliance with ICC criteria for referenced standards given in Section 3.6 of Council Policy #CP 28 will be posted on the ICC website on or before September 24, 2009.

ICCFILENAME: HIRSCHLER-RB-5-R202-R703.13

Public Hearing Results

Analysis: Review of proposed new standards indicated that, in the opinion of ICC Staff, these standards did comply with ICC standards criteria.

Committee Action: Disapproved

Committee Reason: The committee has serious concerns about the product as to the effect of time after installation will have the fire test results. The committee feels that NFPA 289 is not the appropriate test for the product application.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Marcelo M. Hirschler, GBH International, representing American Fire Safety Council, requests Approval as Modified by this Public Comment.

Replace the proposal as follows:

Polypropylene siding. A shaped material, made principally from polypropylene homopolymer, or copolymer, which in some cases may contain fillers and/or reinforcements, that is used to clad exterior walls of buildings.

R703.13 Polypropylene Siding. Polypropylene siding shall be certified and labeled as conforming to the requirements of ASTM D 7254 and those of R703.13.1 or those of R703.13.2 by an approved quality control agency. Polypropylene siding shall be installed in accordance with the requirements of R703.13.3 and in accordance with the manufacturer's installation instructions. Polypropylene siding shall be secured to the building so as to provide weather protection for the exterior walls of the building.

R703.13.1 Flame Spread Index. The certification of the flame spread index shall be accompanied by a test report stating that all portions of the test specimen ahead of the flame front remained in position during the test in accordance with ASTM E 84 or UL 723.

R703.13.2 Fire Separation Distance. The fire separation distance between a building with polypropylene siding and the adjacent building shall be no less than 10 feet (3.05 m).

R703.13.3 Installation. Polypropylene siding shall be limited to exterior walls of Type VB construction located in areas where the wind speed specified in Figure R301.2(4) does not exceed 100 miles per hours (45 m/s) and the building height is less than or equal to 40 feet (12,192 mm) in Exposure C.

ASTM
D 7254 Standard specification for polypropylene (PP) siding

Commenter's Reason: The committee had a valid concern regarding the use of NFPA 289 for testing this material and this option has been eliminated. Polypropylene siding material does not normally contain flame retardants or any other additives that will prevent it from forming a pool fire as soon as it is exposed to a flame. Therefore, when polypropylene siding is exposed to the flame in the ASTM E 84 Steiner tunnel test it immediately starts melting and burning occurs in the floor of the tunnel, with no material left in the tunnel ceiling where the test sample should be. This material gets a low flame spread index (ASTM D 7254 requires a flame spread index under 200, just like for wood siding) but it is not a valid result because the material is no longer in the test position when the flame comes by.

This is a problem because polypropylene that is not properly flame retarded will generate about 4 times as much heat as vinyl (PVC) or as wood or even as flame retarded polypropylene (see peak heat release rate in the table below) and it ignites much more rapidly. Therefore if polypropylene siding is made with typical polypropylene that has not been treated, the siding is a very dangerous product and polypropylene siding should not be allowed to be used based only on the requirements of ASTM D 7254.

Table: Results of Cone Calorimeter (ASTM E 1354) Tests (4 inch x 4 inch test sample)			
Material	**Peak Heat Release Rate**	**Time to Ignition**	**Effective Heat of Combustion**
	kW/m^2	s	MJ/kg
PVC (vinyl)	190	36	9
Wood	220	34	15
Non FR Polypropylene	770	23	40
FR Polypropylene	200	60	25

It is possible to make properly flame retarded polypropylene and use it for siding because flame retarded polypropylene can easily be compounded so that it does not melt/drip and pass the requirements of a flame spread index of 200 in the ASTM E 84 test. In fact, the original proposal includes an ASTM E 84 test with an FR polypropylene material that gave a flame spread index of 50. Such a material should be permitted for use but not the unsafe material normally offered for sale.

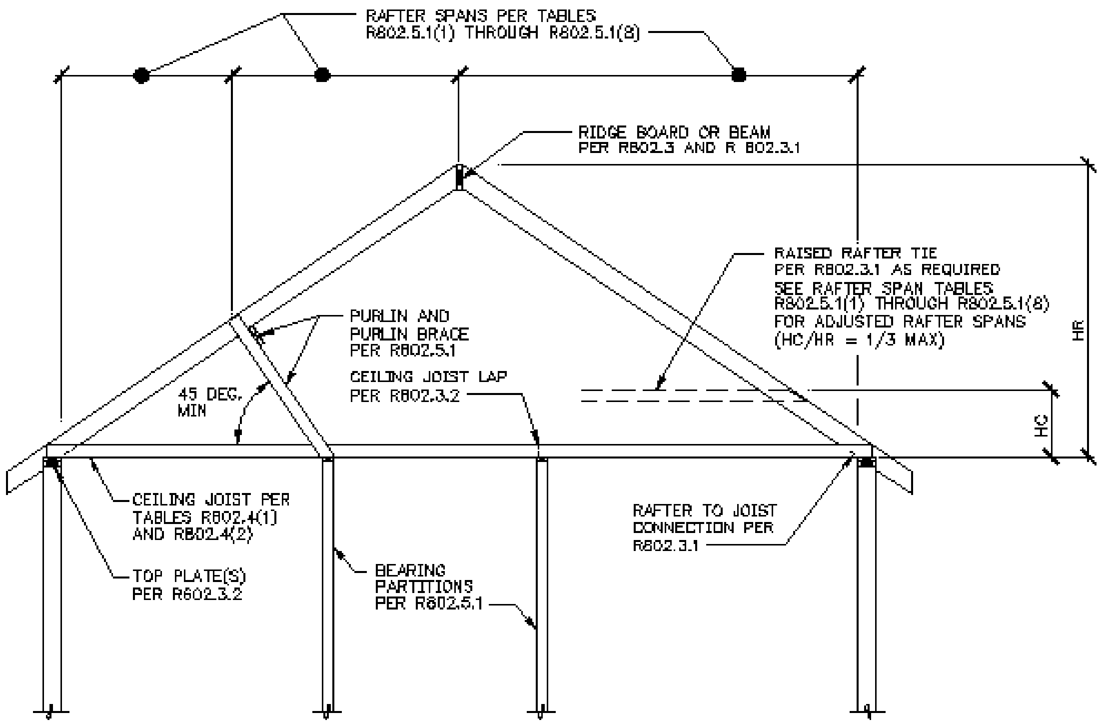
Final Action: AS AM AMPC____ D

RB151-09/10
Figure R802.5.1

Proposed Change as Submitted

Proponent: Robert Rice, Grants Pass, OR, representing Josephine County Building Safety and Southern Oregon Chapter of ICC

Delete existing Figure R802.5.1 and replace as follows:



For SI: 1 inch = 25.4 mm, 1 foot = 305 mm, 1 degree = 0.018 rad.
Note: Where ceiling joints run perpendicular to the rafter, rafter ties shall be installed per R802.3.1
HC = Height of ceiling joists or rafter ties measured vertically above the top of rafter support walls
HR = Height of roof ridge measured vertically above the top of the rafter support walls.

FIGURE R802.5.1
BRACED RAFTER CONNECTION

Reason: The existing figure is lacking in some information and references to pertinent sections of code. This proposal updates the figure.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: RICE-RB-4-F. R802.5.1

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: Based on the proponent's published reason. This change makes improvements to the figure.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Robert Rice, Josephine County Oregon, representing Josephine County Oregon and Southern Oregon Chapter of ICC, requests Approval as Modified by this Public Comment.

Modify the proposal as:

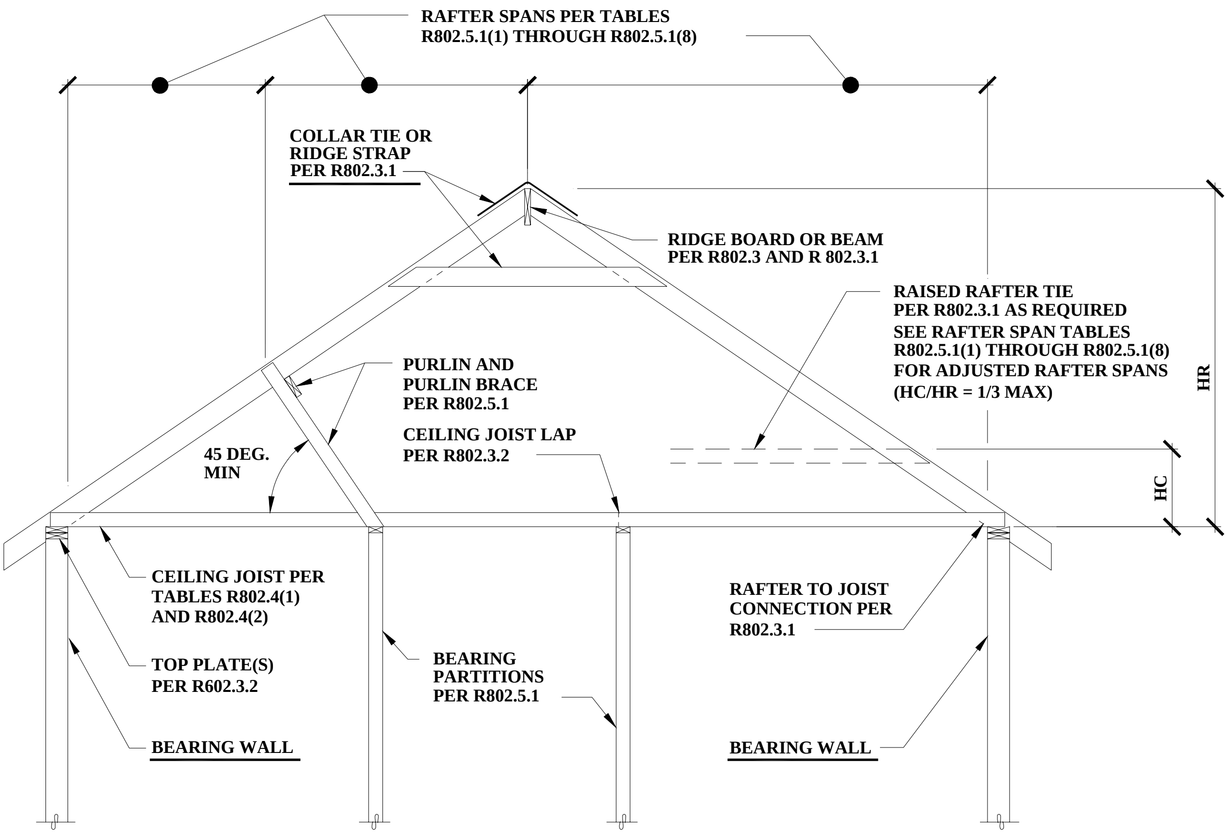


FIGURE R802.5.1
BRACED RAFTER CONNECTION

For SI: 1 inch = 25.4 mm, 1 foot = 305 mm, 1 degree = 0.018 rad.
Note: Where ceiling joints run perpendicular to the rafter, rafter ties shall be installed per R802.3.1
HC = Height of ceiling joists or rafter ties measured vertically above the top of rafter support walls
HR = Height of roof ridge measured vertically above the top of the rafter support walls.

Commenter's Reason: The figure submitted in the original proposal was approved As Submitted by the committee in Baltimore. This modification merely adds the collar tie/ridge strap requirement and a note to see R802.3.1. The requirements already exist in the code. This amendment does not add any requirements to the code. Also, notes were added stating that the exterior walls are bearing walls.

Final Action: AS AM AMPC____ D

RB152-09/10

R802.7, R802.7.1, R802.7.1.1 (New), Figure R802.7.1.1 (New), R802.7.1.2 (New), Figure R802.7.1.2

Proposed Change as Submitted

Proponent: Dennis Pitts, American Forest and Paper Association

1. Revise as follows:

R802.7 Cutting, drilling and notching. Structural roof members shall not be cut, bored or notched in excess of the limitations specified in this section.

R802.7.1 Sawn lumber. Cuts, notches, and holes, ~~Notches~~ in solid lumber joists, rafters, blocking and beams shall ~~not exceed one-sixth of the depth of the member, shall not be longer than one-third of the depth of the member and shall not be located in the middle one-third of the span. Notches at the ends of the member shall not exceed one-fourth the depth of the member. The tension side of members 4 inches (102 mm) or greater in nominal thickness shall not be notched except at the ends of the members. The diameter of the holes bored or cut into members shall not exceed one-third the depth of the member. Holes shall not be closer than 2 inches (51 mm) to the top or bottom of the member, or to any other hole located in the member. Where the member is also notched, the hole shall not be closer than 2 inches (51 mm) to the notch~~ comply with the provisions of R502.8.1 except that cantilevered portions of rafters shall be permitted in accordance with Section R802.7.1.1.

R802.7.1.1 Cantilevered portions of rafters. ~~**Exception:**~~ Notches on cantilevered portions of rafters are permitted provided the dimension of the remaining portion of the rafter is not less than ~~4~~ 3-1/2-inch ~~nominal~~ (~~102~~ 89 mm) and the length of the cantilever does not exceed 24 inches (610 mm) in accordance with Figure R802.7.1.1.

2. Add new figure as follows:

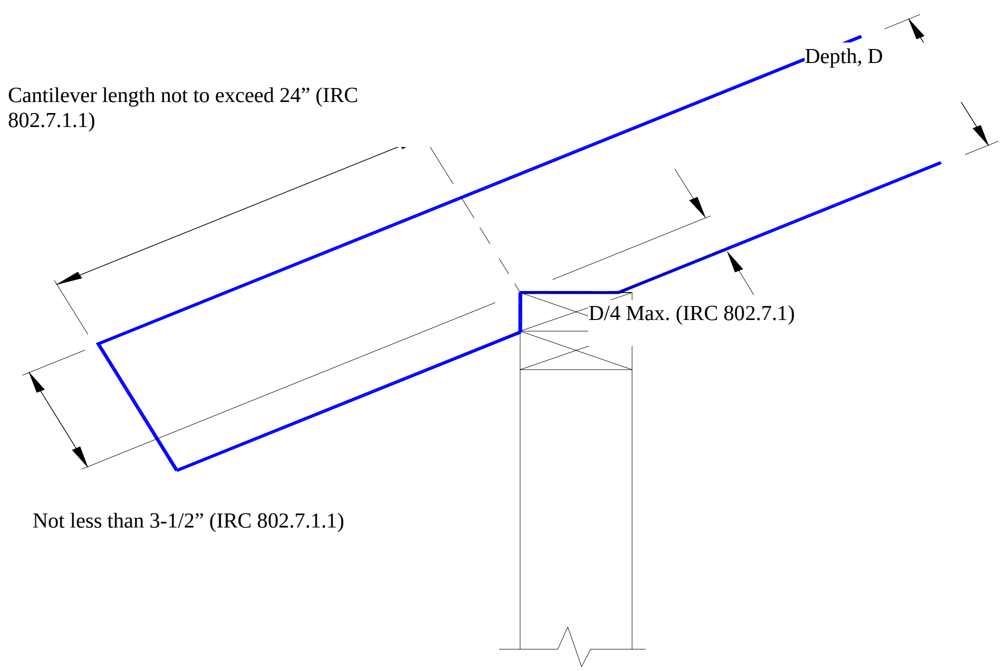

FIGURE R802.7.1.1
RAFTER NOTCH

3. Add new text as follows:

R802.7.1.2 Ceiling joist taper cut. Taper cuts at the ends of the ceiling joist shall not exceed one-fourth the depth of the member in accordance with Figure R802.7.1.2.

4. Add new figure as follows:

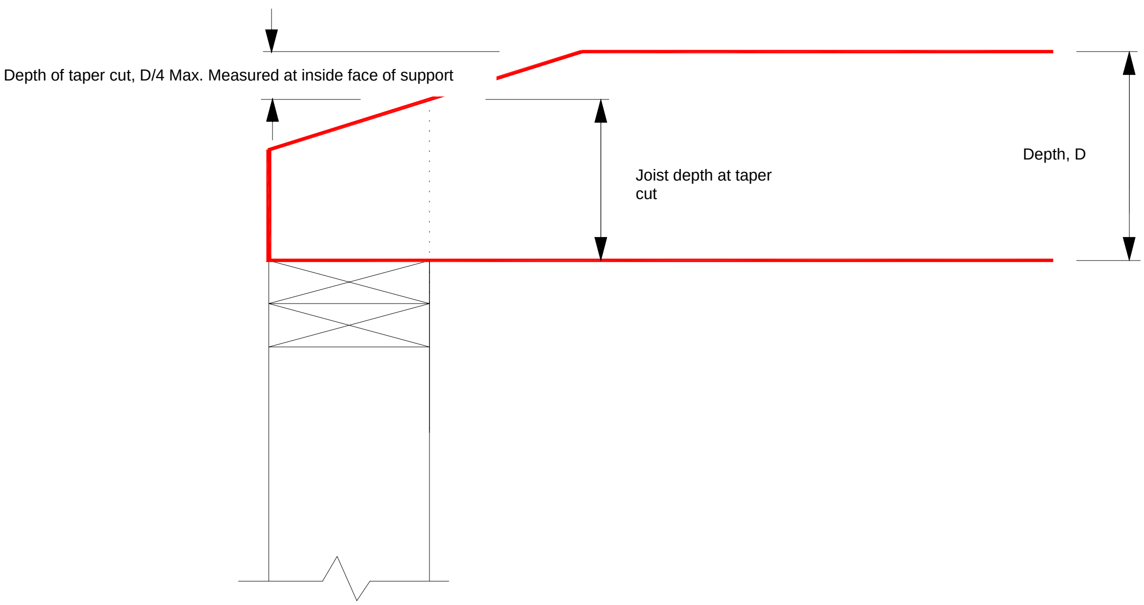

FIGURE R802.7.1.2
CEILING JOIST TAPER CUT

Reason: The revision simplifies text by referencing material elsewhere in the code. The exception is re-written as a section on cantilever portions of rafters and includes a figure to clarify the intent. The actual dimension "3-1/2 inch" replaces "4-inch nominal" to clarify the minimum dimension remaining after the notching. "Nominal" is typically used to describe standard sizes. The section on ceiling joist taper cut is added to clarify application of the D/4 provision to a ceiling joist taper cut.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: PITTS-RB-6-R802.7

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: This change adds clarification for cutting, drilling and notching of roof members. Adds figures for rafter notch and ceiling joist taper cut.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Rick Davidson, City of Maple Grove, representing self, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R802.7.1 Sawn lumber. Cuts, notches, and holes, in solid lumber joists, rafters, blocking and beams shall not exceed one-sixth of the depth of the member, shall not be longer than one-third of the depth of the member and shall not be located in the middle one-third of the span. Notches at the ends of the member shall not exceed one-fourth the depth of the member. The tension side of members 4 inches (102 mm) or greater in nominal thickness shall not be notched except at the ends of the members. The diameter of the holes bored or cut into members shall not exceed one-third the depth of the member. Holes shall not be closer than 2 inches (51 mm) to the top or bottom of the member, or to any other hole located in the member. Where the member is also notched, the hole shall not be closer than 2 inches (51 mm) to the notch ~~comply with the provisions of R502.8.1 except that cantilevered portions of rafters shall be permitted in accordance with Section R802.7.1.1~~.

Exception: Cantilevered portions of rafters shall be permitted in accordance with Section R802.7.1.1.

(Portions of proposal not shown remain unchanged)

Commenter's Reason: This modification retains the original proposal but does not delete the language dealing with cuts, notches, and holes. Deleting existing language and referring the user of the code to another section is not user friendly. It does not improve the use of the code. If you are providing copies for the public, you must provide pages from two chapters. Let's leave this language where it is. This modification leaves the original proposal intact except for reinserting previously existing language.

Final Action: AS AM AMPC____ D

RB154-09/10
R301.2.1

Proposed Change as Submitted

Proponent: T. Eric Stafford, PE, representing the Institute for Business and Home Safety

1. Revise as follows:

R301.2.1 Wind limitations. Buildings and portions thereof shall be limited by wind speed, as defined in Table R301.2(1) and construction methods in accordance with this code. Basic wind speeds shall be determined from Figure R301.2(4). Where different construction methods and structural materials are used for various portions of a building, the applicable requirements of this section for each portion shall apply. Where loads for wall coverings, curtain walls, roof coverings, exterior windows, skylights, garage doors and exterior doors are not otherwise specified, the loads listed in Table R301.2(2) adjusted for height and exposure using Table R301.2(3) shall be used to determine design load performance requirements for wall coverings, curtain walls, roof coverings, exterior windows, skylights, garage doors and exterior doors. Asphalt shingles shall be designed for wind speeds in accordance with Section R905.2.6. A continuous load path shall be provided to transmit the applicable uplift forces in Section R802.11.1 from the roof assembly to the foundation.

TABLE R602.3(1)
FASTENER SCHEDULE FOR STRUCTURAL MEMBERS

ITEM	DESCRIPTION OF BUILDING ELEMENTS	NUMBER AND TYPE OF FASTENER[a,b,c]	SPACING OF FASTENERS
5	Rafter or roof truss to plate, toe nail	~~2~~3-16d box nails (3½"x0.135") or 3-10d common nails (3"x0.148")	2 toe nails on one side and 1 toe nail on opposite side of each rafter or truss[j]

(Portions of table not shown remain unchanged)

a. through i. (No change)
j. Where a rafter is fastened to an adjacent parallel ceiling joist in accordance with this schedule, provide two toe-nails on one side of the rafter and toe-nails from the ceiling joist to top plate in accordance with this schedule. The toe-nail on the opposite side of the rafter shall not be required.

2. Delete without substitution:

~~**R802.10.5 Truss to wall connection.** Trusses shall be connected to wall plates by the use of *approved* connectors having a resistance to uplift of not less than 175 pounds (779 N) and shall be installed in accordance with the manufacturer's specifications. For roof assemblies subject to wind uplift pressures of 20 pounds per square foot (960 Pa) or greater, as established in TableR301.2(2), adjusted for height and exposure per Table R301.2(3), see section R802.11.~~

3. Revise as follows:

R802.11.1 Uplift resistance. Roof assemblies shall have uplift resistance in accordance with Sections R802.11.1.2 and R802.11.1.3 ~~which are subject to wind uplift pressures of 20 pounds per square foot (960 Pa) or greater shall have roof rafters or trusses attached to their supporting wall assemblies by connections capable of providing the resistance~~

~~required in Table R802.11. Wind uplift pressures shall be determined using an effective wind area of 100 square feet (9.3 m2) and Zone 1 in Table R301.2(2), as adjusted for height and exposure per Table R301.2(3).~~

Where the uplift force does not exceed 200 pounds, rafters and trusses spaced not more than 24 inches on center shall be permitted to be attached to their supporting wall assemblies in accordance with Table R602.3(1).

Where the basic wind speed does not exceed 90 mph, the wind exposure category is B, the roof pitch is 5:12 or greater, and the roof span is 32 feet or less, rafters and trusses spaced not more than 24 inches on center shall be permitted to be attached to their supporting wall assemblies in accordance with Table R602.3(1).

~~A continuous load path shall be designed to transmit the uplift forces from the rafters or trusses to the foundation.~~

4. Add new text as follows:

R802.11.1.2 Truss uplift resistance. Trusses shall be attached to supporting wall assemblies by connections capable of resisting uplift forces as specified on the Truss Design Drawings. Uplift forces shall be permitted to be determined as specified by Table R802.11, if applicable, or as determined by accepted engineering practice.

R802.11.1.3 Rafter uplift resistance. Individual rafters shall be attached to supporting wall assemblies by connections capable of resisting uplift forces as determined by Table R802.11 or as determined by accepted engineering practice, Connections for beams used in a roof system shall be designed in accordance with accepted engineering practice.

5. Delete existing Table R802.11 and replace as follows:

	42	302	263	372	324	524	456	691	601
	48	338	294	416	362	587	511	775	674
24" o.c.	12	188	164	228	198	314	273	412	358
	18	240	209	292	254	408	355	536	466
	24	292	254	358	311	502	437	660	574
	28	328	285	402	350	566	492	744	647
	32	364	317	448	390	628	546	828	720
	36	400	348	492	428	692	602	912	793
	42	454	395	558	485	786	684	1040	905
	48	508	442	626	545	882	767	1166	1014

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 mph = 0.447 m/s, 1 pound = 0.454 kg.

a. The uplift connection forces are based on a maximum 33 foot mean roof height and Wind Exposure Category B or C. For Exposure D, the uplift connection force shall be selected from the Exposure C portion of the table using the next highest tabulated basic wind speed. The Adjustment Coefficients in Table R301.2(3) shall not be used to multiply the above forces for Exposures C and D or for other mean roof heights.
b. The uplift connection forces include an allowance for roof and ceiling assembly dead load of 15 psf.
c. The tabulated uplift connection forces are limited to a maximum roof overhang of 24 inches.
d. The tabulated uplift connection forces shall be permitted to be multiplied by 0.75 for connections not located within 8 feet of building corners.
e. For buildings with hip roofs with 5:12 and greater pitch, the tabulated uplift connection forces shall be permitted to be multiplied by 0.70. This reduction shall not be combined with any other reduction in tabulated forces.
f. For wall-to-wall and wall-to-foundation connections, the uplift connection force shall be permitted to be reduced by 60 plf for each full wall above.
g. Linear interpolation between tabulated roof spans and wind speeds shall be permitted.
h. The tabulated forces for a 12" on center spacing shall be permitted to be used to determine the uplift load in pounds per linear foot.

(Portions of proposal not shown remain unchanged)

Reason: The issue of roof uplift connections, the limits of conventional nailed connections, and the point at which pre-engineered metal clips or straps are required has been a topic of much debate over the last several code cycles. A 200 pound maximum capacity for conventional rafter-to-wall or truss-to-wall connections has been suggested, based largely on capacities calculated directly from AF&PA's NDS. At the same time, the existing Table R802.11 has not been updated in some time and is overly conservative for many typical houses. The uplift loads are based on low-slope (4:12 pitch or less) roofs. The table does not account for the reduction in uplift loads that occur on higher-slope (5:12 pitch or greater) roofs or on hip roofs per ASCE 7. Thus the code does not encourage the use of high-slope roofs, which have been shown to experience significantly less damage in high-wind events. The triggers proposed by the insurance industry, coupled with the current table, would subject many houses in low-wind areas to a requirement for roof-to-wall ties (not to mention continuous straps to the foundation) that is not justified by the actual performance of roof systems in low-wind areas. This requirement is particularly unjustified on higher-slope roofs where the uplift loads can be substantially reduced through a detailed analysis using ASCE 7.

This proposal rolls together elements of several proposals concerning roof uplift connections (RB132-07/08, RB206-07/08, and RB207-07/08) from the last cycle. First, three options are provided for selection of the roof uplift: Table R802.11, the truss designer, or an engineered approach. In many jurisdictions (particularly rural ones), an engineered truss design is not required and the local truss fabricator will run the software from the plate company. These jurisdictions may also have limited or no plan review. Thus, there is less opportunity to insure the proper wind speed, building dimensions, mean roof height, etc. are used, and a possibility that overly conservative roof uplift loads will be generated on the truss design drawing. Hence, the ability to determine an uplift load from Table R802.11 even when there are truss drawings must be preserved. However, to address issues previously raised by code officials in relation to this section, we have introduced language to limit the use of Table R802.11 to roof rafters and single-ply trusses within the applicability limits of R802.10.1.1, and to clarify that and girder trusses and roof beams require engineered connections and/or use of the truss design drawing values.

Second, this proposal replaces the current Table R802.11 with a new table based on Table 2.2A of the WFCM, which is based on the latest ASCE 7 wind load provisions. The new table expands upon both the existing IRC table and the WFCM table by incorporating values for high-slope roofs. These factors were derived using the ASCE 7 wind provisions and the calculation method used to develop Table 2.2A of the WFCM. A factor for hip roofs is also added, as hip roofs have seen similar improved performance in high-wind events. This table was proposed as part of the public comment to RB207-07/08. The failure of the public comment was due to concerns over the triggering language. The technical content of the proposed table was unchallenged; in fact a number of industry groups including IBHS, SBCA, AF&PA, and the Foam Sheathing Coalition who are not often in agreement with each other spoke in favor of the proposed revisions.

By introducing clarity to the trigger language for uplift connectors and providing this revised table, the IRC provisions for roof uplift connections will be substantially improved. Builders and building officials will have improved direction for when pre-engineered metal connectors are actually required. Additionally, the use of hip roofs and high-slope roofs will be encouraged, as designers, engineers and builders will be able to appropriately reduce uplift loads and avoid triggering uplift connector requirements for building locations and for roof configurations where the requirements are not justified.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: STAFFORD-RB-1-R301.2.1-T. R602.3(1)-R802

Public Hearing Results

Committee Action: Approved as Submitted

Committee Reason: The committee feels like this change should be merged with RB156-09/10. This change should be brought back with a public comment to correlate with RB156-09/10.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Bonnie Manley, American Iron and Steel Institute (AISI), representing Steel Framing Alliance, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R301.2.1 Wind limitations. Buildings and portions thereof shall be limited by wind speed, as defined in Table R301.2(1) and construction methods in accordance with this code. Basic wind speeds shall be determined from Figure R301.2(4). Where different construction methods and structural materials are used for various portions of a building, the applicable requirements of this section for each portion shall apply. Where loads for wall coverings, curtain walls, roof coverings, exterior windows, skylights, garage doors and exterior doors are not otherwise specified, the loads listed in Table R301.2(2) adjusted for height and exposure using Table R301.2(3) shall be used to determine design load performance requirements for wall coverings, curtain walls, roof coverings, exterior windows, skylights, garage doors and exterior doors. Asphalt shingles shall be designed for wind speeds in accordance with Section R905.2.6. A continuous load path shall be provided to transmit the applicable uplift forces in Section R802.11.1 <u>or Section R804.3.9</u> from the roof assembly to the foundation.

(Portions of proposal not shown remain unchanged)

Commenter's Reason: This modification simply adds the comparable reference to the section on cold-formed steel roof framing.

Analysis: This proposal contains conflicts with RB156-09/10 as follows:

	RB154 -09/10	**RB156-09/10**
Section R802.11.1	Uplift force trigger of 200 pounds	Uplift force trigger of 230 pounds
Table R802.11	Contains uplift force values for High-slope roofs	Footnote allows adjustment and provides adjustment factors for uplift force for high-slope roofs

Final Action: AS AM AMPC____ D

RB156-09/10
Table R602.3(1), Section R602.10.1.2.1, R802.10.5, R802.11.1, Table R802.11

Proposed Change as Submitted

Proponent: Gary Ehrlich, PE, National Association of Home Builders (NAHB)

1. Revise as follows:

TABLE R602.3(1)
FASTENER SCHEDULE FOR STRUCTURAL MEMBERS

ITEM	DESCRIPTION OF BUILDING ELEMENTS	NUMBER AND TYPE OF FASTENER[a,b,c]	SPACING OF FASTENERS
5	Rafter or roof truss to plate, toe nail	~~2~~3-16d box nails (3½"x0.135") or 3-10d common nails (3"x0.148")	2 toe nails on one side and 1 toe nail on opposite side of each rafter or truss[j]

(Portions of table not shown remain unchanged)

a. through i. *(No change)*
j. Where a rafter is fastened to an adjacent parallel ceiling joist in accordance with this schedule, provide two toe-nails on one side of the rafter and toe-nails from the ceiling joist to top plate in accordance with this schedule. The toe-nail on the opposite side of the rafter shall not be required.

R602.10.1.2.1 Braced wall panel uplift load path. *Braced wall panels* located at exterior walls that support roof rafters or trusses (including stories below top *story*) shall have the framing members connected in accordance with one of the following:

1. Fastening in accordance with Table R602.3(1) where~~:~~
   ~~1.1. The basic wind speed does not exceed 90 mph (40 m/s), the wind exposure category is B, the roof pitch is 5:12 or greater, and the roof span is 32 feet (9754 mm) or less, or~~
   ~~1.2.~~ The net uplift value at the top of a wall does not exceed ~~100~~ 115 plf. The net uplift value shall be determined in accordance with Section R802.11 and shall be permitted to be reduced by 60 plf (86 N/mm) for each full wall above.
2. Where the net uplift value at the top of a wall exceeds ~~100~~ 115 plf (146 N/mm), installing *approved* uplift framing connectors to provide a continuous load path from the top of the wall to the foundation. The net uplift value shall be as determined in Item 1.2 above.
3. Bracing and fasteners designed in accordance with accepted engineering practice to resist combined uplift and shear forces.

2. Delete without substitution:

~~**R802.10.5 Truss to wall connection.** Trusses shall be connected to wall plates by the use of *approved* connectors having a resistance to uplift of not less than 175 pounds (779 N) and shall be installed in accordance with the manufacturer's specifications. For roof assemblies subject to wind uplift pressures of 20 pounds per square foot (960 Pa) or greater, as established in TableR301.2(2), adjusted for height and exposure per Table R301.2(3), see section R802.11.~~

3. Delete and substitute as follows:

~~**R802.11.1 Uplift resistance.** Roof assemblies which are subject to wind uplift pressures of 20 pounds per square foot (960 Pa) or greater shall have roof rafters or trusses attached to their supporting wall assemblies by connections capable of providing the resistance required in Table R802.11.Wind uplift pressures shall be determined using an effective wind area of 100 square feet (9.3m2) and Zone 1 inTableR301.2(2), as adjusted for height and exposure per Table R301.2(3). A continuous load path shall be designed to transmit the uplift forces from the rafter or truss ties to the foundation.~~

R802.11.1 Uplift resistance. Individual rafters and trusses shall be attached to supporting wall assemblies by connections capable of resisting uplift forces as determined by one of the following methods:

1. as specified in Table R802.11; or
2. as specified on the Truss Design Drawings; or

3. as specified by a registered design professional.

Where the uplift force does not exceed 230 pounds, rafters and trusses shall be permitted to be attached to their supporting wall assemblies in accordance with Table R602.3(1).

Connections for girder trusses and roof beams shall be designed in accordance with the uplift forces specified on the Truss Design Drawings or as determined by a registered design professional.

	42	209	285	449	630	454	558	786	1040
	48	232	318	502	706	508	626	882	1166

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 mph = 0.447 m/s, 1 pound = 0.454 kg.

a. The tabulated uplift connection forces are based on a maximum 33 foot mean roof height, and Wind Exposure Category B or C. For Exposure D, the uplift connection force shall be selected from the Exposure C portion of the table using the next highest tabulated basic wind speed. The Adjustment Coefficients in Table R301.2(3) shall not be used to multiply the above forces for Exposures C and D or for other mean roof heights. Linear interpolation between tabulated roof spans and wind speeds shall be permitted.
b. The tabulated uplift connection forces include an allowance for roof and ceiling assembly dead load of 15 psf.
c. The tabulated uplift connection forces are limited to a maximum roof overhang of 24 inches.
d. The tabulated uplift connection forces shall be permitted to be multiplied by one of the reduction factors listed in the table below. Tabulated reduction factors shall not be combined.

Roof Type	Roof Pitch	Connection Location	Adjustment Factor
Any	Any	Within 8 feet of building corners	1.00
		8 feet or more from building corners	0.75
Monoslope or gable roof	5:12 or greater	Within 8 feet of building corners	0.87
		8 feet or more from building corners	0.75
Hip roof	5:12 or greater	Within 8 feet of building corners	0.70
		8 feet or more from building corners	0.75

e. The tabulated forces for a 12" on center spacing shall be permitted to be used to determine the uplift load in pounds per linear foot.

Reason: The purpose of this proposal is to provide sensible and simplified requirements for roof uplift connections. The issue of roof uplift connections, the limits of conventional nailed connections, and the point at which pre-engineered metal clips or straps are required has been a topic of much debate over the last several code cycles. The insurance industry and others have been trying to mandate a 200 pound maximum capacity for conventional rafter-to-wall or truss-to-wall connections, based largely on capacities calculated directly from AF&PA's NDS. At the same time, the existing Table R802.11 has not been updated in some time and is overly conservative for many typical houses. The uplift loads are based on low-slope (4:12 pitch or less) roofs. The table does not account for the reduction in uplift loads that occur on higher-slope (5:12 pitch or greater) roofs or on hip roofs per ASCE 7. Thus the code does not encourage the use of high-slope roofs, which have been shown to experience significantly less damage in high-wind events. The triggers proposed by the insurance industry, coupled with the current table, would subject many houses in low-wind areas to a requirement for roof-to-wall ties (not to mention continuous straps to the foundation) that is not justified by the actual performance of roof systems in low-wind areas. This requirement is particularly unjustified on higher-slope roofs where the uplift loads can be substantially reduced through a detailed analysis using ASCE 7.

This proposal is similar to a companion proposal which rolls together elements of several proposals concerning roof uplift connections (RB132-07/08, RB206-07/08, and RB207-07/08) from the last cycle. The key difference is the proposed trigger of 230 pounds in this proposal. This value is consistent with the capacities seen in uplift testing of both individual components and roof assemblies conducted by the NAHB Research Center, Clemson University, State Farm, and others. It is a modest increase from the 200 pound capacity previously proposed by IBHS. The benefit in this small yet technically-justified increase is an ability to simplify the proposed code language by including a house with a 32' span low-slope roof in 90mph Exposure B in the scope of conventional connections. This will allow the prescriptive kick-out for the 32' high-slope condition to be removed and the overall table to be simplified.

By introducing clarity to the trigger language for uplift connectors and providing this revised table, the IRC provisions for roof uplift connections will be substantially improved. Builders and building officials will have improved direction for when pre-engineered metal connectors are actually required. Additionally, the use of hip roofs and high-slope roofs will be encouraged, as designers, engineers and builders will be able to appropriately reduce uplift loads and avoid triggering uplift connector requirements for building locations and for roof configurations where the requirements are not justified.

Cost Impact: The code change proposal will not increase the cost of construction.

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: This change adds a simplified method for roof uplift connections as stated in the proponent's published reason.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Gary J. Ehrlich, P.E., National Association of Home Builders, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

~~**R802.11.1 Uplift resistance.** Individual rafters and trusses shall be attached to supporting wall assemblies by connections capable of resisting uplift forces as determined by one of the following methods:~~

1. ~~as specified in Table R802.11; or~~
2. ~~as specified on the Truss Design Drawings; or~~
3. ~~as specified by a registered design professional.~~

~~Where the uplift force does not exceed 230 pounds, rafters and trusses shall be permitted to be attached to their supporting wall assemblies in accordance with Table R602.3(1).~~

~~Connections for girder trusses and roof beams shall be designed in accordance with the uplift forces specified on the Truss Design Drawings or as determined by a registered design professional.~~

R802.11.1 Uplift resistance. Roof assemblies shall have uplift resistance in accordance with Sections R802.11.1.2 and R802.11.1.3.

Where the uplift force does not exceed 230 pounds, rafters and trusses spaced not more than 24 inches on center shall be permitted to be attached to their supporting wall assemblies in accordance with Table R602.3(1).

R802.11.1.2 Truss uplift resistance. Trusses shall be attached to supporting wall assemblies by connections capable of resisting uplift forces as specified on the Truss Design Drawings for the basic wind speed as determined by Figure R301.2(4) and listed in Table R301.2(1). Where Truss Design Drawings are not required to be prepared by a registered design professional in accordance with R802.10.2, uplift forces shall be permitted to be determined from Table R802.11. Connections for girder trusses shall be designed in accordance with the uplift forces specified on the Truss Design Drawings or shall be determined in accordance with accepted engineering practice.

R802.11.1.3 Rafter uplift resistance. Individual rafters shall be attached to supporting wall assemblies by connections capable of resisting uplift forces as determined by Table R802.11 or as determined by accepted engineering practice. Connections for beams used in a roof system shall be designed in accordance with accepted engineering practice.

TABLE R802.11
RAFTER OR TRUSS UPLIFT CONNECTION FORCES FROM WIND (POUNDS PER CONNECTION)
(No changes to table values)

a. through c. *(No changes)*
d. The tabulated uplift connection forces shall be permitted to be multiplied by one of the reduction factors listed in the table below. Tabulated reduction factors shall not be combined.

Roof Type	Roof Pitch	Connection Location	Adjustment Factor
Any	Any	Within 8 feet of building corners	1.00
		8 feet or more from building corners	0.75
Monoslope or gable roof	5:12 or greater	Within 8 feet of building corners	0.90 ~~0.87~~
		8 feet or more from building corners	0.75
Hip roof	5:12 or greater	Any ~~Within 8 feet of building corners~~	0.75 ~~0.70~~
		~~8 feet or more from building corners~~	~~0.75~~

e. The tabulated forces for a 12" on center spacing shall be permitted to be used to determine the uplift load in pounds per linear foot.

(Portions of proposal not shown remain unchanged)

Commenter's Reason: At the public hearings in Baltimore, proposals RB154-09/10 and RB156-09/10 were both approved by the IRC-Building/Energy Committee. The Committee liked the simplified table of uplift loads and tabulated footnote adjustments supplied by RB156-09/10. At the same time, the Committee preferred the charging language in RB154-09/10 and asked it be merged with RB156-09/10. This public comment adopts the language from RB154-09/10 with a few enhancements. A pointer to the Climatic and Geographic Design Criteria table and the Basic Wind Speed Figure is added to the truss language. This emphasizes the need for the Truss Designer to correctly select the proper wind speed and other criteria in the software. This is to insure the Truss Design Drawings reflect the correct uplift reactions for the site in question, not those from a higher wind speed because the operator forgot or chose not to change the settings. This is important as the builder (and homeowner) should not be required to install extra (or larger) uplift connectors simply because the Truss Design Drawings reflect a conservative setting for the wind speed.

The original charging language of RB154 allowed the use of Table R802.11 for trusses "if applicable". It is unclear exactly what makes the table "applicable" for trusses. That requirement is replaced here with a reference to the requirements for an engineered truss design in R802.10.2. If a jurisdiction does not require signed and sealed truss drawings, it is logical to allow the builder to use the prescriptive table to select the uplift loads. In fact, it is when the Truss Design Drawings are not prepared under the supervision of an engineer that it is most likely for the software to be run with an overly conservative wind speed.

Finally, the factor for the high-slope roof condition is adjusted. The relative effect of the dead load in resisting the uplift reaction decreases as the span and wind speed increase. In order to achieve the goal of preserving conventional practice in low-hazard areas, the high-slope factor was originally selected based on a 90mph basic wind speed. However, the increase to a 230-lb trigger in this proposal, relative to the 200-lb trigger in RB154-09/10, achieves a similar intent. By implementing this modest increase (consistent with testing at the NAHB Research Center), the factor can be adjusted to the more conservative value.

Public Comment 2:

Randall Shackelford, Simpson Strong-Tie Company, requests Disapproval.

Commenter's Reason: During the Baltimore Code Development Hearings, both RB154 and RB156 were approved. Both of these changes are part of a larger process that has been undertaken in the last two code cycles to fix the wind resistance provisions of the IRC, so that the windspeed where the structural requirements of the IRC are permitted can be increased from 100 to 110 miles per hour.

Fixing the roof tiedown requirements was the last item needed for the wind resistance provisions to be corrected. Both RB154 and RB156 did the same thing. The primary difference is that RB154 set the trigger for roof tiedown at 100 plf, while RB156 set the trigger for roof tiedown at 115 plf.

Among the groups that had been working on this code change, 100 plf had generally been the agreed on trigger. In fact, this number was actually a compromise to get the many involved groups to agree to the code change.

If the capacity of the proposed nails is calculated according to the code referenced standard for calculating the capacity of nails, the AF&PA NDS-05, the code capacity would be as follows:

3-16d box nails: 147 lbs.
3-10d common nails: 138 lbs.

And that assumes that the toenails are properly installed.

The 100 plf in RB154 is a good compromise that allows small structures in low wind areas to be built without additional connections. The proponent did not offer any technical justification for increasing the trigger to 115 plf in RB156.

Further, RB156 proposes to also change the trigger for additional uplift connections in the wall bracing section (R602.10.1.2.1) to 115 plf. The ICC Ad Hoc Wall Bracing Committee put this requirement into the IRC in the last cycle with the agreed upon trigger of 100 plf, also as a compromise. For studs, the connection of the stud to the top and bottom plates has a calculated capacity of zero if end nails are used. Again, no justification was submitted to change the agreed-upon trigger from 100 to 115 plf.

Although both are a step in the right direction, approving RB 154 and RB156 creates a conflict that will be difficult to resolve.

We urge the membership to disapprove RB156, and if given the opportunity, support RB154.

Analysis: This proposal contains conflicts with RB154-09/10 as follows:

	RB154 -09/10	**RB156-09/10**
Section R802.11.1	Uplift force trigger of 200 pounds	Uplift force trigger of 230 pounds
Table R802.11	Contains uplift force values for High-slope roofs	Footnote allows adjustment and provides adjustment factors for uplift force for high-slope roofs

Final Action: AS AM AMPC____ D

RB157-09/10
R806.1, R806.2, R806.3 (New)

Proposed Change as Submitted

Proponent: Michael Fischer, The Kellen Company, representing the Roof Attic Ventilation Coalition

1. Revise as follows:

R806.1 Ventilation required. Enclosed *attics* and enclosed rafter spaces formed where ceilings are applied directly to the underside of roof rafters shall have cross ventilation for each separate space by ventilating openings protected against the entrance of rain or snow. Ventilation openings shall have a least dimension of 1/16 inch (1.6 mm) minimum and 1/4 inch (6.4 mm) maximum. Ventilation openings having a least dimension larger than 1/4 inch (6.4 mm) shall be provided with corrosion-resistant wire cloth screening, hardware cloth, or similar material with openings having a least dimension of 1/16 inch (1.6 mm) minimum and 1/4 inch (6.4 mm) maximum. Openings in roof framing members shall conform to the requirements of SectionR802.7. Required ventilation openings shall open directly to the outside air.

R806.2 Minimum area. The total net free ventilating area shall not be less than 1/150 of the area of the attic or rafter ~~space ventilated except that reduction of the total area to 1/300 is permitted provided that at least 50 percent and not more than 80 percent of the required ventilating area is provided by ventilators located in the upper portion of the space to be ventilated at least 3 feet (914 mm) above the eave or cornice vents with the balance of the required ventilation provided by eave or cornice vents~~. As an alternative, the net free cross-ventilation area may be reduced to 1/300 when a Class I or II vapor retarder is installed on the warm-in-winter side of the ceiling.

2. Add new text as follows:

R806.3 Cross-ventilation. At least 40 percent and not more than 50 percent of the required ventilating area shall be provided by ventilators located in the upper portion of the attic or rafter space. Upper ventilators shall be located no more than 3 feet (914 mm) below the ridge or highest point of the space, measured vertically, with the balance of the required ventilation provided by eave or cornice vents.

> **Exception.** Where the location of wall or roof framing members conflicts with the installation of upper ventilators, installation more than 3 feet below the ridge or highest point of the space shall be permitted.

Reason: The code sets minimum requirements for ventilated attics. This proposal establishes an appropriate requirement for cross-ventilation as the default condition instead of allowing a reduction in ventilation for what is the most commonly recommended practice for ventilated attics. An exception for conditions where framing might preclude cross-ventilation to the specific location required allows some design flexibility for non-typical roof/wall assemblies. The proposal further clarifies that ventilators open to outside air, as opposed to adjacent attic or rafter spaces or some other interior space.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: FISCHER-RB-5-R806.1

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee feels there is no technical justification for this change. There are questions about the amount of ventilation needed. The committee would like to see this combined with RB159-09/10 and brought back.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Michael D. Fischer, The Kellen Company, representing The Roof Assembly Ventilation Coalition, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R806.2 Minimum area. The total net free ventilating area shall not be less than 1/150 of the area of the attic or rafter space.

Exceptions: As an alternative, the net free cross-ventilation area may be reduced to 1/300 when one or more of the following conditions are met:

1. A Class I or II vapor retarder is installed on the warm-in-winter side of the ceiling.
2. At least 40 percent and not more than 50 percent of the required ventilating area is provided by ventilators located in the upper portion of the attic or rafter space. Upper ventilators shall be located no more than 3 feet (914 mm) below the ridge or highest point of the space, measured vertically, with the balance of the required ventilation provided by eave or cornice vents. Where the location of wall or roof framing members conflicts with the installation of upper ventilators, installation more than 3 feet below the ridge or highest point of the space shall be permitted.

~~**2. R806.3 Cross-ventilation.** At least 40 percent and not more than 50 percent of the required ventilating area shall be provided by ventilators located in the upper portion of the attic or rafter space. Upper ventilators shall be located no more than 3 feet (914 mm) below the ridge or highest point of the space, measured vertically, with the balance of the required ventilation provided by eave or cornice vents.~~

~~**Exception.** Where the location of wall or roof framing members conflicts with the installation of upper ventilators, installation more than 3 feet below the ridge or highest point of the space shall be permitted.~~

(Portions of proposal not shown remain unchanged)

Commenter Reason: This proposal as submitted contained two concepts- the first was removing the option for reduction in ventilator area based upon cross ventilation, and the other was the rewrite of the current confusing language. During debate, the committee objected to eliminating the reduction in area. This comment removes the reduction, but moves forward with the appropriate rewrite of the cross ventilation requirement. This part of the proposal received positive testimony from proponents and opponents alike.

Final Action: AS AM AMPC____ D

RB158-09/10
R806.2

Proposed Change as Submitted

Proponent: Joseph Lstiburek, Building Science Corporation

Revise as follows:

R806.2 Minimum area. The total net free ventilating area shall not be less than ~~1/150~~ 1/300 of the area of the space ventilated where ~~except that reduction of the total area to 1/300 is permitted provided that~~ at least 50 percent and not more than 80 percent of the required ventilating area is provided by ventilators located in the upper portion of the space to be ventilated at least 3 feet (914 mm) above the eave or cornice vents with the balance of the required ventilation provided by eave or cornice vents. ~~As an alternative, the net free cross-ventilation area may be reduced to 1/300 when~~ In climate zones 5, 6, 7 and 8 a Class I or II vapor retarder ~~is~~ shall be installed on the warm-in-winter side of the ceiling.

Reason: This language is now more consistent with the IBC, which only allows one ventilation ratio. It also is consistent with the appropriate building science/physics.

The previous wording encouraged installing vapor retarders in ceilings in hot humid climates in order to reduce ventilation areas. That is very bad in terms of the governing physics. This wording fixes that.

Vapor retarders are required in cold climates regardless of ventilation area. This wording makes that clear as well.

Bottom line: if you choose to vent a roof this language says vent it according to the 1:300 ratio everywhere. In cold climates you need to add a vapor retarder. The language relating to vapor retarders is now consistent with the vapor retarder changes made to wall assemblies in the two previous code cycles.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: LSTIBUREK-RB-3-R806.2

Public Hearing Results

Committee Action: Disapproved

Committee Reason: Based upon the proponent's request for disapproval. This change needs additional work and will be brought back.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Joseph Lstiburek, Building Science Corporation, representing self, requests Approval as Modified by this Public Comment.

Replace the proposal as follows:

R806.2 Minimum <u>vent</u> area. ~~The total net free ventilating area shall not be less than 1/150 of the area of the space ventilated except that reduction of the total area to 1/300 is permitted provided that at least 50 percent and not more than 80 percent of the required ventilating area is provided by ventilators located in the upper portion of the space to be ventilated at least 3 feet (914 mm) above the eave or cornice vents with the balance of the required ventilation provided by eave or cornice vents. As an alternative, the net free cross-ventilation area may be reduced to 1/300 when a Class I or II vapor retarder is installed on the warm-in-winter side of the ceiling.~~
<u>The minimum net free ventilating area shall be 1/150 of the area of the vented space.</u>

<u>**Exception:** The minimum net free ventilating area shall be 1/300 of the vented space provided the following conditions are met.</u>

1. <u>At least 50 percent and not more than 80 percent of the ventilating area is located at least 3 feet (914 mm) above the eave or cornice vents.</u>
2. <u>The balance of the required ventilation is provided by eave or cornice vents.</u>
3. <u>In climate zones 6, 7 and 8 a Class I or Class II vapor retarder is installed on the warm-in-winter side of the ceiling.</u>

Commenter's Reason: The first sentence of the existing section is eight lines long. This replaces the awkward code language with a series of clear statements.

The requirement for a vapor retarder is modified to limit it to northern climates, as a vapor retarder in southern climates can lead to moisture problems.

Final Action: AS AM AMPC____ D

RB160-09/10
R806.4 (New)

Proposed Change as Submitted

Proponent: Michael D. Fischer, The Kellen Company, representing the Roof-Attic Ventilation Coalition

Add new text as follows:

<u>**R806.4 Installation and weather protection.** Ventilators shall be installed in accordance with manufacturer's installation instructions. Installation of ventilators in roof systems shall be in accordance with the requirements of R903. Installation of ventilators in wall systems shall be in accordance with the requirements of Section R703.1.</u>

(Renumber subsequent sections)

Reason: The code sets minimum requirements for ventilated attics. This proposal requires that ventilators be installed in accordance with the manufacturers' installation instructions. This requirement is essential if ventilation systems are to provide proper cross-ventilation and perform as intended. The proposal further clarifies that the weather protection requirements applicable for roof and wall penetrations, including flashing requirements, are considered.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: FISCHER-RB-4-R806.4

Public Hearing Results

Committee Action: Disapproved

Committee Reason: The committee feels this additional text is unnecessary as it is already addressed in the code. Also, this would require ventilators to be provided.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Michael D. Fischer, The Kellen Company, representing The Roof Assembly Ventilation Coalition, requests Approval as Submitted.

Commenter's Reason: Wall and Roof ventilators are subject to code requirements for structural loading as elements of components and cladding. These products often bear labels to demonstrate compliance with the applicable code requirements. One example of an ICC-ES report includes the following language:

> *Installation of the ridge vents described in this report must comply with this report, the manufacturers published installation instructions and the requirements of the applicable code. The manufacturer's published installation instructions must be available at the jobsite at all times during installation.*

This is important to ensure that the selected vent is appropriate for the specific roof or wall covering material.
The proposal includes a requirement that the ventilators be installed with these instructions, and also includes reference to the applicable weathering section of the code.

Final Action: AS AM AMPC____ D

RB162-09/10
R903.2.1

Proposed Change as Submitted

Proponent: Mike Rice, Maplewood, MN, representing the Association of Minnesota Building Officials

Revise as follows:

R903.2.1 Locations. Flashings shall be installed at wall and roof intersections, wherever there is a change in roof slope or direction and around roof openings. <u>Kick out flashing shall be installed where the lower portion of a sloped roof stops within the plane of an intersecting wall cladding in such a manner as to divert or kick out water away from the assembly.</u> Where flashing is of metal, the metal shall be corrosion resistant with a thickness of not less than 0.019 inch (0.5 mm) (No. 26 galvanized sheet).

Reason: This would be consistent with the code change proposal of R703.8. This change would also complement the current code addressing wall and roof intersections and prevent water from entering the wall cavity or penetrating to the structural building components. Step flashing at wall and roof intersections is incomplete without the kick out flashing, where the lower portion of a sloped roof stops within the plane of an intersecting wall. The water must be diverted away or it will find a way behind the water-resistive barrier and the siding or in some cases, it will go through the siding. The benefit of adding the kick out flashing would far exceed the cost, as the cost would be little.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: RICE-RB-1-R903.2.1

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: Based on the committee's previous action on RB146-09/10.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment 1:

Scott Dornfeld, City of Delano, representing Association of Minnesota Building Officials, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R903.2.1 Locations. Flashings shall be installed at wall and roof intersections, wherever there is a change in roof slope or direction and around roof openings. ~~Kick out flashing shall be installed where the lower portion of a sloped roof stops within the plane of an intersecting wall cladding in such a manner as to divert or kick out the water away from the assembly.~~ A flashing shall be installed to divert the water away from where the eave of a sloped roof intersects a vertical sidewall. Where flashing is of metal, the metal shall be corrosion resistant with a thickness of not less than 0.019 inch (0.5 mm) (No.26 galvanized sheet).

Commenter's Reason: When this was brought forward in Baltimore the thought of adding this flashing was a good idea, but the committee needed the language cleaned up. Removing the phrases that the committee needed definitions for and going to language that was reader friendly and by moving this change to below the current language it put the change in location that helps clarify the need for the flashing. We have seen for years the damage that water does to the structural frame over time. Flashing will help remove the water damage that goes behind the exterior wall finish at the roof slope bottom edge at an intersecting a wall.

Public Comment 2:

Theresa A. Weston, PhD, DePont Building Innovations, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

KICK OUT FLASHING. Corrosion resistant flashing used to divert or kick out water away from the lower portion of a sloped roof assembly with an intersecting wall cladding.

(Portions of proposal not shown remain unchanged)

Commenter's Reason: This comment is submitted to respond to the committee's reason for disapproval. The committee's reason for disapproval of RB162 was *"based on the committee's previous action on RB146-09/10"*. This references the committee's reason for disapproval of RB146 which was *"The committee feels this needs to be addressed but it belongs in Chapter 9. The proponent needs to rework and bring this back. This needs a detail or definition of "kick out flashing".*

I am commenting on RB162 rather than RB146 because is covers the appropriate section in Chapter 9 as directed in the committee's reason for disapproval. Also in response to the committee's request a definition for "kick-out flashing" has been added.

Final Action: AS AM AMPC____ D

RB164-09/10
R905.1

Proposed Change as Submitted

Proponent: W. Harvey Cappel, PE, Racelectric Engineering

Revise as follows:

R905.1 Roof covering application. Roof coverings shall be applied in accordance with the applicable provisions of this section and the manufacturer's installation instructions. Unless ~~otherwise specified in this section,~~ specifically waived by a listed exception in the appropriate code section, roof coverings shall be installed to resist the component and cladding loads specified in Table R301.2(2), adjusted for height and exposure in accordance with Table R301.2(3).

Reason: The term "otherwise specified" without a definition basically means "anything specified" which makes this Section R905.1 meaningless and basically void. The original intent here is to require roof coverings to be installed to resist specific wind loads. With this undefined "otherwise specified" loophole the intent of R905.1 is cancelled. We want roof coverings to be installed to resist the wind loads so let's be clear about what we want.

Cost Impact: There will be no cost impact (as compared to the original intent of the Code) related to this proposed code change.

ICCFILENAME: CAPPEL-RB-3-R905.1

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The committee feels the existing language is clear and the new text is not needed and is confusing.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

W. Harvey Cappel, PE. representing himself, requests Approval as Submitted

Commenter's Reason: The problem with the wording in IRC Article R905.1 (Roof covering application) is that it is being interpreted wrongly. "Otherwise specified" is being taken as anything stated and therefore the requirement to be installed to resist the component and cladding loads is being completely ignored. For example: R905.2.6 Attachment (of composite shingles) then becomes 1) Perform an adhesive test per ASTM D-3161 or ASTM D-7158 (neither one test fasteners) and 2) Follow manufacturer's installation instructions. Composite shingle manufacturer's installation instructions typically do not address the wind speed, structure mean roof height and exposure considerations required for adequate fastener design. This is a particularly significant problem in the hurricane prone regions of Texas along the Gulf Coast where, because of this misinterpretation, shingles are being installed inadequately. The wrongly installed shingles experienced failure rates in excess of 50% as everyone could see by counting the blue FEMA roof tarps after hurricanes Rita and Ike. Making the true meaning of this code article clearer can help to solve this very serious cost and safety problem. Shingles that were replaced after hurricane Rita failed at about the same rate during hurricane Ike (only four years later) as they did during hurricane Rita.

Final Action: AS AM AMPC____ D

RB165-09/10
R905.2.4.1

Proposed Change as Submitted

Proponent: W. Harvey Cappel, PE, Racelectric Engineering

Revise as follows:

R905.2.4.1 Wind resistance of asphalt ~~shingles~~ adhesive strips. Asphalt shingles shall be tested for wind resistance of the adhesive strips (required to secure the shingle tabs) in accordance with ASTM D 7158. Asphalt shingles shall meet the classification requirements of Table R905.2.4.1 (1) for the appropriate maximum basic wind speed. Asphalt shingle packaging shall bear a label to indicate compliance with ASTM D 7158 and the required classification in Table R905.2.4.1 (1).

> **Exception:** Asphalt shingles not included in the scope of ASTM D 7158 shall be tested and labeled to indicate compliance with ASTM D 3161 and the required classification in Table R905.2.4.1 (2).

Reason: The referenced test standards test the adhesive and its resistance to failure due to wind loads (test simulated) on the upwind side of the roof. These tests do not test fasteners or the resistance of fasteners to withdrawal from the wood deck. The tests aren't even (test simulated) on the correct side of the roof (downwind) required for testing the fasteners. Mr. Mike Noone, Chairman of ASTM Subcommittee D08-02 (the authors of ASTM D 3161 and similar test codes) will confirm this. The problem with the current wording is that it is misleading causing some to believe that use of the manufactures' nail standard during this test is a test of the nails and therefore the standard nailing required, for these shingles, on any roof for winds up to the test standard wind speeds. This is not true. For high wind areas (110 mph or greater) the fasteners must be designed for the wind speed, mean roof height and exposure. Fasteners are not tested nor do they need to be. Sufficient data is already available to Engineers for the design of fastener systems.

Cost Impact: The only impact this code change proposal will have on cost is to those that have been wrongly interpreting the intent of the Code. In this case the cost of only a few more nails per shingle will be insignificant especially as compared to the cost of a failed shingle system cause by inadequate nailing.

ICCFILENAME: CAPPEL-RB-1-R905.2.4.1

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The shingle, not the adhesive strip, is what is required to be wind resistant. Shingle rigidity is a factor in wind resistant. The term "adhesive strips" implies more than one is required. This would exclude interlocking shingles.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

W. Harvey Cappel, PE., representing self, requests Approval as submitted.

Commenter's Reason: The problem with the wording in IRC Article R905.2.4.1 (Wind resistance of asphalt shingles) is that it is being interpreted wrongly.

The adhesive testing performed by ASTM D3161 and ASTM D 7158 is just that adhesive test. The test simulation is on the wrong side of the roof (upwind) to even test fasteners. Fastener testing into structural elements is not even required. Fastener test data is readily available to Engineers for fastener design. This wrong interpretation leads some to believe that fastener design is not required; just simply follow manufacturer's installation instructions. This is simply not true. Composite shingle manufacturer's installation instructions typically do not address the wind speed, structure mean roof height and exposure considerations required for adequate fastener design. This is a particularly significant problem in the hurricane prone regions of Texas along the Gulf Coast where, because of this misinterpretation, shingles are being installed inadequately. The wrongly installed shingles experienced failure rates in excess of 50% as everyone could see by counting the blue FEMA roof tarps after hurricanes Rita and Ike. Making the true meaning of this code article clearer can help to solve this very serious cost and safety problem. Shingles that were replaced after hurricane Rita failed at about the same rate during hurricane Ike (only four years later) as they did during hurricane Rita.

Final Action: AS AM AMPC____ D

RB166-09/10
R905.2.5

Proposed Change as Submitted

Proponent: W. Harvey Cappel, PE, Racelectric Engineering

Revise as follows:

R905.2.5 Fasteners. Fasteners for asphalt shingles shall be galvanized steel, stainless steel, aluminum or copper roofing nails, minimum <u>11 gage (0.1205 (3mm)</u> ~~12 gage (0.105 inch (3mm))~~ shank with a minimum 3/8-inch (10 mm) diameter head, ASTM F 1667, of a length to penetrate through the roofing materials and <u>penetrate through the minimum required roof sheathing or penetrate to an equivalent embedment into the thicker than minimum required roof sheathing.</u> ~~a minimum of ¾ inch (19 mm) into the roof sheathing. Where the roof sheathing is less than ¾ inch (19mm) thick, the fasteners shall penetrate through the sheathing.~~ Fasteners shall comply with ASTM F 1667.

Reason: 1) The 12 gage nails are rarely if ever used anymore and in many cases inadequate. The outdated standard is copied from the typical manufacturer's installation instructions (also outdated). The minimum standard needs to be updated.

2) The current Section wording is outdated (copied from the typical shingle manufacturer's installation instructions, also outdated) and ambiguous. It implies an either or standard with the in between not in compliance with the Code. This is ridiculous. If a 3/8 inch penetration is in compliance with the Code then all greater penetrations and embedment's up to and including the other Code required ¾ inch penetration are also in compliance with the Code. The problem with this incorrect wording is that it is being used as evidence of non compliance, which is senseless.

Cost Impact: 1) Probably no cost impact at all to go to the new 11 gage nail since the 12 gage nail isn't normally being used anyway, but even where it is, the cost impact will be minimal.

2) There will be no cost impact related to this proposed Code change; only less confusion and potentially a cost savings.

ICCFILENAME: CAPPEL-RB-2-R905.2.5

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: There is no technical data justifying this change and it exceeds the tested manufacturer's specification.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

W. Harvey Cappel PE representing self, requests Approval as submitted.

Commenter's Reason: The problem with the wording in IRC Article R905.2.5 (Fasteners) is that it is being interpreted wrongly. One would expect that if a 3/8-inch penetration thru a wood sheathing would be acceptable that all other deeper penetrations either thru or into the same wood sheathing would also be acceptable, actually better. Not so by the current wording. By the current wording if the wood sheathing is not at least ¾-inch thick then the fastener penetrations must be thru the sheathing. This is ridiculous. The National Design Specification For Wood Construction (NDS) Table 11.2C Nail and Spike Withdrawal Values makes no distinction (including no footnotes) between penetration thru or into wood sheathing. This antiquated wording needs to be changed to reflect true engineering of fastener design.

Final Action: AS AM AMPC____ D

RB167-09/10
R905.2.6

Proposed Change as Submitted

Proponent: W. Harvey Cappel, PE, Racelectric Engineering

Revise as follows:

R905.2.6 Attachment. Asphalt shingles shall have the minimum number of fasteners required by the manufacturer, but not less than four fasteners per strip shingle or two fasteners per individual shingle. Where the roof slope exceeds 21 units vertical in 12 units horizontal (21:12, 175 percent slope), <u>or where the basic wind speed is equal to or exceeds100 mph </u>shingles shall be installed as required by the manufacturer<u>, but with not less than six nails per shingle and as required to comply with Section R905.1.</u>

Reason: The current code is being misinterpreted (mainly because of a misunderstanding of the ASTM D 3161 test [it only tests adhesives] requirement for high wind areas) regarding the fastening requirements to resist wind loads. This proposed change will help reinforce the known requirement that additional fasteners are required in high wind areas. The shingle manufacturers cannot be relied on for this requirement since they cannot and do not take responsibility for fastening design or fastening installation in high wind areas. Their wind related limit of warranty and responsibility typically stops with assurance against manufacturer's defects and compliance with one of the ASTM adhesive tests standards. Knowing that four nails per shingle are typically inadequate in high wind areas, here is an opportunity to set a minimum standard for high wind areas. The extreme number of shingle failures as a result of recent hurricanes Rita and Ike with wind speeds well below the typical coastal design standards, should be sufficient motivation to make a change in our shingle installation codes. What we have in force now, (basically four nails per shingle everywhere) is not working.

Cost Impact: There will be no cost impact (as compared to the original intent of the Code) related to this proposed Code change. Even if this change causes some construction projects to use six nails per shingle instead of the incorrect four nails per shingle, the additional cost will be minimal, especially as compared to the cost of an inadequate and failed shingle installation.

ICCFILENAME: CAPPEL-RB-4-R905.2.6

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: This change is not necessary. Additional fasteners are not the controlling factor for shingle blow off, the shingle is. Improvement in the shingle and ASTM D 7158 has improved the wind resistance of shingles.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

W. Harvey Cappel, PE., representing self, requests Approval as submitted.

Commenter's Reason: The problem with the wording in IRC Article R905.2.6 (Attachment) is that it leaves the fastener design to the shingle manufacturer. Shingle manufacturers do not design fastening (into structural sheathing) systems, cannot control the field application of same and therefore do not even warrant fastener design. Composite shingle manufacturer's installation instructions typically do not address the wind speed, structure mean roof height and exposure considerations required for adequate fastener design. Also the testing performed by ASTM D-3161 and or ASTM D-7158 is only a test of the tab adhesive. These tests do not test fasteners; the wind test simulation isn't even on the correct side of the roof. The test is on the upwind side of the roof which does not load the fasteners. Shingle fastener testing is not required. Fastener design data is readily available to Engineers for design purposes. The wording here leads one to believe wrongly that the only requirement for shingle fastener design is what it says on a shingle package. This is devastatingly wrong. This is a particularly significant problem in the hurricane prone regions of Texas along the Gulf Coast where, because of this misinterpretation, shingles are being installed inadequately. The wrongly installed shingles experienced failure rates in excess of 50% as everyone could see by counting the blue FEMA roof tarps after hurricanes Rita and Ike. Making the true meaning of this code article clearer can help to solve this very serious cost and safety problem. Shingles that were replaced after hurricane Rita failed at about the same rate during hurricane Ike (only four years later) as they did during hurricane Rita.

Final Action: AS AM AMPC____ D

RB168-09/10
R905.2.8.3

Proposed Change as Submitted

Proponent: Gary Ehrlich, PE, National Association of Home Builders (NAHB)

Revise as follows:

R905.2.8.3 Sidewall flashing. Flashing against a vertical sidewall shall be ~~by the step-flashing method. The flashing shall be~~ a minimum of 4 inches (102 mm) high and 4 inches (102 mm) wide~~. At the end of the vertical sidewall the step flashing shall be turned out in a manner that~~ <u>and shall</u> direct~~s~~ water away from the <u>vertical side</u>wall ~~and~~ onto the roof and/or <u>into the</u> gutter. <u>Where siding is provided on the vertical sidewall, the vertical leg of the flashing shall be continuous under the siding.</u>

Reason: The purpose of this proposal is to clarify the requirements for the use of flashing at a vertical wall-to-roof intersection. The use of "step flashing" is fine for masonry wall construction; but to use it where siding is provided is incorrect. Walls with siding should be provided with continuous "J"-shaped sections of flashing, with the vertical leg continuous under the siding. A "J" turn back lip on the horizontal leg of the siding controls the water and directs it down the roof to the gutter. Step flashing does not have the return lip. "J"-shaped flashing sections are continuous, requiring fewer joints, look much better, and also reduce the opportunity for water to have multiple points of possible entry.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: EHRLICH-RB-11-R905.2.8.3

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: Based on the proponent's request for disapproval. The language is unclear and too restrictive. The proponent will work with industry and submit a public comment for Final Action.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Gary J. Ehrlich, PE, National Association of Home Builders (NAHB), requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R905.2.8.3 Sidewall flashing. Base flashing ~~Flashing~~ against a vertical sidewall shall be continuous or step flashing and shall be a minimum of 4 inches (102 mm) in height ~~high~~ and 4 inches (102 mm) in width ~~wide~~ and shall direct water away from the vertical sidewall onto the roof and/or into the gutter. Where siding is provided on the vertical sidewall, the vertical leg of the flashing shall be continuous under the siding. Where anchored masonry veneer is provided on the vertical sidewall, the base flashing shall be provided in accordance with this section and counterflashing shall be provided in accordance with Section R703.7.2.2. Where exterior plaster or adhered masonry veneer is provided on the vertical sidewall, the base flashing shall be provided in accordance with this section and Section R703.6.3.

Commenter's Reason: The purpose of this public comment is to address issues raised by ARMA, BIA, and others at the public hearings. First, it is clarified that both continuous flashing and step flashing are considered acceptable methods for the base flashing at the sidewall. This allows the builder, in conjunction with the roofer and roofing manufacturer, to select the appropriate flashing method for the site conditions and the project schedule. Second, a reference is provided to the counterflashing requirements for anchored masonry veneer in Chapter 7. The counterflashing needs to be step flashing so it can be inserted into the mortar joints of the veneer. The base flashing can be continuous if desired. Finally, a reference is provided to Section R703.6.3 for exterior plaster (stucco) and adhered masonry veneer. That section calls for installing the vertical leg of the flashing between the two layers of water-resistant barrier required behind the stucco or veneer.

Final Action: AS AM AMPC____ D

RB170-09/10
R905.2.8.5 (New)

Proposed Change as Submitted

Proponent: Logan G. Sauter, Salt Lake City Corporation, representing the Utah Chapter of ICC

Add new text as follows:

R905.2.8.5 Drip Edge. Provide drip edge at eaves and gables of shingle roofs. Overlap to be a minimum of 2 inches (51 mm). Eave drip edges shall extend 0.25 inch (6.4 mm) below sheathing and extend back on the roof a minimum of 2 inches (51 mm). Drip edges shall be mechanically fastened a maximum of 12 inches (305 mm) o.c.

Reason: Unlike the IBC, the IRC does not include drip edge requirements for shingle roofs. This new text brings the IRC into uniformity with the IBC, reflects manufacturers' requirements for shingle roof installations, and uses identical wording and placement as found in IBC 1507.2.9.3.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: SAUTER-RB-1-R905.2.8.5

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: This is a good change that will provide protection of the shingles and gives rigidity to the shingle edges. This is consistent with the IBC.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment 1:

Rick Davidson, City of Maple Grove, representing self, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R905.2.8.5 Drip Edge. ~~Provide drip~~ Drip edge shall be provided at eaves and gables of shingle roofs. ~~Overlap to be~~ Adjacent pieces of drip edge shall be overlapped a minimum of 2 inches (51 mm). ~~Eave drip~~ Drip edges shall extend a minimum of 0.25 inch (6.4 mm) below the roof sheathing and ~~extend back on~~ extend up the roof deck a minimum of 2 inches (51 mm). Drip edges shall be mechanically fastened to the roof deck at a maximum of 12 inches (305 mm) o.c. with fasteners as specified in Section R905.2.5. Underlayment shall be installed over the drip edge along eaves and under the underlayment on gables. Unless specified differently by the shingle manufacturer, shingles are permitted to be flush with the drip edge.

Commenter's Reason: While we would disagree with the suggestion that the proposal reflects manufacturer's requirements for drip edge (R905.1 requires roofing be installed according to manufacturer's installation instructions so if they require it, it need not be repeated in the code), if such regulation must be in the code, better direction must be included for a proper installation. The direction provided in this modification comes from the Asphalt Roofing Manufacturer's Association.

Public Comment 2:

Gary Ehrlich, National Association of Home Builders (NAHB), requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R905.2.8.5 Drip Edge. ~~Provide~~ A drip edge shall be provided at rake edges and at the upper and lower eaves ~~and gables~~ of shingle roofs. The horizontal leg of the drip edge shall ~~O~~ overlap ~~to be~~ roof sheathing a minimum of 2 inches (51 mm). The vertical leg of the ~~Eave~~ drip edge~~s~~ shall extend 0.25 inch (6.4 mm) minimum below the bottom of the roof sheathing and shall be offset 0.25 inches (6.4mm) minimum from the edge of the roof sheathing or fascia board ~~extend back on the roof a minimum of 2 inches (51 mm)~~. Drip edges shall be mechanically fastened a maximum of 12 inches (305 mm) o.c. Where an ice barrier or other roof underlayment is provided at rake edges, the drip edge shall be installed over the underlayment. Where an ice barrier or other roof underlayment is provided along an eave, the underlayment shall be installed over the drip edge. Where a gutter is provided, the drip edge shall be installed to direct water into the gutter.

Commenter's Reason: The purpose of this public comment is to revise and clarify the drip edge provisions that were approved at the Public Hearings in Baltimore. The provisions are vague, use incorrect terminology, and are not written in proper code language. The following changes are proposed:

1. The approved language requires a drip edge at "gables of shingle roofs". The proper term for this location is the "rake edge".
2. The language is revised to clarify the horizontal overlap of the drip edge with the roof sheathing.
3. The language is revised to specify the proper length and location of the vertical leg of the drip edge. The ¼" offset is critical to insure water is directed away from the fascia board.
4. Additional language is added to insure the installation of the drip edge is properly coordinated with the installation of ice barriers or other roof underlayment and with the installation of gutters.

These changes are critical to insure that the drip edge is installed correctly. If this public comment is not approved, it is possible that incorrect installations will occur and cause the exact moisture problems that the drip edges are supposed to protect against.

Final Action: AS AM AMPC____ D

RB177-09/10-PART I
AG106.2 (New), AG108 (New), Chapter 44 (New)

Proposed Change as Submitted

Proponent: Jesse J. Beitel, Hughes Associates, Inc., representing the Pool Safety Council

PART I – IRC BUILDING/ENERGY

1. Add new text as follows:

<u>**AG106.2 Vacuum relief system required.** All pool and spa single- or multiple-outlet circulation systems that incorporate submerged suction outlet fittings shall be equipped with an approved or engineered vacuum relief system as follows:</u>

1. <u>Safety vacuum release systems conforming to ASME A112.19.17 or ASTM F 2387; or</u>
2. <u>An approved gravity drainage system.</u>

2. Add new standards to Chapter 44 and AG108 as follows:

ANSI/ASME
<u>A112.19.17-02</u> <u>Manufactured Safety Vacuum Release Systems (SVRS) For Residential and Commercial Swimming Pool, Spa, Hot Tub and Wading Pool Suction Systems</u>

ASTM
<u>F 2387-04</u> <u>Standard Specification for Manufactured Safety Vacuum Release Systems (SVRS) For Swimming Pools, pas, Hot Tubs</u>

Reason: This code change provides a final layer of protection against potential entrapments. While the APSP-7 provides partial protection against entrapment, it does not protect swimmers or waders in the event that problems occur with improperly designed pools, some types of blocked drains, etc. These events can and do occur and when they occur, this proposal provides a mechanism to help prevent entrapment.

Cost Impact: The code change proposal will increase the cost of construction.

Analysis: A review of the standards proposed for inclusion in the code, ANSI/ASME A112.19.17 and ASTM F 2387, for compliance with ICC criteria for referenced standards given in Section 3.6 of Council Policy #CP 28 will be posted on the ICC website on or before September 24, 2009.

ICCFILENAME: BEITEL-RB-2-APDX G-IBC-G-1- 3109.5.1

Public Hearing Results

Analysis: Review of proposed new standards indicated that, in the opinion of ICC Staff, the standards did comply with ICC standards criteria.

PART I - IRC
Committee Action: **Disapproved**

Committee Reason: The committee feels that this change is not needed at this time. The Federal Law will cover this and we have an approved ANSI/APSP-7 Standard. ICC is developing a Swimming Pool Code and this issue should be considered within that process.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jesse J. Beitel, Hughes Associates, Inc., representing Pool Safety Council, requests Approval as Submitted.

Commenter's Reason: Commenter's Reason: The Pool Safety Council as well as others, continue to believe that the proposed code change provides the best solution to prevent entrapments. This proposal provides the final layer of protection that is in the best safety interest for everyone who uses pools, spas, etc.

The Federal Law does require entrapment safety, and the proposed changes provide additional requirements so as to bring the IRC and the IBC into compliance with the Federal Law.

Final Action: AS AM AMPC____ D

RB177-09/10-PART II

3109.5.1 (New), Chapter 35 (New)

Proposed Change as Submitted

Proponent: Jesse J. Beitel, Hughes Associates, Inc., representing the Pool Safety Council

PART II – IBC GENERAL

1. Add new text as follows:

<u>**3109.5.1 Vacuum relief system required.** All pool and spa single- or multiple-outlet circulation systems that incorporate submerged suction outlet fittings shall be equipped with an approved or engineered vacuum relief system as follows:</u>

1. <u>Safety vacuum release systems conforming to ASME A112.19.17 or ASTM F 2387; or</u>
2. <u>An approved gravity drainage system.</u>

2. Add new standards to Chapter 35 as follows:

ANSI/ASME

<u>A112.19.17-02</u> <u>Manufactured Safety Vacuum Release Systems (SVRS) For Residential and Commercial Swimming Pool, Spa, Hot Tub and Wading Pool Suction Systems</u>

ASTM

<u>F 2387-04</u> <u>Standard Specification for Manufactured Safety Vacuum Release Systems (SVRS) For Swimming Pools, Spas, Hot Tubs</u>

Reason: This code change provides a final layer of protection against potential entrapments. While the APSP-7 provides partial protection against entrapment, it does not protect swimmers or waders in the event that problems occur with improperly designed pools, some types of blocked drains, etc. These events can and do occur and when they occur, this proposal provides a mechanism to help prevent entrapment.

Cost Impact: The code change proposal will increase the cost of construction.

Analysis: A review of the standards proposed for inclusion in the code, ANSI/ASME A112.19.17 and ASTM F 2387, for compliance with ICC criteria for referenced standards given in Section 3.6 of Council Policy #CP 28 will be posted on the ICC website on or before September 24, 2009.

ICCFILENAME: BEITEL-RB-2-APDX G-IBC-G-1- 3109.5.1

Public Hearing Results

Analysis: Review of proposed new standards indicated that, in the opinion of ICC Staff, the standards did comply with ICC standards criteria.

PART II - IBC
Committee Action: **Disapproved**

Committee Reason: The proposal was disapproved consistent with the action taken on Part I and at the proponent's request. ICC has begun the process of developing a swimming pool code. The development process for the new code will provide a better forum to resolve the various contentious issues related to this proposal and similar proposals heard by the IRC – Building and Energy Code Development Committee.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jesse J. Beitel, Hughes Associates, Inc., representing Pool Safety Council, requests Approval as Submitted.

Commenter's Reason: See RB177-09/10, Part I

Final Action: AS AM AMPC____ D

RB184-09/10
R302.1, Table R302.1(1), Table R302.1(2) (New), R309.5 (New)

Proposed Change as Submitted

Proponent: Tom Lariviere, Chairman - Joint Fire Service Review Committee

1. Revise as follows:

R302.1 Exterior walls. Construction, projections, openings and penetrations of *exterior walls* of *dwellings* and accessory buildings shall comply with Table R302.1(1); or for *dwellings* equipped throughout with an *automatic sprinkler system* installed in accordance with Section P2904 shall comply with Table R302.1(2).

Exceptions:

1. Walls, projections, openings, or penetrations in walls perpendicular to the line used to determine the *fire separation distance*.
2. Walls of *dwellings* and *accessory structures* located on the same lot.
3. Detached tool sheds and storage sheds, playhouses and similar structures exempted from permits are not required to provide wall protection based on location on the *lot*. Projections beyond the *exterior wall* shall not extend over the *lot line*.
4. Detached garages accessory to a *dwelling* located within 2 feet (610 mm) of a *lot line* are permitted to have roof eave projections not exceeding 4 inches (102 mm).
5. Foundation vents installed in compliance with this code are permitted.

TABLE R302.1(1)
EXTERIOR WALLS

Exterior Wall Element		Minimum Fire-Resistance Rating	Minimum Fire Separation Distance
Walls	(Fire-resistance rated)	1 hour-tested in accordance with ASTM E 119 or UL 263 with exposure from both sides	<5 feet
	(Not fire-resistance rated)	0 hours	5 feet
Projections	(Fire-resistance rated)	1 hour on the underside	2 feet to 5 feet
	(Not fire-resistance rated)	0 hours	5 feet
Openings in walls	Not allowed	N/A	<3 feet
	25% Maximum of Wall Area	0 hours	3 feet
	Unlimited	0 hours	5 feet
Penetrations	All	Comply with Section R317.3	<5 feet
		None required	5 feet

For SI: 1 foot = 304.8 mm.
N/A = Not Applicable

TABLE R302.1(2)
EXTERIOR WALLS – DWELLINGS WITH FIRE SPRINKLERS

Exterior Wall Element		Minimum Fire-Resistance Rating	Minimum Fire Separation Distance
Walls	(Fire-resistance rated)	1 hour-tested in accordance with ASTM E 119 or UL 263 with exposure from the outside	0 feet
	(Not fire-resistance rated)	0 hours	3 feet[a]
Projections	(Fire-resistance rated)	1 hour on the underside	2 feet[a]
	(Not fire-resistance rated)	0 hours	3 feet
Openings in walls	Not allowed	N/A	<3 feet
	Unlimited	0 hours	3 feet[a]
Penetrations	All	Comply with Section R317.3	<3 feet
		None required	3 feet[a]

For SI: 1 foot = 304.8 mm.
N/A = Not Applicable
a. For residential subdivisions where all dwellings are equipped throughout with an automatic sprinkler systems installed in accordance with Section P2904, the fire separation distance for non-rated exterior walls and rated projections shall be permitted to be reduced to zero feet, and unlimited unprotected openings and penetrations shall be permitted, where the adjoining lot provides an open setback yard that is 6 feet or more in width on the opposite side of the property line.

2. Add new text as follows:

R309.5 Fire Sprinklers. Private garages shall be protected by fire sprinklers where the garage wall has been designed based on Table R302.1(2), Footnote a. Sprinklers in garages shall be connected to an automatic sprinkler system that complies with Section P2904. Garage sprinklers shall be residential sprinklers or quick-response sprinklers, designed to provide a density of 0.05 gpm/ft^2. Garage doors shall not be considered obstructions with respect to sprinkler placement.

Reason: In the last code cycle, Proposal RB67-07/08 (which was withdrawn at the Final Action Hearings) provided as one of its sprinkler alternatives a reduction in exterior wall fire ratings that we believe still is a reasonable and justifiable sprinkler incentive. This proposal will provide a reasonable sprinkler alternative in the IRC when residential sprinkler systems are installed.

This proposal provides a significant financial and design incentive for residential sprinklers. From a financial perspective, the proposal permits cost reductions related to exterior wall construction and, in the case of a planned community, could result in more developable lots. From a design advantage perspective, the proposal permits homes to have larger footprints without triggering fire-rated exterior walls and permits more flexible use of windows on walls facing property lines.

From a fire safety perspective, the proposed requirements under new Table R302.1(2) generally put the code back where it was in 2000 and 2003, so there is essentially no concession compared to how homes have been built under the IRC since the code was first published in 2000. In 2006, the IRC's fire separation distances for non-rated exterior walls were increased from 3 feet to 5 feet for the purpose of coordinating the IRC's residential separation distances with those in the IBC (Code Change G128-03/04). History shows that residential sprinklers reliably limit fire spread to the room of origin, and with such protection, allowing the code to revert to a 3-foot separation distance provides a reasonable compensation for sprinklers. Certainly, the probability of a favorable outcome in the event of a fire is much better for a sprinklered building with a 3-foot separation versus a nonsprinklered building with a 5-foot separation, so encouraging sprinklers is a preferred approach.

The proposed garage requirement for R309.5 provides a limitation on the application of new Table R302.1(2) by only allowing use of sprinkler incentives in areas where sprinklers are provided. Normally, garages aren't required to have sprinklers; however, where a designer chooses to take advantage of reduced separation requirements for a garage wall, it is appropriate for the garage to be provided with sprinklers as a means of property protection. Proposed design criteria for sprinklers were derived from NFPA 13R Section 6.8.3.3, which addresses sprinkler protection for garages in buildings protected by NFPA 13R sprinkler systems. Often, garage protection is provided by dry pendent or dry sidewall sprinklers connected to a wet pipe sprinkler system.

The original Table R302.1(1) has been retained for jurisdictions that may adopt this edition of the Code without the mandatory sprinkler requirements that are presently in the 2009 IRC and for cases where there are additions or modifications to an existing non-sprinklered property.

Cost Impact: This code change proposal will decrease the cost of construction.

ICCFILENAME: LARIVIERE-RB2-R302.1

Public Hearing Results

Committee Action: Disapproved

Committee Reason: The committee feels that sprinklers inside one house will not protect the adjacent house that may or may not be sprinklered. The footnote to the table invokes entire subdivisions and conditions that may or may not exist and this is way outside the scope of the IRC.

Assembly Action: Approved as Submitted

Individual Consideration Agenda

This code change proposal is on the agenda for individual consideration because the proposal received a successful assembly action and a public comment was submitted. Note that the assembly action, Approved as Submitted, will be the initial motion on the floor for consideration when this item is called.

Public Comment:

Rick Thornberry, The Code Consortium, Inc, representing Cellulose Insulation Manufacturers Association (CIMA), requests Disapproval.

Commenter's Reason: We are submitting this Public Comment to oppose the assembly action for approved as submitted of this Code Change Proposal in order to support the International Residential Code Building/Energy Code Development Committee's recommendation for disapproval. We certainly agree with the Committee's reason for disapproval in that there will be many cases where a new dwelling unit will be constructed next to an existing dwelling unit where the new dwelling unit may be sprinklered but the existing dwelling unit may not. So it would not be prudent to allow for these reduced fire separation distances for requirements invoking 1-hour rated exterior walls or projections, limitations on unprotected openings in exterior walls, and protection of penetrations.

Also the proposed new Table R302.1(2) Exterior Walls – Dwellings with Fire Sprinklers is somewhat confusing regarding the minimum fire separation distances specified. For example, for exterior walls where a 1-hour rating is required, the minimum fire separation distance specified is zero (0) feet. What happens if the minimum fire separation distance is greater than zero (0) feet but less than 3 feet? Similarly, for projections required to be 1-hour fire-resistance rated on the underside where the minimum fire separation distance is specified as 2 feet, what happens if the minimum fire separation distance is greater than 2 feet but less than 3 feet? It should also be noted that this new table will allow unlimited unprotected openings in a nonrated exterior wall where the fire separation distance is at least 3 feet. This compares to the current code that would only allow 25% of the exterior wall area to have unprotected openings where the fire separation distance is between 3 feet and 5 feet. This is significant in that a fire in one building which breaks out of the unprotected opening can expose the adjacent building not only by radiant heat, but also by convected heat in the form of a flame plume which may project as much as 5 to 6 feet beyond the face of the building.

These trade-offs all presume that the automatic sprinkler system will perform as designed and prevent the fire from breaking out an exterior window and burning on the exterior so as to expose an adjacent dwelling. But what if the fire occurs in the attic where there are no sprinklers and breaks out of a vent in the side wall?

The IRC will allow an NFPA 13D or equivalent sprinkler system to be used for these trade-offs. As we all know, an NFPA 13D sprinkler system is primarily a life safety system and not a full property protection system. This is clearly stated in Section 1.2 Purpose of NFPA 13D as follows:

1.2.1 The purpose of this standard shall be to provide a sprinkler system that aids in the detection and control of residential fires and thus provides improved protection against injury and life loss.

1.2.2 A sprinkler system designed and installed in accordance with this standard shall be expected to prevent flashover (total involvement) in the room of fire origin, where sprinklered, and to improve the chance for occupants to escape or be evacuated.

These trade-offs rely on the owners of the adjacent buildings to maintain their automatic sprinkler systems in an operative condition at all times. Unfortunately, there is no supervision required for these systems and no fire department connection is provided for the fire department to boost the sprinkler system water supply as is typical of an NFPA 13 sprinkler system. Furthermore, the water supply to the system could be shut off for repairs and not turned back on since no supervision of the control valve supplying the water supply to the sprinkler system is required if the valve is locked open. Obviously, the owner of the townhouse would have the key to the lock on the valve so there would be nothing to prevent the owner from unlocking the lock and closing the valve for whatever reason. And it is not uncommon for the valve to remain closed since there is no supervisory reminder that the valve remains closed. It could easily be forgotten after the repairs have been made to the system.

There is also the question of the reliability of the sprinkler system water supply. Will it be available at all times when there is the possibility of a fire occurring? This is especially important in high seismic activity areas where fires often start soon after an earthquake and the water supplies in many cases are out of service due to main breaks and loss of power for extended periods of time.

We also have a concern with the proposed new Section R309.5 Fire Sprinklers which requires private garages to be protected by fire sprinklers where the garage has been designed to have exterior walls protected in accordance with Table R302.1(2), Footnote a. In our opinion, this will actually provide a lesser degree of protection in cold weather climates where the sprinkler system in the garage may be subject to freezing. It is very difficult to prevent the sprinkler piping from freezing where it passes through attics of residential dwellings in these cold climate areas, but that problem is significantly increased where sprinklers are required in private garages as an extension of the sprinkler system in the adjacent dwelling. So if the garage sprinkler freezes, it could damage and rupture the piping, thus, causing failure of the sprinkler system in the dwelling that it is adjacent to by draining the water from the sprinkler system. This would be especially critical in a case where the sprinkler system is supplied by a fixed storage tank rather than a municipal water supply system. So the sprinkler water supply system could be totally drained due to the rupture caused in the frozen piping of the garage sprinkler system.

In conclusion, we believe it is unwise to allow for these automatic sprinkler system trade-offs based on sprinkler systems designed in accordance with NFPA 13D which are not as reliable, nor as effective in providing property protection, as an NFPA 13 sprinkler system. Therefore, we urge the Class A voting members to support the Committee's recommendation for disapproval of this code change.

Final Action: AS AM AMPC____ D

Proponent: Gene Boecker, Code Consultants, Inc.

PART I – IEBC

CHAPTER 5
REPAIRS

SECTION 504
MEANS OF EGRESS

504.1 General. Repairs shall be done in a manner that maintains the level of protection provided for the means of egress.

SECTION 505
ACCESSIBILITY

505.1 General. Repairs shall be done in a manner that maintains the level of accessibility provided.

CHAPTER 6
ALTERATIONS—LEVEL 1

SECTION 604
MEANS OF EGRESS

604.1 General. Repairs shall be done in a manner that maintains the level of protection provided for the means of egress.

SECTION 605
ACCESSIBILITY

605.1 General. A building, facility or element that is altered shall comply with the applicable provisions in Sections 605.1.1 through 605.1.14, Chapter 11 of the International Building Code and ICC A117.1 unless it is technically infeasible. Where compliance with this section is technically infeasible, the alteration shall provide access to the maximum extent that is technically feasible.

A building, facility or element that is constructed or altered to be accessible shall be maintained accessible during occupancy.

Exceptions:

1. The altered element or space is not required to be on an accessible route unless required by Section 605.2.
2. ~~Accessible means of egress required by Chapter 10 of the International Building Code are not required to be provided in existing buildings and facilities.~~ The altered element or space is not required to provide accessible means of egress, unless required by Section 805.4.

3. Type B dwelling or sleeping units required by Section 1107 of the *International Building Code* are not required to be provided in existing buildings and facilities.
4. The alteration to Type A individually owned dwelling units within a Group R-2 occupancy shall meet the provisions for Type B dwelling units and shall comply with the applicable provisions in Chapter 11 of the *International Building Code* and ICC A117.1.

605.2 Alterations affecting an area containing a primary function. Where an *alteration* affects the accessibility to, or contains an area of *primary function*, the route to the *primary function* area shall be *accessible*. The accessible route to the primary function area shall include toilet facilities or drinking fountains serving the area of primary function.

Exceptions:

1. The costs of providing the accessible route are not required to exceed 20 percent of the costs of the alterations affecting the area of primary function.
2. This provision does not apply to alterations limited solely to windows, hardware, operating controls, electrical outlets and signs.
3. This provision does not apply to alterations limited solely to mechanical systems, electrical systems, installation or alteration of fire protection systems and abatement of hazardous materials.
4. This provision does not apply to alterations undertaken for the primary purpose of increasing the accessibility of an existing building, facility or element.

CHAPTER 7
ALTERATIONS—LEVEL 2

SECTION 705
MEANS OF EGRESS

705.1 Scope. The requirements of this section shall be limited to work areas that include exits or corridors shared by more than one tenant within the work area in which Level 2 alterations are being performed, and where specified they shall apply throughout the floor on which the work areas are located or otherwise beyond the work area.

705.2 General. The means of egress shall comply with the requirements of this section.

Exceptions:

1. Where the work area and the means of egress serving it complies with NFPA 101.
2. Means of egress conforming to the requirements of the building code under which the building was constructed shall be considered compliant means of egress if, in the opinion of the code official, they do not constitute a distinct hazard to life.
3. <u>The altered element or space is not required to provide accessible means of egress, unless required by Section 805.4.</u>

705.3 Number of exits. The number of exits shall be in accordance with Sections 705.3.1 through 705.3.3.

705.3.1 Minimum number. Every story utilized for human occupancy on which there is a work area that includes exits or corridors shared by more than one tenant within the work area shall be provided with the minimum number of exits based on the occupancy and the occupant load in accordance with the *International Building Code*. In addition, the exits shall comply with Sections 705.3.1.1 and 705.3.1.2.

SECTION 706
ACCESSIBILITY

706.1 General. A building, facility, or element that is altered shall comply with Section 605 <u>and 706</u>.

706.2 Stairs and escalators in existing buildings. In alterations where an escalator or stair is added where none existed previously, an accessible route shall be provided in accordance with Sections 1104.4 and 1104.5 of the *International Building Code*.

706.3 Accessible dwelling units and sleeping units. Where Group I-1, I-2, I-3, R-1, R-2 or R-4 dwelling or sleeping units are being added, the requirements of Section 1107 of the *International Building Code* for accessible units and Chapter 9 of the *International Building Code* for visible alarms apply only to the quantity of spaces being added.

706.4 Type A dwelling or sleeping units. Where more than 20 Group R-2 dwelling or sleeping units are being added, the requirements of Section 1107 of the International Building Code for Type A units and Chapter 9 of the International *Building Code* for visible alarms apply only to the quantity of the spaces being added.

706.5 Type B dwelling or sleeping units. Where four or more Group I-1, I-2, R-1, R-2, R-3 or R-4 dwelling or sleeping units are being added, the requirements of Section 1107 of the *International Building Code* for Type B units and Chapter 9 of the *International Building Code* for visible alarms apply only to the quantity of the spaces being added.

CHAPTER 8
ALTERATIONS—LEVEL 3

SECTION 805
MEANS OF EGRESS

805.1 General. The means of egress shall comply with the requirements of Section 705 except as specifically required in Sections 805.2 and 805.3.

805.2 Means-of-egress lighting. Means of egress from the highest work area floor to the floor of exit discharge shall be provided with artificial lighting within the exit enclosure in accordance with the requirements of the *International Building Code*.

805.3 Exit signs. Means of egress from the highest work area floor to the floor of exit discharge shall be provided with exit signs in accordance with the requirements of the *International Building Code*.

805.4 Accessible means of egress. Additions and buildings or portions thereof undergoing a change of occupancy or alterations shall provide accessible means of egress in accordance with Section 805.4.1 and Section 1007 of the *International Building Code*.

Exceptions:

1. Accessible means of egress is not required in existing buildings where the alterations are less than Level 3.
2. Accessible means of egress is not required in existing building undergoing a change of occupancy where the change or occupancy is in conjunction with alterations that are less than Level 3.

805.4.1 Means of egress through the existing building. Where the accessible means of egress from any portion of a building being altered, undergoing a change of occupancy or addition requires occupants to egress through portions of the existing building, compliance with Section 1007 of the *International Building Code* is required, unless technically infeasible. Where compliance with this provision is *technically infeasible*, the accessible means of egress through the existing building shall provide access to the maximum extent technically feasible.

SECTION 806
ACCESSIBILITY

806.1 General. A building, facility or element that is altered shall comply with Sections 605 and 706.

CHAPTER 9
CHANGE OF OCCUPANCY

SECTION 905
MEANS OF EGRESS

905.1 General. Means of egress in portions of buildings undergoing a change of occupancy classification shall comply with Section 912.

SECTION 906
ACCESSIBILITY

906.1 General. Accessibility in portions of buildings undergoing a change of occupancy classification shall comply with Section 912.8.

SECTION 912
CHANGE OF OCCUPANCY CLASSIFICATION

912.4 Means of egress, general. Hazard categories in regard to life safety and means of egress shall be in accordance with Table 912.4.

TABLE 912.4
MEANS OF EGRESS HAZARD CATEGORIES

RELATIVE HAZARD	OCCUPANCY CLASSIFICATIONS
1 (Highest Hazard)	H
2	I-2, I-3, I-4
3	A, E, I-1, M, R-1, R-2, R-4
4	B, F-1, R-3, S-1
5 (Lowest Hazard)	F-2, S-2, U

912.4.1 Means of egress for change to higher hazard category. When a change of occupancy classification is made to a higher hazard category (lower number) as shown in Table 912.4, the means of egress shall comply with the requirements of Chapter 10 of the *International Building Code*.

Exceptions:

1. Stairways shall be enclosed in compliance with the applicable provisions of Section 803.1.
2. Existing stairways including handrails and guards complying with the requirements of Chapter 8 shall be permitted for continued use subject to approval of the code official.
3. Any stairway replacing an existing stairway within a space where the pitch or slope cannot be reduced because of existing construction shall not be required to comply with the maximum riser height and minimum tread depth requirements.
4. Existing corridor walls constructed of wood lath and plaster in good condition or 1/ 2-inch-thick (12.7 mm) gypsum wallboard shall be permitted. Such walls shall either terminate at the underside of a ceiling of equivalent construction or extend to the underside of the floor or roof next above.
5. Existing corridor doorways, transoms and other corridor openings shall comply with the requirements in Sections 705.5.1, 705.5.2 and 705.5.3.
6. Existing dead-end corridors shall comply with the requirements in Section 705.6.
7. An existing operable window with clear opening area no less than 4 square feet (0.38 m^2) and minimum opening height and width of 22 inches (559 mm) and 20 inches (508 mm), respectively, shall be accepted as an emergency escape and rescue opening.
8. Accessible means of egress is not required for areas undergoing a change of occupancy unless required by Section 805.4.

912.4.2 Means of egress for change of use to equal or lower hazard category. When a change of occupancy classification is made to an equal or lesser hazard category (higher number) as shown in Table 912.4, existing elements of the means of egress shall comply with the requirements of Section 805 for the new occupancy classification. Newly constructed or configured means of egress shall comply with the requirements of Chapter 10 of the *International Building Code*.

Exceptions:

1. Any stairway replacing an existing stairway within a space where the pitch or slope cannot be reduced because of existing construction shall not be required to comply with the maximum riser height and minimum tread depth requirements.
2. Accessible means of egress is not required for areas undergoing a change of occupancy unless required by Section 805.4.

912.4.3 Egress capacity. Egress capacity shall meet or exceed the occupant load as specified in the *International Building Code* for the new occupancy.

912.4.4 Handrails. Existing stairways shall comply with the handrail requirements of Section 705.9 in the area of the change of occupancy classification.

912.4.5 Guards. Existing guards shall comply with the requirements in Section 705.10 in the area of the change of occupancy classification.

912.8 Accessibility. Existing buildings that undergo a change of group or occupancy classification shall comply with this section.

912.8.1 Partial change in occupancy. Where a portion of the building is changed to a new occupancy classification, any alterations shall comply with Sections 605 and 706, as applicable.

912.8.2 Complete change of occupancy. Where an entire building undergoes a change of occupancy, it shall comply with Section 912.8.1 and shall have all of the following accessible features unless technically infeasible. Where compliance with this provision is technically infeasible, provide access to the maximum extent technically feasible.

1. At least one accessible building entrance.
2. At least one accessible route from an accessible building entrance to primary function areas.
3. Signage complying with Section 1110 of the *International Building Code*.
4. Accessible parking, where parking is provided.
5. At least one accessible passenger loading zone, where loading zones are provided.
6. At least one accessible route connecting accessible parking and accessible passenger loading zones to an accessible entrance.

Where it is technically infeasible to comply with the new construction standards for any of these requirements for a change of group or occupancy, the above items shall conform to the requirements to the maximum extent technically feasible.

CHAPTER 10
ADDITIONS

SECTION 1004
MEANS OF EGRESS

1004.1 General. The means of egress shall comply with the requirements of Chapter 10 of the *International Building Code*.

Exception: Accessible means of egress is not required for additions unless required by Section 805.4.

SECTION 1005
ACCESSIBILITY

1005.1 Minimum requirements. Accessibility provisions for new construction shall apply to additions. An addition that affects the accessibility to, or contains an area of, primary function shall comply with the requirements of Sections 605, ~~and~~ 706 and 806, as applicable.

CHAPTER 11
HISTORIC BUILDINGS

SECTION 1103
FIRE SAFETY

1103.1 Scope. Historic buildings undergoing alterations, changes of occupancy, or that are moved shall comply with Section 1103.

1103.2 General. Every historic building that does not conform to the construction requirements specified in this code for the occupancy or use and that constitutes a distinct fire hazard as defined herein shall be provided with an approved automatic fire-extinguishing system as determined appropriate by the code official. However, an automatic fire-extinguishing system shall not be used to substitute for, or act as an alternative to, the required number of exits from any facility.

1103.3 Means of egress. Existing door openings and corridor and stairway widths less than those specified elsewhere in this code may be approved, provided that, in the opinion of the code official, there is sufficient width and height for a person to pass through the opening or traverse the means of egress. When approved by the code official, the front or main exit doors need not swing in the direction of the path of exit travel, provided that other approved means of egress having sufficient capacity to serve the total occupant load are provided.

Exception: Accessible means of egress are not required in historic buildings being altered or undergoing a change of occupancy.

SECTION 1104
ALTERATIONS

1104.1 Accessibility requirements. The provisions of 605 and 706, as applicable, shall apply to buildings and facilities designated as historic structures that undergo alterations, unless technically infeasible. Where compliance with the requirements for accessible routes, entrances or toilet facilities would threaten or destroy the historic significance of the building or facility, as determined by the code official, the alternative requirements of Sections 1104.1.1 through 1104.1.4 for that element shall be permitted.

1104.1.1 Site arrival points. At least one main entrance shall be accessible.

1104.1.2 Multilevel buildings and facilities. An accessible route from an accessible entrance to public spaces on the level of the accessible entrance shall be provided.

1104.1.3 Entrances. At least one main entrance shall be accessible.

Exceptions:

1. If a main entrance cannot be made accessible, an accessible nonpublic entrance that is unlocked while the building is occupied shall be provided; or
2. If a main entrance cannot be made accessible, a locked accessible entrance with a notification system or remote monitoring shall be provided.

1104.1.4 Toilet and bathing facilities. Where toilet rooms are provided, at least one accessible family or assisted-use toilet room complying with Section 1109.2.1 of the *International Building Code* shall be provided.

SECTION 1105
CHANGE OF OCCUPANCY

1105.6 Means of egress. Existing door openings and corridor and stairway widths less than those that would be acceptable for nonhistoric buildings under these provisions shall be approved, provided that, in the opinion of the code official, there is sufficient width and height for a person to pass through the opening or traverse the exit and that the capacity of the exit system is adequate for the occupant load, or where other operational controls to limit occupancy are approved by the code official.

Exception: Accessible means of egress are not required in historic buildings undergoing a change of occupancy.

1105.15 Accessibility requirements. The provisions of Section 912.8 shall apply to buildings and facilities designated as historic structures that undergo a change of occupancy, unless technically infeasible. Where compliance with the requirements for accessible routes, ramps, entrances, or toilet facilities would threaten or destroy the historic significance of the building or facility, as determined by the authority having jurisdiction, the alternative requirements of Sections 1104.1.1 through 1104.1.5 for those elements shall be permitted.

Reason: The interplay between an existing building and additions or alterations is not well defined. While the text is clear that the addition is required to meet the accessibility provisions it is not clear how the addition will impact the accessibility requirements for the existing building. Similarly, although the statement exists that alterations do not require a retroactive requirement for accessible means of egress, this statement negates the scope of the alteration. Federal Accessibility regulations and common sense dictate that where major changes occur consideration for the accessible means of egress should also occur. Additionally, the simple idea that accessibility should be intentionally denied to a segment of the population does not seem appropriate. The proposal seeks to finesse some of these issues.

It is important to remember that the requirements in the IBC only require a maximum of two accessible means of egress (based on travel distance limitations) as noted in Section 1007.1. And, an elevator can be counted as being one of the accessible means of egress. Thus, it may be easier in some cases to provide an accessible means of egress than one that fully complies with the requirements for new construction.

Some sections shown do not contain changes, but were shown for context and appropriate referencing.

IEBC:

In addition to the items noted above which relate to only Chapter 3, specific direction is provided for each condition as elaborated in the various chapters of the IEBC. Chapter 3 of the IEBC parallels Chapter 34 in the IBC. However, the IEBC also contains provisions that are more in depth than the prescriptive methods described.

The existing language is maintained that requires repairs to not reduce the level of current accessibility; but there is no additional requirement for accessibility in Chapter 5.

605.1, exception #2: Rather than refer to the IBC, specific provisions are being added to the IEBC. The wording is changed to reflect that.

705.2, exception #3: Similar to 605.1, reference to the accessible means of egress is added to allow the code user to understand where the scope of changes will require work in this area. Without this exception, it is unclear whether the reference to making the means of egress comply is intended to include the accessible means of egress as well as other aspects of egress design.

706.1: A reflective reference is added which was lacking. Compliance with another section was mandated but not the section itself.

805.4: The language and intent is the same as noted above for IEBC Section 310.8 and its two exceptions. The exceptions in this case use the language of the IEBC which define the level of work in more definitive terms – using Levels to describe the threshold rather than percentages of work.

805.4.1: This language is replicating that noted above from Section 310.8.1 relative to egress through an existing building.

912.4.1, exception #8: The added exception continues the scoping by including with the Change of Occupancy Chapter a reference back to the main section addressing when accessible means of egress must be provided – 805.4.

912.4.2, exception #2: A new exception is added to this section so that it is clear that whether the change in occupancy is to a higher category or lower category, the requirement to provide accessible means of egress is found in Section 805.4.

912.8.2: This added language does not address accessible means of egress. It addresses the consistent recognition of technical infeasibility. The language informs the code user of this application as it relates to changes in occupancy.

1004.1: Chapter 10 (Additions) does not address means of egress specifically. A reference to compliance with the means of egress provisions in Chapter 10 of the IBC is included. This is consistent with the first sentence in Section 302.1. The added language in inserted before the accessibility section in like manner to other chapters.

1004.1, exception: The exception is consistent with the other changes noted above that refer to Section 805.4 for the thresholds for compliance with the accessible means of egress requirements.

1005.1: Reference is currently provided to the sections relative to accessibility in Chapter 6 and 7 but not 8. The proposal corrects that.

1105.6: Similar to the language in 3411.10 in the IBC, this clearly indicates that accessible means of egress is not required for historic buildings.

<u>IBC/IEBC</u>:

1007.1: The section is changed to indicate that existing building provisions are noted in Chapter 34. This is the proper scoping location for issues dealing with existing buildings – not Chapter 10.

3411.4/310.4: A cross reference is added to direct the code user to the central location for issues relative to existing buildings and accessible means of egress; the proposed 3411.8.

3411.4.2/310.4.2: The paragraph following the text already mentions what happens when the effort is "technically infeasible" but there is no language that states that these items are limited to conditions where technical infeasibility is not a problem. The added language clarifies the intent with respect to technical infeasibility.

3411.5/310.5: A cross reference to the section addressing accessible means of egress is added.

3411.6/310.6: Where accessible means of egress are required, it is necessary to direct the code user to the proper section. The reference to 1007 does that.

3411.6/310.6, exception #2: The exception seems to imply that nothing is required for the existing building relative to accessible means of egress. However, since the addition is impacting the existing building, the egress through the existing building is more similar to an alteration of the existing egress system. The revised text points to the central section addressing what must be done.

3411.8/310.8: A new section is added to specifically address the accessible means of egress. Rather than the blanket statement in Section 1007.1 of the building code, this section will address the scope and extent of work necessary to address accessible means of egress. It directs the code user to Section 1007 for the technical requirements when an accessible means of egress is necessary as well as clearly delineate that when a change of occupancy or alteration occurs, the accessible means of egress must be provided. This is no different than the general requirements in 3404.1/303.1 and 3408.1/307.1 which require alterations and changes in occupancy to meet "new code."

3411.8/310.8, exception #1: Alterations with some magnitude should address accessible means of egress, if the alteration is relatively small then there is reason to limit the requirement. The threshold of 50% of the building area is intended to delineate the difference between IEBC Alterations – Level 2 and Alterations – Level 3

3411.8/310.8, exception #2: Similarly, if the change in occupancy is only to a portion of the building, full compliance with the accessible means of egress is not required. The position should be that if the occupancy is totally changed then the building should be made to comply with the new requirements. For "regular" egress this may mean that the occupant load changes resulting in wider or additional stairways. The least that should be done is to make an effort to provide accessible means of egress.

3411.8.1/310.8.1: If an addition is designed such that the means of egress must enter the existing building then the egress design must meet the requirements for the addition as it passes through the existing building. As this relates to egress design, it includes a continuation of the design in the addition for egress width, corridor protection, panic hardware (as applicable) and similar concerns. The same should be true for the design of the accessible means of egress. If one of the accessible egress paths leads through the existing building, it too needs to meet/continue the level of protection as designed in the addition. The limitation to this is if the effort to make the existing means of egress accessible is "technically infeasible" then work should be done to what is possible. One example of this may be making sure that the slopes along the path in the existing building's corridor are proper even if the width cannot be altered to allow the proper approach to the exit door.

3411.10: The language requires compliance with the accessible means of egress as written with the only defense being the "technically infeasible" option. The exception makes it clear that for historic buildings undergoing major alterations of a change in occupancy an accessible means of egress is not required.

A companion change is being proposed for the IEBC so that the changes here a reflected in that code as well.

While more can always be done if possible, the code identifies the minimums necessary for life safety. The proposed changes identify what is appropriate so that the disabled community has similar levels of life safety to the general public and still sets reasonable thresholds based on the extent of work for the project. The standard of "technical Infeasible" is identified clearly in new sections where it may have been interpreted previously as not applying. The "20% of the cost" criteria identified in 3411.7, exception #1 of the IBC (605.2, exception #1 of the IEBC) relative to alterations affecting the primary function is also maintained.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: BOECKER-E5-1007.1

Public Hearing Results

PART I - IEBC
Committee Action: **Disapproved**

Committee Reason: The committee felt that exception 8 to Section 912.4.1 was confusing in its reference back to 805.4 where it discussed changes of occupancy in a chapter about alterations. Further, Section 805.4 does not contain the current 20 percent cost limitation. Without this limit the costs will get unreasonable.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Gene Boecker, representing Code Consultants, Inc., requests Approval as Submitted.

Commenter's Reason: The committee did not vote to disapprove based on the concept but on a misunderstanding of what the Existing Building Code already allows. The prime comment was the mention that 20 percent cost limitation was not included in the referenced Section 805.4. The reason is that it already exists. Section 805 of the Existing Building Code requires compliance with Section 605; and, Section 605 clearly already contains the 20 percent limitation provision. It isn't included in 805 because it isn't needed. One comment by the committee felt that the reference from 912.4.1 to 805.4 was confusing. I am not sure how that is confusing since the codes make reference to other sections all the time.

An additional comment was the question of cost to which there are two answers. First, there is the 20 percent rule which exists although the committee did not recognize that at the time. Second, there will be additional cost. That is not to be denied. The question is whether or not it is within the power of the ICC to make the accessible means of egress available in existing buildings. If the ICC is intent on Life Safety then it is important that the organization address the fact that there are currently only requirements for accessible means of egress in new construction while we acknowledge a potential loss of a portion of our population by ignoring accessible means of egress in existing buildings. I maintain that the ICC does care and that it is the proper place to address this deficiency in life safety needs.

Questions about whether this is in conflict with the federal guidelines are in error. The proposed language in the new ADA guidelines recognize the International Code Council as the expert in addressing means of egress, deferring to the ICC those decisions on how best to provide life safety in the form of means of egress to those individuals with disabilities. It is time we take a position to include at least some effort to address accessible means of egress in existing buildings. We strain over much greater minutia than this. I urge the membership to do the right thing and approve this proposal as submitted.

Final Action: AS AM AMPC____ D

Proponent: Gene Boecker, Code Consultants, Inc.

Proposed Change as Submitted

PART II – IBC GENERAL

3411.4 (IEBC [B] 310.4) Change of occupancy. Existing buildings that undergo a change of group or occupancy shall comply with this section. Accessible means of egress shall be provided in accordance with Section 3411.8.

3411.4.1 (IEBC [B] 310.4.1) Partial change in occupancy. Where a portion of the building is changed to a new occupancy classification, any alterations shall comply with Sections 3411.6, 3411.7, ~~and~~ 3411.8 and 3411.9.

3411.4.2 (IEBC [B] 310.4.2) Complete change of occupancy. Where an entire building undergoes a change of occupancy, it shall comply with Section 3411.4.1 and shall have all the following accessible features unless *technically infeasible*. Where compliance with this provision is *technically infeasible*, provide access to the maximum extent technically feasible.

1. At least one accessible building entrance.

2. At least one accessible route from an accessible building entrance to primary function areas.
3. Signage complying with Section 1110.
4. Accessible parking, where parking is provided.
5. At least one accessible passenger loading zone, when loading zones are provided.
6. At least on accessible route connecting accessible parking and accessible passenger loading zones to an accessible entrance.

3411.5 (IEBC [B] 310.5) Additions. Provisions for new construction shall apply to additions. An addition that affects the accessibility to, or contains an area of, a primary function shall comply with the requirements in Section 3411.7 <u>and 3411.8</u>.
3411.6 (IEBC [B] 310.6) Alterations. A building, facility or element that is altered shall comply with the applicable provisions in <u>Section 1007,</u> Chapter 11 of this code and ICC A117.1, unless technically infeasible. Where compliance with this section is technically infeasible, the alteration shall provide access to the maximum extent technically feasible.

Exceptions:

1. The altered element or space is not required to be on an accessible route, unless required by Section 3411.7.
2. Accessible means of egress required by Chapter 10 are not required to be provided in existing buildings and facilities <u>being altered unless required by Section 3411.8</u>.
3. The alteration to Type A individually owned dwelling units within a Group R-2 occupancy shall meet the provision for a Type B dwelling unit and shall comply with the applicable provisions in Chapter 11 and ICC A117.1.

3411.7 (IEBC [B] 310.7) Alterations affecting an area containing a primary function. Where an alteration affects the accessibility to, or contains an area of primary function, the route to the primary function area shall be accessible. The accessible route to the primary function area shall include toilet facilities or drinking fountains serving the area of primary function.

Exceptions:

1. The costs of providing the accessible route are not required to exceed 20 percent of the costs of the alterations affecting the area of primary function.
2. This provision does not apply to alterations limited solely to windows, hardware, operating controls, electrical outlets and signs.
3. This provision does not apply to alterations limited solely to mechanical systems, electrical systems, installation or alteration of fire protection systems and abatement of hazardous materials.
4. This provision does not apply to alterations undertaken for the primary purpose of increasing the accessibility of an existing building, facility or element.

<u>**3411.8 (IEBC [B] 310.8) Accessible means of egress.** Additions and buildings or portions thereof undergoing a change of occupancy or alterations shall provide accessible means of egress in accordance with Sections 1007 and 3411.8.1.</u>

<u>**Exceptions:**</u>

1. <u>Accessible means of egress is not required in existing buildings where the alterations are less than 50 percent of the aggregate building area.</u>
2. <u>Accessible means of egress is not required in existing building undergoing a change of occupancy where the change or occupancy is in conjunction with alterations that are less than 50 percent of the aggregate building area.</u>

<u>**3411.8.1 (IEBC [B] 310.8.1) Means of egress through the existing building**. Where the accessible means of egress from any portion of a building being altered, undergoing a change of occupancy or addition requires occupants to egress through portions of the existing building, compliance with Section 1007 is required, unless technically infeasible. Where compliance with this provision is technically infeasible, the accessible means of egress through the existing building shall provide access to the maximum extent technically feasible.</u>

(Renumber subsequent sections)

~~3411.9~~ <u>3411.10</u> (IEBC [B] ~~310.9~~ <u>310.10</u>) Historic buildings. These provisions shall apply to buildings and facilities designated as historic structures that undergo alterations or a change of occupancy, unless *technically infeasible*. Where compliance with the requirements for *accessible* routes, entrances or toilet facilities would threaten or destroy the historic significance of the building or facility, as determined by the applicable governing authority, the alternative requirements of Sections ~~3411.9.1~~ 3411.10.1 through ~~3411.9.4~~ 3411.10.4 for that element shall be permitted.

Exception: Accessible means of egress are not required in historic buildings being altered or undergoing a change of occupancy.

(Renumber subsequent sections)

Reason: The interplay between an existing building and additions or alterations is not well defined. While the text is clear that the addition is required to meet the accessibility provisions it is not clear how the addition will impact the accessibility requirements for the existing building. Similarly, although the statement exists that alterations do not require a retroactive requirement for accessible means of egress, this statement negates the scope of the alteration. Federal Accessibility regulations and common sense dictate that where major changes occur consideration for the accessible means of egress should also occur. Additionally, the simple idea that accessibility should be intentionally denied to a segment of the population does not seem appropriate. The proposal seeks to finesse some of these issues.

It is important to remember that the requirements in the IBC only require a maximum of two accessible means of egress (based on travel distance limitations) as noted in Section 1007.1. And, an elevator can be counted as being one of the accessible means of egress. Thus, it may be easier in some cases to provide an accessible means of egress than one that fully complies with the requirements for new construction.

Some sections shown do not contain changes, but were shown for context and appropriate referencing.

IEBC:

In addition to the items noted above which relate to only Chapter 3, specific direction is provided for each condition as elaborated in the various chapters of the IEBC. Chapter 3 of the IEBC parallels Chapter 34 in the IBC. However, the IEBC also contains provisions that are more in depth than the prescriptive methods described.

The existing language is maintained that requires repairs to not reduce the level of current accessibility; but there is no additional requirement for accessibility in Chapter 5.

605.1, exception #2: Rather than refer to the IBC, specific provisions are being added to the IEBC. The wording is changed to reflect that.

705.2, exception #3: Similar to 605.1, reference to the accessible means of egress is added to allow the code user to understand where the scope of changes will require work in this area. Without this exception, it is unclear whether the reference to making the means of egress comply is intended to include the accessible means of egress as well as other aspects of egress design.

706.1: A reflective reference is added which was lacking. Compliance with another section was mandated but not the section itself.

805.4: The language and intent is the same as noted above for IEBC Section 310.8 and its two exceptions. The exceptions in this case use the language of the IEBC which define the level of work in more definitive terms – using Levels to describe the threshold rather than percentages of work.

805.4.1: This language is replicating that noted above from Section 310.8.1 relative to egress through an existing building.

912.4.1, exception #8: The added exception continues the scoping by including with the Change of Occupancy Chapter a reference back to the main section addressing when accessible means of egress must be provided – 805.4.

912.4.2, exception #2: A new exception is added to this section so that it is clear that whether the change in occupancy is to a higher category or lower category, the requirement to provide accessible means of egress is found in Section 805.4.

912.8.2: This added language does not address accessible means of egress. It addresses the consistent recognition of technical infeasibility. The language informs the code user of this application as it relates to changes in occupancy.

1004.1: Chapter 10 (Additions) does not address means of egress specifically. A reference to compliance with the means of egress provisions in Chapter 10 of the IBC is included. This is consistent with the first sentence in Section 302.1. The added language in inserted before the accessibility section in like manner to other chapters.

1004.1, exception: The exception is consistent with the other changes noted above that refer to Section 805.4 for the thresholds for compliance with the accessible means of egress requirements.

1005.1: Reference is currently provided to the sections relative to accessibility in Chapter 6 and 7 but not 8. The proposal corrects that.

1105.6: Similar to the language in 3411.10 in the IBC, this clearly indicates that accessible means of egress is not required for historic buildings.

IBC/IEBC:

1007.1: The section is changed to indicate that existing building provisions are noted in Chapter 34. This is the proper scoping location for issues dealing with existing buildings – not Chapter 10.

3411.4/310.4: A cross reference is added to direct the code user to the central location for issues relative to existing buildings and accessible means of egress; the proposed 3411.8.

3411.4.2/310.4.2: The paragraph following the text already mentions what happens when the effort is "technically infeasible" but there is no language that states that these items are limited to conditions where technical infeasibility is not a problem. The added language clarifies the intent with respect to technical infeasibility.

3411.5/310.5: A cross reference to the section addressing accessible means of egress is added.

3411.6/310.6: Where accessible means of egress are required, it is necessary to direct the code user to the proper section. The reference to 1007 does that.

3411.6/310.6, exception #2: The exception seems to imply that nothing is required for the existing building relative to accessible means of egress. However, since the addition is impacting the existing building, the egress through the existing building is more similar to an alteration of the existing egress system. The revised text points to the central section addressing what must be done.

3411.8/310.8: A new section is added to specifically address the accessible means of egress. Rather than the blanket statement in Section 1007.1 of the building code, this section will address the scope and extent of work necessary to address accessible means of egress. It directs the code user to Section 1007 for the technical requirements when an accessible means of egress is necessary as well as clearly delineate that when a change of occupancy or alteration occurs, the accessible means of egress must be provided. This is no different than the general requirements in 3404.1/303.1 and 3408.1/307.1 which require alterations and changes in occupancy to meet "new code."

3411.8/310.8, exception #1: Alterations with some magnitude should address accessible means of egress, if the alteration is relatively small then there is reason to limit the requirement. The threshold of 50% of the building area is intended to delineate the difference between IEBC Alterations – Level 2 and Alterations – Level 3

3411.8/310.8, exception #2: Similarly, if the change in occupancy is only to a portion of the building, full compliance with the accessible means of egress is not required. The position should be that if the occupancy is totally changed then the building should be made to comply with the new

requirements. For "regular" egress this may mean that the occupant load changes resulting in wider or additional stairways. The least that should be done is to make an effort to provide accessible means of egress.
3411.8.1/310.8.1: If an addition is designed such that the means of egress must enter the existing building then the egress design must meet the requirements for the addition as it passes through the existing building. As this relates to egress design, it includes a continuation of the design in the addition for egress width, corridor protection, panic hardware (as applicable) and similar concerns. The same should be true for the design of the accessible means of egress. If one of the accessible egress paths leads through the existing building, it too needs to meet/continue the level of protection as designed in the addition. The limitation to this is if the effort to make the existing means of egress accessible is "technically infeasible" then work should be done to what is possible. One example of this may be making sure that the slopes along the path in the existing building's corridor are proper even if the width cannot be altered to allow the proper approach to the exit door.
3411.10: The language requires compliance with the accessible means of egress as written with the only defense being the "technically infeasible" option. The exception makes it clear that for historic buildings undergoing major alterations of a change in occupancy an accessible means of egress is not required.

A companion change is being proposed for the IEBC so that the changes here a reflected in that code as well.

While more can always be done if possible, the code identifies the minimums necessary for life safety. The proposed changes identify what is appropriate so that the disabled community has similar levels of life safety to the general public and still sets reasonable thresholds based on the extent of work for the project. The standard of "technical Infeasible" is identified clearly in new sections where it may have been interpreted previously as not applying. The "20% of the cost" criteria identified in 3411.7, exception #1 of the IBC (605.2, exception #1 of the IEBC) relative to alterations affecting the primary function is also maintained.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: BOECKER-E5-1007.1

Public Hearing Results

PART II – IBC GENERAL
Committee Action: **Disapproved**

Committee Reason: The committee felt that as with EB10-09/10 Part I this proposal does not adequately address costs involved with providing accessibility to existing buildings

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Gene Boecker, representing Code Consultants, Inc., requests Approval as Submitted.

Commenter's Reason: See EB10-09/10, Part I

Final Action: AS AM AMPC____ D

EB10-09/10, Part III

IEBC 605.1, 705.2, 706.1, 805.4 (New), 805.4.1 (New), 912.4.1, 912.4.2, 912.8.2, 1004.1(New), 1005.1, 1103.3, 1105.6; IBC 3411.4, 3411.4.1, 3411.4.2, 3411.5, 3411.6, 3411.8(New), 3411.8.1(New), 3411.9; (IEBC [B] 310.4, 310.4.1, 310.4.2, 310.5, 310.6, 310.8(New), 310.8.1 (New), 310.9), 1007.1 (IFC [B] 1007.1)

Proposed Change as Submitted

Revise as follows:

1007.1 (IFC [B] 1007.1) Accessible means of egress required. Accessible means of egress shall comply with this section. Accessible spaces shall be provided with not less than one accessible means of egress. Where more than one means of egress is required by Section 1015.1 or 1021.1 from any accessible space, each accessible portion of the space shall be served by not less than two accessible means of egress.

Exceptions:

1. Accessible means of egress ~~are not required in alterations to~~ for existing buildings shall be provided as required in Section 3411.8.
2. One accessible means of egress is required from an accessible mezzanine level in accordance with Section 1007.3, 1007.4 or 1007.5.
3. In assembly areas with sloped or stepped aisles, one accessible means of egress is permitted where the common path of travel is accessible and meets the requirements in Section 1028.8.

Reason: The interplay between an existing building and additions or alterations is not well defined. While the text is clear that the addition is required to meet the accessibility provisions it is not clear how the addition will impact the accessibility requirements for the existing building. Similarly, although the statement exists that alterations do not require a retroactive requirement for accessible means of egress, this statement negates the scope of the alteration. Federal Accessibility regulations and common sense dictate that where major changes occur consideration for the accessible means of egress should also occur. Additionally, the simple idea that accessibility should be intentionally denied to a segment of the population does not seem appropriate. The proposal seeks to finesse some of these issues.

It is important to remember that the requirements in the IBC only require a maximum of two accessible means of egress (based on travel distance limitations) as noted in Section 1007.1. And, an elevator can be counted as being one of the accessible means of egress. Thus, it may be easier in some cases to provide an accessible means of egress than one that fully complies with the requirements for new construction.

Some sections shown do not contain changes, but were shown for context and appropriate referencing.

IEBC:

In addition to the items noted above which relate to only Chapter 3, specific direction is provided for each condition as elaborated in the various chapters of the IEBC. Chapter 3 of the IEBC parallels Chapter 34 in the IBC. However, the IEBC also contains provisions that are more in depth than the prescriptive methods described.

The existing language is maintained that requires repairs to not reduce the level of current accessibility; but there is no additional requirement for accessibility in Chapter 5.

605.1, exception #2: Rather than refer to the IBC, specific provisions are being added to the IEBC. The wording is changed to reflect that.

705.2, exception #3: Similar to 605.1, reference to the accessible means of egress is added to allow the code user to understand where the scope of changes will require work in this area. Without this exception, it is unclear whether the reference to making the means of egress comply is intended to include the accessible means of egress as well as other aspects of egress design.

706.1: A reflective reference is added which was lacking. Compliance with another section was mandated but not the section itself.

805.4: The language and intent is the same as noted above for IEBC Section 310.8 and its two exceptions. The exceptions in this case use the language of the IEBC which define the level of work in more definitive terms – using Levels to describe the threshold rather than percentages of work.

805.4.1: This language is replicating that noted above from Section 310.8.1 relative to egress through an existing building.

912.4.1, exception #8: The added exception continues the scoping by including with the Change of Occupancy Chapter a reference back to the main section addressing when accessible means of egress must be provided – 805.4.

912.4.2, exception #2: A new exception is added to this section so that it is clear that whether the change in occupancy is to a higher category or lower category, the requirement to provide accessible means of egress is found in Section 805.4.

912.8.2: This added language does not address accessible means of egress. It addresses the consistent recognition of technical infeasibility. The language informs the code user of this application as it relates to changes in occupancy.

1004.1: Chapter 10 (Additions) does not address means of egress specifically. A reference to compliance with the means of egress provisions in Chapter 10 of the IBC is included. This is consistent with the first sentence in Section 302.1. The added language in inserted before the accessibility section in like manner to other chapters.

1004.1, exception: The exception is consistent with the other changes noted above that refer to Section 805.4 for the thresholds for compliance with the accessible means of egress requirements.

1005.1: Reference is currently provided to the sections relative to accessibility in Chapter 6 and 7 but not 8. The proposal corrects that.

1105.6: Similar to the language in 3411.10 in the IBC, this clearly indicates that accessible means of egress is not required for historic buildings.

IBC/IEBC:

1007.1: The section is changed to indicate that existing building provisions are noted in Chapter 34. This is the proper scoping location for issues dealing with existing buildings – not Chapter 10.

3411.4/310.4: A cross reference is added to direct the code user to the central location for issues relative to existing buildings and accessible means of egress; the proposed 3411.8.

3411.4.2/310.4.2: The paragraph following the text already mentions what happens when the effort is "technically infeasible" but there is no language that states that these items are limited to conditions where technical infeasibility is not a problem. The added language clarifies the intent with respect to technical infeasibility.

3411.5/310.5: A cross reference to the section addressing accessible means of egress is added.

3411.6/310.6: Where accessible means of egress are required, it is necessary to direct the code user to the proper section. The reference to 1007 does that.

3411.6/310.6, exception #2: The exception seems to imply that nothing is required for the existing building relative to accessible means of egress. However, since the addition is impacting the existing building, the egress through the existing building is more similar to an alteration of the existing egress system. The revised text points to the central section addressing what must be done.

3411.8/310.8: A new section is added to specifically address the accessible means of egress. Rather than the blanket statement in Section 1007.1 of the building code, this section will address the scope and extent of work necessary to address accessible means of egress. It directs the code user to Section 1007 for the technical requirements when an accessible means of egress is necessary as well as clearly delineate that when a change of occupancy or alteration occurs, the accessible means of egress must be provided. This is no different than the general requirements in 3404.1/303.1 and 3408.1/307.1 which require alterations and changes in occupancy to meet "new code."

3411.8/310.8, exception #1: Alterations with some magnitude should address accessible means of egress, if the alteration is relatively small then there is reason to limit the requirement. The threshold of 50% of the building area is intended to delineate the difference between IEBC Alterations – Level 2 and Alterations – Level 3

3411.8/310.8, exception #2: Similarly, if the change in occupancy is only to a portion of the building, full compliance with the accessible means of egress is not required. The position should be that if the occupancy is totally changed then the building should be made to comply with the new requirements. For "regular" egress this may mean that the occupant load changes resulting in wider or additional stairways. The least that should be done is to make an effort to provide accessible means of egress.
3411.8.1/310.8.1: If an addition is designed such that the means of egress must enter the existing building then the egress design must meet the requirements for the addition as it passes through the existing building. As this relates to egress design, it includes a continuation of the design in the addition for egress width, corridor protection, panic hardware (as applicable) and similar concerns. The same should be true for the design of the accessible means of egress. If one of the accessible egress paths leads through the existing building, it too needs to meet/continue the level of protection as designed in the addition. The limitation to this is if the effort to make the existing means of egress accessible is "technically infeasible" then work should be done to what is possible. One example of this may be making sure that the slopes along the path in the existing building's corridor are proper even if the width cannot be altered to allow the proper approach to the exit door.
3411.10: The language requires compliance with the accessible means of egress as written with the only defense being the "technically infeasible" option. The exception makes it clear that for historic buildings undergoing major alterations of a change in occupancy an accessible means of egress is not required.

A companion change is being proposed for the IEBC so that the changes here a reflected in that code as well.

While more can always be done if possible, the code identifies the minimums necessary for life safety. The proposed changes identify what is appropriate so that the disabled community has similar levels of life safety to the general public and still sets reasonable thresholds based on the extent of work for the project. The standard of "technical Infeasible" is identified clearly in new sections where it may have been interpreted previously as not applying. The "20% of the cost" criteria identified in 3411.7, exception #1 of the IBC (605.2, exception #1 of the IEBC) relative to alterations affecting the primary function is also maintained.

Cost Impact: The code change proposal will increase the cost of construction.

Proposed Change as Submitted

Proponent: Dominic Marinelli, United Spinal Association

PART I – IEBC

Revise as follows:

CHAPTER 6
ALTERATIONS—LEVEL 1

SECTION 605
ACCESSIBILITY

605.1 General. A building, facility or element that is altered shall comply with the applicable provisions in Sections 605.1.1 through 605.1.14, Chapter 11 of the International Building Code and ICC A117.1 unless it is technically infeasible. Where compliance with this section is technically infeasible, the alteration shall provide access to the maximum extent that is technically feasible.

A building, facility or element that is constructed or altered to be accessible shall be maintained accessible during occupancy.

Exceptions:

1. The altered element or space is not required to be on an accessible route unless required by Section 605.2.
2. Accessible means of egress required by Chapter 10 of the International Building Code are not required to be provided in existing buildings and facilities.
3. Type B dwelling or sleeping units required by Section 1107 of the International Building Code are not required to be provided in existing buildings and facilities undergoing less than a Level III alteration.
4. The alteration to Type A individually owned dwelling units within a Group R-2 occupancy shall meet the provisions for Type B dwelling units and shall comply with the applicable provisions in Chapter 11 of the International Building Code and ICC A117.1.

605.1.8 Accessible dwelling or sleeping units. Where Group I-1, I-2, I-3, R-1, R-2 or R-4 dwelling or sleeping units are being altered, the requirements of Section 1107 of the International Building Code for accessible units and Chapter 9 of the International Building Code for visible alarms apply only to the quantity of the spaces being altered.

605.1.9 Type A dwelling or sleeping units. Where more than 20 Group R-2 dwelling or sleeping units are being altered, the requirements of Section 1107 of the International Building Code for Type A units and Chapter 9 of the International Building Code for visible alarms apply only to the quantity of the spaces being altered.

605.2 Alterations affecting an area containing a primary function. Where an alteration affects the accessibility to a, or contains an area of, primary function, the route to the primary function area shall be accessible. The accessible route to the primary function area shall include toilet facilities or drinking fountains serving the area of primary function.

Exceptions:

1. The costs of providing the accessible route are not required to exceed 20 percent of the costs of the alterations affecting the area of primary function.
2. This provision does not apply to alterations limited solely to windows, hardware, operating controls, electrical outlets and signs.
3. This provision does not apply to alterations limited solely to mechanical systems, electrical systems, installation or alteration of fire protection systems and abatement of hazardous materials.
4. This provision does not apply to alterations undertaken for the primary purpose of increasing the accessibility of an existing building, facility or element.
5. This provision does not apply to altered areas limited to Type B dwelling and sleeping units.

CHAPTER 7
ALTERATIONS—LEVEL 2

SECTION 706
ACCESSIBILITY

706.1 General. A building, facility, or element that is altered shall comply with this section and Section 605.

706.3 Accessible dwelling units and sleeping units. Where Group I-1, I-2, I-3, R-1, R-2 or R-4 dwelling or sleeping units are being added, the requirements of Section 1107 of the International Building Code for accessible units and Chapter 9 of the International Building Code for visible alarms apply only to the quantity of spaces being added.

706.4 Type A dwelling or sleeping units. Where more than 20 Group R-2 dwelling or sleeping units are being added, the requirements of Section 1107 of the International Building Code for Type A units and Chapter 9 of the International Building Code for visible alarms apply only to the quantity of the spaces being added.

706.5 Type B dwelling or sleeping units. Where four or more Group I-1, I-2, R-1, R-2, R-3 or R-4 dwelling or sleeping units are being added, the requirements of Section 1107 of the International Building Code for Type B units and Chapter 9 of the International Building Code for visible alarms apply only to the quantity of the spaces being added.

CHAPTER 8
ALTERATIONS—LEVEL 3

SECTION 806
ACCESSIBILITY

806.1 General. A building, facility or element that is altered shall comply with this section and Sections 605 and 706.

806.2 Type B dwelling or sleeping units. Where four or more Group I-1, I-2, R-1, R-2, R-3 or R-4 dwelling or sleeping units are being altered or added the requirements of Section 1107 of the International Building Code for Type B units and Chapter 9 of the International Building Code for visible alarms apply only to the quantity of the spaces being altered or added.

CHAPTER 9
CHANGE OF OCCUPANCY

912.8 Accessibility. Existing buildings that undergo a change of group or occupancy classification shall comply with this section.

> **Exception:** Type B dwelling or sleeping units required by Section 1107 of the International Building Code are not required to be provided in existing buildings and facilities undergoing a change of occupancy in conjunction with less than a Level III alteration.

912.8.1 Partial change in occupancy. Where a portion of the building is changed to a new occupancy classification, any alterations shall comply with Sections 605, ~~and~~ 706 and 806, as applicable.

912.8.2 Complete change of occupancy. Where an entire building undergoes a change of occupancy, it shall comply with Section 912.8.1 and shall have all of the following accessible features:

1. At least one accessible building entrance.
2. At least one accessible route from an accessible building entrance to primary function areas.
3. Signage complying with Section 1110 of the International Building Code.
4. Accessible parking, where parking is provided.
5. At least one accessible passenger loading zone, where loading zones are provided.
6. At least one accessible route connecting accessible parking and accessible passenger loading zones to an accessible entrance.

Where it is technically infeasible to comply with the new construction standards for any of these requirements for a change of group or occupancy, the above items shall conform to the requirements to the maximum extent technically feasible.

> **Exception:** The accessible features listed in Items 1 through 6 are not required for an accessible route to Type B units.

CHAPTER 10
ADDITIONS

SECTION 1005
ACCESSIBILITY

1005.1 Minimum requirements. Accessibility provisions for new construction shall apply to additions. An addition that affects the accessibility to, or contains an area of, primary function shall comply with the requirements of Sections 605, ~~and~~ 706 and 806, as applicable.

CHAPTER 11
HISTORIC BUILDINGS

SECTION 1104
ALTERATIONS

1104.1 Accessibility requirements. The provisions of 605<u>,</u> ~~and~~ 706 <u>and 806</u>, as applicable, shall apply to buildings and facilities designated as historic structures that undergo alterations, unless *technically infeasible*. Where compliance with the requirements for accessible routes, entrances or toilet facilities would threaten or destroy the historic significance of the building or facility, as determined by the *code official*, the alternative requirements of Sections 1104.1.1 through 1104.1.4 for that element shall be permitted.

> <u>**Exception:** Type B dwelling or sleeping units required by Section 1107 of the *International Building Code* are not required to be provided in historical buildings.</u>

SECTION 1105
CHANGE OF OCCUPANCY

1105.15 Accessibility requirements. The provisions of Section 912.8 shall apply to buildings and facilities designated as historic structures that undergo a *change of occupancy*, unless *technically infeasible*. Where compliance with the requirements for accessible routes, ramps, entrances, or toilet facilities would threaten or destroy the historic significance of the building or facility, as determined by the authority having jurisdiction, the alternative requirements of Sections 1104.1.1 through 1104.1.5 for those elements shall be permitted.

> <u>**Exception:** Type B dwelling or sleeping units required by Section 1107 of the *International Building Code* are not required to be provided in historical buildings.</u>

Reason: The intent of this proposal is to take a small step towards increasing the availability of housing with minimum accessibility requirements. With the fastest grouping group in the United States being people over 65 years old, there is a definite need. The last U.S. Census information indicated that 41% of people of 65 have some level of disability.

Type of units covered under the Fair Housing Act include apartments, condominiums, dormitories, fraternities, sororities, convents, monasteries, assisted living facilities, nursing homes, group homes, etc. The Fair Housing Act is applicable to building first occupied after March 1991. While the department of Housing and Urban Development has been active in enforcement of these regulations, there are a lot of existing buildings that were constructed since 1991 that did not comply with this federal law. The legacy building codes first started requiring Type B units in apartments and condominiums in 1996/1997. With code changes that added congregate living facilities and Institutional facilities, the IBC requirements for Type B units was declared a 'safe harbor' document by HUD in 2002. Reasonably, buildings in jurisdictions that have adopted 2003 or 2006 IBC meet FHA. United Spinal's concern is the buildings that were built before that.

There are a considerable number of existing buildings that should have complied with FHA and did not. When a major alteration is being performed, there is a prime opportunity to have those buildings move towards compliance. This will not only be a benefit for people that need that housing to live in, but will also help the building owners lessen or avoid complaints filed under FHA. Also, this is the most cost effective opportunity to make these revisions.

What this proposal is asking for, is that when buildings are undergoing a Level 3 alteration, or a change of occupancy that includes a Level 3 alteration, that whatever elements are altered, those elements are brought up to meet Type B requirements. If the element is not part of the alteration, it is not required to be altered. This is consistent with current building code philosophy for alterations. There are still the allowances for technically infeasible. The exceptions for non-elevator buildings, site limitations and flood zones currently indicated in Section 1107.7 are still applicable under *Extent of Application* (IBC 3409.3, IEBC 310.3, 605.1.14). Historical buildings, by their reference back to general provisions could be affected, therefore a general exception for Type B units is proposed for historical buildings.

In addition, when the area being altered is for Type B units, there is an exception for the additional route requirements currently in IBC Sections 3411.4.2 and 3411.7 and IEBC Section 310.4.2, 310.7, 605.2 and 912.8.2. United Spinal hopes that this address the concerns of site impracticality brought up during the last hearings by the Building Owners Managers Association, the National Association of Home Builders and the National Multi-Housing Council. This also reinforces the intent that this provision is not meant to require elevators when alterations are performed on upper floors in non-elevator buildings (see exceptions in Section 1107.7). These areas would have been exempted if built new under FHA and IBC, and should continue to be exempted.

The intent is that the same requirements for housing in existing buildings are included in IBC and IEBC. The wording is slightly different because IBC does not include a definition for Level 3 alterations. The terminology used – "work areas exceeds 50 percent of the aggregate area of the building" - can be found in IEBC 405.1. Some sections included in this proposal are not revised, but are included for context.

Cost Impact: The code change proposal will increase the cost of construction

ICCFILENAME: MARINELLI-EB1-605.2.DOC

Public Hearing Results

PART I- IEBC
Committee Action: **Approved as Submitted**

Committee Reason: The proposal was approved as it was felt that making the changes for Type B units were not that difficult. In addition this requirement would only apply for more substantial level III alterations and change of occupancy that involves level III alterations. There were some concerns expressed that approval of this proposal would exceed the fair housing requirements.

Assembly Action: **None**

Individual Consideration Agenda

These items are on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Dominic Marinelli, representing United Spinal Association, requests Approval as Submitted.

Commenter's Reason: EB 14 requires existing residential buildings undergoing Level III alterations to comply with the requirements of the Federal Fair Housing Act Accessibility Guidelines and the Type B requirements of the A117.1 accessibility standard.

There is no trigger for compliance without significant work (50 percent of the aggregate area of the building) associated with a Level III alteration.

The requirement will also allow multiple dwellings that were originally required to comply with the Federal law but did not to take this opportunity to do so when significant work is being done anyways.

Exceptions dealing with existing conditions (i.e., site impracticality, technical infeasibility) are included to recognize hardships in providing an accessible route to an altered dwelling unit or achieving the clearances within the altered dwelling unit.

Public Comment 2:

Lawrence Brown, representing National Association of Home Builders (NAHB), requests Disapproval.

Commenter's Reason: The proposed change far exceeds the Federal Fair Housing Act (FHAct) requirements for accessibility and should be Disapproved. The I-Codes should be used for the purpose of providing construction requirements to address life-safety concerns, not as a vehicle to orchestrate social change. Of most importance is that the proposed Section 806.1, requiring compliance with IBC "Type B Units", is contrary to Federal law. First, the proposed change expands the Federal law that only multifamily "buildings" constructed for first occupancy after March 13, 1991 need to be constructed to the FHAct requirements. Second, this change would apply to ALL existing buildings converted to multifamily use, no matter when they were first constructed. But, Federal law does not require existing buildings to comply with the FHAct. Another problem is that this change seems to be an attempt to circumvent and nullify the FHAct and the rulings handed down by the Federal Courts. The FHAct Rules includes a two-year statute of limitations on bringing suit and making corrections to an existing non-compliant multifamily building, a statute of limitations being upheld by the Federal Circuit Courts of Appeals. There is also the aspect of Federal preemption. By adopting the proposed change the I-Codes will be contrary to Federal Law. As Federal Law will preempt any state or local law, there will be challenges to the adoption of this Code. There is no benefit for any state or local jurisdiction to have to fight a challenge in court if the adoption of the I-Codes contains this provision. It appears this proposal is an attempt by a department of the federal government to mandate social change without going through the Federal Administrative Procedure Act rulemaking process. If it is intended that HUD will be adding this type of provision to the requirements of the FHAct, then this type of requirement should not be included in the I-Codes until such time as they are enacted into Federal law.

Proposed Change as Submitted

PART II – IBC GENERAL

Revise as follows:

SECTION 3411 (IEBC [B] 310)
ACCESSIBILITY FOR EXISTING BUILDINGS

3411.1 (IEBC [B] 310.1) Scope. The provisions of Sections 3411.1 through 3411.9 apply to maintenance, change of occupancy, additions and alterations to existing buildings, including those identified as *historic buildings*.

> ~~**Exception:** Type B *dwelling* or sleeping units required by Section 1107 of this code are not required to be provided in existing buildings and facilities being altered or undergoing a change of occupancy.~~

3411.4 (IEBC [B] 310.4) Change of occupancy. Existing buildings that undergo a change of group or occupancy shall comply with this section.

> **Exception:** Type B dwelling or sleeping units required by Section 1107 of this code are not required to be provided in existing buildings and facilities undergoing a change of occupancy in conjunction with alterations where the work area is 50 percent or less of the aggregate area of the building.

3411.4.1 (IEBC [B] 310.4.1) Partial change in occupancy. Where a portion of the building is changed to a new occupancy classification, any alterations shall comply with Sections 3411.6, 3411.7 and 3411.8.

3411.4.2(IEBC [B] 310.4.2) Complete change of occupancy. Where an entire building undergoes a change of occupancy, it shall comply with Section 3411.4.1 and shall have all of the following accessible features:

1. At least one accessible building entrance.
2. At least one accessible route from an accessible building entrance to primary function areas.
3. Signage complying with Section 1110.
4. Accessible parking, where parking is being provided.
5. At least one accessible passenger loading zone, when loading zones are provided.
6. At least one accessible route connecting accessible parking and accessible passenger loading zones to an accessible entrance.

Where it is technically infeasible to comply with the new construction standards for any of these requirements for a change of group or occupancy, the above items shall conform to the requirements to the maximum extent technically feasible.

> **Exception:** The accessible features listed in Items 1 through 6 are not required for an accessible route to Type B units.

3411.5 (IEBC [B] 310.5) Additions. Provisions for new construction shall apply to additions. An addition that affects the accessibility to, or contains an area of, a primary function shall comply with the requirements in Section 3411.7.

3411.6 (IEBC [B] 310.6) Alterations. A building, facility or element that is altered shall comply with the applicable provisions in Chapter 11 of this code and ICC A117.1, unless technically infeasible. Where compliance with this section is technically infeasible, the alteration shall provide access to the maximum extent technically feasible.

Exceptions:

1. The altered element or space is not required to be on an accessible route, unless required by Section 3411.7.
2. Accessible means of egress required by Chapter 10 are not required to be provided in existing buildings and facilities.
3. The alteration to Type A individually owned dwelling units within a Group R-2 occupancy shall meet the provision for a Type B dwelling unit and shall comply with the applicable provisions in Chapter 11 and ICC A117.1.
4. Type B dwelling or sleeping units required by Section 1107 of this code are not required to be provided in existing buildings and facilities undergoing a change of occupancy in conjunction with alterations where the work area is 50 percent or less of the aggregate area of the building.

3411.7 (IEBC [B] 310.7) Alterations affecting an area containing a primary function. Where an alteration affects the accessibility to, or contains an area of primary function, the route to the primary function area shall be accessible. The accessible route to the primary function area shall include toilet facilities or drinking fountains serving the area of primary function.

Exceptions:

1. The costs of providing the accessible route are not required to exceed 20 percent of the costs of the alterations affecting the area of primary function.
2. This provision does not apply to alterations limited solely to windows, hardware, operating controls, electrical outlets and signs.
3. This provision does not apply to alterations limited solely to mechanical systems, electrical systems, installation or alteration of fire protection systems and abatement of hazardous materials.
4. This provision does not apply to alterations undertaken for the primary purpose of increasing the accessibility of an existing building, facility or element.
5. This provision does not apply to altered areas limited to Type B dwelling and sleeping units.

3411.8 (IEBC [B] 310.8) Scoping for alterations. The provisions of Sections 3411.8.1 through 3411.8.12 shall apply to alterations to existing buildings and facilities.

3411.8.7 (IEBC [B] 310.8.7) Accessible dwelling or sleeping units. Where Group I-1, I-2, I-3, R-1, R-2 or R-4 dwelling or sleeping units are being altered or added, the requirements of Section 1107 for Accessible units apply only to the quantity of spaces being altered or added.

3411.8.8 (IEBC [B] 310.8.8) Type A dwelling or sleeping units. Where more than 20 Group R-2 dwelling or sleeping units are being altered or added, the requirements of Section 1107 for Type A units apply only to the quantity of the spaces being altered or added.

3411.8.9 (IEBC [B] 310.8.9) Type B dwelling or sleeping units. Where four or more Group I-1, I-2, R-1, R-2, R-3 or R-4 dwelling or sleeping units are being added, the requirements Section 1107 for Type B units apply only to the quantity of the spaces being added. Where Group I-1, I-2, R-1, R-2, R-3 or R-4 dwelling or sleeping units are being altered and where the work area is greater than 50 percent of the aggregate area of the building, the requirements Section 1107 for Type B units apply only to the quantity of the spaces being altered.

3411.9 (IEBC [B] 310.9) Historic buildings. These provisions shall apply to buildings and facilities designated as historic structures that undergo alterations or a change of occupancy, unless technically infeasible. Where compliance with the requirements for accessible routes, entrances or toilet facilities would threaten or destroy the historic significance of the building or facility, as determined by the applicable governing authority, the alternative requirements of Sections 3411.9.1 through 3411.9.4 for that element shall be permitted.

Exception: Type B dwelling or sleeping units required by Section 1107 of the International *Building Code* are not required to be provided in historical buildings.

SECTION 3412 (IEBC [B] CHAPTER 13) COMPLIANCE ALTERNATIVES

3412.2.5 (IEBC [B] 1301.2.5) Accessibility requirements. All portions of the buildings proposed for *change of occupancy* shall conform to the accessibility provisions of Section 3411 (IEBC 308).

Reason: The intent of this proposal is to take a small step towards increasing the availability of housing with minimum accessibility requirements. With the fastest grouping group in the United States being people over 65 years old, there is a definite need. The last U.S. Census information indicated that 41% of people of 65 have some level of disability.

Type of units covered under the Fair Housing Act include apartments, condominiums, dormitories, fraternities, sororities, convents, monasteries, assisted living facilities, nursing homes, group homes, etc. The Fair Housing Act is applicable to building first occupied after March 1991. While the department of Housing and Urban Development has been active in enforcement of these regulations, there are a lot of existing buildings that were constructed since 1991 that did not comply with this federal law. The legacy building codes first started requiring Type B units in apartments and condominiums in 1996/1997. With code changes that added congregate living facilities and Institutional facilities, the IBC requirements for Type B units was declared a ‘safe harbor’ document by HUD in 2002. Reasonably, buildings in jurisdictions that have adopted 2003 or 2006 IBC meet FHA. United Spinal’s concern is the buildings that were built before that.

There are a considerable number of existing buildings that should have complied with FHA and did not. When a major alteration is being performed, there is a prime opportunity to have those buildings move towards compliance. This will not only be a benefit for people that need that housing to live in, but will also help the building owners lessen or avoid complaints filed under FHA. Also, this is the most cost effective opportunity to make these revisions.

What this proposal is asking for, is that when buildings are undergoing a Level 3 alteration, or a change of occupancy that includes a Level 3 alteration, that whatever elements are altered, those elements are brought up to meet Type B requirements. If the element is not part of the alteration, it is not required to be altered. This is consistent with current building code philosophy for alterations. There are still the allowances for technically infeasible. The exceptions for non-elevator buildings, site limitations and flood zones currently indicated in Section 1107.7 are still applicable under *Extent of Application* (IBC 3409.3, IEBC 310.3, 605.1.14). Historical buildings, by their reference back to general provisions could be affected, therefore a general exception for Type B units is proposed for historical buildings.

In addition, when the area being altered is for Type B units, there is an exception for the additional route requirements currently in IBC Sections 3411.4.2 and 3411.7 and IEBC Section 310.4.2, 310.7, 605.2 and 912.8.2. United Spinal hopes that this address the concerns of site impracticality brought up during the last hearings by the Building Owners Managers Association, the National Association of Home Builders and the National Multi-Housing Council. This also reinforces the intent that this provision is not meant to require elevators when alterations are performed on upper floors in non-elevator buildings (see exceptions in Section 1107.7). These areas would have been exempted if built new under FHA and IBC, and should continue to be exempted.

The intent is that the same requirements for housing in existing buildings are included in IBC and IEBC. The wording is slightly different because IBC does not include a definition for Level 3 alterations. The terminology used – "work areas exceeds 50 percent of the aggregate area of the building" - can be found in IEBC 405.1. Some sections included in this proposal are not revised, but are included for context.

Cost Impact: The code change proposal will increase the cost of construction

Public Comment 2:

Lawrence Brown, representing National Association of Home Builders (NAHB), requests Disapproval.

Commenter's Reason: See EB14-09/10, Part I

Final Action: AS AM AMPC____ D

EB17-09/10
606.3.2

Proposed Change as Submitted

Proponent: David Bonowitz, SE, National Council of Structural Engineers Associations, Code Advisory Committee, Existing Buildings Subcommittee (NCSEA EBS)

Revise as follows:

606.3.2 Roof diaphragms resisting wind loads in high-wind regions. Where roofing materials are removed from more than 50 percent of the roof diaphragm or section of a building located where the basic wind speed is greater than 90 mph or in a special wind region, as defined in Section 1609 of the *International Building Code*, roof diaphragms and connections that are part of the main wind-force resisting system shall be evaluated for the wind loads specified in the *International Building Code*, including wind uplift. If the diaphragms and connections in their current condition ~~do not comply with those wind provisions,~~ are not capable of resisting at least 75% of those wind loads, they shall be replaced or strengthened in accordance with the loads specified in the *International Building Code*.

Reason: This proposal makes a reasonable allowance for "reduced" wind loads for certain triggered upgrades. Justifications and precedents include:

For the work triggered by Section 606.3.2, the major deficiencies – lack of basic load path elements or load path continuity – will still be caught if reduced wind loads are used.
Seismic evaluations typically use reduced loads, in part to avoid triggering upgrades to marginally overstressed elements. Wind provisions should reasonably do the same.
The seismic 75% factor is partly based on a reasonable "grandfathering" approach. Many existing buildings were designed with a (now obsolete) 1/3 overstress allowance for wind loads. Current ASCE 7 load combinations for strength design no longer make the same allowance, so even well-designed existing buildings would unreasonably be caught by a trigger that requires 100% of current loads.
FEMA (Disaster Assistance Policy 9527.4, available online) has stated a position that lateral force levels for new construction are generally considered unreasonable when applied to triggered repairs.
New designs are expected to remain elastic under 100% of current wind loads. A structure that can resist at least 75% of these loads can still reasonably be expected to perform acceptably, given the differences between minimum yield and expected ultimate strengths and due to the generally conservative nature of new design.
ASCE 7 requires a load factor of 1.6 for wind loads. Even at 75%, the effective load factor is still greater than 1.0.
Though not based on any quantified theory, observed performance, or a "grandfathering" strategy, the proposed 75% value is consistent with the factor used to reduce seismic loads.
The 75% value does not reach as low as past codes did when identifying dangerous conditions; buildings were deemed dangerous only if they could not resist 50% or 67% of design wind loads.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: BONOWITZ-EB27-606.3.2-2.DOC

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: This code change reduces the threshold for diaphragm and connections to 75 percent of the IBC wind load, before requiring an upgrade of these items to meet full code wind loads. There is a need to grandfather in existing buildings and this change allows the use of judgment for buildings that have been designed under previous codes.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

T. Eric Stafford, representing Institute for Business and Home Safety, requests Disapproval.

Commenter's Reason: Commenter's Reason: We are requesting Disapproval of EB17-09/10. The proponent draws correlations to the seismic 75% factor for basis for this proposed change. However, wind loads and seismic loads are based on different philosophies regarding structural design make this comparison weak. Arbitrarily applying a lower threshold for wind load retrofits just because the seismic provisions permit it is unsubstantiated and irrelevant to wind loads. The reference to the FEMA position that lateral force levels for new construction are generally unreasonable when applied to triggered repairs is misleading. This section of the IEBC applies to uplift as well as lateral loads as specifically stated in this section. The proponent argues in his reason statement that "Many existing buildings were designed with a (now obsolete) 1/3 overstress allowance for wind loads. Current ASCE 7 load combinations for strength design no longer make the same allowance…" ASCE 7 load combinations for strength design have never permitted a 1/3 overstress. The 1/3 stress increase was permitted for allowable stress design. While ASCE 7-98 and later do prohibit the use of the 1/3 stress increase when using the provisions, ASCE 7-98 and later editions also included an across-the-board 15% reduction in wind loads in the form of the directionality factor (K_d = 0.85 for buildings).

A general comparison reveals the flaws in the proposal. For buildings built prior to ASCE 7-98, wind loads for many buildings were essential reduced to 75% of the calculated loads by virtue of the 1/3 stress increase (1/1.33 = .75188). In ASCE 7-98 and later, these wind loads have essentially been reduced by 15%. By reducing the threshold for triggering retrofits an additional 25%, these elements would only be required to resist 64% of the loads the building was designed for. This effective threshold is much lower than what it appeared the proponent was hoping to obtain based on the testimony at the public hearing.

The proponent is seeking a trigger reduction on a part of buildings that are the most vulnerable to wind loads which is the roof and it's connections to the sheathing and the wall supporting the roof. If a building suffers damage for high winds, the majority of the time there is some form or roof related damage also associated with the event. This retrofit is triggered when roofing materials are removed 50% of the roof diaphragm, which is an ideal time to make needed retrofits.

The logic behind this proposal is flawed and we think it represents poor judgment. We urge your disapproval of this proposal.

Final Action: AS AM AMPC____ D

EB31-09/10
912.5.1

Proposed Change as Submitted

Proponents: Joseph A. McGrath, PE, RA, representing New York State Dep. of State, Division of Code Enforcement and Administration

Revise as follows:

912.5.1 Height and area change to higher hazard category. When a change of occupancy classification is made to a higher hazard category as shown in Table 912.5, heights and areas of buildings and structures shall comply with the requirements of Chapter 5 of the *International Building Code* for the new occupancy classification.

> **Exception**: In other than Groups H, F-1 and S-1, in lieu of fire walls, use of fire barriers <u>and horizontal assemblies</u> having a fire-resistance rating of not less than that specified in Table 706.4 of the *International Building Code*, constructed in accordance with Section<u>s</u> 707 <u>and 712</u> of the *International Building Code*, shall be permitted to meet the area limitations required for the new occupancy in buildings protected throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 of the *International Fire Code*. <u>The maximum allowable area between fire barriers, horizontal assemblies or any combination thereof shall not exceed the tabular area specified in Table 503 of the *International Building Code* without any area increase allowed for an automatic sprinkler system in accordance with Section 506 of the *International Building Code*. Where horizontal assemblies are used to limit the maximum allowable area, the required fire-resistance rating of the horizontal assemblies shall be permitted to be reduced by 1-hour provided the height and number of stories increases allowed by Section 504.2 for an automatic sprinkler system are not used for the building.</u>

Reason: This proposal is a follow-up to code change EB33-06/07 that was approved as modified by Public Comment #1 submitted by the Alliance for Fire and Smoke Containment and Control (AFSCC) at the ICC Final Action Hearings in Rochester, New York in May, 2007. The reason for the original EB33 proposal is the need to reuse existing mill buildings that are sprinklered and the fact that the original code requirement for fire walls is not financially or physically practicable. This proposal will provide an additional measure of safety to the current requirements of this section.

At the 2007 hearings the AFSCC proposed that if fire barriers were used in lieu of fire walls, a significant reduction in allowable building and fire areas should occur. We agree, so this proposal reduces the allowable building area by allowing fire fighting access (open space) credits but not sprinklering credits. An example, to use the most probable application of this proposal, would be a Type IIIB construction mill building being converted from an F-1 (moderate hazard) occupancy to an R-2 (residential) occupancy. This change in occupancy would be considered a change to a higher hazard.

Under the proposed change, the mill building described above would be allowed to have a floor area of 28,000 square feet and a total maximum floor area for all stories of 84,000 square feet between fire barriers with a maximum 75% increase allowed for open space. Present requirements for a new building would allow 60,000 square feet for a single floor area and 180,000 square feet of total floor area with the additional increase allowed for an automatic sprinkler system.

The logic behind not allowing area increases for sprinklering is because under the circumstances of the substitution of fire barriers for fire walls in these buildings, the required sprinklers should not be given extra credit.

The concept of allowing horizontal assemblies to be used to subdivide the building presumes that the fire would be contained within the six sided box formed by the fire barrier walls and horizontal assemblies and/or exterior walls and roof which is limited to the area prescribed in this proposed code change. Thus, the volume of the building separated from the rest of the building by the required fire-resistance rated construction would be comparable.

The logic behind allowing a 1-hour reduction in the required fire-resistance rating for the horizontal assemblies is based on the fact that the automatic sprinkler system provided would not be used for a height increase both in number of stories and in total feet (1 story and 20 feet), yet the building will still be compartmented with fire-resistive horizontal assemblies having, in most cases, a minimum fire-resistance rating of 2-hours and, in some cases, as low as 1-hour but only 1 hour less than what would otherwise be required by Table 705.4 by this exception for the fire barriers. Thus, the sprinkler credit that would otherwise be given for the increase in height currently allowed by Chapter 5 of the International Building Code would be used for the reduction of 1-hour in the required fire- resistance rating of the horizontal assembly. We believe this provides a reasonable equivalent level of fire and life safety protection for existing buildings being converted under this exception as modified by this code change proposal.

Cost Impact: The code change proposal will result in added costs to construction if the building is over a specific size as to require more fire barriers than the present requirements. However, the cost and practicality of converting existing buildings is still greatly improved from the requirements in the 2003 IEBC.

ICCFILENAME: MCGRATH-EB1-912.5.1.DOC

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: There was an agreement that horizontal assemblies should be acknowledged as a valid alternative for decreasing building area but it was felt that an increase for sprinklers should be allowed.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jason Thompson, National Concrete Masonry Alliance (NCMA), representing Masonry Alliance for Codes and Standards (MACS), requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

912.5.1 Height and area change to higher hazard category. When a change of occupancy classification is made to a higher category as shown in Table 912.5, heights and areas of buildings and structures shall comply with the requirements of Chapter 5 of the International Building Code for the new occupancy classification.

> ~~**Exception:** In other than Groups H, F-1 and S-1, in lieu of fire walls, use of fire barriers and horizontal assemblies having a fire-resistance rating of not less than that specified in Table 705.4 of the International Building Code, constructed in accordance with Section 706 and 711 of the International Building Code, shall be permitted to meet the area limitations required for the new occupancy in buildings protected throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 of the International Fire Code. The maximum allowable area between fire barriers, horizontal assemblies or any combination thereof shall not exceed the tabular area specified in Table 503 of the International Building Code without any area increase allowed for an automatic sprinkler system in accordance with Section 506 of the International Building Code. Where horizontal assemblies are used to limit the maximum allowable area, the required fire-resistance rating of the horizontal assemblies shall be permitted to be reduced by 1-hour provided the height and number of stories increases allowed by Section 504.2 for an automatic sprinkler system are not used for the building.~~

912.5.1.1 Fire wall alternative. In other than Group F-1, H and S-1, fire barriers and horizontal assemblies constructed in accordance with Sections 707 and 712, respectively, of the *International Building Code* shall be permitted to be used in lieu of fire walls to subdivide the building into separate buildings for the purpose of complying with the area limitations required for the new occupancy where all of the following conditions are met:

1. The buildings are protected throughout with an automatic sprinkler system in accordance with Section 903.3.1.1 of the *International Fire Code*.
2. The maximum allowable area between fire barriers, horizontal assemblies, or any combination thereof shall not exceed the maximum allowable area determined in accordance with Chapter 5 of the International Building Code without an increase allowed for an automatic sprinkler system in accordance with Section 506 of the *International Building Code*.
3. The fire-resistance rating of the fire barriers and horizontal assemblies shall not be less than that specified for fire walls in Table 706.4 of the *International Building Code*.

> **Exception:** Where horizontal assemblies are used to limit the maximum allowable area, the required fire-resistance rating of the horizontal assemblies shall be permitted to be reduced by 1-hour provided the height and number of stories increases allowed for an automatic sprinkler system by Section 504.2 of the *International Building Code* are not used for the buildings.

Commenter's Reason: We are submitting this Public Comment to revise the original Code Change Proposal in an effort to respond to the International Existing Building Code Development Committee's concerns expressed during the ICC Code Development Committee Hearings held in Baltimore, MD last year, as well as those testifying in opposition to this Code Change. We have discussed the revisions proposed in this Public Comment with the proponents of Code Change EB31-09/10 and they have indicated their approval.

It should be noted that the Committee agreed with the Code Change including horizontal assemblies as being allowed to substitute for fire walls in subdividing a building to determine its allowable height and area. However, the Committee felt that an increase for automatic sprinklers should be allowed. We would point out that the Code Change already allows for the automatic sprinkler system to be used to reduce the requirement for fire walls to separate the existing building to meet the allowable height and areas by allowing the use of fire barriers and horizontal assemblies. This is a significant sprinkler trade-off since fire walls create separate buildings, whereas fire barriers and horizontal assemblies compartmentize a building.

This Code Change also allows the sprinkler system to be used to either increase the building height and number of stories or to reduce the required fire-resistance ratings for the horizontal assemblies by 1-hour. The only thing that isn't allowed for the automatic sprinkler system is an area increase which we believe results in too much reliance on the automatic sprinkler system for this application. However, this Code Change still allows the open space perimeter increase calculations to be used to increase the base tabular areas in Table 503.

We believe that the judicious use of automatic sprinkler systems allowed by this Code Change recognizes the value that automatic sprinkler systems bring to the overall level of fire and life safety provided in the existing building, while also recognizing that certain minimum requirements for compartmentation should be maintained when changing the occupancy of existing buildings. To us, this is a "win-win" situation that will provide a great deal of flexibility in rehabilitating the existing building stock without violating the intent of the building code for providing a reasonable level of fire and life safety to the building and its occupants.

We have also reformatted this Code Change by deleting the very lengthy Exception. Instead, we have provided a new Subsection 912.5.1.1 Fire Wall Alternative. This section is formatted in a way to make it much more straightforward and easy to understand and apply the provisions that will allow the substitution of fire barriers and horizontal assemblies for fire walls to subdivide existing buildings for the purpose of determining the allowable height and area based upon the new occupancy classification caused by the change in occupancy(s) of the existing building.

For these reasons we respectfully request the Class A voting members overturn the International Existing Building Code Development Committee's recommendation for disapproval and approve this Public Comment for approval as revised of Code Change EB31-09/10.

Final Action: AS AM AMPC____ D

EB32-09/10, Part I

IEBC 912.8, 912.8.1, 912.8.2; IBC 3411.4, 3411.4.1, 3411.4.2 (IEBC [B] 310.4, 310.4.1, 310.4.2)

Proposed Change as Submitted

Proponent: Maureen Traxler, City of Seattle, WA, Seattle Dept of Planning & Development

PART I – IEBC

Revise as follows:

912.8 Accessibility. ~~Existing buildings that undergo a change of group or occupancy shall comply with this section.~~

~~**912.8.1 Partial change in occupancy.**~~ Where ~~a~~ all or any portion of ~~the~~ a building is changed to a new occupancy classification, any alterations shall comply with Sections 605 and 706, as applicable.

~~**912.8.2 Complete change of occupancy.** Where an entire building undergoes a change of occupancy, it shall comply with Section 3411.4.1 and shall have all of the following accessible features:~~

1. ~~At least one accessible building entrance.~~
2. ~~At least one accessible route from an accessible building entrance to primary function areas.~~
3. ~~Signage complying with Section 1110.~~
4. ~~Accessible parking, where parking is being provided.~~
5. ~~At least one accessible passenger loading zone, when loading zones are provided.~~
6. ~~At least one accessible route connecting accessible parking and accessible passenger loading zones to an accessible entrance.~~

~~Where it is technically infeasible to comply with the new construction standards for any of these requirements for a change of group or occupancy, the above items shall conform to the requirements to the maximum extent technically feasible.~~

Reason: When buildings are altered, required improvements in accessibility are limited to 20% of the cost of the alterations according to exception 1 to IBC Section 3411.7 and exception 1 to IEBC Section 605.2. According to the Access Board website [http://www.access-board.gov/ada%2Daba/adaag.cfm#a202], "Department of Justice ADA regulations state, 'Alterations made to provide an accessible path of travel to the altered area will be deemed disproportionate to the overall alteration when the cost exceeds 20% of the cost of the alteration to the primary function area.' (28 CFR 36.403 (f)(1)). See also Department of Transportation ADA regulations, which use similar concepts in the context of public sector transportation facilities (49 CFR 37.43 (e)(1))."

Changes of occupancy shouldn't be required to do more than alterations. Many changes of occupancy are accomplished with little or no construction work—a space may be refurnished and transformed from a Group M retail store to a Group B office. Any construction work that is done would be required to comply with IBC Section 3411.7 (IEBC Section 605.2), and would be subject to the 20% limitation.

The list of priority accessible features has been deleted because it is not necessary for correlation with the ADAAG, and because such a prescriptive requirement does not allow the flexibility to spend money improving the accessible route where it makes the most sense. It is our understanding that while the list was originally proposed for adoption in the new ADAAG, ultimately, it was decided to allow that flexibility, and the list does not appear in the updated ADAAG.

We think the proposal presented above is the most comprehensive and cleanest way to address our issues. However, if the Committee decides that keeping the priority list is a necessity, we would be open to a modification of the proposal that would retain all the existing language that is shown as being struck through in IBC Sections 3411.4, 3411.4.1, and 3411.4.2, but instead, just inserts an exception just after the list in Section 3411.4.2 as follows:

3411.4.2 Complete change of occupancy. Where an entire building undergoes a change of occupancy, it shall comply with Section 3411.4.1 and shall have all of the following *accessible* features:

1. At least one *accessible* building entrance.
2. At least one *accessible* route from an *accessible* building entrance to *primary function* areas.
3. Signage complying with Section 1110.
4. Accessible parking, where parking is being provided.
5. At least one *accessible* passenger loading zone, when loading zones are provided.
6. At least one *accessible* route connecting *accessible* parking and *accessible* passenger loading zones to an *accessible* entrance.

Exception: The costs of providing an *accessible* route or *accessible* features are not required to exceed 20 percent of the costs of the *alterations* affecting the area of *primary function*.

Where it is *technically infeasible* to comply with the new construction standards for any of these requirements for a change of group or occupancy, the above items shall conform to the requirements to the maximum extent technically feasible.

The corresponding changes would have to be made to IEBC Section 912.8 if this alternative is chosen (i.e., retain struck-through text in 912.8, 912.8.1, and 912.8.2, and add the new exception to 912.8.2). This would still address the issue capping the required costs of accessibility upgrades, without affecting the priority list.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: TRAXLER-G11-3411.4.2

Public Hearing Results

PART I- IEBC
Committee Action: Disapproved

Committee Reason: The proposal which would have only required accessible features when an alteration was required was disapproved as it was felt that a modification addressing an upper limit on cost at 20% instead of fully exempting changes of occupancy without alterations was more appropriate.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Maureen Traxler, representing the City of Seattle Department of Planning & Development, requests Approval as Modified by this Public Comment.

Replace the proposal as follows:

Part I—IEBC

912.8 Accessibility. Existing buildings that undergo a change of group or occupancy shall comply with this section.
912.8.1 Partial change in occupancy. Where a portion of a building is changed to a new occupancy classification, any alterations shall comply with Sections 605 and 706, as applicable.
912.8.2 Complete change of occupancy. Where an entire building undergoes a change of occupancy, it shall comply with Section 912.8.1 and shall have all of the following accessible features:
1. At least one accessible building entrance.
2. At least one accessible route from an accessible building entrance to primary function areas.
3. Signage complying with Section 1110 of the International Building Code.
4. Accessible parking, where parking is provided.
5. At least one accessible passenger loading zone, when loading zones are provided.
6. At least one accessible route connecting accessible parking and accessible passenger loading zones to an accessible entrance.

Exception: The costs of providing an *accessible* route as required in items 1 through 6 are not required to exceed 20 percent of the costs of the *alterations* affecting the area of *primary function*.

Where it is technically infeasible to comply with the new construction standards for any of these requirements for a change of group or occupancy, the above items shall conform to the requirements to the maximum extent technically feasible.

Commenter's Reason: This purpose of the original proposal and this comment is to apply the same accessibility requirements to changes of occupancy as apply to alterations. Existing code provisions for alterations limit the cost of accessibility improvements to 20% of the cost of the alterations. No such limit applies to changes of occupancy. This public comment retains the existing language in both the IBC and IEBC and adds an exception that applies the "20% rule" to changes of occupancy. The Code Development Committee expressed a preference for a modification similar to this, but while this text was included in our original reason statement, when we attempted to introduce it as a floor modification, it was ruled out of order as being too hard for the committee to easily understand in the short time available. The only changes to existing language proposed by this comment is to add the exception after Item 6 in both codes.

Final Action: AS AM AMPC____ D

EB32-09/10, Part II
IEBC 912.8, 912.8.1, 912.8.2; IBC 3411.4, 3411.4.1, 3411.4.2 (IEBC [B] 310.4, 310.4.1, 310.4.2)

Proposed Change as Submitted

Proponent: Maureen Traxler, City of Seattle, WA, Seattle Dept of Planning & Development

PART II – IBC GENERAL

Revise as follows:

3411.4 (IEBC [B] 310.4) Change of occupancy. ~~Existing buildings that undergo a change of group or occupancy shall comply with this section.~~

~~**3411.4.1 (IEBC [B] 310.4.1) Partial change in occupancy.**~~ Where ~~a~~ all or any portion of ~~the~~ a building is changed to a new occupancy classification, any alterations shall comply with Sections 3411.6, 3411.7 and 3411.8.

~~**3411.4.2 (IEBC [B] 310.4.2) Complete change of occupancy.** Where an entire building undergoes a change of occupancy, it shall comply with Section 3411.4.1 and shall have all of the following accessible features:~~

1. ~~At least one accessible building entrance.~~
2. ~~At least one accessible route from an accessible building entrance to primary function areas.~~
3. ~~Signage complying with Section 1110.~~
4. ~~Accessible parking, where parking is being provided.~~
5. ~~At least one accessible passenger loading zone, when loading zones are provided.~~
6. ~~At least one accessible route connecting accessible parking and accessible passenger loading zones to an accessible entrance.~~

~~Where it is technically infeasible to comply with the new construction standards for any of these requirements for a change of group or occupancy, the above items shall conform to the requirements to the maximum extent technically feasible.~~

Reason: When buildings are altered, required improvements in accessibility are limited to 20% of the cost of the alterations according to exception 1 to IBC Section 3411.7 and exception 1 to IEBC Section 605.2. According to the Access Board website [http://www.access-board.gov/ada%2Daba/adaag.cfm#a202], "Department of Justice ADA regulations state, 'Alterations made to provide an accessible path of travel to the altered area will be deemed disproportionate to the overall alteration when the cost exceeds 20% of the cost of the alteration to the primary function area.' (28 CFR 36.403 (f)(1)). See also Department of Transportation ADA regulations, which use similar concepts in the context of public sector transportation facilities (49 CFR 37.43 (e)(1))."

Changes of occupancy shouldn't be required to do more than alterations. Many changes of occupancy are accomplished with little or no construction work—a space may be refurnished and transformed from a Group M retail store to a Group B office. Any construction work that is done would be required to comply with IBC Section 3411.7 (IEBC Section 605.2), and would be subject to the 20% limitation.

The list of priority accessible features has been deleted because it is not necessary for correlation with the ADAAG, and because such a prescriptive requirement does not allow the flexibility to spend money improving the accessible route where it makes the most sense. It is our understanding that while the list was originally proposed for adoption in the new ADAAG, ultimately, it was decided to allow that flexibility, and the list does not appear in the updated ADAAG.

We think the proposal presented above is the most comprehensive and cleanest way to address our issues. However, if the Committee decides that keeping the priority list is a necessity, we would be open to a modification of the proposal that would retain all the existing language that is shown as being struck through in IBC Sections 3411.4, 3411.4.1, and 3411.4.2, but instead, just inserts an exception just after the list in Section 3411.4.2 as follows:

3411.4.2 Complete change of occupancy. Where an entire building undergoes a change of occupancy, it shall comply with Section 3411.4.1 and shall have all of the following *accessible* features:

1. At least one *accessible* building entrance.
2. At least one *accessible* route from an *accessible* building entrance to *primary function* areas.
3. Signage complying with Section 1110.
4. Accessible parking, where parking is being provided.
5. At least one *accessible* passenger loading zone, when loading zones are provided.
6. At least one *accessible* route connecting *accessible* parking and *accessible* passenger loading zones to an *accessible* entrance.

Exception: The costs of providing an *accessible* route or *accessible* features are not required to exceed 20 percent of the costs of the *alterations* affecting the area of *primary function*.

Where it is *technically infeasible* to comply with the new construction standards for any of these requirements for a change of group or occupancy, the above items shall conform to the requirements to the maximum extent technically feasible.

The corresponding changes would have to be made to IEBC Section 912.8 if this alternative is chosen (i.e., retain struck-through text in 912.8, 912.8.1, and 912.8.2, and add the new exception to 912.8.2). This would still address the issue capping the required costs of accessibility upgrades, without affecting the priority list.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: TRAXLER-G11-3411.4.2

Public Hearing Results

PART II-IBC GENERAL
Committee Action: Disapproved

Committee Reason: The code change was disapproved to be consistent with the action on Part I of the proposal.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Maureen Traxler, representing City of Seattle Dept. of Planning & Development, requests Approval as Modified by this Public Comment.

Replace the proposal as follows:

3411.4 (IEBC [B] 310.4) Change of occupancy. Existing buildings that undergo a change of group or occupancy shall comply with this section.

3411.4.1 (IEBC [B] 310.4.1) Partial change in occupancy. Where a portion of a building is changed to a new occupancy classification, any alterations shall comply with Sections 3411.6, 3411.7 and 3411.8.

3411.4.2 Complete change of occupancy. Where an entire building undergoes a change of occupancy, it shall comply with Section 3411.4.1 and shall have all of the following *accessible* features:

1. At least one *accessible* building entrance.
2. At least one *accessible* route from an *accessible* building entrance to *primary function* areas.
3. Signage complying with Section 1110.
4. Accessible parking, where parking is ~~being~~ provided.
5. At least one *accessible* passenger loading zone, when loading zones are provided.
6. At least one *accessible* route connecting *accessible* parking and *accessible* passenger loading zones to an *accessible* entrance.

Exception: The costs of providing an *accessible* route as required in items 1 through 6 are not required to exceed 20 percent of the costs of the *alterations* affecting the area of *primary function*.

Where it is *technically infeasible* to comply with the new construction standards for any of these requirements for a change of group or occupancy, the above items shall conform to the requirements to the maximum extent technically feasible.

Commenter's Reason: See EB32-09/10, Part I

Final Action: AS AM AMPC____ D

EB34-09/10
912.8.2

Proposed Change as Submitted

Proponent: Lawrence Brown, CBO, National Association of Home Builders (NAHB)

Revise as follows:

912.8.2 Complete change of occupancy. Where an entire building undergoes a *change of occupancy*, it shall comply with Section 912.8.1 and shall have all of the following accessible features:

1. At least one accessible building entrance.
2. At least one accessible route from an accessible building entrance to *primary function* areas.
3. Signage complying with Section 1110 of the *International Building Code*.
4. Accessible parking, where parking is provided.
5. At least one accessible passenger loading zone, where loading zones are provided.
6. At least one accessible route connecting accessible parking and accessible passenger loading zones to an accessible entrance.

Where it is *technically infeasible* to comply with the new construction standards for any of these requirements for a change of group or occupancy, the above items shall conform to the requirements to the maximum extent technically feasible.

<u>**Exception:** Type B dwelling or sleeping units required by Section 1107 of the *International Building Code* are not required to be provided in existing buildings and facilities.</u>

Reason: The purpose of this Proposal is to reinstate this Exception that was deleted during the 2007-08 Code Development Cycle. The deletion of the Exception is contrary to the U.S. Federal Law Fair Housing Act accessibility requirements. The Federal Fair Housing Act does not require existing buildings that are converted to residential use to comply with the Fair Housing Act accessibility requirements. The IBC does not require existing buildings with a change of occupancy to residential use to contain Type B units. In fact, with the deletion of this Exception caused an inconsistency between the IBC and the IEBC. Section 3411.1 of the IBC states:

3409.1 Scope. The provisions of Sections 3411.1 through 3411.9 apply to maintenance, change of occupancy, additions and alterations to existing buildings, including those identified as historic buildings.

Exception: Type B dwelling or sleeping units required by Section 1107 are not required to be provided in existing buildings and facilities.

Federal Law for the implementing the accessibility requirements of the Fair Housing Act only apply to new buildings as described in the HUD Fair Housing Act Design Manual as follows: *"The Fair Housing Act does not require any renovations to existing buildings. Its design requirements apply to new construction only – to covered <u>multifamily dwellings</u> that are built for <u>first occupancy</u> after March 13, 1991. <u>First occupancy is defined as "a building that has never before been used for any purpose</u>."*
As the Federal law states, any existing building that is converted to residential use, no matter when it was constructed, is NOT required to comply with the Fair Housing Act. It also needs to be understood that the I-Codes contain provisions The I-Codes should not contain requirements that are contrary to Federal public law.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: BROWN-EB1-912.8.2.DOC

<u>Public Hearing Results</u>

Committee Action: **Disapproved**

Committee Reason: The proposal was disapproved to be consistent with the action taken on EB14. There was also some concern that where the exception is proposed is awkward as it has no relationship to the list related to the accessible path features. Some members of the committee were concerned that without this proposed exception the FHA would be exceeded.

Assembly Action: **None**

<u>Individual Consideration Agenda</u>

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Lawrence Brown, CBO, representing the National Association of Home Builders (NAHB), requests Approval as Submitted.

Commenter's Reason: The purpose of this Proposal is to reinstate this Exception that allowed the IBC to be in compliance with Federal Law. The Exception was deleted during the 2007-08 Code Development Cycle. By deleting the Exception the IBC exceeded the Federal Fair Housing (FHAct) Requirements for accessibility. Most importantly, that change had the effect of putting the IBC in conflict with the Federal Law - a law that only requires multifamily "buildings" constructed for first occupancy after March 13, 1991 to be constructed to the FHAct requirements. This change applies to ALL existing buildings converted to multifamily use, no matter when they were first constructed. The FHAct does not require any existing building that is converted to residential use to comply with the Fair Housing Act accessibility requirements.

The Federal Law for implementing the accessibility requirements of the Fair Housing Act only applies to new buildings as described in the HUD Fair Housing Act Design Manual as follows: *"The Fair Housing Act does not require any renovations to existing buildings. Its design requirements apply to new construction only – to covered <u>multifamily dwellings</u> that are built for <u>first occupancy</u> after March 13, 1991. <u>First occupancy is defined as "a building that has never before been used for any purpose</u>."*

As the Federal Law states, any existing building that is converted to residential use, no matter when it was constructed, is NOT required to comply with the Fair Housing Act. The I-Codes should be used for the purpose of providing construction requirements to address life-safety concerns, not as a vehicle to orchestrate social change. Another problem is that this change causes the IBC requirements to circumvent and nullify the FHAct and the rulings handed down by the Federal Courts, and the aspect of Federal preemption. From an enforcement standpoint, as Federal Law will preempt any state or local law, there will be challenges to the adoption of this Code. There is no benefit for any state or local jurisdiction to have to fight a challenge in court if the adoption of the I-Codes does not contain this Exception. It appears the deletion of the Exception was an attempt by a department of the Federal Government to mandate social change without going through the Federal Administrative Procedure Act rulemaking process. If it is intended that HUD will be adding this type of provision to the requirements of the FHAct, then this type of requirement should not be included in the I-Codes until such time as they are enacted into Federal Law.

Final Action: AS AM AMPC____ D

EB36-09/10
1101.2

Proposed Change as Submitted

Proponent: David Bonowitz, SE, National Council of Structural Engineers Associations, Code Advisory Committee, Existing Buildings Subcommittee (NCSEA EBS)

THIS PROPOSAL IS ON THE AGENDA OF THE IBC STRUCTURAL CODE DEVELOPMENT COMMITTEE. SEE THE TENTATIVE HEARING ORDER FOR THE IBC STRUCTURAL CODE DEVELOPMENT COMMITTEE.

Revise as follows:

1101.2 Report. A historic building undergoing repair, alteration, or change of occupancy shall be investigated and evaluated. If it is intended that the building meet the requirements of this chapter, a written report shall be prepared and filed with the code official by a registered design professional when such a report is necessary in the opinion of the code official. Such report shall be in accordance with Chapter 1 and shall identify each required safety feature that is in compliance with this chapter and where compliance with other chapters of these provisions would be damaging to the contributing historic features. For buildings assigned to Seismic Design Category D, E, or F, a structural evaluation describing, at a minimum, <u>the vertical and horizontal elements of the lateral force resisting system and any strengths or weaknesses therein</u> ~~a complete load path and other earthquake-resistant features~~ shall be prepared. Additionally, the report shall describe each feature that is not in compliance with these provisions and shall demonstrate how the intent of these provisions is complied with in providing an equivalent level of safety.

Reason: This is an editorial proposal. The current provision requires the engineer to describe a complete load path whether one is present or not. Further, the term “earthquake resistant features” is vague. This proposal clarifies that the provision’s intent is to require some description of the designed or *de facto* lateral system and to identify its salient features. The proposed language should be clearer, more enforceable, and more effective at producing a useful report.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: BONOWITZ-EB22-1101.2.DOC

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: This code change was approved as it provides a more precise definition of the lateral force-resisting system description that is required for the written report on a historic building.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Maureen Traxler, representing the City of Seattle Department of Planning & Development, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

1101.2 Report. A historic building undergoing repair, alteration, or change of occupancy shall be investigated and evaluated. If it is intended that the building meet the requirements of this chapter, a written report shall be prepared and filed with the code official by a registered design professional when such a report is necessary in the opinion of the code official. Such report shall be in accordance with Chapter 1 and shall identify each required safety feature that is in compliance with this chapter and where compliance with other chapters of these provisions would be damaging to the contributing historic features. For buildings assigned to Seismic Design Category D, E, or F, a structural evaluation describing, at a minimum, the ~~vertical and horizontal~~ elements of the lateral force resisting system and any strengths or weaknesses therein shall be prepared. Additionally, the report shall describe each feature that is not in compliance with these provisions and shall demonstrate how the intent of these provisions is complied with in providing an equivalent level of safety.

Commenter's Reason: This proposed modification is consistent with the proponent's intention to require the engineer to describe the lateral force resisting system. By limiting the requirement to vertical and horizontal elements, important diagonal bracing or other elements may be missed.

Final Action: AS AM AMPC____ D

EB39-09/10
1202.8 (New)

Proposed Change as Submitted

Proponent: Randall R. Dahmen, WI Registered PE, WI Licensed Commercial Building Inspector

Add new text as follows:

<u>**1202.8 Building envelope**. A relocated or moved building shall comply with the *International Energy Conservation Code* for building envelope requirements when the building is relocated or moved to a different climate zone.</u>

Reason: In order to create efficient building energy performance, this code change requires those buildings that change regions of climate where there are more restrictive building envelope requirements, to meet the more restrictive performance criteria of the IECC for the new location Buildings are many times relocated or moved from regions of the country which are typically warm, and which require minimal insulation at the time of original construction, to regions that are extremely cold, whose minimum requirements for building insulation are significantly greater.
Similarly, buildings that are relocated or moved from a cold climate to a warm climate may find that they may need to make changes to the existing glazing in order to comply with the Solar Heat Gain Coefficient (SHGC) requirements.

At present, there are no rules requiring that the relocated building install additional insulation to the building envelope assemblies. This seems inappropriate, since the original design was intended for the original building location, not the proposed relocation.
It is the opinion of this author that this proposal is an extension of the snow load requirements already addressed under IEBC 1202.5. Clearly, it has been established that when a building changes locations, it needs to be modified so as to appropriately accommodate the climatic conditions of the new site. This is a continuation of that thought process.

Cost Impact: Minimal. Exact costs would be dependent on the significance in the change in climate for the moved or relocated building.

ICCFILENAME: DAHMEN-EB2-1202.8.DOC

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The proposal was disapproved as it has no exception for historic buildings that are moved or relocated into a different climate zone.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Randall R. Dahmen, WI Registered PE, WI Licensed Commercial Building Inspector, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

1207.8 Building envelope. A relocated or moved building shall comply with the *International Energy Conservation Code* for building envelope requirements when the building envelope requirements at the new location are more restrictive than those at the previous location.

Exception: Historic buildings complying with Chapter 11.

Commenter's Reason: The exception is requested to be added so as to address those buildings of historical significance. As originally worded, historical buildings which would be relocated or moved could be required to be altered in order to be insulated to current IECC requirements. The requirement to add insulation to historical buildings may cause modifications not indicative of the original building construction. Such action would take away a portion of the historical perspective of the building.

Note that the wording of the exception could be altered so as to be more consistent with other code provisions, as long as the intent of the exception is still met.

Final Action: AS AM AMPC____ D

EB55-09/10
A401.2

Proposed Change as Submitted

Proponent: Gary R. Searer, Wiss, Janney, Elstner Associates, Inc., representing National Council of Structural Engineers Association (NCSEA) Existing Buildings Subcommittee

Revise as follows:

A401.2 Scope. The provisions of this chapter shall apply to all existing Occupancy Group R-1 and R-2 buildings of wood construction or portions thereof where the structure has a soft, weak, or open-front wall line, and there exists one or more stories above. ~~:~~

1. ~~The ground floor portion of the wood-frame structure contains parking or other similar open floor space, which causes soft, weak or open-front wall lines as defined in this chapter, and there exists one or more stories above., or~~
2. ~~The walls of any story or basement of wood construction are laterally braced with nonconforming structural materials as defined in this chapter, a soft or weak wall line exists as defined in this chapter and there exist two or more stories above.~~
3. ~~The structure is assigned to Seismic Design Category C, D or E.~~

Reason: This proposal clarifies the scope by removing inapplicable and unnecessary language. Of the three conditions in the current provision, only Condition 1 is appropriate for a clear and limited scope. The proposed wording of Condition 1 removes the reference to parking and open floor space, as well as the requirement that the open floor space be on the ground floor. While these are common conditions, they are not the only ones to which this chapter is meant to apply. The descriptors proposed for removal are better suited for commentary.

Current Condition 2 recognizes the possibility of a weak or soft story condition without an open front wall line, but with the revision to Condition 1, it is no longer necessary, as soft and weak conditions are already covered.

Current Condition 3 indicates the original intent of this chapter to apply to voluntary retrofits in areas of relatively high seismicity. While the provisions were not written originally for SWOF buildings in areas of lower seismicity, they may be used for those buildings. Further, the limitation to SDC C-E no longer applies now that this chapter is referenced from the body of the IEBC as an option for buildings in any seismic design category.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: SEARER-EB8-A401.2.DOC

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: This proposal was approved as it cleans up the scope of Appendix A4 by removing extraneous language.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Gary J. Ehrlich, PE, representing National Association of Home Builders (NAHB), requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

A401.2 Scope. The provisions of this chapter shall apply to all existing Occupancy Group R-1 and R-2 buildings in Seismic Design Category C, D or E of wood construction or portions thereof where the structure has a soft, weak, or open-front wall line, and there exists one or more stories above.

Commenter's Reason: The purpose of this public comment is to restore the scope of Appendix A4 to moderate- and high-seismic regions. Light-frame wood structures in Seismic Design Category A and B are typically governed by wind loads, not seismic loads. Soft or weak-story, and open-front wall behaviors are unique to seismic events. Where failures of light-frame structures in wind events have occurred, it is due either to a lack of sufficient code-compliant shear walls to resist the basic wind forces, or due to failure of an opening (such as a garage door or plate glass window) that results in an internal pressurization failure.

We note the ASCE 7 seismic provisions for horizontal and vertical irregularities only limit soft-story and weak-story conditions in Seismic Design Categories D through F. The provisions do limit extreme weak-story conditions in Seismic Design Category B and C. However, the limitation is waived if the seismic forces are increased for the purposes of the design. But, as noted above, in Seismic Design Category B wind forces will govern the design. Therefore, there is no need to specially address a condition for a building in low-seismic regions that would never cause a failure of that building.

To avoid any possibility the provisions of this Appendix could be required for a light-frame structure in Seismic Design Category B, the original scope limiting the use of these provisions in Seismic Design Categories C, D, and E should be restored.

Final Action: AS AM AMPC____ D

EB56-09/10
A402

Proposed Change as Submitted

Proponent: David Bonowitz, SE, National Council of Structural Engineers Associations, Code Advisory Committee, Existing Buildings Subcommittee (NCSEA EBS)

Revise definition as follows:

A402
DEFINITIONS

EXPANSION ANCHOR. ~~An approved mechanical fastener placed in hardened concrete that is designed to expand in a self-drilled or pre-drilled hole of a specified size and engage the sides of the hole in one or more locations to develop shear and/or tension resistance to applied loads without grout, adhesive, or drypack.~~ An approved post-installed anchor, inserted into a pre-drilled hole in existing concrete or masonry, that transfers loads to or from the concrete or masonry by direct bearing or friction or both.

Reason: This proposal is editorial. The proposed definition is consistent with that now used in ACI 318 Appendix D and other ICC-ES resources.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: BONOWITZ-EB12- A402-EXPANSION ANCHOR.DOC

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: This proposal was approved as it revises the definition of "Expansion anchor" in Appendix A4 to be consistent with ACI 318, Appendix D. This is also consistent with the committee's action on EB 50-09/10.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

David Bonowitz, SE, representing the National Council of Structural Engineers Associations, Code Advisory Committee, Existing Buildings Subcommittee (NCSEA EBS) requests Disapproval.

Commenter's Reason: NCSEA EBS recommends disapproval of this well-intentioned proposal for the following reasons: We are the proponent of EB56. As discussed at the hearings in Baltimore, EB65 is the preferred proposal. Both EB56 and EB65 were approved as submitted. To avoid confusion, EB56 should now be disapproved so that EB65 can be implemented.

Final Action: AS AM AMPC____ D

EB72-09/10
Appendix C (New)

Proposed Change as Submitted

Proponent: T. Eric Stafford, PE, Institute for Business and Home Safety

Add a new appendix as follows:

APPENDIX C
GUIDELINES FOR WIND RETROFIT OF EXISTING BUILDINGS

The provisions contained in this appendix are not mandatory unless specifically referenced in the adopting ordinance.

CHAPTER C1
GABLE END RETROFIT FOR HIGH WIND AREAS

SECTION C101
GENERAL

C101.1 Intent and purpose. The provisions of this chapter provide prescriptive methods for selected structural retrofitting of existing buildings. Compliance with these provisions will not always meet the requirements for new construction in the *International Building Code* or the *International Residential Code*. The provisions of this chapter are intended to provide methods for strengthening existing buildings to increase the building's resistance to wind loads.

C101.2 Scope. The following prescriptive methods are intended for applications where the gable end wall framing is provided by a wood gable end wall truss or a conventionally framed rafter system. The retrofits are appropriate for wall studs oriented with the wide face parallel to or perpendicular to the gable end surface. Gable ends to be strengthened shall be permitted to be retrofitted using methods prescribed by this chapter.

SECTION C102
DEFINITIONS

ANCHOR BLOCK. A piece of lumber secured to horizontal braces and filling the gap between existing framing members for the purpose of restraining horizontal braces from movement perpendicular to the framing members.

COMPRESSION BLOCK. A piece of lumber used to restrain in the compression mode (force directed towards the interior of the attic) an existing or retrofit stud. It is attached to a horizontal brace and bears directly against the existing or retrofit stud.

CONVENTIONALLY FRAMED GABLE END. A gable end framed with studs whose faces are perpendicular to the gable end wall.

HORIZONTAL BRACE. A piece of lumber used to restrain both compression and tension loads applied by a retrofit stud. It is typically installed horizontally on the top of attic floor framing members (truss bottom chords or ceiling joists) or on the bottom of pitched roof framing members (truss top chord or rafters).

HURRICANE TIES. Manufactured metal connectors designed to provide uplift and lateral restraint for roof framing members.
NAIL PLATE. A manufactured metal plate made of galvanized steel with factory punched holes for fasteners. A nail plate may have the geometry of a strap.

RETROFIT. The voluntary process of strengthening or improving buildings or structures, or individual components of buildings or structures for the purpose of making existing conditions better serve the purpose for which they were originally intended or the purpose that current building codes intend.

RETROFIT STUD. A lumber member used to structurally supplement an existing gable end wall stud.

RIGHT ANGLE BRACKET. A galvanized metal right angle bracket listed by the manufacturer for the material into which they will be attached, masonry (concrete or CMU) or wood.

STUD-TO-PLATE CONNECTOR. A manufactured metal connector designed to connect studs to plates.

TRUSS GABLE END. An engineered factory made truss or site built truss that incorporates factory installed or field installed vertical studs with their faces parallel to the plane of the truss

SECTION C103
MATERIALS OF CONSTRUCTION

C103.1 Existing materials. All existing wood materials that will be part of the retrofit work (trusses, rafters, ceiling joists, top plates, wall studs, etc.) shall be in sound condition and free from defects or damage that substantially reduces the load-carrying capacity of the member. Any wood materials found to be damaged or deteriorated shall be strengthened or replaced with new materials to provide a net dimension of sound wood equivalent to its undamaged original dimensions.

C103.2 New materials. All new materials shall comply with the requirements of the *International Building Code* or the *International Residential Code* as applicable.

C103.3. Material specifications for retrofits. Materials for retrofitting gable end walls shall comply with Sections C103.3.1 through C103.6

C103.3.1 Anchor blocks, compression blocks, and horizontal braces. Anchor blocks, compression blocks, and horizontal braces shall be lumber nominally 2 inch by at least 4 inch wide.

C103.3.2 Nail plate. Nail plates shall be of minimum 20 gauge thickness.

C103.3.3 Retrofit stud. Retrofit studs shall be made of nominal 2-inch lumber.

C103.3.4 Right angle bracket. Right angle brackets shall have a minimum capacity of 350 for uplift and lateral load conditions.

C103.3.5 Stud-to-plate connector. Stud-to-plate connectors shall have a minimum capacity of 500 pounds for uplift.

C103.3.6 Truss gable end. Gable end trusses shall be spaced no greater than 24-iches on center.

C103.4 Metal plate connectors, straps and anchors. Metal plate connectors, plates, straps and anchors shall be a product approved for connecting wood-to-wood or wood-to-concrete as appropriate. Straps and nail plates shall be manufactured from galvanized steel with a minimum thickness of 20 gauge. Nail plates shall have holes sized for a minimum of 8d nails.

C103.5 Twists in straps. Straps shall be permitted to be twisted or bent where they transition between framing members or connection points. Straps shall be bent only once at a given location though it is permissible that they be bent or twisted at multiple locations along their length.

C103.6 Fasteners. Fasteners shall meet the requirements of Sections C103.6.1 and Section C103.6.2, and shall be permitted to be screws or nails meeting the minimum length requirement shown in figures and specified in tables. Fastener spacing shall meet the requirements of Section C103.6.3.

C103.6.1 Screws. Screws shall be a minimum #8 size with head diameters no less than 0.28 inches. Screw lengths shall be no less than indicated in the Figures and in Tables. Permissible screws include deck screws and wood screws. Screws shall have at least 1 inch of thread. Fine threaded screws or drywall screws shall not be permitted. Screws shall be chosen with the appropriate diameter such that the shank adjacent to the head fits through the hole in the strap.

C103.6.2 Nails. Unless otherwise indicated in the provisions or drawings, where fastener lengths are indicated in Figures and Tables. as 1-¼ inches, 8d common nails with shank diameter 0.131 inches and head diameters no less than 0.28 inches shall be permitted. Unless otherwise indicated in the provisions or drawings, where fasteners lengths are indicated in Figures and Tables. as 3 inches, 10d common nails with shank diameter of 0.148 inches and head diameters no less than 0.28 inches shall be permitted.

C103.6.3 General fastener spacing. Fastener spacing for shear connections of lumber-to-lumber shall meet the requirements shown in Figure C103.6.3 and the following conditions.

C103.6.3.1 General fastener spacing. Fastener spacing shall meet the following conditions except as provided for in Section C103.6.3.3

The distance between fasteners and the edge of lumber that is less than 3-1/2 inches deep in the direction of the fastener length shall be a minimum of 3/4 inches.

1. The distance between fasteners and the edge of lumber that is more than 2 inches thick in the direction of the fastener length shall be a minimum of ½ inches.
2. The distance between a fastener and the end of lumber shall be a minimum of 2-½ inches.
3. The distance between fasteners parallel to the grain (center-to-center) shall be a minimum of 2-1/2 inches.
4. The distance between fasteners perpendicular to the grain (center-to-center) in lumber that is less than 3-1/2 inches deep in the direction of the fastener length shall be 1 inch.
5. The distance between fasteners perpendicular to the grain (center-to-center) in lumber that is more than 2 inches thick in the direction of the fastener length shall be ½ inch.

C103.6.3.2 Wood-to-wood connections of two members each 2 inch or less thick. Wood-to-wood connections fastener spacing shall meet the following conditions.

1. The distance between fasteners parallel to grain (center-to-center) shall be a minimum of 2-1/2 inches.
2. The distance between fasteners across grain (center-to-center) shall be a minimum of 1 inch.
3. For wood-to-wood connections of lumber at right angles, fasteners shall be spaced a minimum of 2-1/2 inches parallel to the grain and 1 inch perpendicular to the grain in any direction.

C103.6.3.3 Metal connectors to wood connections. Metal connectors to wood connections shall meet the following conditions.

1. Fastener spacing to edge or ends of lumber shall be as dictated by the prefabricated holes in the connectors and the connectors shall be installed in accordance with the manufacturer.
2. Fasteners in 1-1/4 inch wide metal straps that are installed on the 1-1/2 inch broad face of lumber shall be a minimum 1/4 inches from either edge of the lumber. Consistent with Section C103.6.3.1 fasteners shall be allowed to be spaced according to the fastener holes fabricated into the strap.
3. Fasteners in metal nail plates shall be spaced a minimum of ½ inches across wood grain and a minimum of 1-1/2 inches parallel to wood grain.

SECTION C104
RETROFITTING GABLE END WALLS TO ENHANCE WIND RESISTANCE

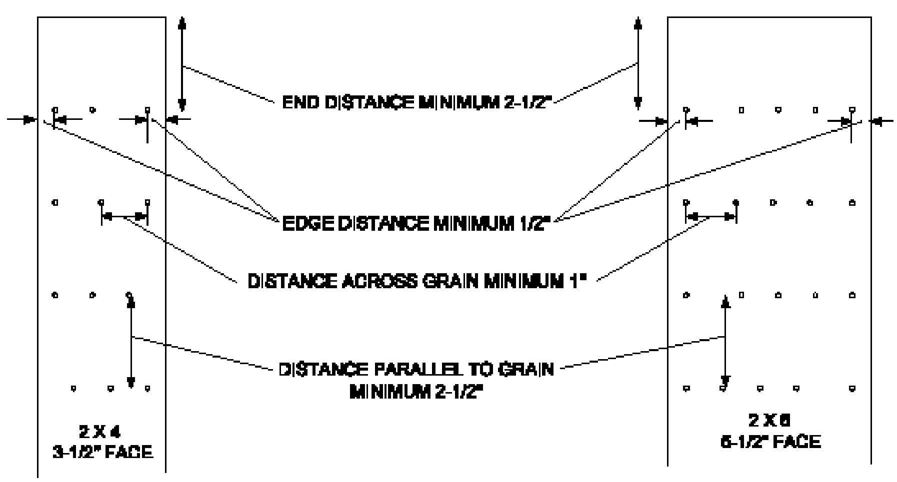

FIGURE C103.6.3
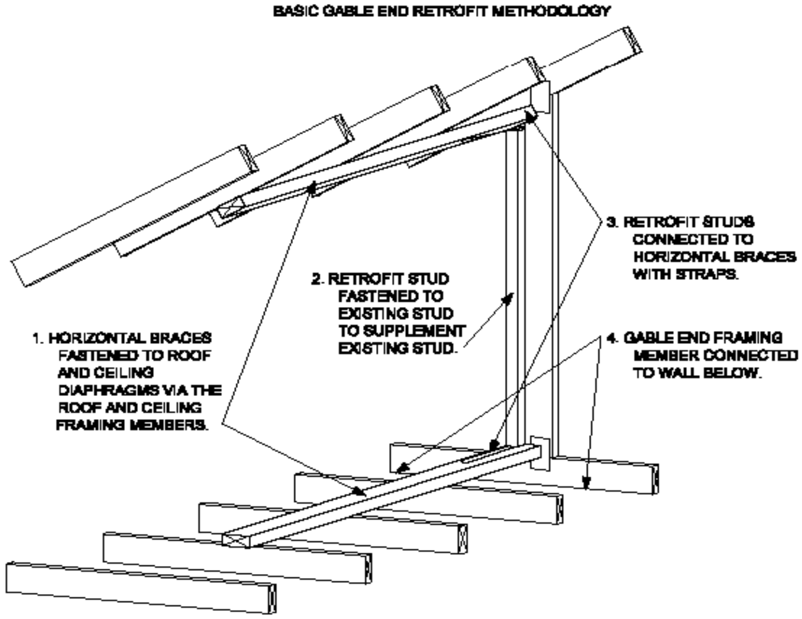
FASTENER SPACINGS FOR LUMBER TO LUMBER CONNECTIONS
OPERATING IN SHEAR PARALLEL TO GRAIN

SECTION C104
RETROFITTING GABLE END WALLS TO ENHANCE WIND RESISTANCE

C104.1 General. These prescriptive methods of retrofitting are intended to increase the resistance of existing gable end construction for out-of-plane wind loads resulting from high wind events. The ceiling diaphragm shall be comprised of minimum ½ inch thick drywall, minimum nominal 3/8 inch thick wood structural panels, or plaster. An overview isometric drawing of one kind of gable end retrofit to improve wind resistance is shown in Figure C104.1.1.

FIGURE C104.1.1
BASIC GABLE END RETROFIT METHODOLOGY



THIS FIGURE SHOWS A TRUSS GABLE END.
THE METHODOLOGY FOR A CONVENTIONALLY FRAMED GABLE END IS SIMILAR.
THE NUMBERS INDICATE A TYPICAL SEQUENCE OF INSTALLATION.
IN ORDER TO SHOW STRAPS COMPRESSION BLOCKS ARE NOT SHOWN.

C104.2 Horizontal braces. Horizontal braces shall be installed approximately perpendicular to the roof and ceiling framing members at the location of each existing gable end stud greater than 3 feet in length. Unless it is adjacent to an omitted horizontal brace location, horizontal braces shall be minimum 2x4 dimensional lumber as defined in Section C103.3. A single horizontal brace is required at the top and bottom of each gable end stud for Retrofit Configuration A, B, or C and two horizontal braces are required for Retrofit Configuration D. Maximum heights of gable end wall studs and associated retrofit studs for each Retrofit Configuration shall not exceed the values listed in Table C104.2. Horizontal braces shall be oriented with their broad faces across the roof or ceiling framing members, be fastened to a minimum of three framing members, and extend at least 6 feet measured perpendicularly from the gable end plus 2-1/2 inches beyond the last top chord or bottom chord member (rafter or ceiling joist) from the gable end as shown in Figure C104.2(1), Figure C104.2(2), Figure C104.2(3), and Figure C104.2(4).

TABLE C104.2
STUD LENGTH LIMITATIONS BASED ON EXPOSURE AND DESIGN WIND SPEED

Exposure Category	**Maximum 3-Sec Gust** Basic Wind Speed [a]	**Maximum Height of Gable End Retrofit Stud** [b]			
C	110	8'-0"	11'-3"	14'-9"	16'-0"
C	120	7'-6"	10'-6"	13'-6"	16'-0"
C	130	7'-0"	10'-0"	12'-3"	16'-0"
C	140	7'-0"	10'-0"	12'-3"	16'-0"
C	150	6'-6"	8"-9"	11'-0"	16'-0"
B	110	8'-0"	12'-3"	16'-0"	N/R [c.]
B	120	8'-0"	11'-3"	14'-9"	16'-0"
B	130	8'-0"	11'-3"	14'-9"	16'-0"
B	140	7'-6"	10'-6"	13'-6"	16'-0"
B	150	7'-0"	10'-0"	12'-3"	16'-0"
	Retrofit Configuration -->	A	B	C	D

For SI: 1 Inch = 25.4mm, 1 Foot = 304.8mm

a. Interpolation between given wind speeds not permitted.

b. Existing gable end studs less than or equal to 3'-0" in height shall not require retrofitting.

c. N/R = Not Required. Configuration C is acceptable to 16'-0" maximum height.

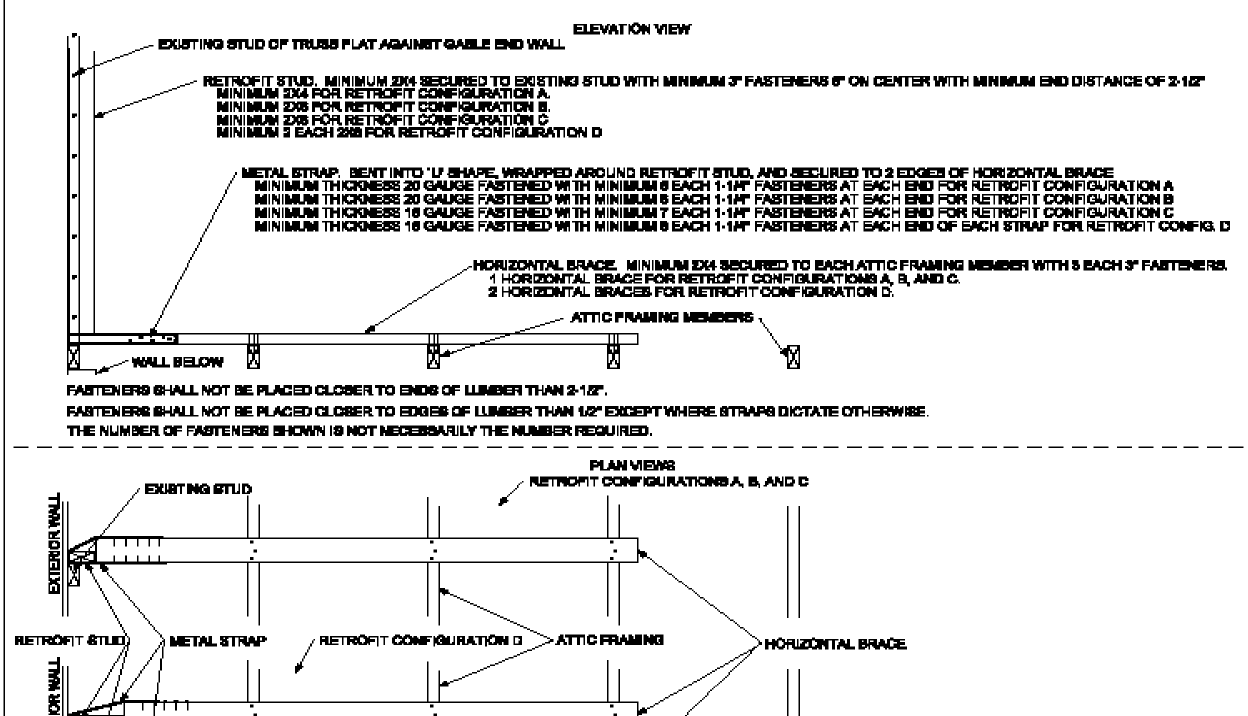

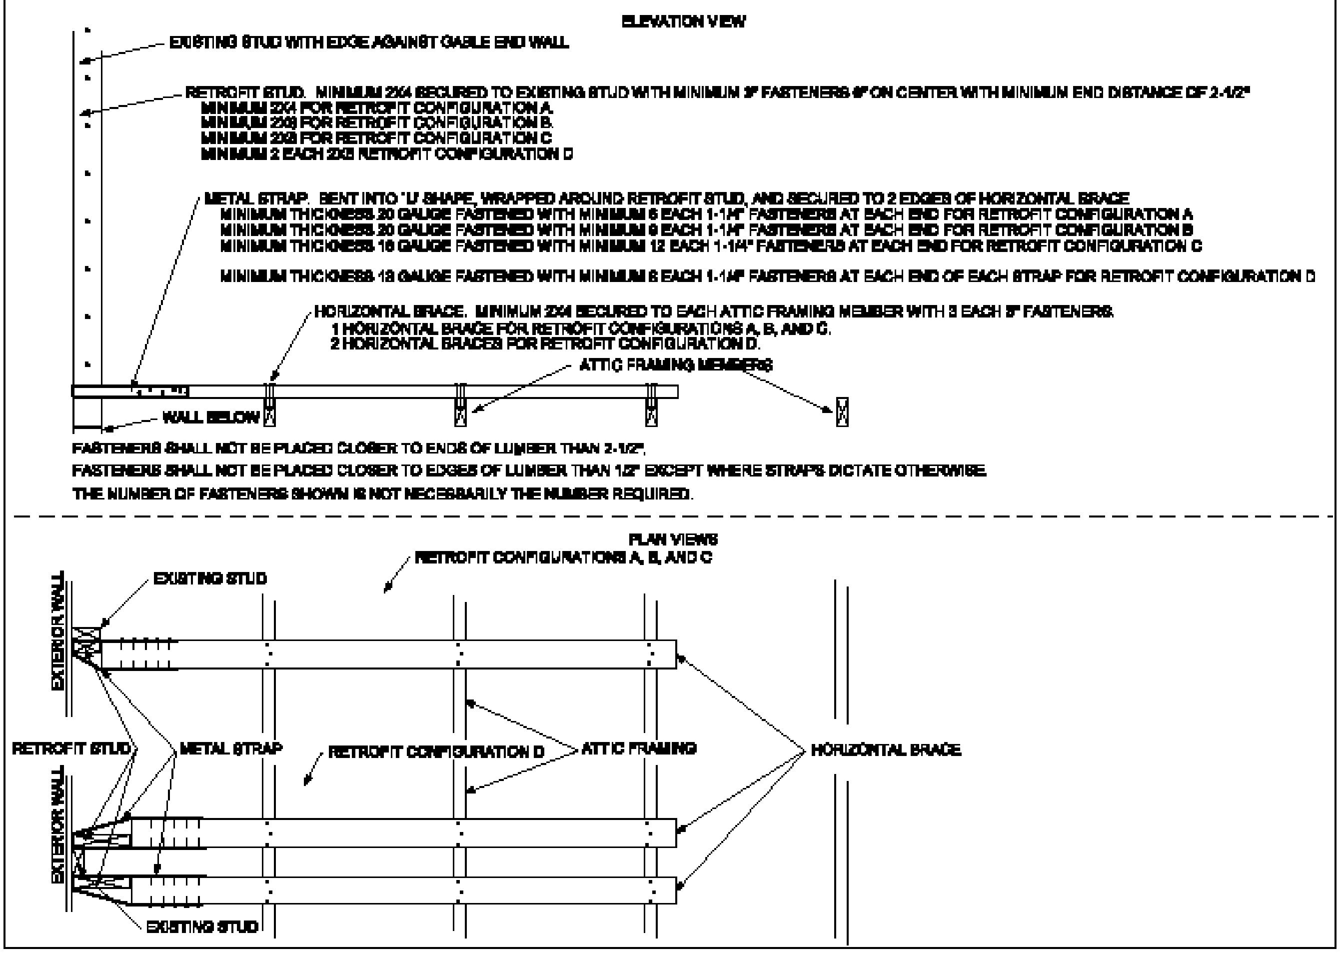

FIGURE C104.2 (4)
CONVENTIONALLY FRAMED GABLE END. U-BENT STRAP

C104.2.1 Existing gable end studs. If the spacing of existing vertical gable end studs in conventionally framed or the truss gable ends is greater than 24 inches, a new stud and corresponding horizontal braces shall be installed such that the maximum spacing between existing and added studs shall be no greater than 24 inches. Additional gable end wall studs shall not be required at locations where their length would be 3 feet or less. Each end of each required new stud shall be attached to the existing roof framing members (truss top chord or rafter and truss bottom chord or ceiling joist) using a minimum of two 3 inch toenail fasteners (#8 wood screws or 10d nails) and a metal connector with minimum uplift capacity of 175 pounds, or nail plates with a minimum of four 1-1/4 inch long fasteners (#8 wood screws or 8d nails).

C104.2.2 Main method of installation. Each horizontal brace shall be fastened to each existing roof or ceiling member that it crosses using three 3-inch long fasteners (#8 wood screws or 10d nails) as indicated in Figure C104.2(1) and Figure C104.2(3) for trusses and Figure C104.2(2) and Figure C104.2(4) for conventionally framed gable end walls. Alternative methods for providing horizontal bracing of the gable end studs as provided in Sections C104.2.3 through C104.2.9 shall be allowed in lieu of this primary installation method.

C104.2.3 Omitted horizontal brace. Where impediments, other permanently attached obstacles or conditions exist that prevent installation in accordance with Section C104.2.2 horizontal braces may be omitted for height limitations corresponding to Retrofit Configurations A and B as defined in Table C104.2 provided installation is as indicated in Figure C104.2.3 and provided all of the following conditions are met. This method is not allowed for Retrofit Configurations C or D.

1. There shall be at least two horizontal braces on each side of an omitted horizontal brace or at least one horizontal brace if it is the end horizontal brace. Omitted horizontal braces must be separated by at least two horizontal braces even if that location is comprised of two retrofit studs and two horizontal braces.

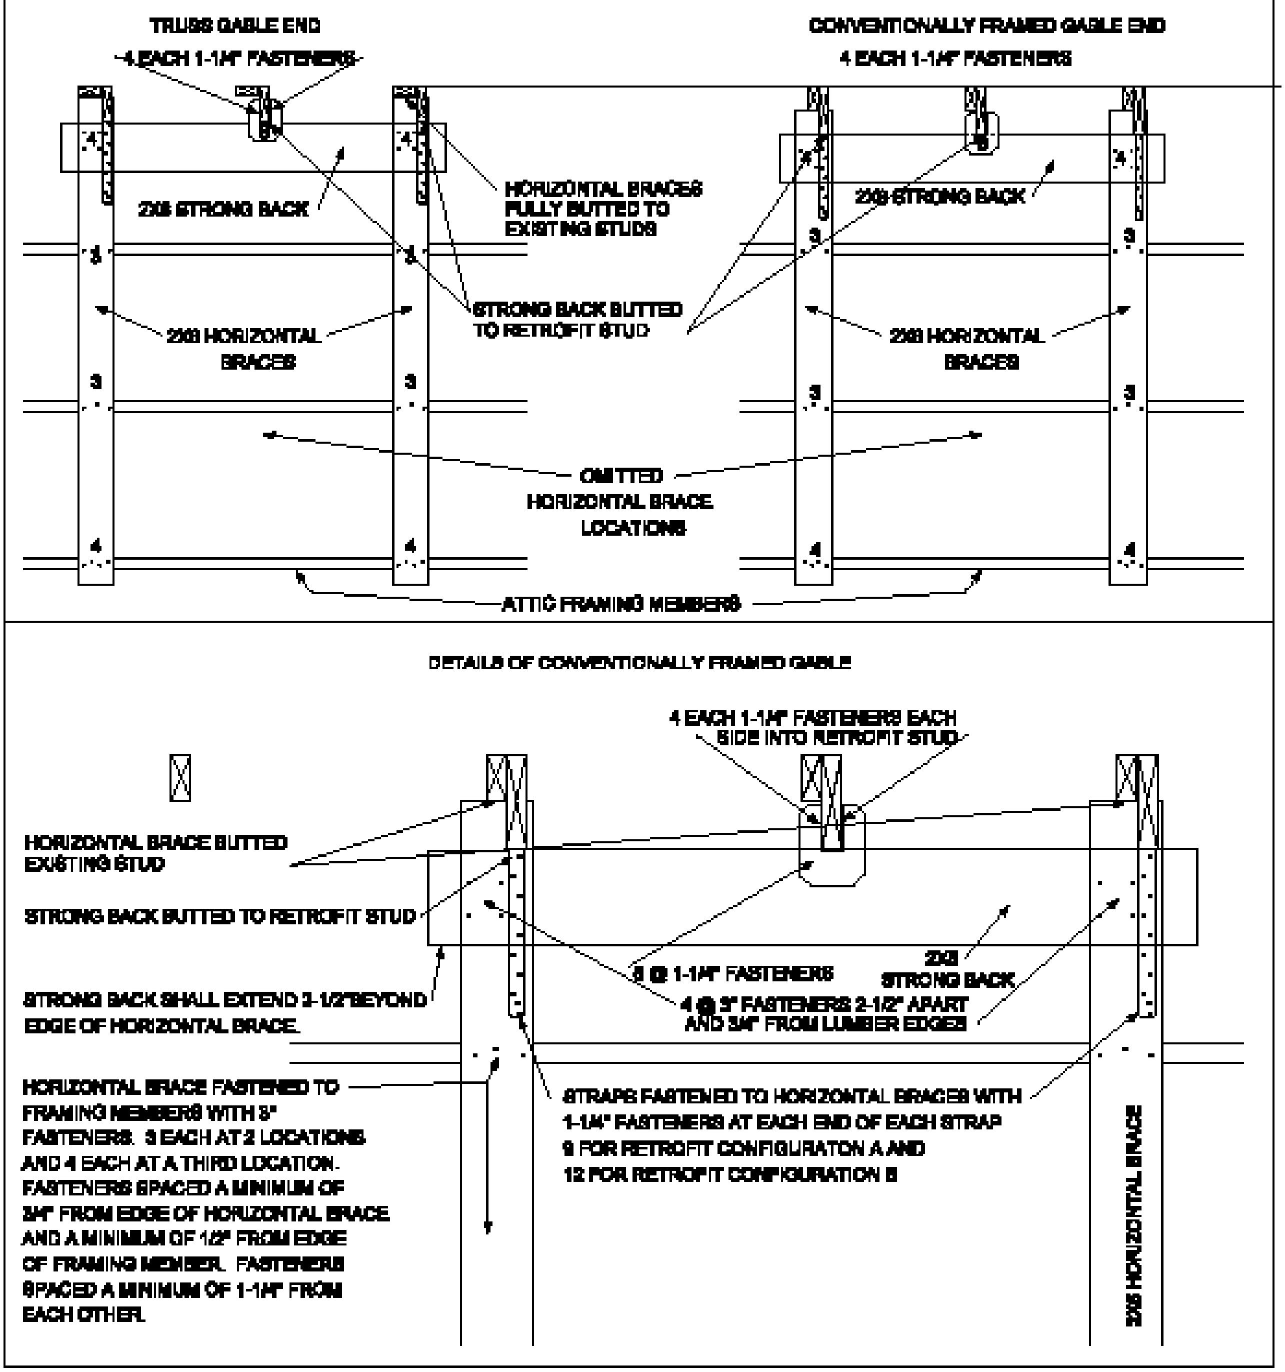
2. Horizontal braces adjacent to the omitted horizontal brace shall be 2x6 lumber, shall butt against the existing studs, and shall be fastened to each existing roof or ceiling member that it crosses using three 3-inch long fasteners (#8 wood screws or 10d nails). For Retrofit Configuration B, 4 fasteners shall be required on at least one of the connections between the horizontal brace and the existing roof and ceiling framing members. Fasteners shall be spaced a minimum of ¾" from the edges of the horizontal braces and a minimum of 1-3/4" from adjacent fasteners.
3. Where the existing studs on each side of an omitted horizontal brace have their broad face perpendicular to the gable end wall, the retrofit studs at those locations and the retrofit stud at the omitted horizontal brace locations shall be sized such that they protrude a minimum of 3-1/2 inches beyond the interior edge of the existing studs for both Retrofit Configurations A and B. The edges of the three retrofit studs facing towards the interior of the attic shall be aligned such that they are the same distance from the gable end wall.
4, Retrofit studs shall be fastened to existing studs in accordance with Section C104.3.
5. Retrofit studs adjacent to the omitted horizontal brace shall be fastened to the horizontal brace using straps in accordance with Table C104.4.1 consistent with the size of the retrofit stud. The method applicable to Table C104.4.2 is not allowed.
6. A strong back made of minimum of 2x8 lumber shall be placed parallel to the gable end and shall be located on and span between horizontal braces on the two sides of the omitted horizontal brace and shall extend beyond each horizontal braces by a minimum of 2-1/2 inches. The strong back shall be butted to the three retrofit studs. The strong back shall be attached to each of the horizontal braces on which it rests with 5 3 inch long fasteners (#8 screws or 8d nails). Those fasteners shall be spaced a minimum of 3/4 inch from any edge of lumber and shall be spaced a minimum of 2-1/2 inch from each other. Additional compression blocks shall not be required at locations where a strong back butts against a retrofit stud.
7. The retrofit stud at the location of the omitted horizontal braces shall be fastened to the strong back using a connector with minimum uplift capacity of 800 pounds and installed such that this capacity is oriented in the direction perpendicular to the gable end wall.
8. The use of shortened horizontal braces using the alternative method of Section C104.2.5 is not allowable for horizontal braces adjacent to the omitted horizontal braces.
9. Horizontal braces shall be permitted to be interrupted in accordance with Section C104.2.8.

FIGURE C104.2.3
OMITTED HORIZONTAL BRACE

OVERVIEW

PLAN VIEWS
RETROFIT CONFIGURATION A AND B ONLY
NOT ALLOWED FOR RETROFIT CONFIGURATION C OR D

UNIDENTIFIED NUMBERS INDICATE THE NUMBER OF FASTENERS.



C104.2.4 Omitted horizontal brace and retrofit stud. Where impediments, other permanently attached obstacles or conditions exist that prevent installation in accordance with Section C104.2.2 or Section C104.2.3 by not permitting installation of horizontal braces, then retrofit studs and horizontal brace shall be permitted to be omitted from those locations by installation of ladder assemblies for Retrofit Configurations A and B as defined in Table C104.2 provided all of the following conditions are met**.** This method is not allowed for Retrofit Configurations C or D.

1. No more than two ladder assemblies are permitted on a single gable end.
2. There shall be at least two retrofit studs and horizontal brace assemblies on either side of the locations where the retrofit studs and horizontal bracing members are omitted (no two ladder braces bearing on a single retrofit stud).
3. Where the existing studs on each side of an omitted horizontal brace have their broad face parallel to the gable end wall the retrofit studs at those locations and the retrofit stud at the omitted horizontal brace locations shall be 2x6 lumber for Retrofit Configuration A and 2x8 lumber for Retrofit Configuration B.
4, Horizontal braces adjacent to the omitted horizontal brace shall be 2x6 lumber and be fastened to each existing roof or ceiling member crossed using three 3-inch long fasteners (#8 wood screws or 10d nails) as indicated in Figure C104.2(1) and Figure C104.2(3) for trusses and Figure C104.2(2) and Figure C104.2(4) for conventionally framed gable end wall. For Retrofit Configuration B, 4 fasteners shall be required on at least one of the connections between the horizontal brace and the existing roof and ceiling framing members.
5. Ladder rungs /shall be provided across the location of the omitted retrofit studs as indicated in Figure C104.2.4(1) for trusses and Figure C104.2.4(2) for conventionally framed gable end walls.
6. Ladder rungs shall be made of at a minimum 2x4 lumber oriented with their broad face horizontal and spaced a maximum of 16-inches on center vertically.
7. Where ladder rungs cross structural members such as the existing stud at the omitted retrofit stud location or gable end vent framing they shall be connected to each other with a metal connector with a minimum capacity of 175 pounds in the direction perpendicular to the gable end wall.
8. Notching of the ladder rungs shall not be permitted unless the net depth of the framing member is a minimum of 3-1/2 inches.

C104.2.5 Short horizontal brace. Where impediments, other permanently attached obstacles or conditions exist that prevent installation in accordance with Sections C104.2.2, C104.2.3, or C104.2.4 by not permitting extension of horizontal braces across the existing framing members such that they can be fastened to a minimum of three framing members and extend at least 6-feet from the gable end wall plus 2-1/2 inches beyond the last roof or ceiling framing member, the horizontal braces may be shortened provided installation is as indicated in Figure C104.2.5 and provided that all of the following conditions are met.

1. The horizontal brace shall be installed across a minimum of two framing spaces, extend a minimum of 4-feet from the gable end wall plus 2-1/2 inches beyond the last roof or ceiling framing member, and be fastened to each existing framing member with three 3-inch long fasteners (#8 wood screws or 10d nails),
2. An anchor block shall be fastened to the side of the horizontal brace in the second framing space from the gable end wall as shown in Figure C104.2.5. The anchor block lumber shall have a minimum edge thickness of 1-1/2 inches and the depth shall be as a minimum the depth of the existing roof or ceiling framing member. Six 3-inch long fasteners (#8 wood screws or 10d nails) shall be used to fasten the anchor block to the side of the horizontal brace.
3. The anchor block shall extend into the space between the roof or ceiling framing members a minimum of one-half the depth of the existing framing members at the location where the anchor block is installed. The anchor block shall be installed tightly between the existing framing members such that the gap at either end shall not exceed $^1/_8$ inch.
4. The use of omitted horizontal braces using the method of Section C104.2.3 adjacent to a short horizontal brace as defined in this section is not permitted.

C104.2.6 Installation of horizontal braces onto webs or vertical members of trusses. Where existing conditions preclude installation of horizontal braces on truss top or bottom chords they shall be permitted to be installed on truss webs or vertical members of trusses provided all of the following conditions are met.

1. Horizontal braces shall be installed as close to the top or bottom chords as practical without altering the truss or any of its components and not more than three times the depth of the truss member to which it would ordinarily be attached.
2. A racking block, comprised of an anchor block meeting the definition of anchor block of Section C102 or comprised of minimum 15/32 inch plywood or 7/16 inch OSB, shall be fastened to the horizontal brace in the second framing space from the gable end wall. The racking block shall extend towards the diaphragm (roof or

ceiling as appropriate) so that the edge of the racking block closest to the diaphragm is within ½ the depth of the existing framing member from the diaphragm surface. They shall be attached to horizontal braces using six fasteners (#8 wood screws or 10d nails) of sufficient length to provide 1-1/2 inches of penetration into the horizontal brace.

3. Racking blocks can be fastened to any face or edge of horizontal braces between each web or truss vertical posts to which a horizontal brace is attached. Racking blocks can be on alternate sides of horizontal braces. Racking blocks shall be installed tightly between the lumber of truss members or truss plates such that the gap at either end shall be a maximum of 1/8 inch.

C104.2.7 Alternative method of installation of horizontal braces at truss ridges. Where impediments such as truss plates or access for installation of fasteners limits or restricts installation of horizontal braces near the peak of the roof, ridge ties may be added to provide support for the required horizontal brace. The top of added ridge tie members shall be installed a maximum of 16-inches below the existing ridge line or 4 inches below impediments. The added ridge tie members shall be installed across a minimum of three bays, but no less than 6-feet from the gable end wall plus 2-1/2 inches beyond the last roof or ceiling framing member to permit fastening of the horizontal brace. A minimum of a 2x4 member shall be used for each ridge tie and fastening shall consist of two 3-inch long wood screws, four 3 inch long 10d nails or two 3-1/2 inch long 16d nails driven through and clinched at each top chord or web member intersected by the ridge tie as illustrated in Figure C104.2.7.

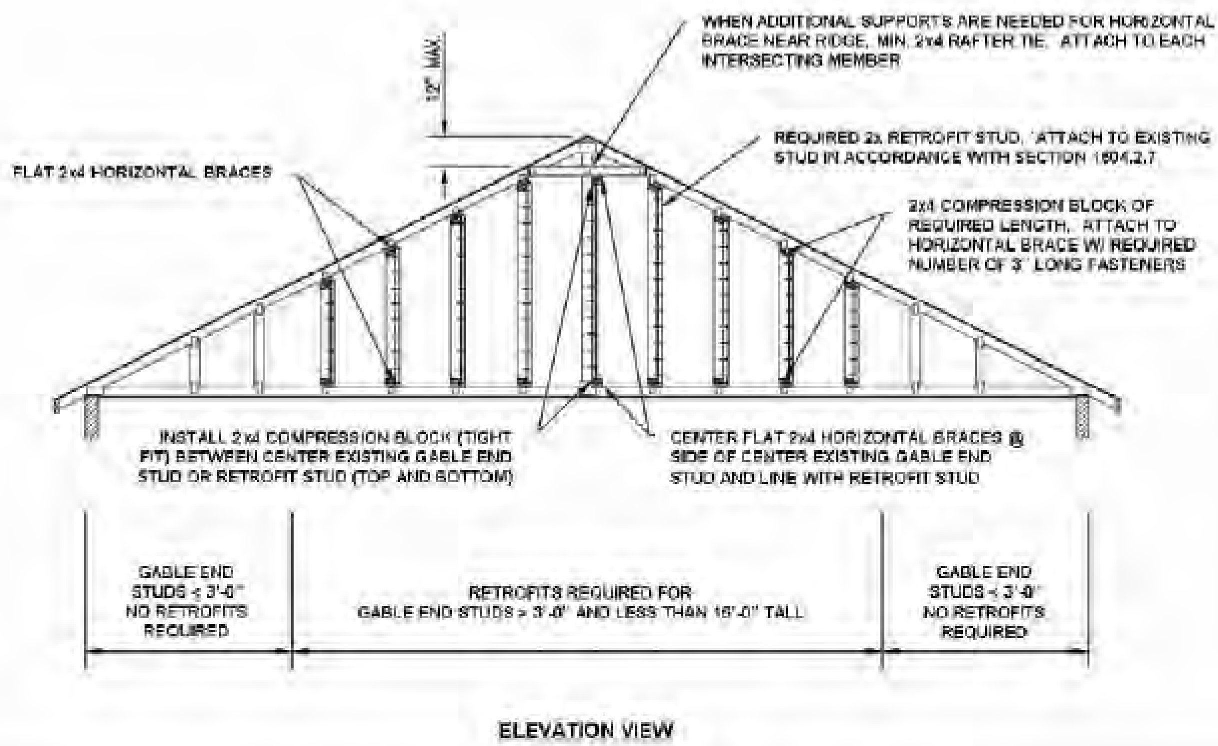


FIGURE C104.2.7 DETAIL OF RETROFIT TIE INSTALLATION

C104.2.8 Interrupted horizontal braces. Where impediments, other permanently attached obstacles or conditions exist that prevent installation of horizontal braces in accordance with Section C104.2.2 by preventing the installation of a single continuous horizontal braces then horizontal braces shall be permitted to be interrupted using the methods shown in Figure C104.2.8(1), Figure C104.2.8(2), and Figure C104.2.8(3). For interruptions that occur in the attic framing space closest to the gable end, nine 3 inch fasteners shall be used to connect each section of the interrupted horizontal braces. For interruptions that occur in the second attic space from the gable end, six 3 inch fasteners shall be used to connect each section of the interrupted horizontal braces. For interruptions that occur in the attic framing space farthest from the gable end, three 3 inch fasteners shall be used to connect each section of the interrupted horizontal braces. Horizontal braces shall be continued far enough to allow connections to three existing roof framing members as shown in Figure C104.2.8(1), Figure C104.2.8(2), or Figure C104.2.8(3). Fasteners shall be spaced in accordance with Section C103.6.3. Lumber members used to form horizontal braces shall be the same width and depth as required for an un-interrupted member.

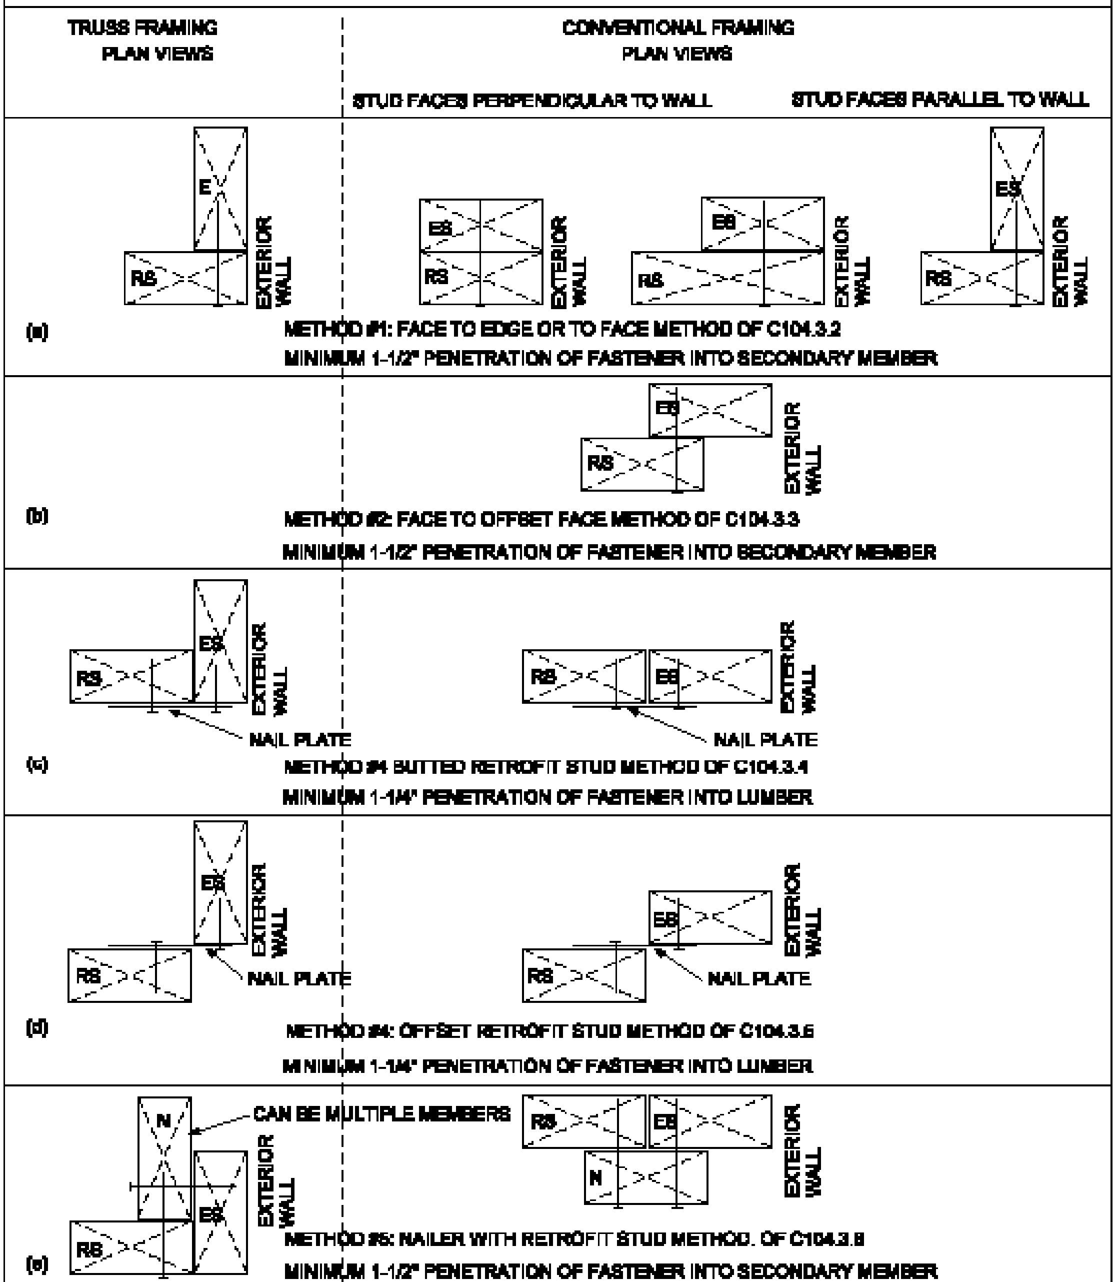
C104.2.9 Piggyback trusses. Piggyback trusses (trusses composed of two members one above the other) shall be permitted to be retrofitted if either of the following cases is true. 1. The existing studs in both the upper truss and the lower truss to which wall sheathing, panel siding, or other wall facade are attached are sufficiently in line that retrofit studs can be installed and connections made between the two with retrofit stud(s). 2. The same as condition 1 except the studs in the upper truss are not sufficiently in line with ones below and the existing studs in the upper truss are 3 feet or shorter. For condition 1 both the lower stud and the upper stud shall be retrofitted using the methods of Section C104.2. For condition two the retrofit stud shall be connected to the lower studs using the methods of Section C104.2 and be continuous from the bottom horizontal brace to the top horizontal brace. No connection is required between the retrofit stud and the upper stud. In both conditions the bottom chord of the piggy back truss section shall be fastened to each retrofit stud using a connector with minimum axial capacity of 175 pounds.

C104.3 Retrofit studs. Retrofit studs shall be installed in accordance with Section C104.3.1 and using one of the five methods of Sections C104.3.2, through C104.3.6 and as shown in Figure C104.3. For the Retrofit Configuration derived from Table C104.2 the size of retrofit studs shall be as indicated in Table C104.4.1 or Table C104.4.2. Retrofit studs shall extend from the top of the lower horizontal brace to the bottom of the upper horizontal brace except that a maximum gap of 1/8 inch is allowed at the bottom and ½ inch at the top. Where wall sheathing, panel siding, or other wall façade is fastened to gable end studs not manufactured into a truss, i.e. are field installed, retrofit studs shall be applied to those field installed studs in accordance with Section C104.2.1.

FIGURE C104.3

METHODS OF INSTALLING RETROFIT STUDS



THE FIGURES DO NOT REFLECT THE NUMBER OF REQUIRED FASTENERS OR SHOW HORIZONTAL BRACES OR STRAPS.
FASTENERS SHALL BE PLACED MAXIMUM 6" ON CENTER AND A MINIMUM OF 2-1/2" FROM ENDS.
3" FASTENERS CAN BE INSTALLED FROM EITHER SIDE OF LUMBER AS LONG AS THERE IS 1-1/2" FASTENER PENETRATION.
ES INDICATES AN EXISTING STUD. RS INDICATES A RETROFIT STUD. N INDICATES A NAILER.

C104.3.1 Fastening. Where nail plates are not used, retrofit studs shall be attached to existing studs using 3 inch fasteners at a maximum of 6 inches on center but no closer than 2-1/2 inches on center with fasteners no closer than 2-1/2 inches to the ends of members~~.~~

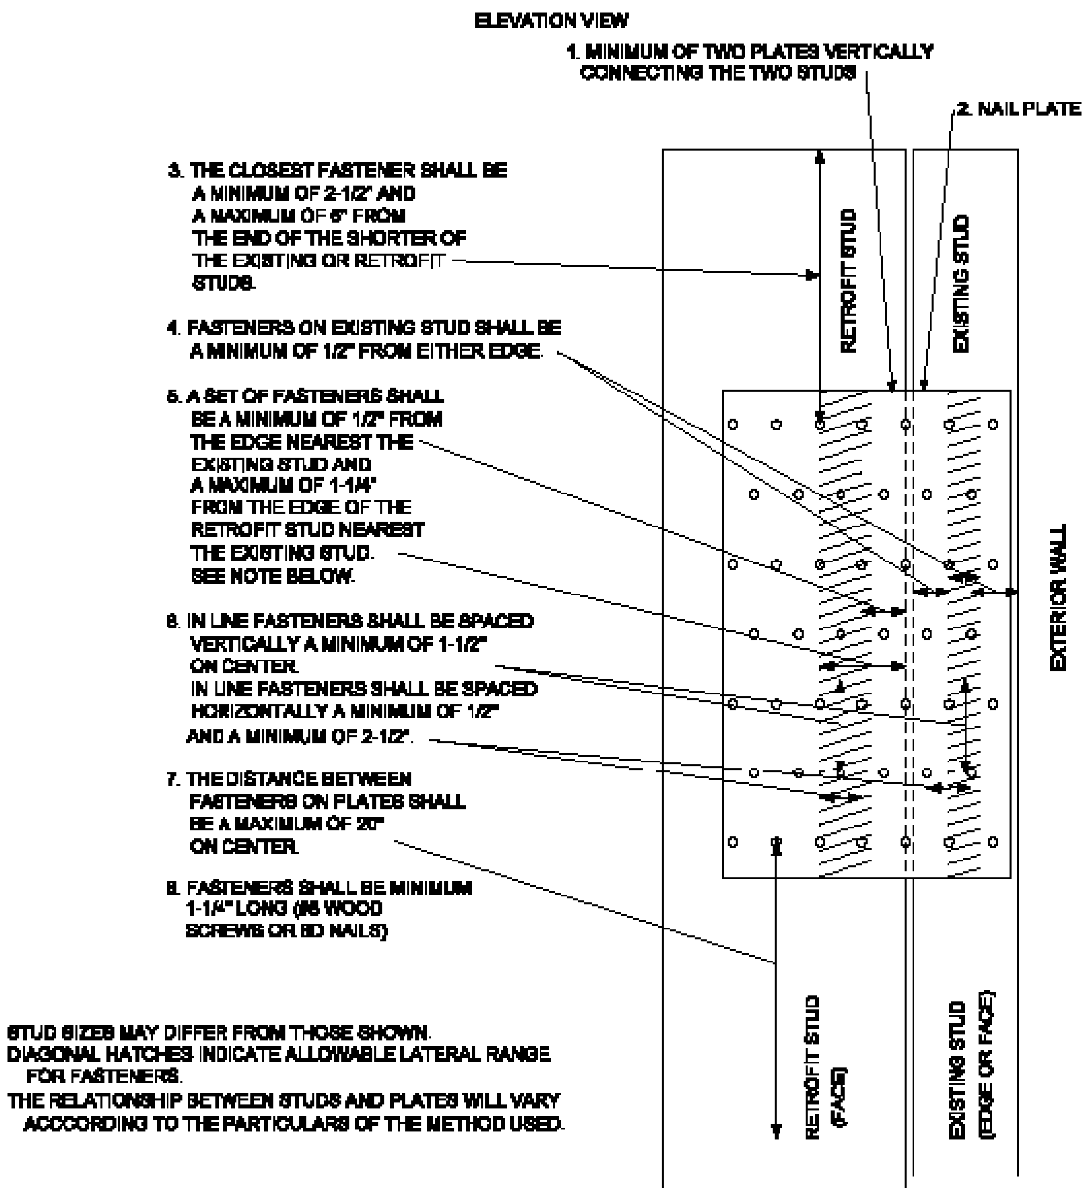
C104.3.2 Method #1: Face to edge or to face method. Retrofit studs shall be installed immediately adjacent to existing (Section C104.2) gable end wall studs as indicated in Figure C104.3(a). The retrofit studs shall overlap the edge or side of the existing stud by a minimum of 1-1/4 inches. Fasteners shall be installed as specified in Section C104.3.1.

C104.3.3 Method #2: Face to face offset method. Retrofit studs shall be installed against the face of existing studs as indicated in Figure C104.3(b) such that the faces overlap a minimum of 1-1/2 inch and the edge distance to fasteners is no less than ¾ inch. Fasteners shall be installed as specified in Section C104.3.1.

C104.3.4 Method #3: Butted retrofit stud method. Provided that all of the following fastening conditions are met retrofit studs shall be permitted to be butted by their edge or face to existing studs with the addition of nail plates as indicated in Figure C104.3(c) and Figure C104.3.4.

1. The 1-1/2 inch edge of retrofit studs shall be installed against the 1-1/2 inch or the broad face of existing studs.
2. A minimum of two nail plates shall be used.
3. Fasteners used to secure nail plates to studs shall be a minimum 1-1/4 inch long (#8 wood screws or 8d nails).
4. Fasteners placed in nail plates shall be a minimum of 2-1/2 inches along the length of lumber. A fastener shall be placed in nail plates a maximum of 6 inches from the ends of the shorter stud.
5. Fasteners shall be placed a minimum of a ½ inch from the edges of the studs. Fasteners shall be placed a maximum of 1-1/2 inches from the abutting vertical edges of existing studs and retrofit studs.
6. There shall be at least 3 fasteners through nail plates into all existing and retrofit studs to which it is attached.
7. Where there are 3 fasteners through nail plates onto a single existing or retrofit stud then nail plates shall be spaced a maximum of 15 inches on center.
8. Where there are more than 3 fasteners though nail plates onto a single existing or retrofit stud then nail plates shall be spaced a maximum of 20 inches on center.
9. In line fasteners used to secure nail plates shall be spaced vertically a minimum of 1-1/2 inches on center. Staggered fasteners used to secure nail plates shall be spaced horizontally a minimum of ½ inches.

FIGURE C104.3.4
NAIL PLATE FASTENING



C104.3.5 Method #4: Offset retrofit stud method. Where retrofit studs are placed as indicated in Figure C104.3(d) retrofit studs shall be permitted to be offset from existing studs by use of nail plates such that the vertical corner of a retrofit stud shall be placed at the vertical corner of an existing stud as indicated in Figure C104.3(d) and Figure C104.3.4 provided the fastening conditions of Section C104.3.4 are met.

C104.3.6 Method #5: Nailer with retrofit stud method. Retrofit studs and existing studs shall be permitted to be connected using non-continuous 2x4 nailers as indicated in Figure C104.3(e) provided the following conditions are met.

1. Both the existing stud and the retrofit stud shall be butted to nailers and both shall be fastened to the nailer with 3 inch long fasteners (#8 wood screws or 8d nails). Fasteners connecting each stud to the nailer shall be spaced 6 inches on center.
2. Fasteners into nailers from any direction shall be offset vertically by a minimum of 2-1/2 inches.
3. Fasteners into nailers shall be a minimum of 2-1/2 inches but not more than 6 inches from the end of the shorter of the existing stud and retrofit stud to which they are fastened.

C104.3.7 Reduced depth of retrofit studs. Retrofit studs may be reduced in depth by notching, tapering, or other methods at any number of locations along their length provided that all of the following conditions are met.

1. The retrofit stud to be reduced in depth shall be sized such that the remaining minimum depth of the member at the location of the notch (including cross cut kerfs) shall not be less than that required by Table C104.4.1 or Table C104.4.2.
2. The retrofit stud reduced in depth shall not be spliced within 12 inches of the location of notches. Splice members shall not be notched.
3. The vertical extent of notches shall not exceed 12 inches as measured at the depth of location of reduced depth.
4. A retrofit stud member reduced in depth shall be fastened to the side of the existing gable end wall studs in accordance with Section C104.3.1. Two additional 3 inch fasteners (#8 wood screws or 10d nails) shall be installed on each side of notches in addition to those required by Section C104.3.1.

C104.3.8 Retrofit stud splices. Retrofit studs greater than 8 feet in height may be field spliced in accordance with Figure C104.3.8.

C104.4 Connection between horizontal braces and retrofit studs. Connections between horizontal braces and retrofit studs shall comply with Section C104.4.1 or Section C104.4.2. Each retrofit stud shall be connected to the top and bottom horizontal brace members with a minimum of a 20 gauge 1-1/4 inch wide flat or coil metal strap with pre-punched holes for fasteners. Straps shall be fastened with 1-1/4 inch long fasteners (#8 wood screws or 8d nails) with the number of fasteners as indicated on Table C104.4.1 and Table C104.4.2. Fasteners shall be no closer to the end of lumber than 2-1/2 inches.

C104.4.1 L-bent strap method. Retrofit studs shall be connected to horizontal braces or to strong backs in accordance with Figure C104.2(1), Figure C104.2(2), or Figure C104.2.3, and shall comply with the following conditions.

1. A strap shall be applied to the edges of a retrofit stud nearest the gable end wall and to the face of horizontal braces using at each end of the strap the number of fasteners specified in Table C104.4.1. Straps shall be long enough so that each strap extends sufficient distance onto the vertical face of the retrofit stud that the fastener closest to the ends of the studs is a minimum of 2-1/2 inches from the end of the stud. Straps shall be allowed to be twisted to accommodate the transition between the tops of retrofit studs and horizontal bracings following roof pitches.
2. Compression blocks shall be installed on the horizontal braces directly against either the existing vertical gable end wall stud or the retrofit stud. Figure C104.2(1) (trusses) and Figure C104.2(2) (conventionally framed) show the installation of the compression block against the existing vertical gable end wall stud with the strap from the retrofit stud running beside the compression block. Compression blocks shall be allowed to be placed over straps. Compression blocks shall be fastened to the horizontal braces with at least the minimum number of 3 inch long fasteners (#8 wood screws or 10d nails) specified in Table C104.4.1. End and edge distances for fasteners shall be in accordance with Section C103.6.3.

TABLE C104.4.1
ELEMENT SIZING AND SPACING FOR L-BENT RETROFIT METHOD

	Retrofit Config.	Retrofit Config.	Retrofit Config.	Retrofit Config.
Retrofit Elements	A	B	C	D
Minimum size and number of Horizontal Braces	2x4	2x4	2x4	2 each 2x4
Minimum size and number of Retrofit Studs	2x4	2x6	2x8	2 each 2x8
Minimum number of fasteners connecting each end of straps to Retrofit Studs or to Horizontal Braces #8 screws or 10d nails 1-1/4" long	6	9	12	8 on each strap
Minimum number of fasteners to connect Compression Blocks to Horizontal Braces #8 screws or 10d nails 3" long	6	8	10	12

For SI: 1 Inch = 25.4mm, 1 Foot = 304.8mm

C104.4.2 U-bent strap method. Retrofit studs shall be connected to horizontal braces in accordance with Figure C104.2(3) or Figure C104.2(4), shall be limited to Retrofit Configurations A and B (Table C104.2), and shall comply with the following conditions.

1. Straps shall be of sufficient length to meet the requirements for the number of fasteners in accordance with Table C104.4.2 and to meet the end distance requirements of Section C103.6.3 shall be shaped around retrofit studs and fastened to the edges of horizontal braces. Straps shall wrap the back edge of the retrofit stud snuggly with a maximum gap of ¼ inches. Rounded bends of straps shall be allowed. One fastener shall be installed that connects each strap to the side of the associated retrofit stud.
2. The horizontal brace shall butt snugly against the retrofit stud with a maximum gap of ¼ inches.
3. Straps shall be allowed to be twisted to accommodate the transition between the tops of retrofit studs and horizontal braces that follow the roof pitch.

TABLE C104.4.2
ELEMENT SIZING AND SPACING FOR U-BENT RETROFIT METHOD

	Retrofit Config.	Retrofit Config.	Retrofit Config.	Retrofit Config.
Retrofit Elements	A	B	C	D
Minimum size and number of Horizontal Braces	2x4	2x4	2x4	2 each 2x4
Minimum size and number of Retrofit Studs	2x4	2x6	2x8	2 each 2x8
Minimum number of fasteners connecting Straps To each edge of Horizontal Braces #8 screws or 10d nails 1-1/4" long	6	7	7	6 on side of each strap

For SI: 1 Inch = 25.4mm, 1 Foot = 304.8mm

C104.5 Connection of gable end wall to wall below. The bottom chords or bottom members of wood framed gable end walls shall be attached to the wall below using one of the methods prescribed in Sections C104.5.1 or C104.5.2. The particular method chosen shall correspond to the framing system and type of wall construction encountered.

C104.5.1 Truss gable end wall. The bottom chords of the gable end wall in a truss gable shall be attached to the wall below using right angle brackets. A minimum of two fasteners shall be installed into the bottom chord. The right angle brackets shall be installed throughout the portion of the gable end where the gable end wall height is greater than 3 feet at the spacing specified in Table C104.5.1. Connection to the wall below shall be by one of the methods listed below:

1, For a wood frame wall below, a minimum of two fasteners shall be installed. The fasteners shall be of the same diameter and style specified by the bracket manufacturer and sufficient length to extend through the double top plate of the wall below.
2. For a concrete or masonry wall below without a sill plate, the type and number of fasteners into the wall shall be consistent with the bracket manufacturer's specifications for fasteners installed in concrete or masonry.
3. For a concrete or masonry wall below with a 2x sill plate, the fasteners into the wall below shall be of the diameter and style specified by the bracket manufacturer for concrete or masonry connections; but, long enough to pass through the wood sill plate and provide the required embedment into the concrete or masonry below. Alternatively, the bracket can be anchored to the sill plate using 4 each 1-1/2 inch long fasteners of the same type as specified by the bracket manufacturer for wood connections, provided that the sill plate is anchored to the wall on each side of the bracket by a 1/4-inch diameter masonry screw with a 2-3/4 inches of embedment into the concrete or masonry wall. A ¼ inch washer shall be placed under the heads of the masonry screws.

TABLE C104.5.1
SPACING OF RIGHT ANGLE BRACKETS

B	150	26-inches

a. See Section C102 for definition of right angle bracket.

C104.5.2 Conventionally framed gable end wall. Each stud in a conventionally framed gable end wall, throughout the length of the gable end wall where the wall height is greater than 3 feet, shall be attached to the bottom or sill plate using a stud to plate connector with minimum uplift capacity of 175 pounds. The bottom or sill plate shall then be connected to the wall below using one of the methods listed below:

1. For a wood frame wall below, the sill or bottom plate shall be connected to the top plate of the wall below using ¼ inch diameter lag bolt fasteners of sufficient length to penetrate the bottom plate of the upper gable end wall and extend through the bottom top plate of the wall below. A washer sized for the diameter of the lag bolt shall be placed under the head of each lag bolt. The fasteners shall be installed at the spacing indicated in Table C104.5.2.
2. For a concrete or masonry wall below, the sill or bottom plate shall be connected to the concrete or masonry wall below using ¼ inch diameter concrete or masonry screws of sufficient length to provide 2-3/4 inches of embedment into the top of the concrete or masonry wall. A washer sized for the diameter of the lag bolt shall be placed under the head of each lag bolt. The fasteners shall be installed at the spacing indicated in Table C104.5.2.

B	150	13-inches

Reason: This proposal, along with a similar proposal, is requesting the creation of a new set of Appendix chapters that are intended to provide guidance for retrofitting existing structures to strengthen their resistance to wind forces. These new proposed chapters are similar in scope to Appendix A which addresses seismic retrofits for existing buildings. We anticipate that, over time, additional retrofit methods will be provided in this Appendix chapter. These retrofits are voluntary, and as such may or may not meet the requirements of new construction. However, these voluntary measures will serve to better protect the public and reduce damage from high wind events.

The purpose of the proposed addition is to provide prescriptive means for retrofitting gable ends to resist high winds. This code addition will facilitate the retrofitting of gable ends without requiring site specific engineering for common applications, thus removing some of the obstacles that might impede this important retrofit in hurricane prone regions.

Reason for adding provisions for retrofitting gable ends

Gable end failures are one of the most common types of structural failures observed in hurricanes. They have been documented in most major hurricanes and in many weaker hurricanes.

The proposed code addition is intended to be a prescriptive approach to reduce retrofitting costs, facilitate retrofitting, minimize the need for engineering, and facilitate code review and inspection. The addition will provide standardized off the shelf methods that can be readily approved and easily inspected by building department personnel. Building departments can thus become creditable third party resources for authenticating retrofitting just as they do for other structural issues of buildings.

It should be recognized that almost no attempt to retrofit will actually weaken or compromise a building or subject surrounding buildings to risk, on the contrary all will benefit. The retrofitting is voluntary.

Reason for adding retrofit measures to the code

Because most America's buildings located in hurricane prone regions were not built to today's building codes standards, there is significant value added to the code if the retrofitting of buildings could be facilitated by the provision of prescriptive means. This would inherently reduce the cost of retrofitting. The need for structural retrofitting has been highlighted in the recent spate of hurricanes and the insurance crises that has developed in the coastal high wind areas of a number of states because of older buildings that do not meet current building code structural requirements. Clearly, it is in the public's health, welfare, and safety to facilitate retrofitting. Given the importance of retrofitting to the public, retrofitting of buildings should be encouraged and facilitated by removing as many impediments as possible. The code can actually facilitate and encourage retrofitting by providing prescriptive means. Such methods should encourage, facilitate, and reduce the cost of improving America's building stock.

Reason for location in code

The preferred approach is to add an appendix chapter that deals specifically with retrofitting of a voluntary nature. The advantage of this approach is that it easily allows for additional retrofit measures to be added without confusing code users by gable end retrofit being in the repair section and then changing its location to a separate chapter in a subsequent edition when more retrofit measures are added. Further by grouping retrofit measures into a separate chapter users will find them and perhaps even use the chapter as a catalog of potential retrofit measures. Additionally, grouping voluntary measures into a separate chapter, a chapter separate from mandatory measures, will make code administration less prone to confusion.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: STAFFORD-EB2-APP C-2.DOC

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: This proposal introduces guidelines for gable retrofits as an appendix. While no IEBC provision will send you to this appendix, jurisdictions will have it available to make that decision. This chapter addresses a recognized hazard and it has been utilized for a number of years in Florida's hurricane regions.

Assembly Action: **None**

Individual Consideration Agenda

These items are on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Gary Ehrlich, representing the National Association of Home Builders, requests Approval as Modified.

Modify the proposal as follows:

C101.1 Intent and purpose. The provisions of this chapter provide prescriptive methods for selected structural retrofitting of existing buildings~~. Compliance with these provisions will not always meet the requirements for new construction in the *International Building Code* or the *International Residential Code*. The provisions of this chapter are intended to provide methods for strengthening existing buildings~~ to increase the building's resistance to wind loads. Except as provided herein, other structural provisions of the *International Building Code* or the *International Residential Code* shall apply, as required.

C101.2 Scope. The following prescriptive methods are intended for applications where the gable end wall framing is provided by a metal plate connected gable end ~~wall truss~~frame or a conventionally framed gable end~~rafter system~~. The retrofits are appropriate for wall studs or webs spaced 24 inches on center maximum and oriented with the wide face either parallel ~~to~~ or perpendicular to the surface of the gable end~~ surface~~. Gable ends to be strengthened shall be permitted to be retrofitted using methods prescribed by this chapter.

RETROFIT STUD. A lumber member used to structurally supplement an existing gable end wall stud or gable end frame web.

~~**RIGHT ANGLE BRACKET.** A galvanized metal right angle bracket listed by the manufacturer for the material into which they will be attached, masonry (concrete or CMU) or wood.~~

~~TRUSS~~ GABLE END FRAME. A~~n engineered~~ factory ~~made truss~~ or site-fabricated frame, installed as a complete assembly,~~ built truss~~ that incorporates~~ factory installed or field installed~~ vertical webs~~ studs~~ with their faces parallel to the plane of the frame.~~ truss~~

C103.3. Material specifications for retrofits. Materials for retrofitting gable end walls shall comply with Table C103.3.~~Sections C103.3.1 through C103.6~~

TABLE C103.3
MATERIAL SPECIFICATIONS FOR RETROFITS[a]

Component	Minimum Size or Thickness	Minimum Material Grade	Minimum Capacity
Anchor blocks, compression blocks, and horizontal braces	2x4 nominal lumber	#2 Spruce-Pine-Fir or better	N/A
Nail plates	20 gauge thickness 8d minimum nail holes	Galvanized sheet steel	N/A
Retrofit studs	2x4 nominal lumber	#2 Spruce-Pine-Fir or better	N/A
Gusset angle	14 gage thickness	Galvanized sheet steel	350 pounds uplift and lateral load
Stud-to-plate connector	20 gage thickness	Galvanized sheet steel	500 pounds uplift
Metal plate connectors, straps, and anchors	20 gage thickness	Galvanized sheet steel	

N/A = Not applicable

a. Metal plate connectors, nail plates, stud-to-plate connectors, straps and anchors shall be products *approved* for connecting wood-to-wood or wood-to-concrete as appropriate.

~~**C103.3.1 Anchor blocks, compression blocks, and horizontal braces.** Anchor blocks, compression blocks, and horizontal braces shall be lumber nominally 2 inch by at least 4 inch wide.~~

~~**C103.3.2 Nail plate**. Nail plates shall be of minimum 20 gauge thickness.~~

~~**C103.3.3 Retrofit stud.** Retrofit studs shall be made of nominal 2-inch lumber.~~

~~**C103.3.4 Right angle bracket**. Right angle brackets shall have a minimum capacity of 350 for uplift and lateral load conditions.~~

~~**C103.3.5 Stud-to-plate connector**. Stud-to-plate connectors shall have a minimum capacity of 500 pounds for uplift.~~

~~**C103.3.6 Truss gable end.** Gable end trusses shall be spaced no greater than 24-iches on center.~~

~~**C103.4 Metal plate connectors, straps and anchors.** Metal plate connectors, plates, straps and anchors shall be a product approved for connecting wood-to-wood or wood-to-concrete as appropriate. Straps and nail plates shall be manufactured from galvanized steel with a minimum thickness of 20 gauge. Nail plates shall have holes sized for a minimum of 8d nails.~~

C103.6 Fasteners. Fasteners shall meet the requirements of Table C103.6, Section~~s~~ C103.6.1 and Section C103.6.2, and shall be permitted to be screws or nails meeting the minimum length requirement shown in the figures and specified in the tables of this Appendix. Fastener spacing shall meet the requirements of Section C103.6.3.

TABLE C103.6
NAIL AND SCREW REQUIREMENTS

Fastener Type	Minimum Shank Diameter	Minimum Head Diameter	Minimum Fastener Length
#8 screws		0.28 inches	1-1/4 inches
8d common nails	0.131 inches	0.28 inches	2-1/2 inches
10d common nails	0.148 inches	0.28 inches	3 inches

C103.6.1 Screws. ~~Screws shall be a minimum #8 size with head diameters no less than 0.28 inches.~~ Unless otherwise indicated in this Appendix, s~~S~~crew sizes and lengths shall be~~ no less than indicated~~ in accordance with ~~the Figures and in~~ Table~~s~~ C103.6. Permissible screws include deck screws and wood screws. Screws shall have at least 1 inch of thread. Fine threaded screws or drywall screws shall not be permitted. Screws shall be chosen with the appropriate diameter such that the shank adjacent to the head fits through the hole in the strap.

C103.6.2 Nails. Unless otherwise indicated in this Appendix, nail sizes and lengths shall be in accordance with Table C103.6.~~the provisions or drawings, where fastener lengths are indicated in Figures and Tables. as 1-¼ inches, 8d common nails with shank diameter 0.131 inches and head diameters no less than 0.28 inches shall be permitted. Unless otherwise indicated in the provisions or drawings, where fasteners lengths are indicated in Figures and Tables. as 3 inches, 10d common nails with shank diameter of 0.148 inches and head diameters no less than 0.28 inches shall be permitted.~~

C104.2 Horizontal braces. Horizontal braces shall be installed~~ approximately~~ perpendicular to the roof and ceiling framing members at the location of each existing gable end stud greater than 3 feet in length. Unless it is adjacent to an omitted horizontal brace location, horizontal braces shall be minimum 2x4 dimensional lumber as defined in Section C103.3. A single horizontal brace is required at the top and bottom of each gable end stud for Retrofit Configuration A, B, or C. Two~~ and two~~ horizontal braces are required at the top and bottom of each gable end stud for Retrofit Configuration D. Maximum heights of gable end wall studs and associated retrofit studs for each Retrofit Configuration shall not exceed the values listed in Table C104.2. Horizontal braces shall be oriented with their broad faces across the roof or ceiling framing members, be fastened to a minimum of three framing members, and extend at least 6 feet measured perpendicularly from the gable end plus 2-1/2 inches beyond the last top chord or bottom chord member (rafter or ceiling joist) from the gable end as shown in Figure C104.2(1), Figure C104.2(2), Figure C104.2(3), and Figure C104.2(4).

C104.2.1 Existing gable end studs. If the spacing of existing vertical gable end studs~~ in conventionally framed or the truss gable ends~~ is greater than 24 inches, a new stud and corresponding horizontal braces shall be installed such that the maximum spacing between existing and added studs shall be no greater than 24 inches. Additional gable end wall studs shall not be required at locations where their length would be 3 feet or less. Each end of each required new stud shall be attached to the existing roof framing members (truss top chord or rafter and truss bottom chord or ceiling joist) using a minimum of two 3 inch toenail fasteners (#8 wood screws or 10d nails) and a metal connector with minimum uplift capacity of 175 pounds, or nail plates with a minimum of four 1-1/4 inch long fasteners (#8 wood screws or 8d nails).

C104.2.2 Main method of installation. Each horizontal brace shall be fastened to each existing roof or ceiling member that it crosses using three 3-inch long fasteners (#8 wood screws or 10d nails) as indicated in Figure C104.2(1) and Figure C104.2(3) for trusses and Figure C104.2(2) and Figure C104.2(4) for conventionally framed gable end walls. Alternative methods for providing horizontal bracing of the gable end studs as provided in Sections C104.2.3 through C104.2.9 shall be allowed~~ in lieu of this primary installation method~~.

C104.2.3 Omitted horizontal brace. Where~~ impediments, other permanently attached obstacles or~~ conditions exist that prevent installation in accordance with Section C104.2.2 horizontal braces shall be permitted to ~~may~~ be omitted for height limitations corresponding to Retrofit Configurations A and B as defined in Table C104.2 provided installation is as indicated in Figure C104.2.3 and provided all of the following conditions are met. This method is not allowed for Retrofit Configurations C or D.

1. *(No changes)*
2. Horizontal braces adjacent to the omitted horizontal brace shall be 2x6 lumber, shall butt against the existing studs, and shall be fastened to each existing roof or ceiling member~~ that it~~ crossed~~s~~ using three 3-inch long fasteners (#8 wood screws or 10d nails). For Retrofit Configuration B, four~~ 4~~ fasteners shall be required on at least one of the connections between the horizontal brace and the existing roof and ceiling framing members. Fasteners shall be spaced a minimum of ¾" from the edges of the horizontal braces and a minimum of 1-3/4" from adjacent fasteners.
3. Where the existing studs on each side of an omitted horizontal brace have their broad face perpendicular to the gable end wall, the retrofit studs at those locations and the retrofit stud at the omitted horizontal brace locations shall extend~~ be sized such that they protrude~~ a minimum of 3-1/2 inches beyond the interior edge of the existing studs for both Retrofit Configurations A and B. The edges of the three retrofit studs facing towards the interior of the attic shall be aligned such that they are the same distance from the gable end wall.
4. *(No changes)*
5. *(No changes)*
6. A strong~~-~~back made of minimum of 2x8 lumber shall be placed parallel to the gable end and shall be located on and span between horizontal braces on the two sides of the omitted horizontal brace and shall extend beyond each horizontal brace~~s~~ by a minimum of 2-1/2 inches. The strong back shall be butted to the three retrofit studs. The strong~~-~~back shall be attached to each of the horizontal braces on which it rests with five~~ 5~~ 3 inch long fasteners (#8 screws or 8d nails). The~~ Those~~ fasteners shall have~~ be spaced~~ a minimum~~ of~~ 3/4 inch ~~from any~~ edge distance~~ of lumber~~ and~~ shall be spaced~~ a minimum~~ of~~ 2-1/2 inch spacing between fasteners~~ from each other~~. Additional compression blocks shall not be required at locations where a strong-back butts against a retrofit stud.
7. *(No changes)*

8. *(No changes)*
9. *(No changes)*

C104.2.4 Omitted horizontal brace and retrofit stud. Where ~~impediments, other permanently attached obstacles or~~ conditions exist that prevent installation in accordance with Section C104.2.2 or Section C104.2.3 ~~by not permitting installation of horizontal braces~~, then retrofit studs and horizontal braces shall be permitted to be omitted from those locations by installation of ladder assemblies for Retrofit Configurations A and B as defined in Table C104.2 provided all of the following conditions are met**.** This method is not allowed for Retrofit Configurations C or D.

1. *(No changes)*
2. *(No changes)*
3. *(No changes)*
4. Horizontal braces adjacent to the omitted horizontal brace shall be 2x6 lumber and be fastened to each existing roof or ceiling member crossed using three 3-inch long fasteners (#8 wood screws or 10d nails) as indicated in Figure C104.2(1) and Figure C104.2(3) for gable end frames ~~trusses~~ and Figure C104.2(2) and Figure C104.2(4) for conventionally framed gable end walls. For Retrofit Configuration B, four ~~4~~ fasteners shall be required on at least one of the connections between the horizontal brace and the existing roof and ceiling framing members.
5. Ladder rungs ~~/~~shall be provided across the location of the omitted retrofit studs as indicated in Figure C104.2.4(1) for gable end frames~~trusses~~ and Figure C104.2.4(2) for conventionally framed gable end walls.
6. Ladder rungs shall be ~~made of at a~~ minimum 2x4 lumber oriented with their broad face horizontal and spaced a maximum of 16 ~~-~~inches on center vertically.
7. Where ladder rungs cross wall framing ~~structural~~ members ~~such as the existing stud at the omitted retrofit stud location or gable end vent framing~~ they shall be connected to the wall framing members ~~each other~~ with a metal connector with a minimum capacity of 175 pounds in the direction perpendicular to the gable end wall.
8. *(No changes)*

C104.2.5 Short horizontal brace. Where ~~impediments, other permanently attached obstacles or~~ conditions exist that prevent installation in accordance with Sections C104.2.2, C104.2.3, or C104.2.4 ~~by not permitting extension of horizontal braces across the existing framing members such that they can be fastened to a minimum of three framing members and extend at least 6-feet from the gable end wall plus 2-1/2 inches beyond the last roof or ceiling framing member~~, the horizontal braces shall be permitted to ~~may~~ be shortened provided installation is as indicated in Figure C104.2.5 and ~~provided that~~ all of the following conditions are met.

1. The horizontal brace shall be installed across a minimum of two framing spaces, extend a minimum of 4 ~~-~~feet from the gable end wall plus 2-1/2 inches beyond the farthest ~~last~~ roof or ceiling framing member from the gable end, and be fastened to each existing framing member with three 3-inch long fasteners (#8 wood screws or 10d nails),
2. *(No changes)*
3. *(No changes)*
4. *(No changes)*

C104.2.6 Installation of horizontal braces onto webs ~~or vertical members~~ of trusses. Where existing conditions preclude installation of horizontal braces on truss top or bottom chords they shall be permitted to be installed on truss webs ~~or vertical members of trusses~~ provided all of the following conditions are met.

1. Horizontal braces shall be installed as close to the top or bottom chords as practical without altering the truss or any of its components and not more than three times the depth of the truss member to which it would ordinarily be attached.
2. A racking block, comprised of an anchor block meeting the definition of anchor block of Section C102 or comprised of minimum 15/32 inch plywood or 7/16 inch OSB, shall be fastened to the horizontal brace in the second framing space from the gable end wall. The racking block shall extend towards the ~~diaphragm (~~roof or ceiling diaphragm ~~as appropriate)~~ so that the edge of the racking block closest to the diaphragm is within ½ the depth of the existing framing member from the diaphragm surface. The racking block ~~They~~ shall be attached to horizontal braces using six fasteners (#8 wood screws or 10d nails) of sufficient length to provide 1-1/2 inches of penetration into the horizontal brace.
3. Racking blocks shall be permitted to ~~can~~ be fastened to any face or edge of horizontal braces between each web or truss vertical posts to which a horizontal brace is attached. Racking blocks shall be permitted to ~~can~~ be on alternate sides of horizontal braces. Racking blocks shall be installed tightly between the lumber of truss members or truss plates such that the gap at either end shall be a maximum of 1/8 inch.

C104.2.7 Alternative method of installation of horizontal braces at truss ridges. Where conditions exist that ~~impediments such as truss plates or access for installation of fasteners~~ limit~~s~~ or restrict~~s~~ installation of horizontal braces near the peak of the roof, ridge ties shall ~~may~~ be added to provide support for the required horizontal brace. The top of added ridge tie members shall be installed a maximum of 12 inches~~16 inches~~ below the existing ridge line or 4 inches below impediments. ~~The added ridge tie members shall be installed across a minimum of three bays, but no less than 6-feet from the gable end wall plus 2-1/2 inches beyond the last roof or ceiling framing member to permit fastening of the horizontal brace.~~ A minimum ~~of a~~ 2x4 nominal member shall be used for each ridge tie and fastening shall consist of two 3-inch long wood screws, four 3 inch long 10d nails or two 3-1/2 inch long 16d nails driven through and clinched at each top chord or web member intersected by the ridge tie as illustrated in Figure C104.2.7.

C104.2.8 Interrupted horizontal braces. Where ~~impediments, other permanently attached obstacles or~~ conditions exist that prevent ~~installation of horizontal braces in accordance with Section C104.2.2 by preventing~~ the installation of a ~~single~~ continuous horizontal brace~~s~~ the~~n~~ horizontal brace~~s~~ shall be permitted to be interrupted using the methods shown in Figure C104.2.8(1), Figure C104.2.8(2), and Figure C104.2.8(3). For interruptions that occur in the attic framing space closest to the gable end, nine 3 inch fasteners shall be used to connect each section of the interrupted horizontal braces. For interruptions that occur in the second attic space from the gable end, six 3 inch fasteners shall be used to connect each section of the interrupted horizontal braces. For interruptions that occur in the attic framing space farthest from the gable end, three 3 inch fasteners shall be used to connect each section of the interrupted horizontal braces. Horizontal braces shall be continued far enough to allow connections to three existing roof framing members as shown in Figure C104.2.8(1), Figure C104.2.8(2), or Figure C104.2.8(3). Fasteners shall be spaced in accordance with Section C103.6.3. ~~Lumber members used to form~~ H~~h~~orizontal braces shall be the same width and depth as required for an uninterrupted member.

C104.2.9 Piggyback ~~trusses~~Gable End Frames. Piggyback ~~trusses~~ gable end frames (~~trusses~~ gable end frames ~~composed~~ built in ~~of~~ two ~~members~~ sections one above the other) shall be permitted to be retrofitted if either of the following cases is true.

1. The existing studs in both the upper ~~truss~~ gable end frame and the lower gable end frame~~truss~~ to which wall sheathing, panel siding, or other wall covering~~facade~~ are attached are sufficiently in line that retrofit studs can be installed and connections made between the two with retrofit stud(s).
2. The ~~same as condition 1 except the~~ existing studs in the upper ~~truss~~ frame are not sufficiently in line with the studs in the frame~~ones~~ below and the existing studs in the upper frame ~~truss~~ are 3 feet or shorter.

For C~~c~~ondition 1 both the lower stud and the upper stud shall be retrofitted using the methods of Section C104.2. For C~~c~~ondition 2 ~~two~~ the retrofit stud shall be connected to the lower studs using the methods of Section C104.2 and be continuous from the bottom horizontal brace to the top horizontal brace. No connection is required between the retrofit stud and the upper stud. In both conditions the bottom chord of the piggyback truss section shall be fastened to each retrofit stud using a connector with minimum axial capacity of 175 pounds.

C104.3 Retrofit studs. Retrofit studs shall be installed in accordance with Section C104.3.1 ~~and~~ using one of the five methods of Sections C104.3.2, through C104.3.6 and as shown in Figure C104.3. For the Retrofit Configuration obtained ~~derived~~ from Table C104.2 the size of retrofit studs shall be as indicated in Table C104.4.1 or Table C104.4.2. Retrofit studs shall extend from the top of the lower horizontal brace to the bottom of the upper horizontal brace except that a maximum gap of 1/8 inch is allowed at the bottom and ½ inch at the top. Where wall sheathing, panel siding, or other wall façade is fastened to a conventionally framed gable end ~~studs not manufactured into a truss, i.e. are field installed~~, retrofit studs shall be applied ~~to those field installed studs~~ in accordance with Section C104.2.1.

FIGURE C104~~.2~~.3
METHOD OF INSTALLING RETROFIT STUDS

C104.3.2 Method #1: Face to edge or face to face method. Retrofit studs shall be installed immediately adjacent to existing ~~(Section C104.2)~~ gable end wall studs as indicated in Figure C104.3(a). The retrofit studs shall overlap the edge or side of the existing stud by a minimum of 1-1/4 inches. Fasteners shall be installed as specified in Section C104.3.1.

C104.3.4 Method #3: Butted retrofit stud method. Provided that all of the following fastening conditions are met retrofit studs shall be permitted to be butted by their edge ~~or face~~ to existing studs with the addition of nail plates as indicated in Figure C104.3(c) and Figure C104.3.4.

1. The narrow~~1-1/2 inch~~ edge of retrofit studs shall be installed against the narrow~~1-1/2 inch~~ or the wide~~broad~~ face of existing studs.
2. A minimum of two nail plates shall be used.
3. Fasteners used to secure nail plates to studs shall be a minimum 1-1/4 inch long (#8 wood screws or 8d nails).
4. Fasteners placed in nail plates shall have ~~be~~ a minimum end distance of 2-1/2 inches for both studs and ~~along the length of lumber. A fastener shall be placed in nail plates~~ a maximum end distance of 6 inches from the ends of the shorter stud.
5. Fasteners shall have ~~be placed~~ a minimum ~~of a~~ ½ inch edge distance ~~from the edges of the studs~~. Fasteners shall be placed a maximum of 1-1/2 inches from the abutting vertical edges of existing studs and retrofit studs.
6. There shall be at least 3 fasteners through nail plates into all existing and retrofit studs to which the nail plate ~~it~~ is attached.
7. Nail plates with ~~Where there are~~ 3 fasteners ~~through nail plates~~ onto a single existing or retrofit stud ~~then nail plates~~ shall be spaced a maximum of 15 inches on center.
8. Nail plates with ~~Where there are~~ more than 3 fasteners ~~though nail plates~~ onto a single existing or retrofit stud ~~then nail plates~~ shall be spaced a maximum of 20 inches on center.
9. ~~In line~~ F~~f~~asteners used to secure nail plates shall be spaced vertically a minimum of 1-1/2 inches on center. Staggered fasteners used to secure nail plates shall be spaced horizontally a minimum of ½ inches.

C104.3.5 Method #4: Offset retrofit stud method. ~~Where retrofit studs are placed as indicated in Figure C104.3(d)~~ R~~r~~etrofit studs shall be permitted to be offset from existing studs by use of nail plates as shown in Figure C104.3(d) such that the vertical corner of a retrofit stud shall align with ~~be placed at~~ the vertical corner of an existing stud as indicated in Figure C104.3(d) and Figure C104.3.4, and ~~provided~~ the fastening conditions of Section C104.3.4 shall be ~~are~~ met.

C104.4 Connection between horizontal braces and retrofit studs. Connections between horizontal braces and retrofit studs shall comply with Section C104.4.1 or Section C104.4.2. Each retrofit stud shall be connected to the top and bottom horizontal brace members with a minimum ~~of a~~ 20 gauge 1-1/4 inch wide flat or coil metal strap with pre-punched holes for fasteners. Straps shall be fastened with 1-1/4 inch long fasteners (#8 wood screws or 8d nails) with the number of fasteners as indicated in ~~on~~ Table C104.4.1 and Table C104.4.2. Fasteners shall be no closer to the end of lumber than 2-1/2 inches.

C104.5.1 ~~Truss gable end~~Gable end frame ~~wall~~. The bottom chords of the gable end frame~~wall in a truss gable~~ shall be attached to the wall below using gusset ~~right~~ angles ~~brackets~~. A minimum of two fasteners shall be installed into the bottom chord. The gusset ~~right~~ angles ~~brackets~~ shall be installed throughout the portion of the gable end where the gable end wall height is greater than 3 feet at the spacing specified in Table C104.5.1. Connection to the wall below shall be by one of the methods listed below:

1, For a wood frame wall below, a minimum of two fasteners shall be installed. The fasteners shall be of the same diameter and style specified by the gusset angle ~~bracket~~ manufacturer and sufficient length to extend through the double top plate of the wall below.

2. For a concrete or masonry wall below without a sill plate, the type and number of fasteners into the wall shall be consistent with the gusset angle ~~bracket~~ manufacturer's specifications for fasteners installed in concrete or masonry.
3. For a concrete or masonry wall below with a 2x sill plate, the fasteners into the wall below shall be of the diameter and style specified by the gusset angle ~~bracket~~ manufacturer for concrete or masonry connections; but, long enough to pass through the wood sill plate and provide the required embedment into the concrete or masonry below. Alternatively, the gusset angle ~~bracket~~ can be anchored to the sill plate using 4 each 1-1/2 inch long fasteners of the same type as specified by the gusset angle ~~bracket~~ manufacturer for wood connections, provided that the sill plate is anchored to the wall on each side of the gusset angle ~~bracket~~ by a 1/4-inch diameter masonry screw with a 2-3/4 inches of embedment into the concrete or masonry wall. A ¼ inch washer shall be placed under the heads of the masonry screws.

(Portions of the proposal not shown remain unchanged)

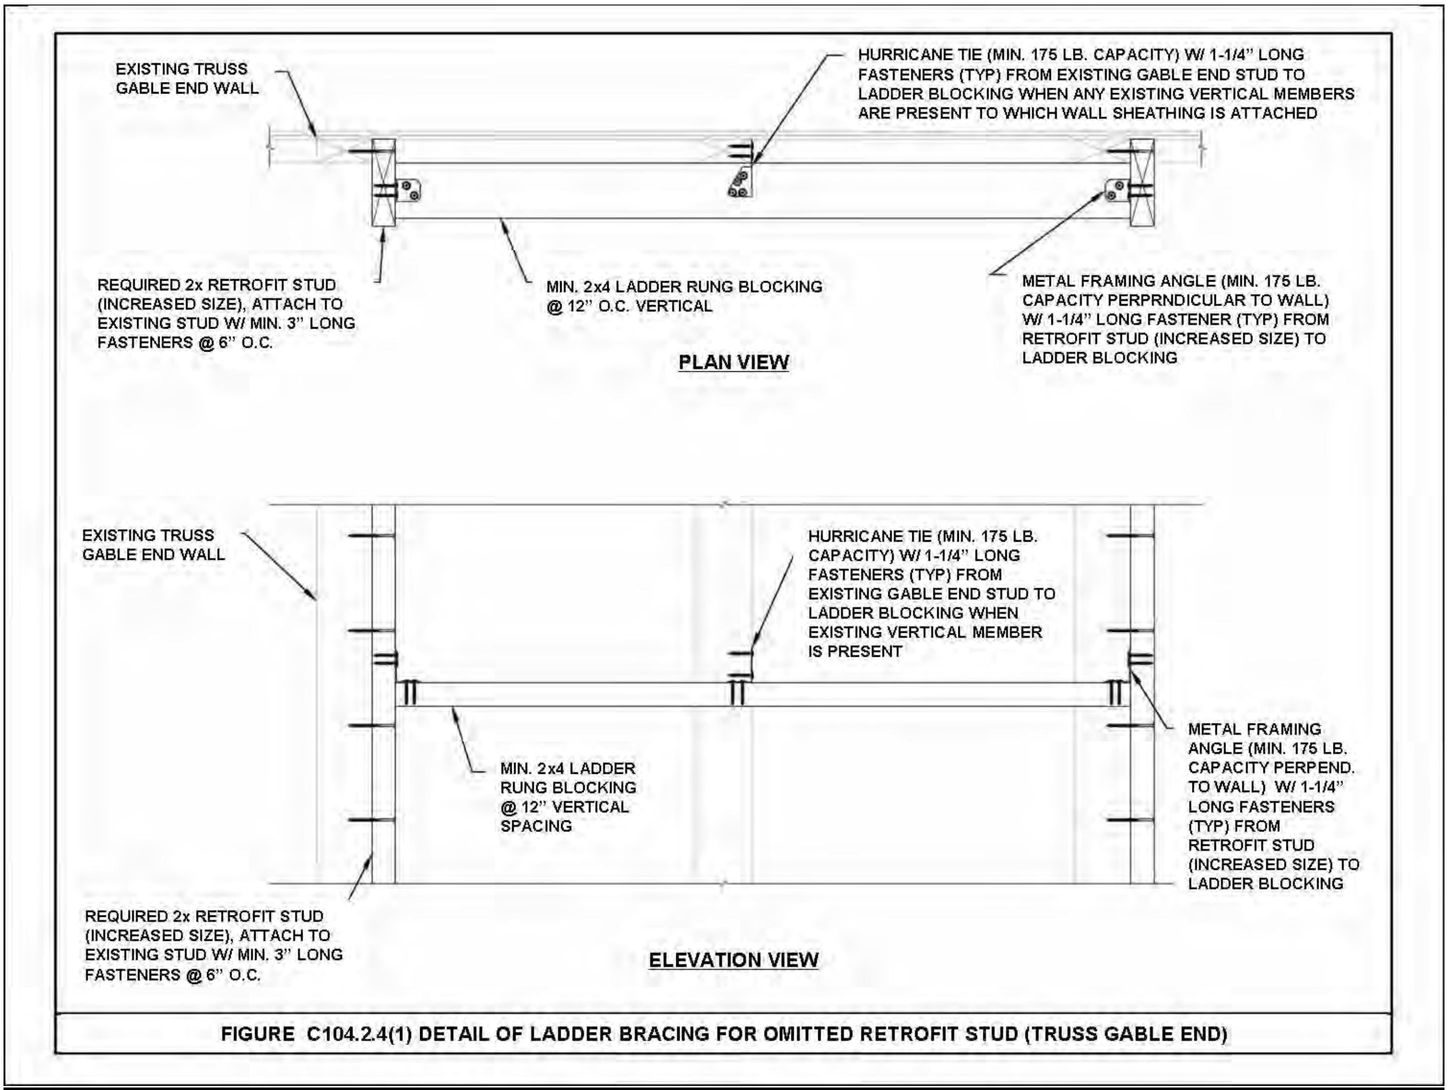
Commenter's Reason: The purpose of this public comment is to clarify the provisions for gable end retrofits. The original language is frequently repetitive, unclear or contains provisions more appropriate for a commentary than in code text. The proposed revisions here clarify and simplify the gable end retrofit provisions, making them easier for builders and code officials to interpret and use.

Public Comment 2:

Name: Gary J. Ehrlich, PE, representing the National Association of Home Builders (NAHB), requests Approval as Modified:

Modify the proposal as follows:

1. Add Figures C104.2.4(1), C104.2.4(2), C104.2.5, and C104.3.8:



<u>**FIGURE C104.2.4(1)**</u>
<u>**LADDER BRACING FOR OMITTED RETROFIT STUD (GABLE END FRAME)**</u>

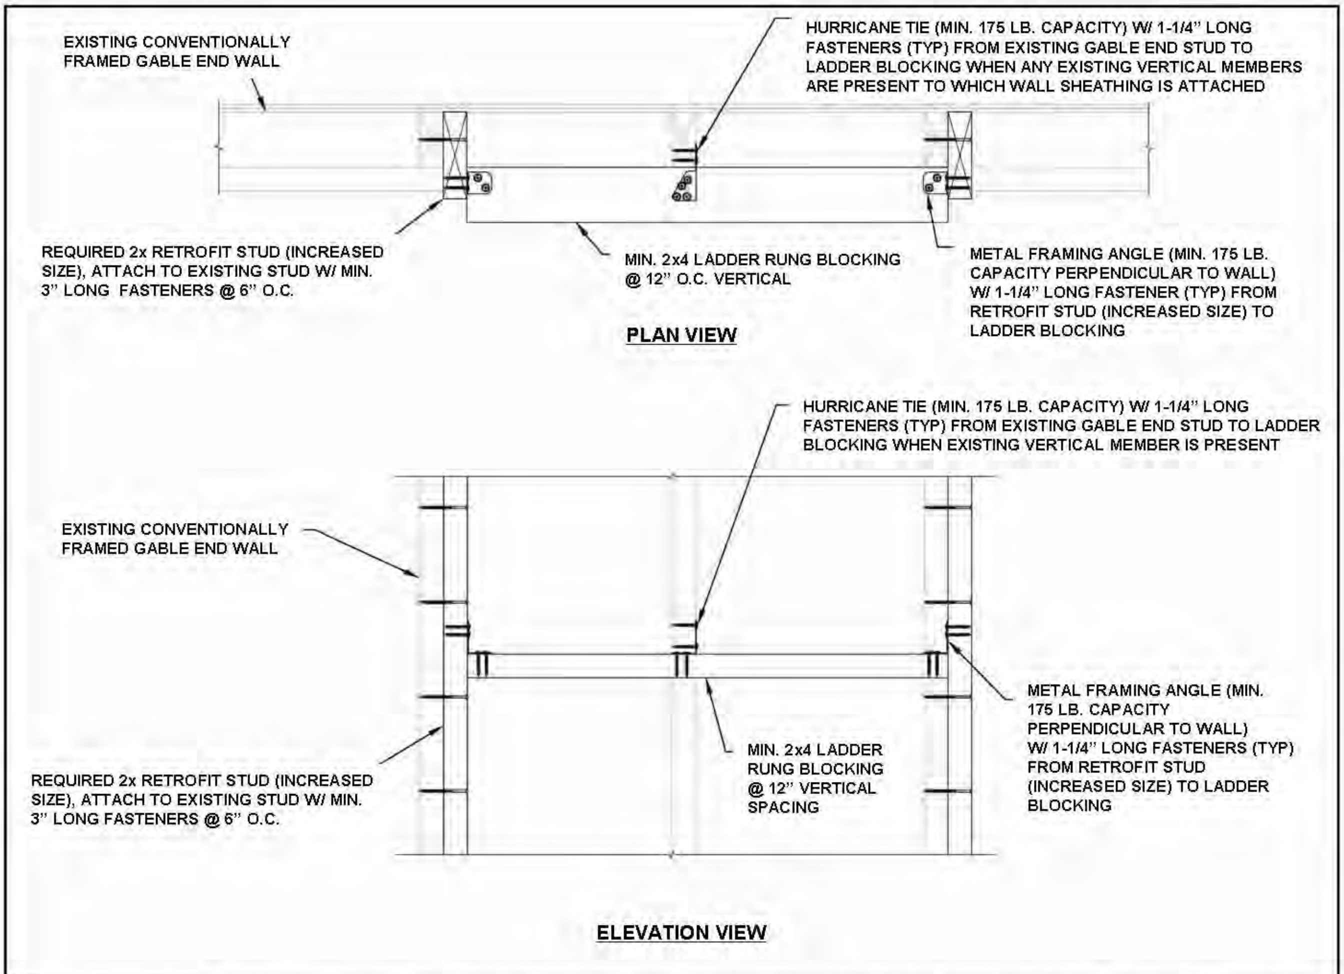


FIGURE C104.2.4(2) DETAIL OF LADDER BRACING FOR OMITTED RETROFIT STUD (CONVENTIONAL FRAMING)

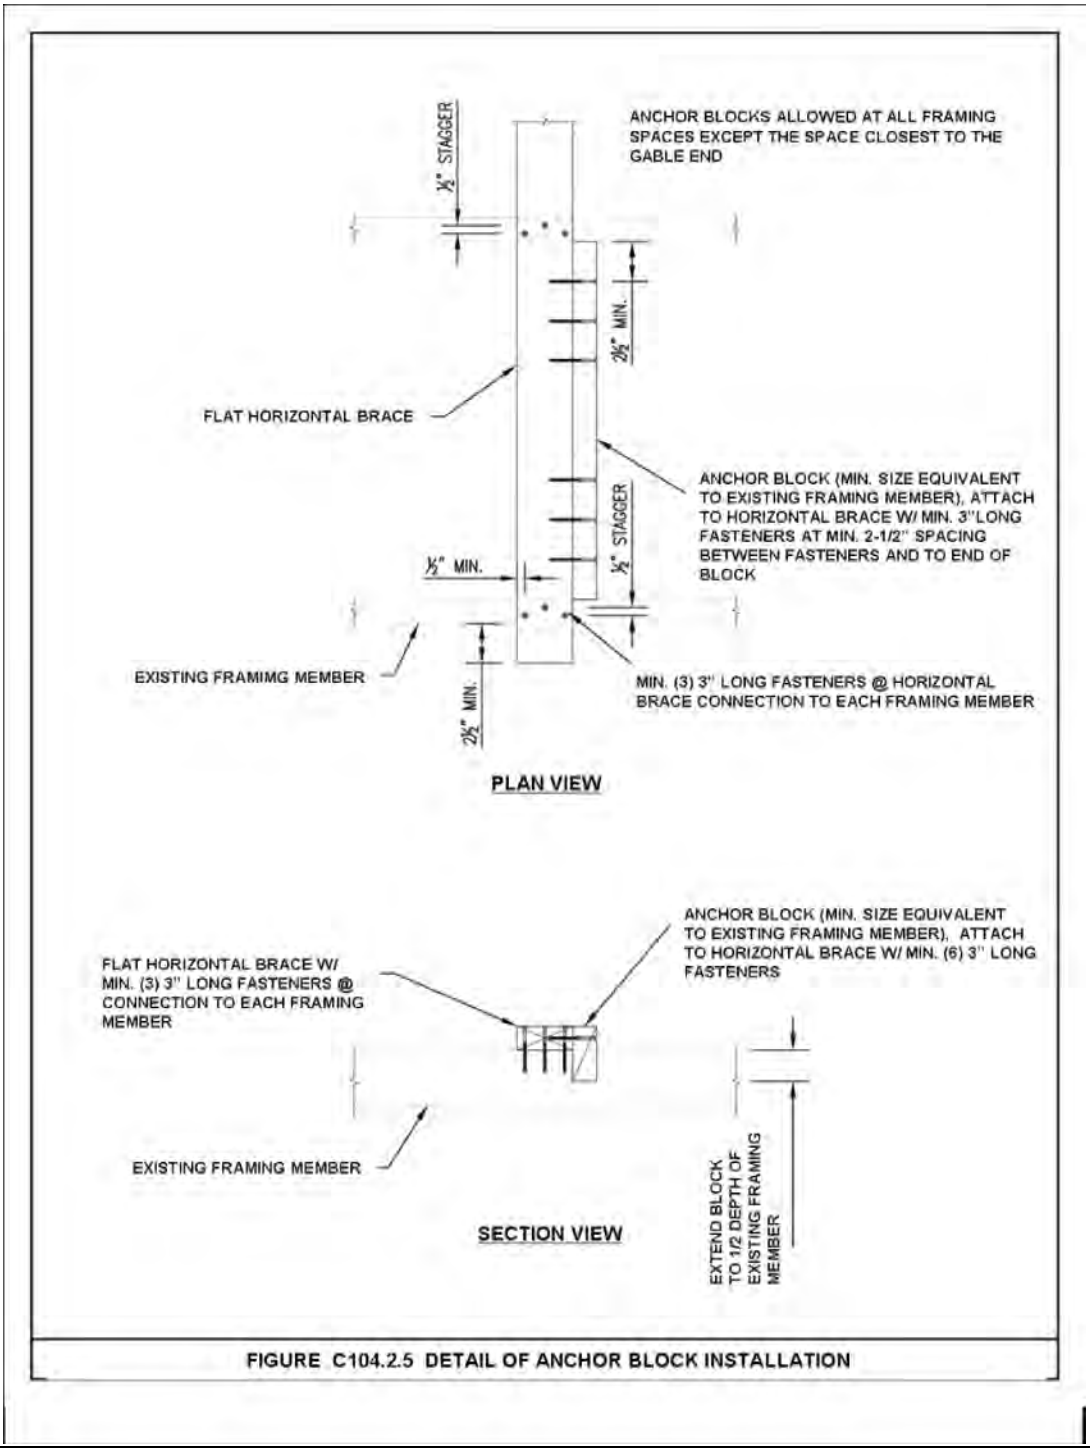
FIGURE C104.2.4(2)
LADDER BRACING FOR OMITTED RETROFIT STUD (CONVENTIONALLY FRAMED GABLE END)



<u>FIGURE C104.2.5</u>
<u>ANCHOR BLOCK INSTALLATION</u>

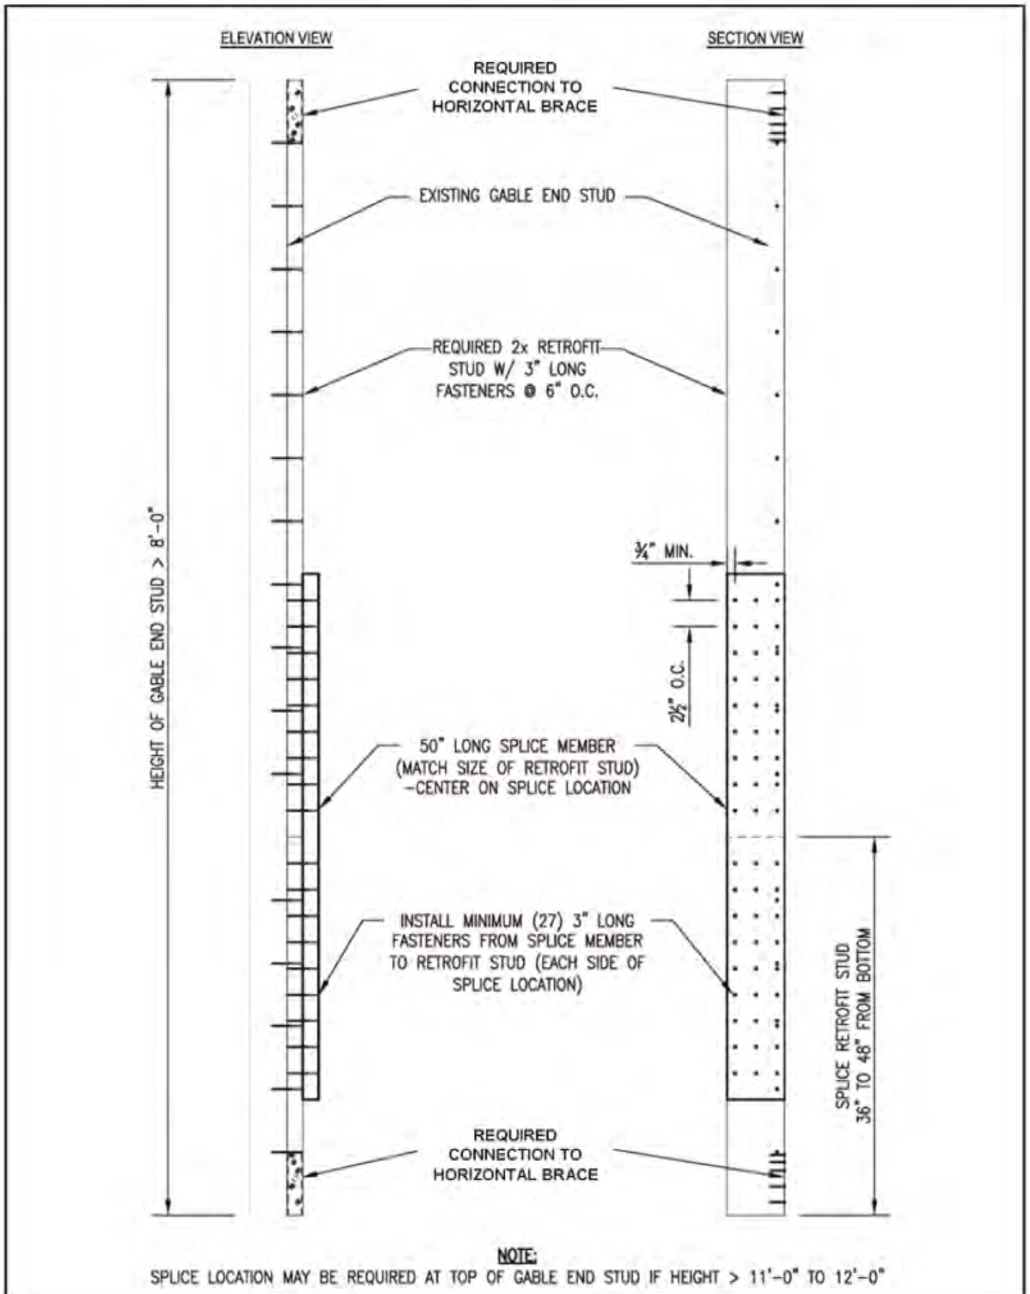


FIGURE C104.3.8 DETAIL OF RETROFIT STUD SPLICE

FIGURE C104.3.8
RETROFIT STUD SPLICES

2. Replace Tables C104.4.1, C104.4.2, and C104.5.1 with the following:

TABLE C104.4.1
ELEMENT SIZING AND SPACING FOR L-BENT RETROFIT METHOD

Retrofit Elements	Retrofit Configuration			
	A	B	C	D
Minimum size and number of Horizontal Braces	2x4	2x4	2x4	2 each 2x4
Minimum size and number of Retrofit Studs	2x4	2x6	2x8	2 each 2x8
Minimum number of fasteners connecting each end of straps to Retrofit Studs or to Horizontal Braces #8 screws or 10d nails 1-1/4" long	6	9	12	8 on each strap
Minimum number of fasteners to connect Compression Blocks to Horizontal Braces #8 screws or 10d nails 3" long	6	8	10	12

For SI: 1 Inch = 25.4mm, 1 Foot = 304.8mm

TABLE C104.4.2
ELEMENT SIZING AND SPACING FOR U-BENT RETROFIT METHOD

Retrofit Elements	Retrofit Configuration			
	A	B	C	D
Minimum size and number of Horizontal Braces	2x4	2x4	2x4	2 each 2x4
Minimum size and number of Retrofit Studs	2x4	2x6	2x8	2 each 2x8
Minimum number of fasteners connecting Straps to each edge of Horizontal Braces #8 screws or 10d nails 1-1/4" long	6	7	7	6 on each side of strap

For SI: 1 Inch = 25.4mm, 1 Foot = 304.8mm

TABLE C104.5.1
SPACING OF GUSSET ANGLES

Exposure Category	Basic Wind Speed (mph)	Spacing of Gusset Angles (inches)
C	110	38
C	120	32

C	140	24
C	150	20
B	110	48
B	120	40
B	130	36
B	140	30
B	150	26

(Portions of the proposal not shown remain unchanged)

Commenter's Reason: The purpose of this public comment is two-fold. First the comment adds four figures – Figures C104.2.4(1), C104.2.4(2), C104.2.5, and C104.3.8 -- which were mistakenly omitted from the original proposal. Second, the comment replaces three proposed Tables C104.4.1, C104.4.2, and C104.5.1 with version reformatted for improved clarity. No technical changes have been made to the reformatted Tables.

Public Comment 3:

Gary Ehrlich, representing the National Association of Home Builders, requests Approval as Modified.

Modify the proposal as follows:

C103.6.3.3 Metal connectors for wood to wood connections. Metal connectors for wood to wood connections shall meet the following conditions.

1. Fastener spacing to edge or ends of lumber shall be as dictated by the prefabricated holes in the connectors and the connectors shall be installed in accordance with the manufacturer.
2. Fasteners in 1-1/4 inch wide metal straps that are installed on the narrow~~1-1/2 inch broad~~ face of lumber shall be a minimum 1/4 inches from either edge of the lumber. Consistent with Section C103.6.3.1 fasteners shall be permitted~~allowed~~ to be spaced according to the fastener holes fabricated into the strap.
3. Fasteners in metal nail plates shall be spaced a minimum of ½ inches perpendicular to ~~across wood~~ grain and a minimum of 1-1/2 inches parallel to ~~wood~~ grain.

C104.3.4 Method #3: Butted retrofit stud method. Provided that all of the following fastening conditions are met retrofit studs shall be permitted to be butted by their edge or face to existing studs with the addition of nail plates as indicated in Figure C104.3(c) and Figure C104.3.4.

1. The narrow ~~1-1/2 inch~~ edge of retrofit studs shall be installed against the narrow ~~1-1/2 inch~~ or the wide ~~broad~~ face of existing studs.

Figure C103.6.3 revise the phrase in the third note from the top "Distance across grain minimum 1 inch" to "Distance perpendicular to grain minimum 1 inch"

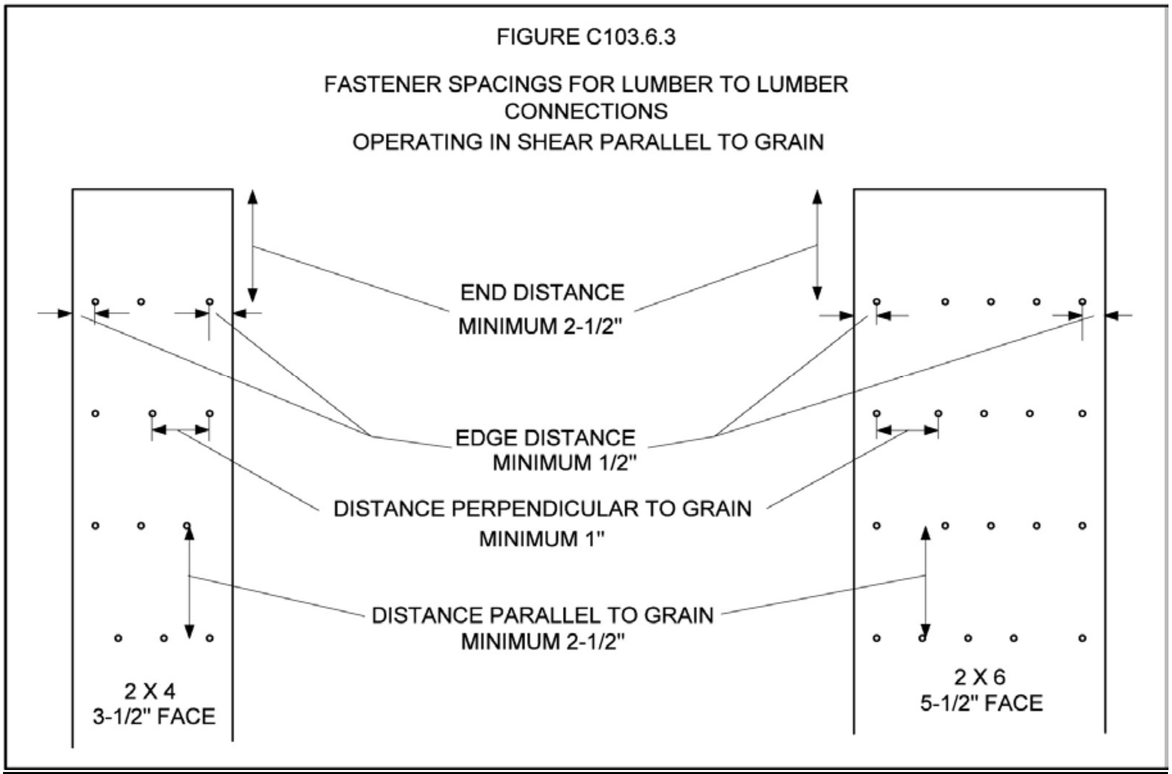

FIGURE C103.6.3
FASTENER SPACINGS FOR LUMBER TO LUMBER CONNECTIONS OPERATING IN SHEAR PARALLEL TO GRAIN

C104.1 General. These prescriptive methods of retrofitting are intended to increase the resistance of existing gable end construction for out-of-plane wind loads resulting from high wind events. The ceiling diaphragm shall be comprised of minimum ½ inch thick gypsum board~~drywall~~, minimum nominal 3/8 inch thick wood structural panels, or plaster. An overview isometric drawing of one kind of gable end retrofit to improve wind resistance is shown in Figure C104.1.1.

C104.2 Horizontal braces. Horizontal braces shall be installed approximately perpendicular to the roof and ceiling framing members at the location of each existing gable end stud greater than 3 feet in length. Unless it is adjacent to an omitted horizontal brace location, horizontal braces shall be minimum 2x4 dimensional lumber as defined in Section C103.3. A single horizontal brace is required at the top and bottom of each gable end stud for Retrofit Configuration A, B, or C and two horizontal braces are required for Retrofit Configuration D. Maximum heights of gable end wall studs and associated retrofit studs for each Retrofit Configuration shall not exceed the values listed in Table C104.2. Horizontal braces shall be oriented with their wide ~~broad~~ faces across the roof or ceiling framing members, be fastened to a minimum of three framing members, and extend at least 6 feet measured perpendicularly from the gable end plus 2-1/2 inches beyond the last top chord or bottom chord member (rafter or ceiling joist) from the gable end as shown in Figure C104.2(1), Figure C104.2(2), Figure C104.2(3), and Figure C104.2(4).

C104.2.2 Main method of installation. Each horizontal brace shall be fastened to each existing roof or ceiling member that it crosses using three 3-inch long fasteners (#8 wood screws or 10d nails) as indicated in Figure C104.2(1) and Figure C104.2(3) for trusses and Figure C104.2(2) and Figure C104.2(4) for conventionally framed gable end walls. Alternative methods for providing horizontal bracing of the gable end studs as provided in Sections C104.2.3 through C104.2.9 shall be permitted~~allowed~~ in lieu of this primary installation method.

C104.2.3 Omitted horizontal brace. Where impediments, other permanently attached obstacles or conditions exist that prevent installation in accordance with Section C104.2.2 horizontal braces may be omitted for height limitations corresponding to Retrofit Configurations A and B as defined in Table C104.2 provided installation is as indicated in Figure C104.2.3 and provided all of the following conditions are met. This method is not permitted~~allowed~~ for Retrofit Configurations C or D.

1. *(No changes)*
2. *(No changes)*
3. Where the existing studs on each side of an omitted horizontal brace have their wide~~broad~~ face perpendicular to the gable end wall, the retrofit studs at those locations and the retrofit stud at the omitted horizontal brace locations shall be sized such that they protrude a minimum of 3-1/2 inches beyond the interior edge of the existing studs for both Retrofit Configurations A and B. The edges of the three retrofit studs facing towards the interior of the attic shall be aligned such that they are the same distance from the gable end wall.
4. *(No changes)*
5. Retrofit studs adjacent to the omitted horizontal brace shall be fastened to the horizontal brace using straps in accordance with Table C104.4.1 consistent with the size of the retrofit stud. The method applicable to Table C104.4.2 is not permitted~~allowed~~.
6. *(No changes)*
7. *(No changes)*
8. The use of shortened horizontal braces using the alternative method of Section C104.2.5 is not permitted~~allowable~~ for horizontal braces adjacent to the omitted horizontal braces.
9. *(No changes)*

C104.2.4 Omitted horizontal brace and retrofit stud. Where impediments, other permanently attached obstacles or conditions exist that prevent installation in accordance with Section C104.2.2 or Section C104.2.3 by not permitting installation of horizontal braces, then retrofit studs and horizontal braces shall be permitted to be omitted from those locations by installation of ladder assemblies for Retrofit Configurations A and B as defined in Table C104.2 provided all of the following conditions are met**.** This method is not permitted~~allowed~~ for Retrofit Configurations C or D.

1. *(No changes)*
2. *(No changes)*
3. Where the existing studs on each side of an omitted horizontal brace have their wide~~broad~~ face parallel to the gable end wall the retrofit studs at those locations and the retrofit stud at the omitted horizontal brace locations shall be 2x6 lumber for Retrofit Configuration A and 2x8 lumber for Retrofit Configuration B.
4. *(No changes)*
5. *(No changes)*
6. Ladder rungs shall be made of at a minimum 2x4 lumber oriented with their wide~~broad~~ face horizontal and spaced a maximum of 16 **-** inches on center vertically.
7. *(No changes)*
8. *(No changes)*

C104.3 Retrofit studs. Retrofit studs shall be installed in accordance with Section C104.3.1 and using one of the five methods of Sections C104.3.2, through C104.3.6 and as shown in Figure C104.3. For the Retrofit Configuration derived from Table C104.2 the size of retrofit studs shall be as indicated in Table C104.4.1 or Table C104.4.2. Retrofit studs shall extend from the top of the lower horizontal brace to the bottom of the upper horizontal brace except that a maximum gap of 1/8 inch is permitted~~allowed~~ at the bottom and ½ inch at the top. Where wall sheathing, panel siding, or other wall covering~~façade~~ is fastened to a conventionally framed gable end studs not manufactured into a truss, i.e. are field installed, retrofit studs shall be applied to those field installed studs in accordance with Section C104.2.1.

C104.3.4 Method #3: Butted retrofit stud method. Provided that all of the following fastening conditions are met retrofit studs shall be permitted to be butted by their edge or face to existing studs with the addition of nail plates as indicated in Figure C104.3(c) and Figure C104.3.4.

1. The 1-1/2 inch edge of retrofit studs shall be installed against the 1-1/2 inch or the wide~~broad~~ face of existing studs.
2. *(No changes)*
3. *(No changes)*
4. *(No changes)*
5. *(No changes)*
6. *(No changes)*
7. *(No changes)*
8. *(No changes)*
9. *(No changes)*

C104.4.1 L-bent strap method. (No changes).

1. A strap shall be applied to the edges of a retrofit stud nearest the gable end wall and to the face of horizontal braces using at each end of the strap the number of fasteners specified in Table C104.4.1. Straps shall be long enough so that each strap extends sufficient distance onto the vertical face of the retrofit stud that the fastener closest to the ends of the studs is a minimum of 2-1/2 inches from the end of the stud. Straps shall be permitted~~allowed~~ to be twisted to accommodate the transition between the tops of retrofit studs and horizontal bracings following roof pitches.
2. Compression blocks shall be installed on the horizontal braces directly against either the existing vertical gable end wall stud or the retrofit stud. Figure C104.2(1) (trusses) and Figure C104.2(2) (conventionally framed) show the installation of the compression block against the existing vertical gable end wall stud with the strap from the retrofit stud running beside the compression block. Compression blocks shall be permitted~~allowed~~ to be placed over straps. Compression blocks shall be fastened to the horizontal braces with at least the minimum number of 3 inch long fasteners (#8 wood screws or 10d nails) specified in Table C104.4.1. End and edge distances for fasteners shall be in accordance with Section C103.6.3.

C104.4.2 U-bent strap method. *(No changes)*

1. Straps shall be of sufficient length to meet the requirements for the number of fasteners in accordance with Table C104.4.2 and to meet the end distance requirements of Section C103.6.3 shall be shaped around retrofit studs and fastened to the edges of horizontal braces. Straps shall wrap the back edge of the retrofit stud snuggly with a maximum gap of ¼ inches. Rounded bends of straps shall be permitted~~allowed~~. One fastener shall be installed that connects each strap to the side of the associated retrofit stud.
2. (No changes)
3. Straps shall be permitted~~allowed~~ to be twisted to accommodate the transition between the tops of retrofit studs and horizontal braces that follow the roof pitch.

(Portions of the proposal not shown remain unchanged)

Commenter's Reason: The purpose of this public comment is to make editorial revisions to the text of EB72 to replace certain words with the proper terms used in building codes and standards.

Public Comment 4:

David Bonowitz, SE, representing the National Council of Structural Engineers Associations, Code Advisory Committee, Existing Buildings Subcommittee (NCSEA EBS), requests Disapproval.

Commenter's Reason: NCSEA EBS recommends disapproval of this well-intentioned proposal for the following reasons:

The proposed Appendix would be inconsistent with the body of the IEBC and with other Appendix Chapters because the proposed Appendix does not state its performance objective. Thus, it is unclear whether compliance with Appendix C would satisfy upgrade requirements triggered by alterations, additions, change of occupancy, or repair. In fact, we believe that Appendix C would *not* satisfy all those triggered requirements, but its inclusion in the code, even as voluntary provisions, gives the wrong impression that it is equivalent. Indeed, the IBC Structural Committee's reason suggests that local jurisdictions might want to cite the proposed Appendix as equivalent or "deemed to comply".

As a matter of code development philosophy, including an appendix that is not cited anywhere by the body of the code is a questionable practice that will not serve code officials well and is likely to lead to confusion. Well-intentioned provisions for voluntary work such as those proposed by EB72 are useful to practitioners, but they are better published elsewhere – especially in a format that would allow ample commentary and guidance to contractors and owners.

The proposed Appendix, while intended for 1-2 family dwellings, provides no scope limitations as to building size or occupancy. As written, the proposed provisions could be used for very tall or wide gables as well as gables typical of a house. Further, they could be applied to schools or assisted living facilities without limitation or guidance appropriate to special occupancies.

By limiting the scope of retrofit work to be practical, the proposed provisions might not result in a complete retrofit solution. That might be acceptable if the proposed Appendix was clear about its limited intent, but no such explanations are provided. (Proposed section C101.1 is clear that Appendix C does not match the requirements for *new* construction, but that only confuses the matter, because it suggests incorrectly that Appendix C *does* or *might* match the typically reduced requirements of the IEBC.) An example of rational engineering provisions missing from proposed Appendix C is found in section C104.1, which requires only a plaster or ½-inch drywall ceiling acting as a structural diaphragm. In hurricane conditions, for which Appendix C is intended, these materials become wet and lose structural capacity. Further, Appendix C is not specific about the force levels or prescriptive details for the load path between this ceiling diaphragm and roof trusses or perimeter wall framing.

We understand the proposed provisions are based on calculations produced for typical 1-2 family dwelling conditions by a qualified engineering consultant. However, some of the limitations and assumptions of those calculations do not appear in the proposed provisions, and some additional details are given in the provisions that were not reviewed by the consultant.

Procedurally, the provisions are incomplete and need significant editing to match the terminology and standards of the IEBC. For examples, proposed sections C104.2.4, C104.2.5, and C104.3.8 refer to a total of four figures that do not exist.

Final Action: AS AM AMPC____ D

EB73-09/10
804.1.1

Proposed Change as Submitted

Errata: This code change was contained in the errata posted on the ICC website.

Proponent: Tom Lariviere, Chairman - Joint Fire Service Review Committee

Revise as follows:

804.1.1 High-rise buildings. ~~In high-rise~~ High-rise buildings~~, work areas~~ shall be provided with automatic sprinkler protection throughout. ~~where the building has a sufficient municipal water supply system to the site. Where the work area exceeds 50 percent of floor area, sprinklers shall be provided in the specified areas where sufficient municipal water supply for design and installation of a fire sprinkler system is available at the site.~~

Reason: IEBC Chapter 8 applies to Level 3 alterations, which by definition already exceed 50% of the floor area. The entire Chapter 8 applies to alterations where the proposed work exceeds 50% of total floor area of the building. Therefore, the reference to 50% in Section 804.1.1 is redundant, and this portion of the Section 804.1.1 is deleted.

The additional part of this proposal is to eliminate the allowance for high-rise buildings to escape from the sprinkler requirements when the available water is inadequate. There are few, if any, water systems that are capable of providing sprinklers in a high rise building without a fire pump. Most newly constructed buildings require a fire pump to overcome low residual pressure in the municipal water system and are not provided an exception based on a "sufficient municipal water supply". High-rise buildings covered in IEBC Chapter 8 should be treated in the same manner as new construction in the requirements for fire detection and automatic fire suppression, and therefore the exception allowing elimination of the sprinkler system is deleted.

The existing language "sufficient municipal water supply" is vague as to application of water volume and/or pressure and fire flow requirement. In a practical sense, the existing municipal water supply could have sufficient volume but not sufficient pressure needed to push the water to the upper stories of the high rise. The exception could allow exclusion of the automatic sprinkler system that would otherwise be required in the IBC or IFC and therefore this exception should be eliminated from the IEBC. Existing fire protection standards supply engineering solutions for the provision of water where the municipal supply is lacking or non-existent.

Cost Impact: This code change proposal will increase the cost of construction.

ICCFILENAME: LARIVIERE-EB2-804.1.1

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The proposal was felt to be too restrictive and would be a disincentive to upgrading existing buildings. In particular it was felt that the IEBC needs to provide an incremental approach to installing sprinklers in high rise buildings. Without the incremental approach the framework of the IEBC will be undermined. Concern was raised that existing tenants located in the building where other tenants are making alterations would then be required to install a sprinkler system.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Joe Pierce, Dallas Fire Department and Joint Fire Service Review Chairman, representing the Joint Fire Service Review Committee, requests Approval as Submitted.

Commenter's Reason: This proposal was Disapproved at the Code Development Hearing because the Code Development Committee felt that the requirement was too restrictive. However, IEBC Section 804.1 only applies to Level 3 alterations, which by definition already exceed 50% of the floor area. In fact, the entire Chapter 8 applies to alterations where the proposed work exceeds 50% of total floor area of the building. So the wording in Section 804.1.1 of requiring fire sprinklers when the work area exceeds 50% is redundant at minimum.

But to the main point of the code change, this current wording allows for a high-rise which is required to install a fire sprinkler system based on this section to waive the requirements for the fire sprinkler system. It would be quite a surprise to find a municipal water system capable of supplying the required water. To understand this dilemma, you need to look at the mechanical requirements of the water system and the sprinkler system.

The fire sprinkler system must supply the required flow at the top floor. This means that the flow (let's estimate at 250 GPM) must be available at the roof (because that is where the sprinklers will be for the top floor). So we have 250 GPM that must be available at about 85 feet above the street, plus a fire hose flow of 100 GPM. To accomplish this, the municipal water supply must provide the 350 GPM at a pressure that can push the water to the roof and still provide enough pressure for the sprinkler to operate properly. To be classified as a "high-rise" the top floor must be at least 75 feet above grade, making the roof at about 85 feet. At 85 feet in height, the pressure required just to lift the water to that elevation is about 37 PSI. In addition to the 37 PSI we will also need the minimum sprinkler operating pressure of 7 PSI or more; plus the friction loss incurred through the piping bringing the water from the street to the building, up to the roof, and from the riser to the furthest sprinkler. This friction loss may be up to 15 PSI. We now have a total required pressure of 59 PSI, and this is a minimum.

Final Action: AS AM AMPC____ D

S3-09/10-PART I
1503.6

Proposed Change as Submitted

Proponent: John Woestman, The Kellen Company representing the Window and Door Manufacturers Association (WDMA)

PART I – IBC STRUCTURAL

Revise as follows:

1503.6 Crickets and saddles. A cricket or saddle shall be installed on the ridge side of any chimney or penetration greater than 30 inches (762 mm) wide as measured perpendicular to the slope. Cricket or saddle coverings shall be sheet metal or of the same material as the roof covering.

> **Exception:** Skylights installed and flashed in accordance with the manufacturer's instructions.

Reason: This code language, as written, precludes the use of engineered skylight systems that are designed to prevent water infiltration into the penetration without the use of a cricket. The proposed change addresses this unintended consequence of this language of the IBC and the IRC.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: WOESTMAN-S4-1503.6

Public Hearing Results

PART I- IBC STRUCTURAL
Committee Action: **Disapproved**

Committee Reason: The proposed exception to Section 1503.6 would apply to all skylights as written. Specifying "unit" skylights may not be enough of a clarification to tie the exception to applicable Chapter 24 requirements. If not completely clear, an exception to allow the use of the manufacturers' instructions could open the door to misapplication.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Jeff Inks, Windows and Door Manufacturer's Association, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

1503.6 Crickets and saddles. A cricket or saddle shall be installed on the ridge side of any chimney or penetration greater than 30 inches (762 mm) wide as measured perpendicular to the slope. Cricket or saddle coverings shall be sheet metal or of the same material as the roof covering.

> **Exception:** Unit skylights installed in accordance with Section 2405.5 and flashed in accordance with the manufacturer's instructions shall be permitted to be installed without a cricket or saddle.

Commenter's Reason: The Structural Committee was not opposed to the intent of the original proposal which is to fix the unintended consequence of the current IBC code text that precludes the use of engineered skylight systems that are designed to prevent water infiltration into the penetration without the use of a cricket or saddle. However, as stated in their reason statement, the Committee was concerned that the exception as proposed could result in a broader application of it than is intended.

That concern is addressed by the modification proposed by this comment which in addition to specifying that the exception only applies to unit skylights, they must also be installed in accordance with Section 2405.5. This language clearly indicates the applicability and limitations of the exception.

Part II of this proposal was identically modified in advance of it being heard by the IRC B&E Committee in Baltimore and was unanimously approved by them without any testimony in opposition to it.

Final Action: AS AM AMPC____ D

S3-09/10-PART II
IRC 903.2.2

Proposed Change as Submitted

Proponent: John Woestman, The Kellen Company representing the Window and Door Manufacturers Association (WDMA)

PART II – IRC BUILDING/ENERGY

Revise as follows:

R903.2.2 Crickets and saddles. A cricket or saddle shall be installed on the ridge side of any chimney or penetration more than 30 inches (762 mm) wide as measured perpendicular to the slope. Cricket or saddle coverings shall be sheet metal or of the same material as the roof covering.

> **Exception:** Skylights installed and flashed in accordance with the manufacturer's instructions.

Reason: This code language, as written, precludes the use of engineered skylight systems that are designed to prevent water infiltration into the penetration without the use of a cricket. The proposed change addresses this unintended consequence of this language of the IBC and the IRC.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: WOESTMAN-S4-1503.6

Public Hearing Results

PART II- IRC B/E
Committee Action: **Approved as Modified**

Modify the proposal as follows:

R903.2.2 Crickets and saddles. A cricket or saddle shall be installed on the ridge side of any chimney or penetration more than 30 inches (762 mm) wide as measured perpendicular to the slope. Cricket or saddle coverings shall be sheet metal or of the same material as the roof covering.

> **Exception:** Unit skylights installed in accordance with Section R308.6 and flashed in accordance with the manufacturer's instructions shall be permitted to be installed without a cricket or saddle.

Committee Reason: The exception is needed to address roof penetration that is engineered to prevent water infiltration without a cricket. The modification clarifies that the exception only applies to unit skylights.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Mark S Graham, National Roofing Contractors Association (NRCA), requests Disapproval.

Commenter's Reason: The IBC portion (Part I) of the code change proposal was disapproved by the IBC Structural Committee. The IRC portion (Part II), which was heard after the IBC portion, was modified by the proponent and was Approved as Modified by the IRC B/E Committee. This Public Comment is seeking a Final Action of Disapproved to Part II so as to keep the requirements of the IBC and IRC consistent on this issue.

The modification offered by the proponents that was approved as modified by the IRC B/E Committee waives the Code's current requirement for crickets behind unit skylight penetrations wider than 30 inches where the skylight has been installed according to IRC Section R308.6. Review of

Section 308.6 reveals this section provides little specific installation guidance other than in R308.6.8, where it is indicated unit skylights installed on roofs of slope 3:12 or greater need to be mounted on 4 inch minimum height curbs, unless otherwise specified in the manufacturer's installation instructions. R308.6.9 indicates units skylights need to be tested and labeled according to AAMA/WDMA/CSA 101/I.S2/A440; this test method does not address the proper installation to or watertightness of the unit skylight interface to the roof covering.

The use of crickets behind vertical roof penetrations, such as unit skylights, of specific widths to direct run-off water away from the backside of the penetrations and proper flashing of vertical penetrations has long been recognized in the roofing industry as the most effective means making and maintaining these vertical penetrations in roof coverings watertight.

1504.3, Chapter 35

Proposed Change as Submitted

Proponent: Mike Ennis representing Single Ply Roofing Industry (SPRI, Inc.)

1. Revise as follows:

1504.3 Wind resistance of nonballasted roofs. Roof coverings installed on roofs in accordance with Section 1507 that are mechanically attached or adhered to the roof deck shall be designed to resist the design wind load pressures for components and cladding in accordance with Section 1609 <u>and shall be installed in accordance with ANSI/SPRI WD-1.</u>

2. Add standard to Chapter 35 as follows:

SPRI

<u>WD-1-08</u> <u>Wind Design Standard Practice for Roofing Assemblies</u>

Reason: The International Building Code provides specific requirements for calculating the wind uplift load pressure on the roof assembly. However it does not currently provide a prescriptive method to enhance the perimeter and corner attachment due to the higher wind loads in these regions. ANSI/SPRI WD-1 is a national consensus standard that has been reviewed by testing laboratories, membrane manufacturers, roofing system component suppliers, contractors and consultants. This standard provides prescriptive requirements for corner and perimeter enhancement. The user first identifies a suitable roof assembly that will resist the calculated wind uplift pressure for the field of the roof, then enhances the fastening pattern to meet the calculated corner and perimeter wind uplift load pressure. Designing the roof system to resist the higher wind loads at the perimeter and corner regions is accomplished by either adding additional fasteners or increasing the amount of adhesive used, depending upon the specific roof system chosen. This approach allows the user to work from one base assembly and enhance the attachment of the base assembly for perimeter and corner regions instead of trying to locate tested assemblies for each of these areas.

The ANSI/SPRI standard also requires that a 2.0 safety factor be applied to tested wind uplift values, unless another value is specified. So, for example, if a roof system passes a wind uplift test at 120 lbs/ft2, this value is divided by 2 before determining if the system will resist the calculated wind uplift pressure loads for the building. The IBC does not currently contain this requirement.

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: A review of the standard(s) proposed for inclusion in the code, SPRI WD-1-08, for compliance with ICC criteria for referenced standards given in Section 3.6 of Council Policy #CP 28 will be posted on the ICC website on or before September 24, 2009.

ICCFILENAME: ENNIS-S1-1504.3

Public Hearing Results

Note: The following analysis was not in the Code Change monograph but was published on the ICC website at <u>http://www.iccsafe.org/cs/codes/Documents/2009-10cycle/ProposedChanges/Standards-Analysis.pdf</u> :

Analysis: Review of proposed new standard SPRI WD-1 indicated that, in the opinion of ICC Staff, the standard complies with ICC standards criteria.

Committee Action: Disapproved

Committee Reason: There was some question on the scope of reference to a "design" standard, SPRI WD-1, for the "installation" requirement as was proposed. Additional clarification should be provided on the derivation of the factor of safety that is employed in the standard. The proposed requirements would be more suitably located in Section 1504.3.1 rather than the charging section. The committee suggests that the proponent address these questions in the public comment phase in addition to including his proposed floor modification.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Mike Ennis, Single Play Roofing Industry (SPRI), requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

1504.3 Wind resistance of nonballasted roofs. Roof coverings installed on roofs in accordance with Section 1507 that are mechanically attached or adhered to the roof deck shall be designed to resist the design wind load pressures for components and cladding in accordance with Section 1609<u>.</u> ~~and~~ <u>Roof systems with built-up, modified bitumen, fully adhered or mechanically attached single ply membranes</u> shall be installed in accordance with ANSI/SPRI WD-1.

(Portions of proposal not shown remain unchanged)

Commenter's Reason: This modification is proposed to address questions raised at the code change hearings, specifically:

1) Questions about the scope of reference of the ANSI/SPRI WD-1 standard.

The scope of the ANSI/SPRI WD-1 standard limits its application to BUR, modified bitumen and single ply roof membrane systems. It was never the intent to extend its application to any other roofing system. Testimony at the code change hearings by members on the metal roofing industry correctly pointed out that in its original format metal roofing systems would be included as part of the code change proposal. The proposed modification limits the scope of the proposal to only those systems called out in the scope of the ANSI/SPRI standard.

2) Additional clarification should be provided on the derivation of the safety factor that is employed in the standard.

The standard recommends a safety factor of 2 that is applied to the tested wind uplift resistance value before comparison to the design pressures. The tested wind uplift resistance is divided by the safety factor. A safety factor of 2 has been commonly used in the roofing industry for many years and has proven through field experience to provide an acceptable level of safety between tested values and ultimate failure values observed in the field.

3) Determine if the proposed requirement would be more suitably located in Section 1504.3.1, rather than the charging section.

The appropriate location for this code change proposal is Section 1504.3 as submitted in the original code change proposal. This conclusion is based on a review of the scope of Sections 1504.3 and Section 1504.3.1

The charging section for the original code change proposal was Section 1504.3 **Wind resistance of nonballasted roofs.** This section describes how to calculate design wind load pressures for nonballasted roof systems and requires that the system be installed in a manner that will resist the design wind loads. Section 1504.3.1 **Other roof systems.** describes the test procedures that are to be used to evaluate the uplift resistance of various types of mechanically attached and fully adhered roof assemblies. ANSI/SPRI WD1 is a wind design standard practice that provides a two-part methodology for designing for wind uplift resistance of nonballasted Built-Up, Modified Bitumen, and Single-Ply roofing system assemblies installed over any type of roof deck. The first part allows the user to determine the rooftop wind uplift design pressures for the field, perimeter and corner areas of a building. In the second part the user selects an appropriate roofing system assembly by comparing the tested wind uplift resistance of that assembly to the wind uplift design pressures determined from the First Part. A safety factor is applied to the tested wind uplift resistance value before comparison to the design pressures. ANSI/SPRI WD1 is a design standard, not a wind uplift test standard and is therefore appropriately referenced in Section 1504.3. The use of the ANSI/SPRI WD1 standard allows the user to meet the intent of Section 1504.3 by calculating the design wind pressures and installing a roof system that will resist these design pressures.

1504.4, 1504.4.1 (New), 1504.4.2 (New), Table 1504.4 (New), 1504.8, Table 1504.8

Proposed Change as Submitted

Proponent: Thomas L Smith, AIA, RRC, TLSmith Consulting Inc. on behalf of the Roofing Industry Ad Hoc Working Group on Roof Aggregate (including, the Federal Emergency Management Agency, the Asphalt Roofing Manufacturers Association and SPRI).

1. Delete and substitute as follows:

~~**1504.4 Ballasted low-slope roof systems.** Ballasted low-slope (roof slope < 2:12) single-ply roof system coverings installed in accordance with Section 1507.12 and 1507.13 shall be designed in accordance with Section 1504.8 and ANSI/SPRI RP-4.~~

<u>**1504.4 Aggregate and paver surfaced low-slope roof coverings.** Aggregate and paver surfaced roof system coverings shall be designed and installed in accordance with Section 1504.4.1 or 1504.4.2 as applicable.</u>

2. Add new text as follows:

1504.4.1 Ballasted surfaced roof coverings. Aggregate and paver surfaced roof system coverings shall be designed and installed in accordance with ANSI/SPRI RP-4.

Exceptions:

1. Aggregate and concrete pavers are not permitted where the building height exceeds 150 feet (45 720 mm).
2. In hurricane-prone regions as defined in Section 1609.2, aggregate is not permitted on Occupancy Category III or IV buildings where the basic wind speed is greater than 100 mph (45 m/s).

1504.4.2 Aggregate surfaced roof coverings. Aggregate surfaced roof system coverings shall be designed and installed in accordance with Table 1504.4 based on the exposure category and basic wind speed at the building site. The aggregate shall comply with ASTM D 1863.

Exceptions:

1. In hurricane-prone regions as defined in Section 1609.2, aggregate is not permitted on Occupancy Category III or IV buildings where the basic wind speed is greater than 100 mph (45 m/s).
2. In hurricane-prone regions as defined in Section 1609.2, aggregate is not permitted on Occupancy Category I or II buildings when the basic wind speed is greater than 110 mph (49 m/s).

~~c. NP = gravel and stone not permitted for any roof height.~~

Reason: Concern with roof aggregate blow-off is not new (Minor, 1977). It has continued to be reinforced by field observations, particularly in regard to damage caused to glazing on surrounding buildings as well as the building from which the aggregate was lifted into the airstream. Most problems have been associated with extreme wind events such as hurricanes and have involved roofs not in compliance with RP-4 and with aggregate surfaced roofs for which the RP4 standard was not intended to address. As a result, recent building code changes (i.e., IBC 2006 and 2009) have severely restricted the use of aggregate surfaced roofs. However, these new restrictions were not based on the K-W design method (Kind Wardlaw 1976), the wind tunnel studies underlying the K-W design method (Kind 1977), or a quantitative analysis of observed good and bad roofing system performances in real wind events. Instead, current building code limitations are based on variation in surface pressure with building height which is known to be an inappropriate predictor of aggregate blow-off or scour due to pressure equalization effects (Smith, 1997). Furthermore, these recent restrictions do not address critical parameters such as aggregate size and parapet height which govern performance.

This code change proposal addresses two types of roof coverings: ballasted single ply roofs and those with aggregate surfaces, such as Built-up roofs (BUR) and certain spray polyurethane roof systems. Reasoning statements are provided for each new section:

New section1504.4.1 - Over 6 billion square feet of ballasted single ply roofing applications have been installed over the last two decades The vast majority of these systems have performed very well with respect to their resistance to wind pressure loads. However some damage has been observed due to aggregate blowing off non-code compliant roofs during high wind events. The above proposals are based on over 200 wind tunnel tests in addition to over 40 years of field experience and observations from hurricane investigation teams. These proposals provide restrictions on the use of ballasted single ply roof systems that will allow for the responsible use of aggregate surfacing that is a cost effective method to keep the roof system in place and to improve the energy performance of the building.

ANSI/SPRI RP-4 is the code referenced design guide for ballasted single ply roof systems. The requirements contained in the guide are based on over 200 wind tunnel tests along with extensive field studies. One of the design criteria of ANSI/SPRI RP-4 is to prevent gravel blow-off. Wind tunnel testing conducted at the National Research Council Canada evaluated conventional stone ballasted and stone and paver ballasted protected membrane roofs. For the systems containing stone ballasting the primary objective was to determine 4 critical wind speeds:

1. U_{c1} – the wind speed at which one or more stones were first observed to move an appreciable distance (i.e. several inches)
2. U_{c2} – the wind speed above which scouring of stones would continue more or less indefinitely as long as the wind speed is maintained.
3. U_{c3} – the wind speed at which stones were first observed to leave the roof by going over the upstream parapet (this was the parapet adjacent to the wind direction)
4. U_{c4} – the wind speed at which stones were first observed to leave the roof by going over the downstream parapet (opposite side from the wind)

In these experiments three nominal stone sizes were used. Each nominal stone size represented a mixture of stone sizes (larger and smaller) similar to the gradation, which would be obtained from a stone quarry. These experiments evaluated the impact of the following variables on the critical wind speeds defined above:

Stone size
Parapet height
Building height
Building geometry
Direction of wind impacting the building

Rooftop wind speed, rooftop gust wind speed, and the shape of the approaching wind velocity profile

In addition to the extensive wind tunnel test program, observed field performance was also a basis for the requirements included in ANSI/SPRI RP-Two of the most critical controlling factors identified through this extensive test program on the various critical wind speeds were stone size and parapet height. A brief summary of the wind tunnel test program, and reports written as part of this program follows.

LTR-LA-142 Estimation of Critical Wind Speeds for Scouring of Gravel or Crushed Stone on Rooftops January 1974

Objectives:

- Determine the critical wind speeds and corresponding surface shear stress that cause movement of various stone sizes and shapes by taking direct measurements of these values via wind tunnel testing.
- Use this data to determine constants that can be used in equations to calculate critical surface shear stress
- Obtain guidance about the effects of parapets and obstacles, which cause strong three-dimensional effects, notably vortices.

Conclusions:

- The surface shear stress required to cause stone motion is directly proportional to nominal stone diameter.
- The constant of proportionality appears to be essentially independent of stone size and shape and of the detailed shape of the velocity profile near the gravel surface.
- Critical wind speeds to initiate stone motion can therefore be easily predicted if the relationship between surface shear stress and wind speed is known for the situation of interest.
- The dead air region behind a parapet extended downstream about 15 parapet heights. The turbulence of natural wind will tend to reduce the dead air zone.

LTR-LA-162 Wind Tunnel Tests on Some Building Models to Measure Wind Speeds at Which Gravel is Blown Off Rooftops June 1974

Objectives:

- This series of tests was conducted to build upon the data obtained in the January 1974 test series. Specifically to provide data for some typical building geometries and to investigate the effects of building form, building height, parapet height, wind direction, and gravel size on the critical wind speeds required to cause scouring and blow-off of roofing gravel.
- In this series 1/10 scale models were evaluated in a 30’ x 30’ wind tunnel.

Conclusions

- The critical wind speeds at which scouring of nominal 0.9”, 1.5” and 2.8” diameter gravel (scaled to 1/10 size) occurs and begins to blow-off rooftops were investigated. The nominal sizes represent the average size of a typical mixture.
- The critical wind speeds are lowest when the wind direction is at or about 45 to the walls of the building.
- For a given building configuration the critical wind speeds are proportional to the square root of the gravel size.
- The critical wind speeds increase with increasing parapet height and decrease with increasing building height.
- The length:width ratio of the building is unimportant as long as the width and length are large compared to the parapet height.

NRC No. 15544 Design of Rooftops Against Gravel Blow-Off September 1976

Objectives:

- This report describes a procedure that can be used to estimate the wind speeds at which gravel of a given nominal size will be blown off rooftops.
- The report also describes a procedure for determining design wind speeds at rooftop level.
- The gravel blow-off procedure is based on data obtained from previous wind tunnel tests described above.

Conclusions

- The results of wind tunnel tests conducted to determine critical wind speeds for scour or blow-off of roofing gravel for a specific low-rise building shape can be generalized to apply to any low-rise rectangular building having a flat rooftop.
- Similar generalization is possible for high-rise shapes of any particular length:width ratio.
- This permits development of a general, easy to use procedure for estimating critical wind speeds required to cause scour or blow-off of roofing gravel from various building configurations.

LTR-LA-189 Further Wind Tunnel Tests on Building Models to Measure Wind Speeds at Which Gravel is Blown Off Rooftops August 1977

Objectives:

- Obtain additional data to permit previously obtained results to be generalized so as to be applicable to any rectangular flat-roofed low-rise building.
- Provide data on the effects of substituting solid paving blocks for loose gravel in the most wind sensitive areas of the rooftop.

Conclusions:

- The wind speed at rooftop level appears to be the dominant factor in controlling gravel scour and blow-off as opposed to the wind velocity profile.
- The measured wind speeds at rooftop level were used to reinterpret the data from previous wind tunnel tests.
- Within the boundaries of experimental scatter the critical wind speeds are independent of the rooftop level in the wind boundary layer, allowing for generalization of results to various building heights and geometries.

LTR-LA-234 Model Studies of the Wind Resistance of Two Loose-Laid Roof-Insulation Systems May 1979

Objectives:

- Investigate the resistance of protected membrane roof systems to damage from high winds.
- Identify wind speeds and failure mechanisms for protected membrane roof systems.

Conclusions:

- The results show that wind flows induce pressure distributions underneath the roof-insulation systems as well as on their exterior surfaces.
- These pressure differences cause uplift and are responsible for system failure.
- The wind speed to cause failure for the 2 ft. x 2 ft. paver slabs was found to be proportional to the square root of the system weight per unit area. This relationship should also be true for different geometries.

LTR-LA-269 Further Model Studies of the Wind Resistance of Two Loose-Laid Roof-Insulation Systems (High Rise Buildings) April 1984

Objectives:

- This study is an extension of the May 1979 study, to investigate the resistance of various protected membrane roof systems to damage from high winds when they are installed on high-rise buildings.

Conclusions:

- The mechanisms for wind damage are the same as those identified in earlier tests, namely gravel scour and uplifting of boards by pressure forces.
- The static pressure underneath boards or pavers tend to become equal to the exterior surface because of airflow through the joints between boards or pavers. Complete equalization cannot occur, however, in regions where the exterior pressure distribution is highly non-linear and uplifting pressure differences occur in those regions. System failure therefore tends to occur in these regions.
- High parapets are very effective in increasing resistance to wind damage.

Mechanical interconnection of boards or pavers by use of strapping, tongue & groove, etc. is an effective method for increasing wind resistance.

For any particular system configuration, the wind speed to cause failure is proportional to the square root of the system weight per unit area.

Gust speed at rooftop level is the pertinent speed for use in assessing the resistance of the roofing system to wind damage.

LTR-LA-294 Further Wind Tunnel Tests of Loose-Laid Roofing Systems April 1987

Objectives:

Conduct extensive wind tunnel work to further assess the resistance to wind damage of protected membrane roofing system using paver slabs, or similar elements.

Low, intermediate and high-rise buildings were tested, each with several parapet heights.

Conclusions:

When a membrane is loose-laid on a leaky roof deck, ballooning will occur due to air flowing through holes in the deck from the interior of the building. This will normally result in failure at wind speeds well below those required to product failure by other mechanisms.

In the case of immobile membranes, failure results from pressure differences, which develop across elements in some regions of the roof.

Increased parapet height generally resulted in more favorable pressure distributions. That is, maximum suctions were reduced and suction peaks were broadened, so that pressure was less non-uniform and therefore increased failure speeds could be expected.

Element size has a noticeable effect on failure speed, i.e. failure speeds were higher for larger elements.

Pressure non-uniformity is reduced by vortex generators mounted on the parapets near the upwind corner of the roof, thus increasing failure wind speeds.

LTR-LA-295 Pressure Distribution Data Measured During the September 1986 Wind Tunnel Tests on Loose-Laid Roofing Systems September 1987

Objectives:

This report supplements LTR-LA-294 by including contour plots of mean and peak roof surface pressure coefficients and mean and peak coefficients for pressure differential between the upper surface and the underside of the roofing system.

New Section 1504.4.2 and New Table 1504.4 – The new Section 1504.2 provides prescriptive design requirements to avoid blow-off of loose aggregate used on roof systems such as BUR and certain SPF roofs. Based on the Kind-Wardlaw design method, blow-off of loose aggregate is avoided by using minimum parapet heights determined by wind speed, Exposure Category, roof height, Building Category and aggregate size.

The Kind-Wardlaw design method ("K-W" design method) for prevention of scour and blow-off of aggregate from aggregate surfaced roofs has been available since the 1970s (Kind & Wardlaw 1976). It saw limited use until the 1980s when adopted as the basis for the initial 1988 edition of ANSI/SPRI RP-4, "Wind Design Standard for Ballasted Single-Ply Roofing Systems," (RP-4) standard which, in its updated form, continues to be used by the single-ply roofing industry for ballasted roofs (SPRI 2008). SPRI utilized the K-W design method as the basis for aggregate ballasted roof systems to prevent ballast scour.

For aggregate surfaced roof systems, a main wind-related issue of concern is with aggregate blow-off. Scour is not considered important to aggregate surfaced roofs, except to the extent that it might require maintenance (re-distribution of aggregate) after an extreme wind event to maintain fire resistance and the long-term durability of the roof system against degradation caused by solar (U-V) radiation or cause pile-up of aggregate on a downwind parapet.

The technical underpinnings of this proposal are three-fold:

1. The wind tunnel basis of the K-W design method was re-evaluated to confirm or make technically supported improvements with respect to prevention of aggregate blow-off
2. Quantitative field observations of roofing system performance in extreme wind events were compared with the K-W design method
3. Prescriptive design requirements to prevent aggregate blow-off based on items 1 and 2 were developed as a new Table 1504.4 for inclusion in the IBC.

As a result of this study (Crandell, 2009), improvements are recommended for a modified K-W design method for aggregate surfaced roofs. The improvements include a reconfiguration of the design method that allows critical wind velocity for initiation of aggregate blow-off to be predicted as a linear relationship directly with parapet height. This approach greatly simplifies the design method at no loss of accuracy, thereby improving the utility of the method for design practitioners to address a recognized deterrent to broader application of the K-W design method (Smith, 1997). It also avoids inefficiencies (generally overdesign) caused by use of non-dimensional building geometry-based parameters to determine roof design requirements of actual buildings (e.g., wind speed limit, aggregate size, and parapet height).

In addition, the effect of gravel size on critical velocity for blow-off is improved based on the reviewed wind tunnel data which shows a clear relationship between critical velocity for blow-off and the cube-root of the aggregate diameter (not the square-root as used in the K-W design method).

Finally, the modified K-W design method using the above improvements is compared to field observations with sufficient quantitative data (e.g., local wind speed, exposure, aggregate size, parapet height, and building height) available to allow for a meaningful comparison. As a result, a calibration factor is proposed to bring the modified K-W design method in line with observations of successful performance while still maintaining adequate requirements to eradicate clearly problematic observations of aggregate blow-off. Use of such a calibration approach is consistent the RP-4 standard's application of the K-W design method.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: SMITH-S1-1504.4

Public Hearing Results

Committee Action: Disapproved

Committee Reason: There are concerns with the ten percent fines that would be permitted in the ballast, since testing indicates these fines are a problem in glass breakage. The proposed restrictions (exceptions) that are based on a building's Occupancy Category do not properly address the debris hazard posed to (or by) adjacent buildings, since the Occupancy Category is not relevant to the ballast blowing off the roof. There were concerns raised on correlating the parapet height to the area of the roof.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Michael D. Fischer, The Kellen Company, representing Roofing Industry Ad Hoc Working Group on Aggregate (including the Federal Emergency Management Agency, the Asphalt Roofing Manufacturers Association and SPRI), requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

1504.4 Ballasted and aAggregate ~~and paver~~ surfaced low-slope (roof slope < 2:12) roof coverings. Ballasted and aAggregate ~~and paver~~ surfaced roof system coverings shall be designed and installed in accordance with Section 1504.4.1 or 1504.4.2 as applicable.

1504.4.1 Ballasted surfaced roof coverings. Ballasted surfaced roof ~~Aggregate and paver surfaced roof system~~ coverings and parapets shall be designed and installed in accordance with ANSI/SPRI RP-4. Special inspection for compliance with ANSI/SPRI RP-4 shall be required in accordance with Section 1706.

Exceptions:

1. Ballasted surfaced roof coverings ~~Aggregate and concrete pavers~~ are not permitted where the building height exceeds 150 feet (45 720 mm) or where the wind speed limits prescribed in ANSI/SPRI RP-4 are exceeded.
2. In hurricane-prone regions as defined in Section 1609.2, stone ~~aggregate~~ is not permitted on Occupancy Category III or IV buildings where the basic wind speed is greater than 100 mph (45 m/s).

1504.4.2 Aggregate surfaced roof coverings. Aggregate surfaced roof system coverings shall be designed and installed in accordance with Table 1504.4 based on the exposure category and basic wind speed at the building site. The aggregate shall comply with ASTM D 1863. Special inspection for compliance with this section shall be required in accordance with Section 1706.

Exceptions:

1. Aggregate is not permitted where the building height exceeds 150 feet (45 720 mm) or where the basic wind speed exceeds 120 mph (54 m/s) in accordance with the limits of Table 1504.4.
2. In the hurricane-prone-regions as defined in Section 1609.2, aggregate is not permitted on Occupancy Category III or IV buildings where the basic wind speed is greater than 100 mph (45 m/s).
3. In hurricane-prone regions as defined in Section 1609.2, aggregate is not permitted on Occupancy Category I or II buildings when the basic wind speed is greater than 110 mph (49 m/s).

SI: 1" = 25.4 mm, 1 ft = 0.3 m, 1 mph = 0.44 m/s

n/p = not permitted

a. Interpolation between wind speeds and building heights shall be permitted.

~~b. Aggregate surfaced roofs shall not be permitted for basic wind speeds greater than 120 mph, or where the building height exceeds 150 feet.~~

b ~~c~~. For Occupancy Category III and IV buildings, use the next higher wind speed column.

c ~~d~~. Mean roof height shall be measured from the grade plane to the roof surface at the perimeter of the roof portion under consideration.

d ~~e~~. Wind exposure and basic wind speed shall be determined in accordance with Section 1609 ~~ASCE 7~~.

(Portions of proposal not shown remain unchanged)

Commenter's Reason: The intent of this public comment is to address comments received during the first code development hearing (including the IBC-S committee's reasons for disapproval), provide editorial clarifications, and urge approval as modified by final action. The technical justification for this public comment stands on the scientific basis and references as reported in the original proposal. The technical justification of the original proposal and this public comment is consistent with wind tunnel studies that are reported in the scientific literature, used as a basis for wind risk modeling, applied in the ANSI/RP-4 consensus standard, and confirmed by a quantitative analysis of aggregate surfaced roof systems in a number of hurricane events over the past 20 or more years.

One concern raised was that "ten percent fines are a problem in glass breakage" which refers to concerns with the presence of fines in the aggregate specified for roof ballast or surfacing. The distribution of aggregate size and gradation requirements are consistent with those used in the wind tunnel studies from which these provisions were derived. In addition, they are consistent with a number of quantitative field studies of ballasted and aggregate surfaced roofs that were used to confirm the "real world" effectiveness of these proposed provisions. However, for reason of simplicity and to limit aggregate to the larger gradation, Table 1504.4 is changed to allow only use of No.6 aggregate in the 110 and 120 mph wind zones (which are also the wind zones where special inspection requirements apply). The greater concern then should be with compliance with these proposed provisions, especially in areas where compliance is critical by experience. Thus, this public comment has added reference to special inspection requirements in Chapter 17 and clarified that the required special inspections must ensure compliance with the proposed requirements for ballast or aggregate, parapet height, etc. to ensure intended performance (also as requested by testimony at the first hearing).

A second concern was related to the use of building occupancy to trigger limitations on use of aggregate roof surfacing or ballast because adjacent buildings are the actual hazard, not the building with the aggregate roof surfacing itself. However, these proposed provisions are based on preventing the worst-case aggregate blow-off mechanism which occurs at the windward corner of buildings where vortices first cause aggregate to lift off the roof of a building and then commonly impact the same building. In areas particularly susceptible to wind borne debris hazards (i.e., the wind borne debris region), other code provisions are required to protect adjacent buildings, particularly those of higher importance categories. Thus, together with these improved provisions that prevent roof aggregate blow-off and code provisions to protect glazing against debris damage, this concern is effectively and comprehensively addressed in the code. Also, others suggested that the proposal should rely on the performance requirements in Table 1504.4 rather than prescriptive Occupancy Category limits. But, the building occupancy category limits are retained in this Public Comment as a precautionary action which may be reconsidered in future code development cycles.

There was also concern mentioned with considering the roof area and aspect ratio effect on potential for aggregate blow-off. However, this concern is only relevant if the proposed requirements were based on a less conservative aggregate blow-off mechanism (such as blow-off from the leeward roof side which occurs after and at a higher wind speed than aggregate blow-off of the leading corner of a building). Thus, the concern is addressed by choice of using the most conservative aggregate blow-off mechanism as the basis for the proposed requirements. Furthermore, the requirements are based on a wide range of building aspect ratios and areas both in wind tunnel experiments and a quantitative confirmation of the design approach by comparison to a number and variety of actual roof systems having experienced major hurricane events over the past 20 or more years as reported in the literature.

Finally, an editorial change was made to move the mandatory limitation in footnote ‘b’ of Table 1504.4 to the enabling text in proposed Section 1504.4.2. Also, an editorial change was included in footnote ‘d’ to label the ASCE 7 standard as “ASCE 7-05” to ensure that ICC staff make appropriate correlating changes to this proposal should S84-09/10 be approved in final action resulting in use of ASCE 7-10 and a new basis for the wind speed map. Other changes clarify the proposal in its use of terminology (i.e., using “ballasted surfaced roof covering” in lieu of “aggregate and paver” when ballasted roofs actually use stone and pavers and aggregate surfaced roofs use aggregate).

In conclusion, this public comment proposal stands as a significant improvement to the effectiveness and performance (scientific) basis for building code provisions aimed at controlling and preventing roof aggregate blow-off risk. Current provisions in the IBC 2009 are less effective and provide either overly-conservative or non-conservative solutions in comparison to the state-of-the-art scientific basis for this proposal. Final action approval is urged.

Final Action: AS AM AMPC____ D

S7-09/10
1504.5

Proposed Change as Submitted

Proponent: Mark S. Graham, representing National Roofing Contractors Association (NRCA)

Revise as follows:

1504.5 Edge securement for low-slope roofs. Low-slope ~~membrane~~ built-up, modified bitumen and single-ply roof systems metal edge securement, except gutters, shall be designed and installed for wind loads in accordance with Chapter 16 and tested in accordance with ANSI/SPRI ES-1, except the basic wind speed shall be determined from Figure 1609.

Reason: This proposed code change is intended to add clarity to the code by providing the specific roof membrane types to which Section 1504.5 applies.

The term “…membrane…” is not currently specifically defined in the context of roof systems in Section 1505—Definitions or Chapter 2—Definitions.

The description of roof membranes as “…built-up, modified bitumen and single-ply…” is consistent with other descriptions for membrane-type roof systems already included in Chapter 15.

Cost Impact: The code change proposal will not increase the cost of construction**.**

ICCFILENAME: GRAHAM-S3-1504.5

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: This proposal clarifies the code by listing the specific roof membrane types to which Section 1504.5 applies.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Mike Ennis, Single Ply Roofing Industry (SPRI), requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

1504.5 Edge securement for low-slope roofs. Low-slope ~~built-up, modified bitumen and single-ply~~ roof system~~s~~ metal edge securement, except gutters and <u>metal roof systems</u>, shall be designed and installed for wind loads in accordance with Chapter 16 and tested <u>for resistance</u> in accordance with ANSI/SPRI ES-1, except the basic wind speed shall be determined from Figure 1609.

Commenter's Reason: This code change proposal should be modified because the wind load resistance of edge metal systems should be tested for low slope roof assemblies beyond those specially called out in this code change proposal. ANSI/SPRI ES-1, the test standard called out in Section 1504.5, contains test procedures that can be used to evaluate the attachment of the edge metal securement system, independent of the type of membrane being used. Third party evaluation of wind damage on low-slope (<2:12) roof systems has consistently demonstrated that one of the major causes of damage during wind events is failure of the edge metal securement leading to progressive damage and failure of the rest of the roof system. There are three test procedures contained in ANSI/SPRI ES-1. RE-1 as it is designated within the standard, evaluates the ability of the edge metal system to secure the membrane in mechanically attached and ballasted single ply roof systems. RE-2 evaluates the pull off resistance of edge metal flashing when exposed to design wind load forces. RE-3 evaluates the pull off resistance of copings when exposed to vertical and horizontal wind load forces. RE-1 is specific to mechanically attached or ballasted low-slope roofing assemblies. RE-2 and RE-3 evaluate the securement of the edge metal independent of the type of low-slope assembly being used. Inspection of low-slope roof assemblies after high wind events has clearly demonstrated the importance of keeping the edge securement in place during wind events. The ANSI/SPRI ES-1 test procedure should be used to evaluate edge metal securement for all low slope roof assemblies except metal roof assemblies, which have evaluated edge metal securement in conjunction with individual systems.

Public Comment 2:

Mike Ennis, Single Ply Roofing Industry (SPRI), requests Disapproval.

Commenter's Reason: This code change proposal should be denied because the wind load resistance of edge metal systems should be tested for low slope roof assemblies beyond those specially called out in this code change proposal. ANSI/SPRI ES-1, the test standard called out in Section 1504.5, contains test procedures that can be used to evaluate the attachment of the edge metal securement system, independent of the type of membrane being used. Third party evaluation of wind damage on low-slope (<2:12) roof systems has consistently demonstrated that one of the major causes of damage during wind events is failure of the edge metal securement leading to progressive damage and failure of the rest of the roof system. There are three test procedures contained in ANSI/SPRI ES-1. RE-1 as it is designated within the standard, evaluates the ability of the edge metal system to secure the membrane in mechanically attached and ballasted single ply roof systems. RE-2 evaluates the pull off resistance of edge metal flashing when exposed to design wind load forces. RE-3 evaluates the pull off resistance of copings when exposed to vertical and horizontal wind load forces. RE-1 is specific to mechanically attached or ballasted low-slope roofing assemblies. RE-2 and RE-3 evaluate the securement of the edge metal independent of the type of low-slope assembly being used. Inspection of low-slope roof assemblies after high wind events has clearly demonstrated the importance of keeping the edge securement in place during wind events.

Final Action: AS AM AMPC____ D

S8-09/10
1504.5

Proposed Change as Submitted

Proponent: Mark S. Graham, representing National Roofing Contractors Association (NRCA)

Revise as follows:

1504.5 Edge securement for low-slope roofs. Low-slope membrane roof systems metal edge securement, except gutters, shall be designed and installed for wind loads in accordance with Chapter 16 and tested in accordance with <u>Test Methods RE-1, RE-2 and RE-3 of</u> ANSI/SPRI ES-1, except the basic wind speed shall be determined from Figure 1609.

Reason: This proposed code change is intended to add clarity to the code by providing the specific reference to ANSI/SPRI ES-1's test method requirements (RE-1, RE-2 and RE-3).

ANSI/SPRI ES-1 consists of two primary parts. In the first part the wind loads at a roof edge are determined. In the second part the edge metal flashings' wind resistances are determined according to ANSI/SPRI ES-1's RE-1, RE-2 and RE-3 test methods.

Currently, Section 1504 requires that wind loads be determined according to the code's Chapter 16, not ANSI/SPRI ES-1. Adding specific reference to ANSI/SPRI ES-1's test methods helps clarify that.

This proposed code change is not intended to change the code's current technical requirements; it is only intended to add a specific reference and clarity to which part of ANSI/SPRI ES-1 applies in Section 1504.5.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: GRAHAM-S4-1504.5

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: This code change clarifies the scope of reference to ANSI/SPRI ES-1 in Section 1504.5. By indicating the specific test methods, RE-1, RE-2 and RE-3, the applicable portions of the reference standard are more obvious to the reader.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Mike Ennis, Single Ply Roofing Industry (SPRI), requests Disapproval.

Commenter's Reason: There is no need for this code change, as it adds no additional clarification to the requirements of the code. Section 1504.5 Edge securement for low-slope roofs.states **"**Low-slope membrane roof system metal edge securement, except gutters, shall be designed and installed for wind loads in accordance with Chapter 16 and tested for resistance in accordance with ANSI/SPRI ES-1, except the basic wind speed shall be determined from Figure 1609". The current wording in the code is very clear. The test procedures that are called out for specific reference are all of the test procedures in ANSI/SPRI ES-1, so specifically listing them adds words but no clarification to the intent of the code.

Final Action: AS AM AMPC____ D

S9-09/10

1504.9 (New), Chapter 35

Proposed Change as Submitted

Proponent: Mike Ennis representing Single Ply Roofing Industry (SPRI)

1. Add new text as follows:

1504.9 Roof gardens and landscaped roofs. Roof gardens and landscaped roofs shall comply with Section 1507.16 and shall be installed in accordance with ANSI/SPRI RP14.

2. Add standard to Chapter 35 as follows:

SPRI
RP 14-07 Wind Design Standard for Vegetative Roofing Systems

Reason: Section 1507.16 requires that roof gardens and landscaped roofs comply with the requirements of Chapter 15. Section 1504.1 provides requirements for wind resistance of various roofing assemblies, however no guidance is provided for designing roof gardens and landscaped roofs to withstand wind loads. Roof gardens and landscaped roofs perform in the same manner as ballasted single ply roof assemblies when exposed to wind loads. ANSI/SPRI RP14 is a national consensus standard that has been developed with input from roof membrane manufacturers, component suppliers, contractors, green roofing professionals, testing organizations, and consultants. This design standard is much like the ballast design guide for single-ply roofs currently recognized by the IBC (ANSI/SPRI RP4). It provides the user with a series of tables that define requirements based on design wind speed, building height, parapet height and wind exposure. Three design options are provided. These design options vary in their ability to resist wind loads. Design option 1 uses a 10 lbs/ft2 minimum required load of growth media or trays, Design option 2 also requires minimum 10 lbs/ft2 of growth media or trays in the field of the roof and 13 lbs/ft2 of growth media or interlocking trays or 22 lbs/ft2 of individual trays in the corner and perimeter regions. Design option 3, which is designed for high wind load areas, requires 13 lbs/ft2 of growth media or interlocking trays, or 22 lbs/ft2 of individual trays in the field of the roof and does not allow any loose growth media or trays in the perimeter and corner regions. The perimeter of the building is defined as 40% of the building height. Adjustments are provided to increase the wind resistance of the design based on specific building conditions such as the buildings importance factor, large openings in adjacent walls and rooftop projections to name a few. The standard also provides requirements for newly planted garden roofs that do not have fully developed root systems. Fully developed root systems allow the garden roof assembly to perform very well when exposed to high wind situations, however prior to development of the root system special precautions must be taken.

The basis for the standard includes wind tunnel data generated in support of the ballasted single ply design guide. This wind tunnel testing helped develop an understanding of the impact of particle size and parapet height on the performance of ballasted assemblies. It also provided information regarding the weight of ballast required to keep the roof systems in place at various wind speeds. This data, along with 50-years of garden roof performance data from both the US and Europe were used in the development of this standard.

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: A review of the standard(s) proposed for inclusion in the code, SPRI RP-14 07, for compliance with ICC criteria for referenced standards given in Section 3.6 of Council Policy #CP 28 will be posted on the ICC website on or before September 24, 2009.

ICCFILENAME: ENNIS-S4-1504.9

Public Hearing Results

Note: The following analysis was not in the Code Change monograph but was published on the ICC website at http://www.iccsafe.org/cs/codes/Documents/2009-10cycle/ProposedChanges/Standards-Analysis.pdf :

Analysis: Review of proposed new standard ANSI/SPRI RP 14 indicated that, in the opinion of ICC Staff, the standard did not comply with ICC standards criteria, Section 3.6.3(1) Readily available.

Committee Action: Disapproved

Committee Reason: The committee's disapproval was based on the status of the proposed reference standard. As a draft, it is not readily available.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Mike Ennis, Single Ply Roofing Industry (SPRI), requests Approved as Submitted.

Commenter's Reason: This code change proposal was submitted to address a need for evaluating the wind uplift resistance of roof gardens and landscaped roofs. At the time of the code change hearings the design standard referenced in this proposal (ANSI/SPRI RP14) was only available in draft form and therefore did not meet the requirements of the International Building Code. Since that time the development of this standard has been completed and it is now an ANSI national consensus standard, meeting the requirements of the International Building Code.

Final Action: AS AM AMPC____ D

S12-09/10

1505.8 (New), Chapter 35

Proposed Change as Submitted

Proponent: Mike Ennis representing the Single Ply Roofing Industry

1. Add new text as follows:

1505.8 Roof gardens and landscaped roofs. Roof gardens and landscaped roofs shall comply with Section 1507.16 and shall be installed in accordance with ANSI/SPRI VF-1.

2. Add standard to Chapter 35 as follows:

SPRI

VF-1-08 Fire Design Standard for Vegetative Roofs

Reason: Section 1507.16 requires that roof gardens and landscaped roofs comply with the requirements of Chapter 15. Section 1505 requires that roofing assemblies be fire classified. The current test procedures used to provide this fire classification are not applicable to garden and landscape roofs due to the many variables (plant types, moisture content, etc.) that exist for these types of systems. ANSI/SPRI VF-1 is a national consensus standard that has been developed with input from roof membrane manufacturers, component suppliers, contractors, green roofing professionals, testing organizations, and consultants. This standard provides a design method to assure an acceptable level of performance of roof gardens and landscaped roofs when exposed to exterior fire sources. The general approach used in this standard is to design in fire breaks for large roof areas, around rooftop equipment and penetrations, and next to adjacent walls. Some of the specific requirements are:

Exposed membrane areas must conform to the designed fire resistance requirements as determined by the authority having jurisdiction.
For all vegetated roofing systems abutting combustible vertical surfaces, a Class A (per ASTM E108 or UL790) rated assembly must be achieved for a minimum 6 ft (1.83 m) wide continuous border placed around rooftop structures and all rooftop equipment.
For large roof areas: Partition the roof area into sections not exceeding 15,625 ft2 (1,450 m^2), with each section having no dimension greater than 125 ft (39 m) by installing a minimum of 3ft. (0.9 m) wide, Class A rated assembly barrier zones.

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: A review of the standard(s) proposed for inclusion in the code, VF-1-08, for compliance with ICC criteria for referenced standards given in Section 3.6 of Council Policy #CP 28 will be posted on the ICC website on or before September 24, 2009.

ICCFILENAME: ENNIS-S5-1505.8

Public Hearing Results

Note: The following analysis was not in the Code Change monograph but was published on the ICC website at http://www.iccsafe.org/cs/codes/Documents/2009-10cycle/ProposedChanges/Standards-Analysis.pdf :

Analysis: Review of proposed new standard ANSI/SPRI VF 1 indicated that, in the opinion of ICC Staff, the standard did not comply with ICC standards criteria, Section 3.6.3(1) Readily available.

Committee Action: **Disapproved**

Committee Reason: Disapproval was based on the proponents request for disapproval. Further, the proposed standard SPRI VF-1-08 has not been submitted.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Mike Ennis, Single Ply Roofing Industry (SPRI), request Approval as Submitted.

Commenter's Reason: This code change proposal was submitted to address a need for evaluating the fire resistance of roof gardens and landscaped roofs. At the time of the code change hearings the design standard referenced in this proposal (ANSI/SPRI VF1) was only available in draft form and therefore did not meet the requirements of the International Building Code. Since that time the development of this standard has been completed and it is now an ANSI national consensus standard, meeting the requirements of the International Building Code.

1507.2.8.1, 1507.3.3.3 (New), 1507.4.5 (New), 1507.5.3.1 (New), 1507.6.3.1 (New), 1507.7.3.1 (New), 1507.8.3.1 (New), 1507.9.3.1 (New)

Proposed Change as Submitted

Proponent: T. Eric Stafford, PE, representing Institute for Business and Home Safety

PART I – IBC STRUCTURAL

1. Revise as follows:

1507.2.8.1 High wind attachment. Underlayment applied in areas subject to high winds [above 110 mph (49 m/s) in accordance with Figure 1609] shall be applied with corrosion-resistant fasteners in accordance with manufacturer's installation instructions. Fasteners are to be applied along the overlap at a maximum spacing of 36 inches (914mm) on center.

Underlayment installed where the basic wind speed equals or exceeds 120 mph (54 m/s) shall comply with ASTM D 226 Type II, ASTM D 4869 Type IV, or ASTM D 6757. The underlayment shall be attached in a grid pattern of 12 inches (305 mm) between side laps with a 6 inch (152 mm) spacing at the side laps. Head laps shall be 4 inches (102 mm) and end laps shall be a minimum of 6 inches (152 mm). Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 5/8 inches (41 mm) with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.

Underlayment installed where the basic wind speed equals or exceeds 140 mph (63 m/s) shall be attached using metal cap nails with a head diameter of not less than 1 5/8 inches (41 mm) with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.

2. Add new text as follows:

1507.3.3.3 High wind attachment. Underlayment applied in areas subject to high wind [over 110 mph (49 m/s) in accordance with Figure 1609] shall be applied with corrosion-resistant fasteners in accordance with manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914 mm) on center.

Underlayment installed where the basic wind speed equals or exceeds 120 mph (54 m/s) shall be attached in a grid pattern of 12 inches (305 mm) between side laps with a 6 inch (152 mm) spacing at the side laps. Head laps shall be 4 inches (102 mm) and end laps shall be a minimum of 6 inches (152 mm). Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 5/8 inches (41 mm) with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.

Underlayment installed where the basic wind speed equals or exceeds 140 mph (63 m/s) shall be attached using metal cap nails with a head diameter of not less than 1 5/8 inches (41 mm) with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.

1507.4.5 Underlayment and high wind. Underlayment applied in areas subject to high winds [above 110 mph (49 m/s) in accordance with Figure 1609] shall be applied with corrosion-resistant fasteners in accordance with manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914 mm) on center.

Underlayment installed where the basic wind speed equals or exceeds 120 mph (54 m/s) shall comply with ASTM D 226 Type II, ASTM D 4869 Type IV, or ASTM D 1970. The underlayment shall be attached in a grid pattern of 12 inches (305 mm) between side laps with a 6 inch (152 mm) spacing at the side laps. Head laps shall be 4 inches (102 mm) and end laps shall be a minimum of 6 inches (152 mm). Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 5/8 inches (41mm) with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.

Underlayment installed where the basic wind speed equals or exceeds 140 mph (63 m/s) shall be attached using metal cap nails with a head diameter of not less than 1 5/8 inches (41 mm) with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.

1507.5.3.1 Underlayment and high wind. Underlayment applied in areas subject to high winds [above 110 mph (49 m/s) in accordance with Figure 1609] shall be applied with corrosion-resistant fasteners in accordance with manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914 mm) on center.

Underlayment installed where the basic wind speed equals or exceeds 120 mph (54 m/s) shall comply with ASTM D 226 Type II or ASTM D 4869 Type IV. The underlayment shall be attached in a grid pattern of 12 inches (305 mm) between side laps with a 6 inch (152 mm) spacing at the side laps. Head laps shall be 4 inches (102 mm) and end laps shall be a minimum of 6 inches (152 mm). Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 5/8 inches (41 mm) with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.

Underlayment installed where the basic wind speed equals or exceeds 140 mph (63 m/s) shall be attached using metal cap nails with a head diameter of not less than 1 5/8 inches (41 mm) with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.

1507.6.3.1 Underlayment and high wind. Underlayment applied in areas subject to high winds [above 110 mph (49 m/s) in accordance with Figure 1609] shall be applied with corrosion-resistant fasteners in accordance with manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914mm) on center.

Underlayment installed where the basic wind speed equals or exceeds 120 mph (54 m/s) shall comply with ASTM D 226 Type II. The underlayment shall be attached in a grid pattern of 12 inches (305 mm) between side laps with a 6 inch (152 mm) spacing at the side laps. Head laps shall be 4 inches (102 mm) and end laps shall be a minimum of 6 inches (152 mm). Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 5/8 inches (41 mm) with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.

Underlayment installed where the basic wind speed equals or exceeds 140 mph (63 m/s) shall be attached using metal cap nails with a head diameter of not less than 1 5/8 inches (41 mm) with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.

1507.7.3.1 Underlayment and high wind. Underlayment applied in areas subject to high winds [above 110 mph (49 m/s) in accordance with Figure 1609] shall be applied with corrosion-resistant fasteners in accordance with manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914 mm) on center.

Underlayment installed where the basic wind speed equals or exceeds 120 mph (54 m/s) shall comply with ASTM D 226 Type II or ASTM D 4869 Type IV. The underlayment shall be attached in a grid pattern of 12 inches (305 mm) between side laps with a 6 inch (152 mm) spacing at the side laps. Head laps shall be 4 inches (102 mm) and end laps shall be a minimum of 6 inches (152 mm). Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 5/8 inches (41 mm) with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.

Underlayment installed where the basic wind speed equals or exceeds 140 mph (63 m/s) shall be attached using metal cap nails with a head diameter of not less than 1 5/8 inches (41 mm) with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.

1507.8.3.1 Underlayment and high wind. Underlayment applied in areas subject to high winds [above 110 mph (49 m/s) in accordance with Figure 1609] shall be applied with corrosion-resistant fasteners in accordance with manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914 mm) on center.

Underlayment installed where the basic wind speed equals or exceeds 120 mph (54 m/s) shall comply with ASTM D 226 Type II or ASTM D 4869 Type IV. The underlayment shall be attached in a grid pattern of 12 inches between side laps with a 6 inch (152 mm) spacing at the side laps. Head laps shall be 4 inches (102 mm) and end laps shall be a minimum of 6 inches (152 mm). Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 5/8 inches (41 mm) with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.

Underlayment installed where the basic wind speed equals or exceeds 140 mph (63 m/s) shall be attached using metal cap nails with a head diameter of not less than 1 5/8 inches (41 mm) with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.

1507.9.3.1 Underlayment and high wind. Underlayment applied in areas subject to high winds [above 110 mph (49 m/s) in accordance with Figure 1609] shall be applied with corrosion-resistant fasteners in accordance with manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914 mm) on center.

Underlayment installed where the basic wind speed equals or exceeds 120 mph (54 m/s) shall comply with ASTM D 226 Type II or ASTM D 4869 Type IV. The underlayment shall be attached in a grid pattern of 12 inches (305 mm) between side laps with a 6 inch (152 mm) spacing at the side laps. Head laps shall be 4 inches (102 mm) and end laps shall be a minimum of 6 inches (152 mm). Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 5/8 inches (41 mm) with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.

Underlayment installed where the basic wind speed equals or exceeds 140 mph (63 m/s) shall be attached using metal cap nails with a head diameter of not less than 1 5/8 inches (41 mm) with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.

Reason: Observations of roof underlayment performance following Hurricane Ike in Texas and in two sets of tests conducted at the University of Florida and Florida International University demonstrated that relatively new and new ASTM 226 Type I underlayments performed very poorly when subjected to wind over about 110 mph. In the laboratory tests, specimen covered with ASTM 226 Type I and Type II underlayments performed dramatically differently. ASTM Type I felt (15#) material completely blew off some portions of the specimen as winds exceeded 110 mph and pulled over the plastic caps on other parts of the specimen. In contrast, the ASTM 226 Type II (30#) material remained in place and showed very few signs of distress. Plastic caps deformed much more than the metal caps in several installations. Consequently, the use of metal caps is recommended for areas with the highest basic design wind speeds.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: Stafford-S3-1507.2.8.1

Public Hearing Results

PART I- IBC STRUCTURAL
Committee Action: Disapproved

Committee Reason: As worded, the requirements could be applied to currently used products that do not have problems, excluding self-adhered underlayment unless it is nailed down. This would be an extensive change and the committee was not provided with the data to support these specific requirements. The need for this underlayment requirement is unclear since it is under a covering that is already held down. There is no credit given for the nails through the shingles, for instance. Typically the roof covering manufacturer provides direction on how to install the underlayment and the underlayment varies with the type of roof covering. While the phrase "underlayment … shall be applied with corrosion-resistant fasteners in accordance with the manufacturer's installation instructions" is currently used in Section 1507.2.8.1, there are questions on its intent and the wording should be clear on whether this refers to the fastener or underlayment manufacturer before adding it in several new sections.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

T. Eric Stafford, Institute for Business and Home Safety, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

1507.2.8.1 High wind attachment. Underlayment applied in areas subject to high winds [above 110 mph (49 m/s) in accordance with Figure 1609] shall be applied with corrosion-resistant fasteners in accordance with manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914mm)on center.

Underlayment installed where the basic wind speed equals or exceeds 120 mph (54 m/s) shall comply with ASTM D 226 Type II, ASTM D 4869 Type IV, or ASTM D 6757. The underlayment shall be attached in a grid pattern of 12 inches (305 mm) between side laps with a 6 inch (152 mm) spacing at the side laps. Underlayment shall be applied in accordance with Section 1507.2.8 except all ~~Head~~ laps shall be a minimum of 4 inches (102 mm) ~~and end laps shall be a minimum of 6 inches~~. Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 ~~5/8~~ inches (25.4 ~~41~~ mm) with a thickness ~~shank~~ of at least 32 gauge sheet metal. The cap nail shank shall be a minimum of 12 gage with a length to penetrate through the roof sheathing or a minimum of ¾ inch into the roof sheathing.

Exception: As an alternative, adhered underlayment complying with ASTM D 1970 shall be permitted.

~~Underlayment installed where the basic wind speed equals or exceeds 140 mph shall be attached using metal cap nails with a head diameter of not less than 1 5/8 inches with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.~~

1507.3.3.3 High wind attachment. Underlayment applied in areas subject to high wind [over 110 miles per hour (49 m/s) in accordance with Figure 1609] shall be applied with corrosion-resistant fasteners in accordance with manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914 mm) on center.

Underlayment installed where the basic wind speed equals or exceeds 120 mph (54 m/s) shall be attached in a grid pattern of 12 inches (305 mm) between side laps with a 6 inch (152 mm) spacing at the side laps. Underlayment shall be applied in accordance with Section 1507.3.3.1 and 1507.3.3.2 except all ~~Head~~ laps shall be a minimum of 4 inches (102 mm) ~~and end laps shall be a minimum of 6 inches~~. Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 ~~5/8~~ inches (25.4 ~~41~~ mm) with a thickness ~~shank~~ of at least 32 gauge sheet metal. The cap nail shank shall be a minimum of 12 gauge with a length to penetrate through the roof sheathing or a minimum of ¾ inch into the roof sheathing.

Exception: As an alternative, adhered underlayment complying with ASTM D 1970 shall be permitted.

~~Underlayment installed where the basic wind speed equals or exceeds 140 mph shall be attached using metal cap nails with a head diameter of not less than 1 5/8 inches with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.~~

1507.4.5 Underlayment and high wind. Underlayment applied in areas subject to high winds [above 110 mph (49 m/s) in accordance with Figure 1609] shall be applied with corrosion-resistant fasteners in accordance with manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914mm)on center.

Underlayment installed where the basic wind speed equals or exceeds 120 mph (54 m/s) shall comply with ASTM D 226 Type II, ASTM D 4869 Type IV, or ASTM D 1970. The underlayment shall be attached in a grid pattern of 12 inches (305 mm) between side laps with a 6 inch (152 mm) spacing at the side laps. Underlayment shall be applied in accordance with the manufacturer's installation instructions except all ~~Head~~ laps shall be a minimum of 4 inches (102 mm) ~~and end laps shall be a minimum of 6 inches~~. Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 ~~5/8~~ (25.4 ~~41~~ mm) inches with a thickness ~~shank~~ of at least 32 gauge sheet metal. The cap nail shank shall be a minimum of 12 gauge with a length to penetrate through the roof sheathing or a minimum of ¾ inch into the roof sheathing.

Exception: As an alternative, adhered underlayment complying with ASTM D 1970 shall be permitted.

~~Underlayment installed where the basic wind speed equals or exceeds 140 mph shall be attached using metal cap nails with a head diameter of not less than 1 5/8 inches with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.~~

1507.5.3.1 Underlayment and high wind. Underlayment applied in areas subject to high winds [above 110 mph (49 m/s) in accordance with Figure 1609] shall be applied with corrosion-resistant fasteners in accordance with manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914mm)on center.

Underlayment installed where the basic wind speed equals or exceeds 120 mph (54 m/s) shall comply with ASTM D 226 Type II or ASTM D 4869 Type IV. The underlayment shall be attached in a grid pattern of 12 inches (305 mm) between side laps with a 6 inch spacing (152 mm) at the side laps. Underlayment shall be applied in accordance with the manufacturer's installation instructions except all ~~Head~~ laps shall be a minimum of 4 inches (102 mm) ~~and end laps shall be a minimum of 6 inches~~. Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 ~~5/8~~ inches (25.4 ~~41~~ mm) with a thickness ~~shank~~ of at least 32 gauge sheet metal. The cap nail shank shall be a minimum of 12 gauge with a length to penetrate through the roof sheathing or a minimum of ¾ inch into the roof sheathing.

Exception: As an alternative, adhered underlayment complying with ASTM D 1970 shall be permitted.

~~Underlayment installed where the basic wind speed equals or exceeds 140 mph shall be attached using metal cap nails with a head diameter of not less than 1 5/8 inches with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.~~

1507.6.3.1 Underlayment and high wind. Underlayment applied in areas subject to high winds [above 110 mph (49 m/s) in accordance with Figure 1609] shall be applied with corrosion-resistant fasteners in accordance with manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914mm)on center.

Underlayment installed where the basic wind speed equals or exceeds 120 mph (54 m/s) shall comply with ASTM D 226 Type II. The underlayment shall be attached in a grid pattern of 12 inches (305 mm) between side laps with a 6 inch (152 mm) spacing at the side laps. Underlayment shall be applied in accordance with the manufacturer's installation instructions except all ~~Head~~ laps shall be a minimum of 4 inches (102 mm) ~~and end laps shall be a minimum of 6 inches~~. Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 ~~5/8~~ inches (25.4 ~~41~~ mm) with a thickness ~~shank~~ of at least 32 gauge sheet metal. The cap nail shank shall be a minimum of 12 gauge with a length to penetrate through the roof sheathing or a minimum of ¾ inch into the roof sheathing.

Exception: As an alternative, adhered underlayment complying with ASTM D 1970 shall be permitted.

~~Underlayment installed where the basic wind speed equals or exceeds 140 mph shall be attached using metal cap nails with a head diameter of not less than 1 5/8 inches with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.~~

1507.7.3.1 Underlayment and high wind. Underlayment applied in areas subject to high winds [above 110 mph (49 m/s) in accordance with Figure 1609] shall be applied with corrosion-resistant fasteners in accordance with manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914mm)on center.

Underlayment installed where the basic wind speed equals or exceeds 120 mph (54 m/s) shall comply with ASTM D 226 Type II or ASTM D 4869 Type IV. The underlayment shall be attached in a grid pattern of 12 inches (305 mm) between side laps with a 6 inch (152 mm) spacing at the side laps. Underlayment shall be applied in accordance with the manufacturer's installation instructions except all ~~Head~~ laps shall be a minimum of 4 inches (102 mm) ~~and end laps shall be a minimum of 6 inches~~. Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 ~~5/8~~ inches (25.4 ~~41~~ mm) with a thickness ~~shank~~ of at least 32 gauge sheet metal. The cap nail shank shall be a minimum of 12 gauge with a length to penetrate through the roof sheathing or a minimum of ¾ inch into the roof sheathing.

Exception: As an alternative, adhered underlayment complying with ASTM D 1970 shall be permitted.

~~Underlayment installed where the basic wind speed equals or exceeds 140 mph shall be attached using metal cap nails with a head diameter of not less than 1 5/8 inches with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.~~

1507.8.3.1 Underlayment and high wind. Underlayment applied in areas subject to high winds [above 110 mph (49 m/s) in accordance with Figure 1609] shall be applied with corrosion-resistant fasteners in accordance with manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914mm) on center.

Underlayment installed where the basic wind speed equals or exceeds 120 mph (54 m/s) shall comply with ASTM D 226 Type II or ASTM D 4869 Type IV. The underlayment shall be attached in a grid pattern of 12 inches (305 mm) between side laps with a 6 inch (152 mm) spacing at the side laps. Underlayment shall be applied in accordance with the manufacturer's installation instructions except all ~~Head~~ laps shall be a minimum of 4 inches (102 mm)~~ and end laps shall be a minimum of 6 inches~~. Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 ~~5/8~~ inches (25.4 ~~41~~ mm) with a thickness ~~shank~~ of at least 32 gauge sheet metal. The cap nail shank shall be a minimum of 12 gauge with a length to penetrate through the roof sheathing or a minimum of ¾ inch into the roof sheathing.

Exception: As an alternative, adhered underlayment complying with ASTM D 1970 shall be permitted.

~~Underlayment installed where the basic wind speed equals or exceeds 140 mph shall be attached using metal cap nails with a head diameter of not less than 1 5/8 inches with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.~~

1507.9.3.1 Underlayment and high wind. Underlayment applied in areas subject to high winds [above 110 mph (49 m/s) in accordance with Figure 1609] shall be applied with corrosion-resistant fasteners in accordance with manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914mm) on center.

Underlayment installed where the basic wind speed equals or exceeds 120 mph (54 m/s) shall comply with ASTM D 226 Type II or ASTM D 4869 Type IV. The underlayment shall be attached in a grid pattern of 12 inches (305 mm) between side laps with a 6 inch (152 mm) spacing at the side laps. Underlayment shall be applied in accordance with the manufacturer's installation instructions except all ~~Head~~ laps shall be a minimum of 4 inches (102 mm) ~~and end laps shall be a minimum of 6 inches~~. Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 ~~5/8~~ inches (25.4 ~~41~~ mm) with a thickness ~~shank~~ of at least 32 gauge sheet metal. The cap nail shank shall be a minimum of 12 gauge with a length to penetrate through the roof sheathing or a minimum of ¾ inch into the roof sheathing.

Exception: As an alternative, adhered underlayment complying with ASTM D 1970 shall be permitted.

~~Underlayment installed where the basic wind speed equals or exceeds 140 mph shall be attached using metal cap nails with a head diameter of not less than 1 5/8 inches with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.~~

Commenter's Reason: The modifications proposed in this public comment are essentially identical to the Floor Amendment on S15-09/10 Part II that was approved by the IRC Building/Energy Code Development Committee. S15-09/10 Part II was Approved as Modified by the IRC Building/Energy Code Development Committee. The same amendments approved by that committee are proposed for S15-09/10 Part 1. The modifications proposed by this public comment reflect some compromises with affected industry groups. NAHB and ARMA supported Approval of this code change at the Code Development Hearings with the modifications provided.

The proposed amendments to S15-09/10 Part I include some editorial corrections to the required lap lengths and the thickness of the fastener (12 gage instead of 32 gage). The head diameter of the cap portion of the nail is proposed to be reduced to 1 inches in recognition of the type most commonly used in the field. The language that required the use of metal cap nails where the wind speed exceeds 140 mph is proposed to be deleted reflecting a compromise with affected industry groups. Finally, some on the IBC Structural Code Development Committee felt that the language, as proposed, appeared to exclude the use of a self adhered polymer modified bitumen underlayment. This was not intended by the original language. To clarify that self adhered underlayments are permitted, a new Exception is added specifically permitting the use of a self-adhered underlayment complying with ASTM D 1970.

Public Comment 2:

John Kurtz, International Staple, Nail & Tool Association, requests Approval as Modified by this Public Comment.

Replace the proposal as follows:

1507.2 Underlayment. Underlayment shall be in accordance with Sections 1507.2.1 through 1507.2.3.

1507.2.1 Specifications. Required underlayment shall conform to types listed in Table 1507.2.1.

TABLE 1507.2.1
UNDERLAYMENT STANDARDS

Section	Roof Covering	ASTM Specification: Wind Speed 120 mph or lower	ASTM Specification: Wind Speed over 120 mph
1507.3	Asphalt shingles	D 226 Type I D 4869 Type I D 6757	D 226 Type II D 4869 Type IV D 6757 D 1970
1507.4	Clay and concrete tile	D 226 Type II D 2626 D 6380 Class M	D 1970

(Renumber remaining sections)

~~**1507.2.3 Underlayment.** Unless otherwise noted, required underlayment shall conform to ASTM D 226, Type I, ASTM D 4869, Type I, or ASTM D 6757.~~

(Renumber remaining sections)

~~**1507.2.8 Underlayment application.** For roof slopes from two units vertical in 12 units horizontal (17-percent slope) and up to four units vertical in 12 units horizontal (33-percent slope), underlayment shall be two layers applied in the following manner. Apply a minimum 19-inch-wide (483 mm) strip of underlayment felt parallel with and starting at the eaves, fastened sufficiently to hold in place. Starting at the eave, apply 36-inch-wide (914 mm) sheets of underlayment overlapping successive sheets 19 inches (483 mm), by fastened sufficiently to hold in place. Distortions in the underlayment shall not interfere with the ability of the shingles to seat. For roof slopes of four units vertical in 12 units horizontal (33-percent slope) or greater, underlayment shall be one layer applied in the following manner. Underlayment shall be applied shingle fashion, parallel to and starting from the eave and lapped 2 inches (51 mm), fastened sufficiently to hold in place. Distortions in the underlayment shall not interfere with the ability of the shingles to seal.~~
~~**1507.2.8.1 High wind attachment.** Underlayment applied in areas subject to high winds (greater than 110 mph in accordance with Figure 1609) shall be applied with corrosion-resistant fasteners in accordance with the manufacturer's instructions. Fasteners are to be applied along the overlap at a maximum spacing of 36 inches (914 mm) on center.~~

~~**1507.2.8.2**~~ **1507.3.7 Ice barrier.** In areas where there has been a history of ice forming along the eaves causing a backup of water, an ice barrier that consists of at least two layers of underlayment cemented together or of a self-adhering polymer modified bitumen sheet shall be used in lieu of normal underlayment and extend from the lowest edges of all roof surfaces to a point at least 24 inches (610 mm) inside the *exterior wall* line of the building.

Exception: Detached accessory structures that contain no conditioned floor area.

~~**1507.3.3 Underlayment.** Unless otherwise noted, required underlayment shall conform to: ASTM D 226, Type II; ASTM D 2626 or ASTM D 6380, Class M mineral-surfaced roll roofing.~~

~~**1507.3.3.1 Low-slope roofs.** For roof slopes from 2½ units vertical in 12 units horizontal (21-percent slope), up to four units vertical in 12 units horizontal (33-percent slope), underlayment shall be a minimum of two layers applied as follows:~~

1. ~~Starting at the eave, a 19-inch (483 mm) strip of underlayment shall be applied parallel with the eave and fastened sufficiently in place.~~
2. ~~Starting at the eave, 36-inch-wide (914 mm) strips of underlayment felt shall be applied overlapping successive sheets 19 inches (483 mm) and fastened sufficiently in place.~~

~~**1507.3.3.2 High-slope roofs.** For roof slopes of four units vertical in 12 units horizontal (33-percent slope) or greater, underlayment shall be a minimum of one layer of underlayment felt applied shingle fashion, parallel to, and starting from the eaves and lapped 2 inches (51 nun), fastened only as necessary to hold in place.~~

~~**1507.5.3 Underlayment.** Underlayment shall comply with ASTM D 226, Type I or ASTM D 4869.~~

(Renumber remaining sections)

~~**1507.6.3 Underlayment.** Underlayment shall comply with ASTM D 226, Type I or ASTM D 4869.~~

(Renumber remaining sections)

Commenter's Reason: The original proposal intended to increase the likelihood of holding underlayment in place if roof coverings were lost to high winds. Proposal was disapproved for inherent technical deficiencies, ambiguity, and insufficient supporting data. Our proposed modification would accomplish the intent with commercially available fasteners and better code language. Our proposed modification builds on a successful floor modification to Part II (IRC.)

Our proposed modification corrects deficiencies in the Part II floor modification, namely, (1) specification of fasteners not generally in use, (2) exclusion of successfully used fasteners, and (3) unnecessarily verbose/repetitive code language.

Our proposed modification (1) allows use of power tools currently owned by builders, (2) allows use of a range of successfully used cap nails and cap staples, (3) maintains equivalence to application performance proposed by the Public Hearing floor modification, though it was arbitrary, and (4) summarizes fastening requirements for underlayment in one code section rather than repeating requirements in eight sections for eight separate roof coverings.

Final Action: AS AM AMPC____ D

S15-09/10-PART II

IRC R905.2.7.2, R905.3.3.3, R905.4.3.2 (New), R905.5.3.2 (New), R905.6.3.2 (New), R905.7.3.2 (New), R905.8.3.2 (New), R905.10.5.1 (New)

Proposed Change as Submitted

PART II – IRC BUILDING/ENERGY

1. Revise as follows:

R905.2.7.2 Underlayment and high wind. Underlayment applied in areas subject to high winds [above 110 mph (49 m/s) in accordance with Figure R301.2(4)] shall be applied with corrosion-resistant fasteners in accordance with manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914mm) on center.

Underlayment installed where the basic wind speed equals or exceeds 120 mph (54 m/s) shall comply with ASTM D 226 Type II, ASTM D 4869 Type IV, or ASTM D 6757. The underlayment shall be attached in a grid pattern of 12 inches (305 mm) between side laps with a 6 inch (152 mm) spacing at the side laps. Head laps shall be 4 inches (102 mm) and end laps shall be a minimum of 6 inches (152 mm). Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 5/8 inches (41 mm) with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.

Underlayment installed where the basic wind speed equals or exceeds 140 mph (63 m/s) shall be attached using metal cap nails with a head diameter of not less than 1 5/8 inches (41 mm) with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.

R905.3.3.3 Underlayment and high wind. Underlayment applied in areas subject to high wind [over 110 miles per hour (49 m/s) in accordance with R301.2(4)] shall be applied with corrosion-resistant fasteners in accordance with manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914 mm) on center.

Underlayment installed where the basic wind speed equals or exceeds 120 mph (54 m/s) shall be attached in a grid pattern of 12 inches (305 mm) between side laps with a 6 inch (152 mm) spacing at the side laps. Head laps shall be 4 inches (102 mm) and end laps shall be a minimum of 6 inches (152 mm). Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 5/8 inches (41 mm) with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.

Underlayment installed where the basic wind speed equals or exceeds 140 mph (63 m/s) shall be attached using metal cap nails with a head diameter of not less than 1 5/8 inches (41 mm) with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.

2. Add new text as follows:

R905.4.3.2 Underlayment and high wind. Underlayment applied in areas subject to high winds [above 110 mph (49 m/s) in accordance with Figure R301.2(4)] shall be applied with corrosion-resistant fasteners in accordance with manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914 mm) on center.

Underlayment installed where the basic wind speed equals or exceeds 120 mph (54 m/s) shall comply with ASTM D 226 Type II, ASTM D 4869 Type IV, or ASTM D 1970. The underlayment shall be attached in a grid pattern of 12 inches (305 mm) between side laps with a 6 inch (152 mm) spacing at the side laps. Head laps shall be 4 inches (102 mm) and end laps shall be a minimum of 6 inches (152 mm). Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 5/8 inches (41 mm) with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.

Underlayment installed where the basic wind speed equals or exceeds 140 mph (63 m/s) shall be attached using metal cap nails with a head diameter of not less than 1 5/8 inches (41 mm) with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.

R905.5.3.2 Underlayment and high wind. Underlayment applied in areas subject to high winds [above 110 mph (49 m/s) in accordance with Figure R301.2(4)] shall be applied with corrosion-resistant fasteners in accordance with manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914 mm) on center.

Underlayment installed where the basic wind speed equals or exceeds 120 mph (54 m/s) shall comply with ASTM D 226 Type II or ASTM D 4869 Type IV. The underlayment shall be attached in a grid pattern of 12 inches (305 mm) between side laps with a 6 inch (152 mm) spacing at the side laps. Head laps shall be 4 inches (102 mm) and end laps shall be a minimum of 6 inches (152 mm). Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 5/8 inches (41 mm) with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.

Underlayment installed where the basic wind speed equals or exceeds 140 mph (63 m/s) shall be attached using metal cap nails with a head diameter of not less than 1 5/8 inches (41 mm) with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.

R905.6.3.2 Underlayment and high wind. Underlayment applied in areas subject to high winds [above 110 mph (49 m/s) in accordance with Figure R301.2(4)] shall be applied with corrosion-resistant fasteners in accordance with manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914 mm) on center.

Underlayment installed where the basic wind speed equals or exceeds 120 mph (54 m/s) shall comply with ASTM D 226 Type II or ASTM D 4869 Type IV. The underlayment shall be attached in a grid pattern of 12 inches (305 mm) between side laps with a 6 inch (152 mm) spacing at the side laps. Head laps shall be 4 inches (102 mm) and end laps shall be a minimum of 6 inches (152 mm). Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 5/8 inches (41 mm) with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.

Underlayment installed where the basic wind speed equals or exceeds 140 mph (63 m/s) shall be attached using metal cap nails with a head diameter of not less than 1 5/8 inches (41 mm) with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.

R905.7.3.2 Underlayment and high wind. Underlayment applied in areas subject to high winds [above 110 mph (49 m/s) in accordance with Figure R301.2(4)] shall be applied with corrosion-resistant fasteners in accordance with manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914mm) on center.

Underlayment installed where the basic wind speed equals or exceeds 120 mph (54 m/s) shall comply with ASTM D 226 Type II or ASTM D 4869 Type IV. The underlayment shall be attached in a grid pattern of 12 inches (305 mm) between side laps with a 6 inch (152 mm) spacing at the side laps. Head laps shall be 4 inches (102 mm) and end laps shall be a minimum of 6 inches (152 mm). Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 5/8 inches (41 mm) with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.

Underlayment installed where the basic wind speed equals or exceeds 140 mph (63 m/s) shall be attached using metal cap nails with a head diameter of not less than 1 5/8 inches (41 mm) with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.

R905.8.3.2 Underlayment and high wind. Underlayment applied in areas subject to high winds [above 110 mph (49 m/s) in accordance with Figure R301.2(4)] shall be applied with corrosion-resistant fasteners in accordance with manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914 mm) on center.

Underlayment installed where the basic wind speed equals or exceeds 120 mph (54 m/s) shall comply with ASTM D 226 Type II or ASTM D 4869 Type IV. The underlayment shall be attached in a grid pattern of 12 inches (305 mm) between side laps with a 6 inch (152 mm) spacing at the side laps. Head laps shall be 4 inches (102 mm) and end laps shall be a minimum of 6 inches (152 mm). Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 5/8 inches (41 mm) with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.

Underlayment installed where the basic wind speed equals or exceeds 140 mph (63 m/s) shall be attached using metal cap nails with a head diameter of not less than 1 5/8 inches (41 mm) with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.

R905.10.5.1 Underlayment and high wind. Underlayment applied in areas subject to high winds [above 110 mph (49 m/s) in accordance with Figure R301.2(4)] shall be applied with corrosion-resistant fasteners in accordance with manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914 mm) on center.

Underlayment installed where the basic wind speed equals or exceeds 120 mph (54 m/s) shall comply with ASTM D 226 Type II. The underlayment shall be attached in a grid pattern of 12 inches (305 mm) between side laps with a 6 inch (152 mm) spacing at the side laps. Head laps shall be 4 inches (102 mm) and end laps shall be a minimum of 6 inches (152 mm). Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 5/8 inches (41 mm) with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.

Underlayment installed where the basic wind speed equals or exceeds 140 mph (63 m/s) shall be attached using metal cap nails with a head diameter of not less than 1 5/8 inches (41 mm) with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.

Reason: Observations of roof underlayment performance following Hurricane Ike in Texas and in two sets of tests conducted at the University of Florida and Florida International University demonstrated that relatively new and new ASTM 226 Type I underlayments performed very poorly when subjected to wind over about 110 mph. In the laboratory tests, specimen covered with ASTM 226 Type I and Type II underlayments performed dramatically differently. ASTM Type I felt (15#) material completely blew off some portions of the specimen as winds exceeded 110 mph and pulled over the plastic caps on other parts of the specimen. In contrast, the ASTM 226 Type II (30#) material remained in place and showed very few signs of distress. Plastic caps deformed much more than the metal caps in several installations. Consequently, the use of metal caps is recommended for areas with the highest basic design wind speeds.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: Stafford-S3-1507.2.8.1

Public Hearing Results

PART II- IRC B/E
Committee Action: **Approved as Modified**

Modify the proposal as follows:

R905.2.7.2 Underlayment and high wind. Underlayment applied in areas subject to high winds [above 110 mph (49 m/s) in accordance with Figure R301.2(4)] shall be applied with corrosion-resistant fasteners in accordance with manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914mm) on center.

Underlayment installed where the basic wind speed equals or exceeds 120 mph (54 m/s) shall comply with ASTM D 226 Type II, ASTM D 4869 Type IV, or ASTM D 6757. The underlayment shall be attached in a grid pattern of 12 inches (305 mm) between side laps with a 6 inch (152 mm) spacing at the side laps. Underlayment shall be applied in accordance with Section R905.2.7 except all ~~Head~~ laps shall be a minimum of 4 inches (102 mm) ~~and end laps shall be a minimum of 6 inches (152 mm)~~. Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 ~~5/8~~ inch~~es~~ (~~41~~ 25.4 mm) with a ~~shank~~ thickness of at least 32 gauge sheet metal. The cap-nail shank shall be a minimum of 12 gauge (0.105 inches) with a length to penetrate through the roof sheathing or a minimum of 3/4 inch into the roof sheathing.

Exception: As an alternative, adhered underlayment complying with ASTM D 1970 shall be permitted.

~~Underlayment installed where the basic wind speed equals or exceeds 140 mph (63 m/s) shall be attached using metal cap nails with a head diameter of not less than 1 5/8 inches (41 mm) with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.~~

R905.3.3.3 Underlayment and high wind. Underlayment applied in areas subject to high wind [over 110 miles per hour (49 m/s) in accordance with R301.2(4)] shall be applied with corrosion-resistant fasteners in accordance with manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914 mm) on center.

Underlayment installed where the basic wind speed equals or exceeds 120 mph (54 m/s) shall be attached in a grid pattern of 12 inches (305 mm) between side laps with a 6 inch (152 mm) spacing at the side laps. Underlayment shall be applied in accordance with Section R905.2.7 except all ~~Head~~ laps shall be a minimum of 4 inches (102 mm) ~~and end laps shall be a minimum of 6 inches (152 mm)~~. Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 ~~5/8~~ inch~~es~~ (~~41~~ 25.4 mm) with a ~~shank~~ thickness of at least 32 gauge sheet metal. The cap-nail shank shall be a minimum of 12 gauge (0.105 inches) with a length to penetrate through the roof sheathing or a minimum of 3/4 inch into the roof sheathing.

Exception: As an alternative, adhered underlayment complying with ASTM D 1970 shall be permitted.

~~Underlayment installed where the basic wind speed equals or exceeds 140 mph (63 m/s) shall be attached using metal cap nails with a head diameter of not less than 1 5/8 inches (41 mm) with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.~~

R905.4.3.2 Underlayment and high wind. Underlayment applied in areas subject to high winds [above 110 mph (49 m/s) in accordance with Figure R301.2(4)] shall be applied with corrosion-resistant fasteners in accordance with manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914 mm) on center.

Underlayment installed where the basic wind speed equals or exceeds 120 mph (54 m/s) shall comply with ASTM D 226 Type II, ASTM D 4869 Type IV, or ASTM D 1970. The underlayment shall be attached in a grid pattern of 12 inches (305 mm) between side laps with a 6 inch (152 mm) spacing at the side laps. Underlayment shall be applied in accordance with Section R905.2.7 except all ~~Head~~ laps shall be a minimum of 4 inches (102 mm) ~~and end laps shall be a minimum of 6 inches (152 mm)~~. Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 ~~5/8~~ inch~~es~~ (~~41~~ 25.4 mm) with a ~~shank~~ thickness of at least 32 gauge sheet metal. The cap-nail shank shall be a minimum of 12 gauge (0.105 inches) with a length to penetrate through the roof sheathing or a minimum of 3/4 inch into the roof sheathing.

Exception: As an alternative, adhered underlayment complying with ASTM D 1970 shall be permitted.

~~Underlayment installed where the basic wind speed equals or exceeds 140 mph (63 m/s) shall be attached using metal cap nails with a head diameter of not less than 1 5/8 inches (41 mm) with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.~~

R905.5.3.2 Underlayment and high wind. Underlayment applied in areas subject to high winds [above 110 mph (49 m/s) in accordance with Figure R301.2(4)] shall be applied with corrosion-resistant fasteners in accordance with manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914 mm) on center.

Underlayment installed where the basic wind speed equals or exceeds 120 mph (54 m/s) shall comply with ASTM D 226 Type II or ASTM D 4869 Type IV. The underlayment shall be attached in a grid pattern of 12 inches (305 mm) between side laps with a 6 inch (152 mm) spacing at the side laps. Underlayment shall be applied in accordance with Section R905.2.7 except all ~~Head~~ laps shall be a minimum of 4 inches (102 mm) ~~and end laps shall be a minimum of 6 inches (152 mm)~~. Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 ~~5/8~~ inch~~es~~ (~~41~~ 25.4 mm) with a ~~shank~~ thickness of at least 32 gauge sheet metal. The cap-nail shank shall be a minimum of 12 gauge (0.105 inches) with a length to penetrate through the roof sheathing or a minimum of 3/4 inch into the roof sheathing.

Exception: As an alternative, adhered underlayment complying with ASTM D 1970 shall be permitted.

~~Underlayment installed where the basic wind speed equals or exceeds 140 mph (63 m/s) shall be attached using metal cap nails with a head diameter of not less than 1 5/8 inches (41 mm) with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.~~

R905.6.3.2 Underlayment and high wind. Underlayment applied in areas subject to high winds [above 110 mph (49 m/s) in accordance with Figure R301.2(4)] shall be applied with corrosion-resistant fasteners in accordance with manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914 mm) on center.

Underlayment installed where the basic wind speed equals or exceeds 120 mph (54 m/s) shall comply with ASTM D 226 Type II or ASTM D 4869 Type IV. The underlayment shall be attached in a grid pattern of 12 inches (305 mm) between side laps with a 6 inch (152 mm) spacing at the side laps. Underlayment shall be applied in accordance with Section R905.2.7 except all ~~Head~~ laps shall be a minimum of 4 inches (102 mm) ~~and end laps shall be a minimum of 6 inches (152 mm)~~. Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 ~~5/8~~ inch~~es~~ (~~41~~ 25.4 mm) with a ~~shank~~ thickness of at least 32 gauge sheet metal. The cap-nail shank shall be a minimum of 12 gauge (0.105 inches) with a length to penetrate through the roof sheathing or a minimum of 3/4 inch into the roof sheathing.

Exception: As an alternative, adhered underlayment complying with ASTM D 1970 shall be permitted.

~~Underlayment installed where the basic wind speed equals or exceeds 140 mph (63 m/s) shall be attached using metal cap nails with a head diameter of not less than 1 5/8 inches (41 mm) with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.~~

R905.7.3.2 Underlayment and high wind. Underlayment applied in areas subject to high winds [above 110 mph (49 m/s) in accordance with Figure R301.2(4)] shall be applied with corrosion-resistant fasteners in accordance with manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914mm) on center.

Underlayment installed where the basic wind speed equals or exceeds 120 mph (54 m/s) shall comply with ASTM D 226 Type II or ASTM D 4869 Type IV. The underlayment shall be attached in a grid pattern of 12 inches (305 mm) between side laps with a 6 inch (152 mm) spacing at the side laps. Underlayment shall be applied in accordance with Section R905.2.7 except all ~~Head~~ laps shall be a minimum of 4 inches (102 mm) ~~and end laps shall be a minimum of 6 inches (152 mm)~~. Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 ~~5/8~~ inch~~es~~ (~~41~~ 25.4 mm) with a ~~shank~~ thickness of at least 32 gauge sheet metal. The cap-nail shank shall be a minimum of 12 gauge (0.105 inches) with a length to penetrate through the roof sheathing or a minimum of 3/4 inch into the roof sheathing.

Exception: As an alternative, adhered underlayment complying with ASTM D 1970 shall be permitted.

~~Underlayment installed where the basic wind speed equals or exceeds 140 mph (63 m/s) shall be attached using metal cap nails with a head diameter of not less than 1 5/8 inches (41 mm) with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.~~

R905.8.3.2 Underlayment and high wind. Underlayment applied in areas subject to high winds [above 110 mph (49 m/s) in accordance with Figure R301.2(4)] shall be applied with corrosion-resistant fasteners in accordance with manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914 mm) on center.

Underlayment installed where the basic wind speed equals or exceeds 120 mph (54 m/s) shall comply with ASTM D 226 Type II or ASTM D 4869 Type IV. The underlayment shall be attached in a grid pattern of 12 inches (305 mm) between side laps with a 6 inch (152 mm) spacing at the side laps. Underlayment shall be applied in accordance with Section R905.2.7 except all ~~Head~~ laps shall be a minimum of 4 inches (102 mm) ~~and end laps shall be a minimum of 6 inches (152 mm)~~. Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 ~~5/8~~ inch~~es~~ (~~41~~ 25.4 mm) with a ~~shank~~ thickness of at least 32 gauge sheet metal. The cap-nail shank shall be a minimum of 12 gauge (0.105 inches) with a length to penetrate through the roof sheathing or a minimum of 3/4 inch into the roof sheathing.

Exception: As an alternative, adhered underlayment complying with ASTM D 1970 shall be permitted.

~~Underlayment installed where the basic wind speed equals or exceeds 140 mph (63 m/s) shall be attached using metal cap nails with a head diameter of not less than 1 5/8 inches (41 mm) with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.~~

R905.10.5.1 Underlayment and high wind. Underlayment applied in areas subject to high winds [above 110 mph (49 m/s) in accordance with Figure R301.2(4)] shall be applied with corrosion-resistant fasteners in accordance with manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914 mm) on center.

Underlayment installed where the basic wind speed equals or exceeds 120 mph (54 m/s) shall comply with ASTM D 226 Type II. The underlayment shall be attached in a grid pattern of 12 inches (305 mm) between side laps with a 6 inch (152 mm) spacing at the side laps. Underlayment shall be applied in accordance with Section R905.2.7 except all ~~Head~~ laps shall be a minimum of 4 inches (102 mm) ~~and end laps shall be a minimum of 6 inches (152 mm)~~. Underlayment shall be attached using metal or plastic cap nails with a head diameter of not less than 1 ~~5/8~~ inch~~es~~ (~~41~~ 25.4 mm) with a ~~shank~~ thickness of at least 32 gauge sheet metal. The cap-nail shank shall be a minimum of 12 gauge (0.105 inches) with a length to penetrate through the roof sheathing or a minimum of 3/4 inch into the roof sheathing.

Exception: As an alternative, adhered underlayment complying with ASTM D 1970 shall be permitted.

~~Underlayment installed where the basic wind speed equals or exceeds 140 mph (63 m/s) shall be attached using metal cap nails with a head diameter of not less than 1 5/8 inches (41 mm) with a shank of at least 32 gauge sheet metal with a length to penetrate through the roof sheathing.~~

Committee Reason: This change will add underlayment requirements that will improve the performance of the roof covering in high wind situations. The modification corrects an error with respect to the nailing and adds self-adhering underlayment as an alternate. The committee has concern that eight sections are being added that prescribe the same requirement. The proponent should consolidate these and bring this back later.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

John Kurtz, International Staple, Nail & Tool Association, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows::

R905.1.1 Underlayment. Underlayment shall be in accordance with Sections R905.1.1.1 through R905.1.1.2.

R905.1.1.1 Specifications. Required underlayment shall conform to types listed in Table R905.1.1.1.

TABLE R905.1.1.1
UNDERLAYMENT STANDARDS

Section	Roof Covering	ASTM Specification	
		Wind Speed 120 mph or lower	**Wind Speed over 120 mph**
R905.2	Asphalt shingles	D 226 Type I D 4869 Type I D 6757	D 226 Type II D 4869 Type IV D 6757 D 1970
R905.3	Clay and concrete tile	D 226 Type II D 2626 Type I D 6380 Class M	D 226 Type II D 2626 Type I D 6380 Class M D 1970
R905.4	Metal roof shingles	D 226 Type I or II D 4869 Type I or II D 1970	D 226 Type II D 4869 Type IV D 1970
R905.5	Mineral-surfaced roll roofing	D 226 Type I D 4869 Type I or II	D 226 Type II D 4869 Type IV D 1970
R905.6	Slate and slate-type shingles	D 226 Type I D 4869 Type I or II	D 226 Type II D 4869 Type IV D 1970
R905.7	Wood shingles	D 226 Type I D 4869 Type I or II	D 226 Type II D 4869 Type IV D 1970
R905.8	Wood shakes	D 226 Type I D 4869 Type I or II	D 226 Type II D 4869 Type IV D 1970
R905.10	Metal roof panels	No requirement.	D 226 Type II D 1970

R905.1.1.2 Application. Application and attachment of underlayment shall be in accordance with the following:

1. Underlayment shall be applied in accordance with Table R905.1.1.2(1).
2. Underlayment shall be attached in accordance with Table R905.1.1.2(2).

TABLE R905.1.1.2(1)

~~**R905.2.3 Underlayment.** Unless otherwise noted, required underlayment shall conform to ASTM D 226 Type I, ASTM D 4869 Type I, ASTM D 6757.~~

~~Self-adhering polymer modified bitumen sheet shall comply with ASTM D 1970.~~

(Renumber remaining sections)

~~**R905.2.7 Underlayment application.** For roof slopes from two units vertical in 12 units horizontal (17-percent slope), up to four units vertical in 12 units horizontal (33-percent slope), underlayment shall be two layers applied in the following manner. Apply a 19-inch (483 mm) strip of underlayment felt parallel to and starting at the eaves, fastened sufficiently to hold in place. Starting at the eave, apply 36-inch-wide (914 mm) sheets of underlayment, overlapping successive sheets 19 inches (483 mm), and fastened sufficiently to hold in place. Distortions in the underlayment shall not interfere with the ability of the shingles to seal. For roof slopes of four units vertical in 12 units horizontal (33-percent slope) or greater, underlayment shall be one layer applied in the following manner. Underlayment shall be applied shingle fashion, parallel to and starting from the eave and lapped 2 inches (51 mm), fastened sufficiently to hold in place. Distortions in the underlayment shall not interfere with the ability of the shingles to seal. End laps shall be offset by 6 feet (1829 mm).~~

~~**R905.2.7.1**~~ **R905.2.6 Ice barrier.** In areas where there has been a history of ice forming along the eaves causing a backup of water as designated in Table R301.2(l), an ice barrier that consists of at least two layers of underlayment cemented together or a self-adhering polymer modified bitumen sheet shall be used in place of normal underlayment and extend from the lowest edges of all roof surfaces to a point at least 24 inches (610 mm) inside the exterior wall line of the building.

Exception: Detached accessory structures that contain no *conditioned floor area*.

~~**R905.2.7.2 Underlayment and high wind.** Underlayment applied in areas subject to high winds [above 110 mph (49m/s) per Figure R301.2(4)] shall be applied with corrosion-resistant fasteners in accordance with manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914 mm) on center.~~

~~**R905.3.3 Underlayment.** Unless otherwise noted, required underlayment shall conform to ASTM D 226 Type 11; ASTM D 2626 Type 1; or ASTM D 6380 Class M mineral surfaced roll roofing.~~

~~**R905.3.3.1 Low slope roofs.** For roof slopes from two and one-half units vertical in 12 units horizontal (2½:12), up to four units vertical in 12 units horizontal (4:12), underlayment shall be a minimum of two layers underlayment applied as follows:~~

1. ~~Starting at the eave, a 19-inch (483 mm) strip of underlayment shall be applied parallel with the eave and fastened sufficiently in place.~~
2. ~~Starting at the eave, 36-inch-wide (914 mm) strips of underlayment felt shall be applied, overlapping successive sheets 19 inches (483 mm), and fastened sufficiently in place.~~

~~**R905.3.3.2 High slope roofs.** For roof slopes of four units vertical in 12 units horizontal (4:12) or greater, underlayment shall be a minimum of one layer of underlayment felt applied shingle fashion, parallel to and starting from the eaves and lapped 2 inches (51 mm), fastened sufficiently in place.~~

~~**R905.3.3.3 Underlayment and high wind.** Underlayment applied in areas subject to high wind [over 110 miles per hour (49 m/s) in accordance with Figure R301.2(4)] shall be applied with corrosion-resistant fasteners in accordance with manufacturer's installation instructions. Fasteners are to be applied along the overlap not farther apart than 36 inches (914 mm) on center.~~

(Renumber remaining sections)

~~**R905.4.3 Underlayment.** Underlayment shall comply with ASTM D 226, Type I or Type 11, ASTM D 4869, Type I or Type 11, or ASTM D 1970. Underlayment shall be installed in accordance with the manufacturer's installation instructions.~~

~~**R905.4.3.1**~~ **R905.4.3 Ice barrier.** In areas where there has been a history of ice forming along the eaves causing a backup of water as designated in Table R301.2(l), an ice barrier that consists of at least two layers of underlayment cemented together or a self-adhering polymer modified bitumen sheet shall be used in place of normal underlayment and extend from the lowest edges of all roof surfaces to a point at least 24 inches (610 mm) inside the exterior wall line of the building.

Exception: Detached *accessory structures* that contain no *conditioned floor area.*

~~**R905.5.3 Underlayment.** Underlayment shall comply with ASTM D 226, Type I or ASTM D 4869, Type I or II.~~

~~**R905.5.3.1**~~ **R905.5.3 Ice barrier.** In areas where there has been a history of ice forming along the eaves causing a backup of water as designated in Table R301.2(l), an ice barrier that consists of at least two layers of underlayment cemented together or a self-adhering polymer modified bitumen sheet shall be used in place of normal underpayment and extend from the lowest edges of all roof surfaces to a point at least 24 inches (610 mm) inside the exterior wall line of the building.

Exception: Detached *accessory structures* that contain no *conditioned floor area.*

~~**R905.6.3 Underlayment.** Underlayment shall comply with ASTM D 226, Type 1, or ASTM D 4869, Type I or II. Underlayment shall be installed in accordance with the manufacturer's installation instructions.~~

~~**R905.6.3.1**~~ **R905.6.3 Ice barrier.** In areas where there has been a history of ice forming along the eaves causing a backup of water as designated in Table R301.2(l), an ice barrier that consists of at least two layers of underlayment cemented together or a self-adhering polymer modified bitumen sheet shall be used in lieu of normal underlayment and extend from the lowest edges of all roof surfaces to a point at least 24 inches (610 mm) inside the exterior wall line of the building.

Exception: Detached *accessory structures* that contain no *conditioned floor area.*

~~**R905.7.3 Underlayment.** Underlayment shall comply with ASTM D 226, Type I or ASTM D 4869, Type I or II.~~

~~**R905.7.3.1**~~ **R905.7.3 Ice barrier.** In areas where there has been a history of ice forming along the eaves causing a backup of water as designated in Table R301.2(l), an ice barrier that consists of at least two layers of underlayment cemented together or a self-adhering polymer modified bitumen sheet shall be used in lieu of normal underlayment and extend from the lowest edges of all roof surfaces to a point at least 24 inches (610 mm) inside the exterior wall line of the building.

Exception: Detached *accessory structures* that contain no *conditioned floor area.*

~~**R905.8.3 Underlayment.** Underlayment shall comply with ASTM D 226, Type I or ASTM D 4869, Type I or II.~~

~~**R905.8.3.1**~~ **R905.8.3 Ice barrier.** In areas where there has been a history of ice forming along the eaves causing a backup of water as designated in Table R301.2(l), an ice barrier that consists of at least two layers of underlayment cemented together or a self-adhering polymer modified bitumen sheet shall be used in place of normal underlayment and extend from the lowest edges of all roof surfaces to a point at least 24 inches (610 mm) inside the exterior wall line of the building.

Exception: Detached *accessory structures* that contain no *conditioned floor area.*

~~**R905.10.5 Underlayment.** Underlayment shall be installed in accordance with the manufacturer's installation instructions.~~

Commenter's Reason: The original proposal would increase the likelihood of holding roof covering underlayment in place if roof coverings were lost to high winds. The proposal's fastener types and fastener spacing were arbitrary; they were not developed by consensus tests or engineering analysis, or from commercially available products. The original proposal would make it difficult to build the planned performance level with specified fasteners. Last, the original intent could be achieved with one concise code section rather than adding redundant language to eight code sections.

Our proposed modification provides the same or better underlayment fastening with more fastener options, with concise code language.

Public Comment 2:

Gary J. Ehrlich, P.E., National Association of Home Builders, requests Disapproval.

Commenter's Reason: The purpose of this public comment is to request disapproval of the underlayment provisions approved at the Public Hearings in Baltimore. The proposal added extensive requirements for underlayment in multiple sections of Chapter 9. While we recognize the desire to maintain separate sets of requirements for each roofing material (e.g. asphalt shingles, metal roofing, concrete and clay tiles), the overall section is becoming lengthy, and we are concerned it has become difficult to insure consistent are maintained across all the roofing types covered in Chapter 9.

We question the need to increase the thickness and fastening requirements for the underlayment currently required by the code. The tests referenced by the reason statement were not provided to the committee or the membership for review. Therefore, we cannot verify the proponent's claim that the increased requirements are either justified or consistent with the research. The IBC Structural Committee, usually sympathetic to proposals which increase the stringency of code requirements, specifically noted the absence of technical data in disapproving Part I of this code change.

The underlayment gets installed beneath a roof covering which itself is fastened to the roof deck, purlins, or other substrate. If the underlayment has become exposed to the full wind pressure, clearly the roof covering has been lost. It would make more sense to concentrate on insuring that the roof covering is properly selected and installed for the basic wind speed specified for the dwelling.

Finally, we note that Section R301.2.1.1 limits the wind provisions of the IRC to 110mph. Where the basic wind speed equals or exceeds 110mph, the code user must refer to the applicable provisions of the listed documents in that section. That list of standards includes the ICC-600 *Standard for Residential Construction in High-Wind Regions,* which contains roof covering requirements (including underlayment) in Sections 504 and 505. The ICC-600 requirements would therefore be the governing provisions in areas of 110mph wind speeds and higher. To add high-wind provisions to the IRC itself would risk creating conflicts with ICC-600, as well as making the IRC unwieldy for the majority of code users who are not in high-wind regions.

Final Action: AS AM AMPC____ D

S23-09/10-PART I
1507.17 (New)

Proposed Change as Submitted

Proponent: Bob Eugene, representing Underwriters Laboratories Inc.

PART I – IBC STRUCTURAL

Add new text as follows:

<u>**1507.17 Formed plastic shingles**. The installation of formed plastic shingles shall comply with the provisions of this section.</u>

<u>**1507.17.1 Attachment.** Plastic shingles shall be attached as required by the manufacturer.</u>

<u>**1507.1.1 Wind resistance.** Plastic shingles shall be tested in accordance with procedures adapted from ASTM D 3161.Plastic shingles shall comply with the classification requirements of Table 1507.2.7.1(1) for the appropriate maximum basic wind speed. Plastic shingle packaging shall bear a label to indicate compliance with the procedures adapted from ASTM D 3161 and the required classification from Table 1507.2.7.1(2).</u>

Reason: The proposal provides guidance for installers and code officials regarding the installation of formed plastic shingles. The appropriate design slope and fastening of the shingles are different for each manufacturer's product. For wind resistance, the procedures used in ASTM D 3161 for asphalt shingles are appropriate to use, when adapted for these types of shingles.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: EUGENE-S2-1507.17

Public Hearing Results

PART I- IBC STRUCTURAL
Committee Action: **Disapproved**

Committee Reason: There are concerns with the proposal to adapt an asphalt shingle standard to formed plastic shingles.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Bob Eugene, Underwriters Laboratories, Inc, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

PART I – IBC STRUCTURAL

FORMED PLASTIC SHINGLES. A roof covering composed of plastic in sheets fabricated into shingles.

1507.17 Formed plastic shingles. The installation of formed plastic shingles shall comply with the provisions of this section.

1507.17.1 Sheathing requirements. Formed plastic shingles shall be fastened to solidly sheathed decks.

1507.17.2 Deck slope. Formed plastic shingles shall not be installed on roofs below three units vertical in 12 horizontal (25-percent slope).

1507.17.3 Underlayment. Underlayment shall comply with ASTM D 226, Type I or Type II, ASTM D 4869, Type I or Type II, or ASTM D 1970. Underlayment shall be installed in accordance with the manufacturer's installation instructions.

1507.17.3.1 Ice barrier. In areas where there has been a history of ice forming along the eaves causing a backup of water, an ice barrier that consists of at least two layers of underlayment cemented together or a self-adhering polymer modified bitumen sheet shall be used in place of normal underlayment and extend from the lowest edges of all roof surfaces to a point at least 24 inches (610 mm) inside the exterior wall line of the building.

Exception: Detached *accessory structures* that contain no *conditioned floor area*.

1507.17.4 Material standards. Formed plastic shingles shall be listed in accordance with UL 790.

~~**1507.17.1**~~ **1507.17.5 Attachment.** Formed ~~P~~plastic shingles shall be ~~attached~~ secured to the roof deck in accordance with this chapter and the approved ~~as required by the~~ manufacturer's instructions.

~~**1507.17.1.1**~~ **1507.17.5.1 Wind resistance.** Plastic shingles shall be tested in accordance with procedures adapted from ASTM D 3161.Plastic shingles shall comply with the classification requirements of Table 1507.2.7.1(1) for the appropriate maximum basic wind speed. Plastic shingle packaging shall bear a label to indicate compliance with the procedures adapted from ASTM D 3161 and the required classification from Table 1507.2.7.1(2).

1507.17.6 Flashing. At the juncture of roof vertical surfaces, flashing and counterflashing shall be provided in accordance with this chapter and the manufacturer's installation instructions and, where of metal, shall not be less than 0.019 inch (0.5 mm) (No. 26 galvanized sheet gage) corrosion-resistant metal. The valley flashing shall extend at least 11 inches (279 mm) from the centerline each way and have a splash diverter rib not less than 1 inch (25 mm) high at the flow line formed as part of the flashing. Sections of flashing shall have an end lap of not less than 4 inches (102 mm). Valley flashing shall have a 36-inch-wide (914 mm) underlayment of one layer of Type I underlayment running the full length of the valley, in addition to other required underlayment. In areas where the average daily temperature in January is 25°F (-4°C) or less, metal valley flashing underlayment shall be solid-cemented to the roofing underlayment for slopes less than seven units vertical in 12 units horizontal (58-percent slope) or be of self-adhering polymer modified bitumen sheet.

Commenter's Reason: Formed plastic shingles are routinely installed. UL had proposed adding the supplemental criteria for wind resistant applications, but the committees rightly noted that the basic application for formed plastic shingles was not clearly included in the code. In response, applicable provisions have been incorporated for plastic shingles consistent with other comparable roofing applications already governed by the code. Additionally, the scope of ASTM D3161 is in the process of being broadened to include these products.

Final Action: AS AM AMPC____ D

S23-09/10- PART II
IRC R905.16 (New)

Proposed Change as Submitted

PART II – IRC BUILDING/ENERGY

Add new text as follows:

R905.16 Formed plastic shingles. The installation of formed plastic shingles shall comply with the provisions of this section.

R905.16.1 Attachment. Plastic shingles shall be attached as required by the manufacturer.

R905.16.1.1 Wind resistance. Plastic shingles shall be tested in accordance with procedures adapted from ASTM D 3161. Plastic shingles shall meet the classification requirements of Table R905.2.4.1 (2) for the appropriate maximum basic wind speed. Plastic shingle packaging shall bear a label to indicate compliance with the procedures adapted from ASTM D 3161 and the required classification from Table R905.2.4.1 (2).

Reason: The proposal provides guidance for installers and code officials regarding the installation of formed plastic shingles. The appropriate design slope and fastening of the shingles are different for each manufacturer's product. For wind resistance, the procedures used in ASTM D 3161 for asphalt shingles are appropriate to use, when adapted for these types of shingles.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: EUGENE-S2-1507.17

Public Hearing Results

PART II- IRC B/E
Committee Action: **Disapproved**

Committee Reason: There is no definition of the term "formed plastic shingles". Other requirements need to be addressed, such as deck, underlayment and flashing.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Bob Eugene, Underwriters Laboratories Inc, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

PART II – IRC BUILDING/ENERGY

FORMED PLASTIC SHINGLES. A roof covering composed of plastic in sheets fabricated into shingles.

R905.16 Formed plastic shingles. The installation of formed plastic shingles shall comply with the provisions of this section.

R905.16.1 Sheathing requirements. Formed plastic shingles shall be fastened to solidly sheathed decks.

R905.16.2 Deck slope. Formed plastic shingles shall not be installed on roofs below three units vertical in 12 horizontal (25-percent slope).

R905.16.3 Underlayment. Underlayment shall comply with ASTM D 226, Type I or Type II, ASTM D 4869, Type I or Type II, or ASTM D 1970. Underlayment shall be installed in accordance with the manufacturer's installation instructions.

R905.16.3.1 Ice barrier. In areas where there has been a history of ice forming along the eaves causing a backup of water as designated in Table R301.2(1), an ice barrier that consists of at least two layers of underlayment cemented together or a self-adhering polymer modified bitumen sheet shall be used in place of normal underlayment and extend from the lowest edges of all roof surfaces to a point at least 24 inches (610 mm) inside the exterior wall line of the building.

Exception: Detached *accessory structures* that contain no *conditioned floor area*.

R905.16.4 Material standards. Formed plastic shingles shall be listed in accordance with UL 790.

~~**R905.16.1**~~ **R905.16.5 Attachment.** Formed ~~P~~plastic shingles shall be ~~attached~~ secured to the roof deck in accordance with this chapter and the approved ~~as required by the~~ manufacturer's instructions.

~~**R905.16.1.1**~~ **R905.16.5.1 Wind resistance.** Plastic shingles shall be tested in accordance with procedures adapted from ASTM D 3161. Plastic shingles shall meet the classification requirements of Table R905.2.4.1 (2) for the appropriate maximum basic wind speed. Plastic shingle packaging shall bear a label to indicate compliance with the procedures adapted from ASTM D 3161 and the required classification from Table R905.2.4.1 (2).

R905.16.6 Flashing. At the juncture of roof vertical surfaces, flashing and counterflashing shall be provided in accordance with this chapter and the manufacturer's installation instructions and, where of metal, shall not be less than 0.019 inch (0.5 mm) (No. 26 galvanized sheet gage) corrosion-resistant metal. The valley flashing shall extend at least 11 inches (279 mm) from the centerline each way and have a splash diverter rib not less than 1 inch (25 mm) high at the flow line formed as part of the flashing. Sections of flashing shall have an end lap of not less than 4 inches (102 mm). Valley flashing shall have a 36-inch-wide (914 mm) underlayment of one layer of Type I underlayment running the full length of the valley, in addition to other required underlayment. In areas where the average daily temperature in January is 25°F (-4°C) or less, metal valley flashing underlayment shall be solid-cemented to the roofing underlayment for slopes less than seven units vertical in 12 units horizontal (58-percent slope) or be of self-adhering polymer modified bitumen sheet.

Commenter's Reason: See S23-09/10, Part I

S26-09/10
1509.1, 1509.2.4

Proposed Change as Submitted

Proponent: Homer Maiel, PE, CBO, City of San Jose**,** representing ICC Tri-Chapter (Peninsula, East Bay, Monterey Bay)

Revise as follows:

1509.1 General. The provisions of this section shall govern the construction of rooftop structures and of rooftop mounted enclosures such as mechanical equipment screens.

1509.2.4 Type of construction. Penthouses and other rooftop enclosures shall be constructed with walls, floors and roof as required for the building.

Exceptions:

1. On buildings of Type I construction, the exterior walls and roofs of penthouses with *a fire separation distance* of more than 5 feet (1524 mm) and less than 20 feet (6096 mm) shall be of at least 1-hour fire resistance rated noncombustible construction. Walls and roofs with a *fire separation distance* of 20 feet (6096 mm) or greater shall be of noncombustible construction. Interior framing and walls shall be of noncombustible construction.
2. On buildings of Type I construction two stories above *grade plane* or less in height and Type II construction, the exterior walls and roofs of penthouses with a *fire separation distance* of more than 5 feet (1524 mm) and less than 20 feet (6096 mm) shall be of at least 1-hour fire-resistance-rated noncombustible *or fire-retardant-treated wood* construction. Walls and roofs with *a fire separation distance* of 20 feet (6096 mm) or greater shall be of noncombustible or *fire-retardant-treated wood* construction. Interior framing and walls shall be of noncombustible or fire retardant- treated wood construction.
3. On buildings of Type III, IV and V construction, the exterior walls of penthouses with a *fire separation distance* of more than 5 feet (1524 mm) and less than 20 feet (6096 mm) shall be at least 1-hour fire resistance-rated construction. Walls with a *fire separation distance* of 20 feet (6096 mm) or greater from a common property line shall be of Type IV construction or noncombustible, *or fire-retardant-treated wood* construction. Roofs shall be constructed of materials and fire-resistance rated as required in Table 601 and Section 603 Item 25.3. Interior framing and walls shall be Type IV construction or noncombustible or *fire-retardant-treated wood* construction.
4. On buildings of Type I construction, unprotected noncombustible enclosures including screens housing only mechanical equipment and located with a minimum *fire separation distance* of 20 feet (6096 mm) shall be permitted.
5. On buildings of Type I construction two stories or less above *grade plane* in height, or Type II, III, IV, and V construction, unprotected noncombustible or *fire-retardant-treated wood* enclosures including screens housing only mechanical equipment and located with a *minimum fire separation distance* of 20 feet (6096 mm) shall be permitted.
6. On one-story buildings, combustible unroofed mechanical equipment screens, fences or similar enclosures are permitted where located with a *fire separation distance* of at least 20 feet (6096 mm) from adjacent property lines and where not exceeding 4 feet (1219 mm) in height above the roof surface.
7. Dormers shall be of the same type of construction as the roof on which they are placed, or of the exterior walls of the building.

Reason: The provisions of Section 1509 include more than just "*rooftop structures*" that are defined in Section 1502 as "*an enclosed structure*", such as a penthouse. The section currently contains provisions for unroofed mechanical equipment screens and towers that may be unenclosed. As a result, there have been disagreements between code enforcers and designers regarding the application of fire resistance rules specified within the exceptions to Section 1509.2.4, to *unenclosed* rooftop structures such as mechanical equipment screens. To address this, the scope statement in Section 1509.1 is revised to specifically add rooftop mounted enclosures such as mechanical equipment screens.

Current exceptions 4, 5 and 6 to Section 1509.2.4 address more than just penthouses. According to written interpretations from ICC staff (Paul Wong), these exceptions are intended to address the necessary fire resistance of mechanical equipment screens that are unenclosed rooftop structures. To clarify this intent, the wording in Exceptions 4 and 5 is revised to state "*enclosures including screens*". The wording in exception 6 is not revised because it is clear that it applies to roof screens as currently written. Exception 6 however is limited to screens having a maximum height of 4'-0", and many jurisdictions require taller screens to hide roof mounted HVAC equipment. As a result exceptions 4 and 5 provide rules that can be applied to those taller screens.

Each of these changes in intended to clarify that unenclosed roof screens are specifically included in the provisions.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: MAIEL-S2-1509.1

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: Although the proposal would provide more specific standards and options based on different types of equipment, the committee felt the proposal lacked technical justification. It was not clear what the hazards were regarding mechanical equipment screens that would necessitate that they be more strictly regulated than the roof surface on which they sit.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Homer Maiel, PE., City of San Jose, representing ICC Tri-Chapter (Peninsula, East Bay, Monterey Chapters), requests Approval as Submitted.

Commenter's Reason: Section 1509.2.4 Exception 6 currently regulates unroofed *mechanical equipment screens, fences and similar enclosures*, but only gives guidance for the construction of those elements located on one-story buildings. Clearly, buildings of other story heights utilize rooftop mechanical equipment screens, fences and similar enclosures, but nothing in current Section 1509 specifically address roof screens on those taller buildings.

The fire resistance that is being proposed for mechanical equipment screens will be no more restrictive than those already stated in Exception No. 4 and 5 for the walls of *enclosures housing only mechanical equipment*. We believe that applying the same rules to roof screens is not more restrictive than the current code, it simply clarifies what should be required. The proposed change simply spells out that roof screens are intended to be regulated consistent with ICC staff interpretations of this section and its exceptions.

A question raised by one of the committee members relating to how the fire resistant construction of roof screens compares with what is permitted for roof coverings is not the subject of this proposal. We did not profess in the original reason statement or nor did we ever believe that there is any relationship between roof screens and roof coverings. Instead the premise of the code change was and still is that roof screens are very similar to walls of roof structure enclosures and should be regulated consistent with those existing provisions. We ask that this simple change, to address roof screens on buildings over one-story in height be added to the code.

Final Action: AS AM AMPC____ D

S27-09/10

1509.2-1509.5.2, 1509.6-1509.7.5 (New)

Proposed Change as Submitted

Proponent: Rick Thornberry, PE, The Code Consortium, Inc., representing Alcan Composites USA, Inc. and Jesse J. Beitel, Hughes Associates, Inc., representing, Trespa North America, Ltd.

1. Revise as follows:

1509.1 General. The provisions of this section shall govern the construction of rooftop structures.

1509.2 Penthouses. ~~A penthouse or~~ Penthouses in compliance with Sections 1509.2.1 through ~~1509.2.4~~ 1509.2.5 shall be considered as a portion of the story directly below the roof deck on which such penthouses are located. All other penthouses shall be considered as an additional story of the building.

1509.2.1 Height above roof deck. ~~A penthouse~~ Penthouses ~~or other projection above the roof in structures constructed on~~ buildings of other than Type I construction ~~shall not exceed 28 feet (8534 mm) above the roof where used as an enclosure for tanks or for elevators that run to the roof and in all other cases~~ shall not exceed ~~extend more than~~ 18 feet (5486 mm) in height above the roof deck as measured to the average height of the roof of the penthouse.

Exceptions:

1. Where used to enclose tanks or elevators that travel to the roof level, penthouses shall be permitted to have a maximum height of 28 feet (8534 mm) above the roof deck.
2. Penthouses located on the roof of buildings of Type I construction shall not be limited in height.

1509.2.2 Area limitation. The aggregate area of penthouses and other enclosed rooftop structures shall not exceed one-third the area of the supporting roof deck. Such penthouses and other enclosed rooftop structures shall not be required to be included in determining ~~contribute to either~~ the building area or number of stories as regulated by Section 503.1. The area of ~~the penthouse~~ such penthouses shall not be included in determining the fire area ~~defined~~ specified in Section 901.7 ~~902~~.

1509.2.3 Use limitations. ~~A penthouse~~ Penthouses~~, bulkhead or any other similar projection above the roof~~ shall not be used for purposes other than the shelter of mechanical or electrical equipment or ~~shelter of~~ vertical shaft openings in the roof assembly.

1509.2.4 Weather protection. Provisions such as louvers, louver blades or flashing shall be made to protect the mechanical and electrical equipment and the building interior from the elements. ~~Penthouses or bulkheads used for purposes other than permitted by this section shall conform to the requirements of this code for an additional story. The restrictions of this section shall not prohibit the placing of wood flagpoles or similar structures on the roof of any building.~~

~~**1509.2.4**~~ **1509.2.5 Type of construction.** Penthouses shall be constructed with walls, floors and roof as required for the type of construction of the building on which such penthouses are built.

Exceptions:

1. On buildings of Type I construction, the exterior walls and roofs of penthouses with a fire separation distance ~~of more~~ greater than 5 feet (1524 mm) and less than 20 feet (6096 mm) shall be permitted to have not less than a ~~of at least~~ 1-hour fire resistance-rating ~~rated noncombustible construction~~. The exterior walls and roofs of penthouses with a fire separation distance of 20 feet (6096 mm) or greater shall ~~be of noncombustible construction~~ not be required to have a fire-resistance rating. ~~Interior framing and walls shall be of noncombustible construction.~~
2. On buildings of Type I construction two stories or less in height above grade plane or ~~less in height and~~ Type II construction, the exterior walls and roofs of penthouses with a fire separation distance ~~of more~~ greater than 5 feet (1524 mm) and less than 20 feet (6096 mm) shall be permitted to have not less than a ~~of at least~~ 1-hour fire-resistance-rating ~~rated noncombustible or~~ and be constructed of fire-retardant-treated wood ~~construction~~. The exterior walls and roofs of penthouses with a fire separation distance of 20 feet (6096 mm) or greater shall be permitted to be constructed of ~~noncombustible or~~ fire-retardant-treated wood ~~construction~~ and shall not be required to have a fire-resistance rating. Interior framing and walls shall be permitted to be constructed of ~~noncombustible or~~ fire retardant treated wood ~~construction~~.
3. On buildings of Type III, IV or ~~and~~ V construction, the exterior walls of penthouses with a fire separation distance ~~of more~~ greater than 5 feet (1524 mm) and less than 20 feet (6096 mm) shall be permitted to have not less than a ~~at least~~ 1-hour fire-resistance-rating or a lesser fire-resistance rating as required by Table 602 ~~rated construction~~. The exterior walls of penthouses with a fire separation distance of 20 feet (6096 mm) or greater ~~from a common property line~~ shall be of Type IV construction, or shall be constructed of noncombustible~~,~~ or fire-retardant-treated wood, ~~construction~~ and shall not be required to have a fire-resistance rating. ~~Roofs shall be constructed of materials and fire-resistance rated as required in Table 601 and Section 603, Item 25.3. Interior framing and walls shall be Type IV construction or noncombustible or fire-retardant-treated wood construction.~~
4. ~~On buildings of Type I construction, unprotected noncombustible enclosures housing only mechanical equipment and located with a minimum fire separation distance of 20 feet (6096 mm) shall be permitted.~~

4 ~~5~~. On buildings of ~~Type I construction two stories or less above grade plane in height, or~~ Type ~~II,~~ III, or IV ~~and V~~ construction, ~~unprotected~~ penthouses constructed of noncombustible materials or fire-retardant-treated wood, ~~enclosures~~ housing only mechanical equipment, and located with a ~~minimum~~ fire separation

distance ~~of~~ not less than 20 feet (6096 mm) shall be permitted and shall not be required to be fire-resistance-rated.

6. ~~On one-story buildings, combustible unroofed mechanical equipment screens, fences or similar enclosures are permitted where located with a fire separation distance of at least 20 feet (6096 mm) from adjacent property lines and where not exceeding 4 feet (1219 mm) in height above the roof surface.~~
7. ~~Dormers shall be of the same type of construction as the roof on which they are placed, or of the exterior walls of the building.~~

1509.3 Tanks. Tanks having a capacity of more than 500 gallons (2 m^3) ~~placed in or~~ located on the roof deck of a building shall be supported on masonry, reinforced concrete, steel or Type IV construction provided that, where such supports are located in the building above the lowest story, the support shall be fire-resistance rated as required for Type IA construction.

1509.3.1 Valve and drain. ~~Such tanks shall have~~ In the bottom or on the side near the bottom of the tank, a pipe or outlet~~,~~ fitted with a suitable quick opening valve for discharging the contents in an emergency into a ~~through an adequate~~ drain shall be provided.

1509.3.2 Location. ~~Such~~ Tanks shall not be placed over or near a ~~line of stairs~~ stairway or an elevator shaft, unless there is a solid roof or floor underneath the tank.

1509.3.3 Tank cover. Unenclosed ~~roof~~ tanks shall have covers sloping toward the ~~outer edges~~ perimeter of the tanks.

1509.4 Cooling towers. Cooling towers located on the roof deck of a building and greater than ~~in excess of~~ 250 square feet (23.2 m^2) in base area or greater than ~~in excess of~~ 15 feet (4572 mm) ~~high~~ in height above the roof deck, as measured to the highest point on the cooling tower, where ~~located on building~~ the roof~~s more~~ is greater than 50 feet (15 240 mm) ~~high~~ in height above grade plane shall be constructed of noncombustible materials ~~construction~~. The base area of cooling towers shall not exceed one-third the area of the supporting roof deck ~~area~~.

> **Exception:** Drip boards and the enclosing construction shall be permitted to be ~~of~~ wood not less than 1 inch (25 mm) nominal thickness, provided the wood is covered on the exterior of the tower with noncombustible material.

1509.5 Towers, spires, domes and cupolas. ~~Any tower, spire, dome or cupula~~ Towers, spires, domes and cupolas shall be of a type of construction ~~not less in~~ having fire-resistance ~~rating~~ ratings not less than required for the building ~~to~~ on top of which ~~it~~ such tower, spire, dome or cupola is built. ~~attached, except that any such tower, spire, dome or cupula~~ Towers, spires, domes and cupolas greater than ~~that exceeds~~ 85 feet (25 908 mm) in height above grade plane as measured to the highest point on such structures, and either greater than ~~exceeds~~ 200 square feet (18.6 m2) in horizontal area or ~~is~~ used for any purpose other than a belfry or an architectural embellishment, shall be constructed of and supported on Type I or II construction.

1509.5.1 Noncombustible construction required. ~~Any tower, spire, dome or cupula~~ Towers, spires, domes and cupolas ~~that exceeds~~ greater than 60 feet (18 288 mm) in height above the highest point at which ~~it comes in~~ such structure contacts ~~contact with~~ the roof as measured to the highest point on such structure, or that exceeds 200 square feet (18.6 m^2) in area at any horizontal section, or which is intended to be used for any purpose other than a belfry or architectural embellishment, or is located on the top of a building greater than 50 feet (1524 mm) in building height shall be ~~entirely~~ constructed of and supported by noncombustible materials~~. Such structures~~ and shall be separated from the building below by construction having a fire-resistance rating of not less than 1.5 hours with openings protected in accordance with Section 712. ~~with a minimum 1.5-hour fire protection rating. Structures, except aerial supports 12 feet (3658 mm) high or less, flagpoles, water tanks and cooling towers, placed above~~ Such structures located on the top ~~roof~~ of a ~~any~~ building ~~more~~ greater than 50 feet (15 240 mm) in building height~~, shall be of noncombustible material and~~ shall be supported by noncombustible construction ~~of noncombustible material~~.

1509.5.2 Towers and spires. Enclosed towers and spires ~~where enclosed~~ shall have exterior walls constructed as required for the building ~~to~~ on top of which ~~they~~ such towers and spires are built ~~attached~~. The roof covering of spires shall not be ~~of a~~ less than the same class of roof covering ~~as~~ required for the ~~main roof of the rest of the structure~~ building on top of which the spire is located.

2. Add new text as follows:

1509.6 Mechanical equipment screens. Mechanical equipment screens shall be constructed of the materials specified for the exterior walls in accordance with the type of construction of the building without being required to comply with the fire-resistance rating requirements.

1509.6.1 Height limitations. Mechanical equipment screens shall not exceed 18 feet (5486 mm) in height above the roof deck, as measured to the highest point on the mechanical equipment screen, and the highest point on the mechanical equipment screen, as measured to grade plane, shall not exceed the maximum building height allowed for the building by other provisions of this code.

> **Exception:** Where located on buildings of Type IA construction, the height of mechanical equipment screens shall not be limited.

1509.6.2 Types I, II, III, and IV construction. Regardless of the requirements in Section 1509.6, mechanical equipment screens shall be permitted to be constructed of combustible materials where located on the roof decks of building of Type I, II, III, or IV construction in accordance with any of the following limitations:

1. The fire separation distance shall not be less than 20 feet (6096 mm) and the height of the mechanical equipment screen above the roof deck shall not exceed 4 feet (1219 mm) as measured to the highest point on the mechanical equipment screen.
2. The fire separation distance shall not be less than 20 feet (6096 mm) and the mechanical equipment screen shall be constructed of fire-retardant-treated wood complying with Section 2302.2 for exterior installation.
3. The materials shall have a flame spread index of 25 or less when tested in the minimum and maximum thicknesses intended for use with each face tested independently in accordance with ASTM E 84 or UL 723, the facings shall be tested in the minimum and maximum thicknesses intended for use in accordance with, and shall comply with the acceptance criteria of, NFPA 285, and the facings shall be installed as tested but without any substrates or wall assemblies.

1509.6.3 Type V construction. The height of mechanical equipment screens located on the roof decks of buildings of Type V construction, as measured from grade plane to the highest point on the mechanical equipment screen,shall be permitted to exceed the maximum building height allowed for the building by other provisions of this code where complying with any one of the following limitations, provided the fire separation distance is greater than 5 feet (1524 mm):

1. Where the fire separation distance is not less than 20 feet (6096 mm), the height above grade plane of the mechanical equipment screen shall not exceed 4 feet (1219 mm) more than the maximum building height allowed,
2. The mechanical equipment screen shall be constructed of noncombustible materials,
3. The mechanical equipment screen shall be constructed of fire-retardant-treated wood complying with Section 2303.2 for exterior installation, or
4. Where fire separation distance is not less than 20 feet (6096 mm), the mechanical equipment screen shall be constructed of materials having a flame spread index of 25 or less when tested in the minimum and maximum thicknesses intended for use in accordance with ASTM E 84 or UL 723.

1509.7 Other rooftop structures. Rooftop structures not regulated by Sections 1509.2 through 1509.6 shall comply with Section 1509.7.1 through 1509.7.5 as applicable.

1509.7.1 Aerial supports. Aerial supports shall be constructed of noncombustible materials.

> **Exception:** Aerial supports not greater than 12 feet (3658 mm) in height as measured from the roof deck to the highest point on the aerial supports shall be permitted to be constructed of combustible materials.

1509.7.2 Bulkheads. Bulkheads used for the shelter of mechanical or electrical equipment or vertical shaft openings in the roof assembly shall comply with Section 1509.2 as penthouses. Bulkheads used for any other purpose shall be considered as an additional story of the building.

1509.7.3 Dormers. Dormers shall be of the same type of construction as required for the roof in which such dormers are located or the exterior walls of the building.

1509.7.4 Fences. Fences and similar structures shall comply with Section 1509.6 as mechanical equipment screens.

1509.7.5 Flagpoles. Flagpoles and similar structures shall not be required to be constructed of noncombustible materials and shall not be limited in height or number.

3. Revise as follows:

1502.1 General. The following words and terms shall, for the purposes of this chapter and as used elsewhere in this code, have the meanings shown herein.

MECHANICAL EQUIPMENT SCREEN. A ~~partially enclosed~~ rooftop structure, not covered by a roof, used to aesthetically conceal ~~heating, ventilating and air conditioning (HVAC)~~ plumbing, electrical or mechanical equipment from view.

PENTHOUSE. An enclosed, unoccupied rooftop structure ~~above the roof of a building, other than a tank, tower, spire, dome, cupola or bulkhead.~~ used for sheltering mechanical and electrical equipment, tanks, elevators and related machinery, and vertical shaft openings.

ROOF DECK. The flat or sloped surface constructed on top of the exterior walls of a building or other supports for the purpose of enclosing the story below, or sheltering an area, to protect it from the elements, not including its supporting members or vertical supports.

ROOFTOP STRUCTURE. ~~An enclosed~~ A structure erected on ~~or above~~ top of the roof deck or on top of any part of a building.

Reason: The vast majority of the revisions proposed in this code change are editorial in nature but there are also a few technical changes, some of which are significant. The editorial changes are provided for:

clarification
elimination of redundant language including redundant Exceptions
consistency of terminology and application of requirements to specific types of rooftop structures
reformatting regarding the use of the Exception format
reformatting into subsections that deal with different requirements contained in the same section
determination of the height of rooftop structures

We have also provided phraseology to address how to determine the height of a rooftop structure since that height is not defined, unlike "Building Height" which is defined in Section 502.1. We have also substituted the term "roof deck" for the word "roof" since it is a defined term found in Section 1502.1. We have also proposed to revise the definition for "Roof Deck" to clarify its application and make it more specific.

The specific revisions proposed to each Subsection of Section 1509 are discussed in the following.

1509.2 Penthouses. The revision to the first sentence clarifies that the story below, of which the penthouse would be considered a portion if complying with these provisions, is the story that is located directly below the roof deck on which the penthouse is located. Since there are many stories below the penthouse, although it may be obvious, this clearly indicates that it is the story directly below the roof deck on which the penthouse is located. The second sentence merely makes it clear that any other penthouse not compliant with these provisions would actually be considered as an additional story of the building.

1509.2.1 Height above roof deck. The reference to other projections above the roof has been deleted since the focus of this section is penthouses which are defined in Section 1502.1. In fact, the definition for "Penthouse" is proposed to be revised by this code change to further clarify it based on the intent of the section addressing penthouses. Also, we have added new Sections 1509.6 and 1509.7 which address other projections above the roof. This section has also been reformatted into Exception format to make its application more clear and the wording has been revised to be consistent with other code text used throughout the code. These revisions should not result in any technical changes.

1509.2.2 Area limitation. The word "enclosed" is proposed to be added to modify the term "rooftop structures" to be consistent with the proposed revision to the definition for "rooftop structure" contained in this code change. It is our opinion that a rooftop structure encompasses all of the types of enclosures and other projections that could be located or constructed on the top of a roof deck of a building, so it would include both enclosed and unenclosed structures. So the definition of rooftop structure has been broadened to delete the limitation on enclosed structures. In this way both mechanical equipment screens, for which the definition is also being revised by this code change proposal, and penthouses become subsets of "rooftop enclosures". Mechanical equipment screens are not covered by a roof so they are not enclosed and "penthouses" are truly enclosed structures. The definition for "Mechanical Equipment Screen," as noted, is proposed to be revised to indicate that it is a rooftop structure that is not covered by a roof and is, thus, not enclosed. We believe this is a better definition than relying on the term "partially enclosed" which is proposed to be deleted in the definition for "Mechanical Equipment Screen." In the last sentence rather than referring to the definition for "Fire Area" in Section 902, we believe it is more appropriate to refer to where fire areas are used in Section 901.7 to clarify the intent of this sentence.

1509.2.3 Use limitations. The reference to "bulkhead or any other similar projection above the roof" has been deleted since it is being addressed in a proposed new Section 1509.7.2 as it is out of context in this section on penthouses. This section has also been revised to include electrical equipment as a part of the sheltering function of a penthouse since most mechanical equipment installations will also be associated with electrical equipment. The word "assembly" has been added to the word "roof" since "roof assembly" is a defined term in Section 1502.1.

New Section 1509.2.4 Weather protection. This is a reformatting of the section since this sentence addresses a separate requirement from the use limitations provisions in Section 1509.2.3. Again, "electrical equipment" has also been added for the same reasons as noted above. The second sentence has been deleted since it is redundant as it has already been addressed in Section 1509.2. The last sentence has been deleted since it is out of context as it addresses wood flagpoles or similar structures on the roofs of buildings. It has been relocated to a new Section 1509.7.5.

1509.2.5 Type of construction. The revision to the charging paragraph is basically a clarification for specifying compliance with the type of construction of the building on which the penthouses are built.

Exception 1. These revisions are editorial to be consistent with terminology used throughout the code. The revisions to the second sentence are to implement the intent of these Exceptions which address the fire-resistance ratings not being required. By default, this results in noncombustible construction in a Type I building. The last sentence has been deleted because it is unnecessary as this is a basic requirement for buildings of Type I construction.

Exception 2. Again, these are basically editorial revisions to use terminology consistent with the rest of the code and to be consistent with the revisions to Exception 1 as noted above. The revisions to the last sentence are made for the same reasons as noted in Exception 1 above where noncombustible construction is the requirement for such partitions, but the intent of the section is to allow for the use of fire-retardant-treated wood in lieu of noncombustible construction.

Exception 3. Since this is an Exception, the word “and” has been changed to “or” in the list of the types of construction to which this Exception is applicable. Additional editorial revisions have been made to be consistent with those made to Exceptions 1 and 2 above. The phrase “from a common property line” has been deleted because it is unnecessary since the term “fire separation distance” is a defined term in Section 702.1. The next to the last sentence has been deleted as it is unnecessary based on the charging sentence in Section 1509.2.4 to which this is an Exception. This appears to be a code requirement within an Exception that is not necessary. Similarly, the last sentence has also been deleted since other provisions of the code already allow such construction.

Exception 4. This Exception has been deleted since it is redundant. It is covered by Exception 1 above and is actually more limiting than Exception 1.

Exception 5. The reference to Types I and II construction have been deleted as they are already covered by Exception 2 above, whereas this Exception as noted in Exception 4 above is somewhat more restrictive than Exception 2. The rest of the revisions are editorial by utilizing consistent terminology to that used throughout the rest of the code and to be consistent with the revisions to Exceptions 1 and 2 above.

Exception 6. This Exception is being deleted since it does not address penthouses and is, thus, out of context. The provisions of this Exception, however, have been utilized in the new Sections 1509.6 and 1509.7 being added by this code change which will be discussed later.

Exception 7. This section is also being deleted since it is out of context as it does not address penthouses. It has been editorially revised and relocated as new Section 1509.7.3.

1509.3 Tanks. This entire subsection including sub-subsections .1, .2, and .3 have been editorially revised with no technical changes.

1509.4 Cooling towers. This section has been revised to make it clear that it is only applicable to cooling towers located on the roof deck of a building. It also provides a clarification on how the height of the cooling tower is to be measured for applying the limitations in this section. The rest of the changes are editorial without technical change.

1509.5 Towers, spires, domes, and cupolas. These are editorial revisions to make the section consistent with the previous sections in terms of format and terminology and also to incorporate the method for measuring the height of these structures.

1509.5.1 Noncombustible construction required. The first sentence has been revised to be consistent with Section 1509.5 including how to make the measurements for the height of these structures. The last sentence has been revised and broken up into separate parts with the one part referencing the noncombustible construction limitation incorporated into the first sentence which deals with the construction of these structures, whereas the last sentence deals with the support of these structures under certain conditions. The second sentence has been revised to be included in the first sentence since it is conditional to the application of the first sentence. The reference to the minimum 1.5 hour fire protection rating for protection of openings in the 1.5 hour separation of the structures from the building below has been deleted with a reference to Section 712 provided. Section 712 addresses how to protect openings in horizontal assemblies. Generally speaking, opening protectives with fire protection ratings are not used to protect openings in horizontal assemblies unless those openings are protected with shaft enclosures with openings. However, there are floor fire door assemblies that can be used which have a fire-resistance rating, as opposed to a fire protection rating.

1509.5.2 Towers and spires. These are basically editorial clarifications without any technical change.

1509.6 Mechanical equipment screens. This is a new section being proposed to specifically address mechanical equipment screens which are defined in Section 1502.1. They are not otherwise addressed in Section 1509 with the exception of the out of context Exception 6 to Section 1509.2.4 which only addresses the type of construction of penthouses as previously noted. Also, as previously noted, we are proposing to revise the definition for “Mechanical Equipment Screen” in Section 1502.1 to make it clear that it is a rooftop structure that is not covered by a roof, rather than a “partially enclosed” rooftop structure.

This new section takes what we believe to be a conservative approach to the construction of mechanical equipment screens on roofs by specifying that they must be constructed of the same materials as required by the code for exterior walls based on the type of construction of the building on which they are located. However, it is proposed that they be exempt from the fire-resistance rating requirements since they do not fully enclose a space as they are without a roof and they represent a different exposure hazard than a penthouse, for example. Basically, the exposure hazard of a mechanical equipment screen is the combustibility of the screen itself and the amount of combustible materials it contains.

1509.6.1 Height limitations. The height limits specified in this section are also conservative, in our opinion, as they are based on those required for penthouses in Section 1509.2.1. The height limit is also based on the assumption that the overall height of the mechanical equipment screen should not exceed that allowed for the maximum building height for the type of construction of the building on which it is constructed. Thus, the need for the Exception for mechanical equipment screens located on buildings of Type IA construction which are not limited in height by Table 503.

1509.6.2 Types I, II, III, and IV construction. This new section is, in essence, an Exception to the requirements in Section 1509.6 for these types of construction which require the exterior walls to be constructed of noncombustible materials. The three itemized limitations in this section allow for combustible materials to be used for the construction of mechanical equipment screens based upon the provisions in those three items as discussed in the following.

Item 1. This item is based on Exception 6 to Section 1509.2.4 as previously noted for penthouses which has been deleted. The 1-story building height limitation has not been included since we believe it is not necessary. In our opinion, the hazard of a combustible mechanical equipment screen located on the roof of a Type I, II, III, or IV building with a fire separation distance of not less than 20 feet and with the height of the mechanical equipment screen limited to 4 feet above the roof deck is not a significant fire hazard. It is interesting to note that Table 705.8 Maximum Area of Exterior Wall Openings Based on Fire Separation Distance and Degree of Opening Protection would allow up to 45% of the exterior wall area of a nonsprinklered building to have unprotected openings and would allow unlimited unprotected openings in sprinklered buildings. Thus, for a building having floor-to-floor heights of at least 10 feet, which is very minimal, unprotected window openings around the entire perimeter could be as tall as 4.5 feet. This would represent a greater fire exposure, once the story flashes over and the windows break out, than a burning 4 foot high mechanical equipment screen which will normally be set back some distance from the face of the exterior wall.

Item 2. The provisions of this Item are based on Exceptions 2 and 3 to Section 1509.2.4 for penthouses with the 2-story limit on Type I buildings omitted. We believe this to be a reasonable approach since the hazard doesn’t justify limiting the Type I buildings to two stories in height where fire-retardant-treated wood is used to construct these unenclosed mechanical equipment screens. The main difference between Item 1 above and this Item 2 is that Item 2 does not place a 4 foot height limit on the height of the mechanical equipment screen above the roof deck. That is because it must be constructed of fire-retardant-treated wood as compared to any combustible material allowed by the code being permitted in Item 1. Of course, the height of the mechanical equipment screen is still limited to a maximum of 18 feet above the roof based on Section 1509.6.1. It is also limited to the maximum building height that would be allowed by the type of construction of the building in accordance with Section 1509.6.1 as well.

Item 3. These limitations are based on a totally new concept where the combustible materials used to build the mechanical equipment screen are limited to a maximum flame spread index of 25 (which is also required for fire-retardant-treated wood) and the materials are required to be successfully tested in accordance with NFPA 285 Standard Method of Test for the Evaluation of Flammability Characteristics of Exterior Nonload-Bearing Wall Assemblies Containing Combustible Components. This is the same test method that is used to validate the use of foam-plastic insulations in exterior walls of Types I, II, III, and IV construction, as well as for the use of metal composite materials (MCM) in accordance with Section 1407.10. Although the material would be tested as the outer face (or skin) of the exterior wall in the NFPA 285 test as part of an exterior wall assembly, the test clearly assesses the surface flame spread resistance of the materials constituting the outer face, as well as to a certain degree, the inner face where it is exposed to any open cavities in the wall assembly. The NFPA 285 test is conducted for a full 30 minutes under severe fire exposure conditions to both the inside of the wall assembly and the outside of the wall assembly with an exterior window burner replicating a fire that has gone to post-flashover and has broken out a window, exposing the outside face of the exterior wall finish. Since the materials used to construct the mechanical equipment screen do not comprise a completely enclosed wall assembly, the maximum flame spread index of 25 has been proposed as a conservative limitation for the backside face of the material which may not have been directly exposed to the exterior window burner flame in the NFPA 285 test. Since the NFPA 285 test is used to qualify combustible materials for use where noncombustible exterior walls are required, it seems reasonable to allow its use for this application for mechanical equipment screens without the need to have the entire wall assembly constructed as tested for the mechanical equipment screen, instead utilizing the materials tested on the exterior face of the wall system in accordance with NFPA 285.

1509.6.3 Type V construction. This new section is basically an Exception to the requirements in Section 1509.6.1 Height Limitations for Type V construction where the mechanical equipment screens are allowed to be constructed of combustible materials. The one condition that must be met for all four options in this section is that the minimum fire separation distance must be greater than 5 feet which is consistent with Section 1406 Combustible Materials on the Exterior Side of Exterior Walls.

Item 1. This item is based on Exception 6 to Section 1509.2.4 for penthouses which has been deleted. It was limited to one story buildings. However, we don't see the hazard represented by a 4 foot high increase in the overall height of the mechanical equipment screen on buildings of Type V construction (which are allowed to be constructed entirely of combustible materials) as justifying that one story limitation. This is especially true where the fire separation distance specified is not less than 20 feet. Please refer to the discussion on Item 1 of Section 1509.6.2 above.

Item 2. This seems intuitively obvious to allow these mechanical equipment screens to be taller when they are constructed of noncombustible materials where combustible materials would otherwise be permitted. Noncombustible materials pose no additional fire load or fire exposure to the building.

Item 3. This allows the use of fire-retardant-treated wood which, although combustible, does not pose a significant fire hazard, in our opinion, when constructed as a mechanical equipment screen where there is a minimum 5 foot fire separation distance.

Item 4. This is somewhat similar to Item 3 in that fire-retardant-treated wood is required to have a maximum flame spread index of 25 as proposed for the combustible materials allowed in this item. However, there is an additional requirement that the fire separation distance be not less than 20 feet as compared to the base requirement of 5 feet for these provisions to be allowed to be used. We believe that the fire hazard associated with this type of installation would not be significant so as to allow the greater heights for the mechanical equipment screens installed on these Type V buildings. Again, please refer to the discussion on Item 1 of Section 1509.6.2 above regarding the minimum 20 foot fire separation distance limitation.

1509.7 Other rooftop structures. This new section becomes a catchall section to address other rooftop structures that are not specifically regulated by Sections 1509.2 through 1509.6. In reviewing Section 1509 we found references to such other rooftop structures as aerial supports covered in proposed new Section 1509.7.1, bulkheads covered in proposed new Section 1509.7.2, dormers covered in proposed new Section 1509.7.3, fences covered in proposed new Section 1509.7.4, and flagpoles covered in proposed new Section 1509.7.5. So we believe we have addressed all of the rooftop structures the code currently addresses.

1509.7.1 Aerial supports. The requirements for this section are taken from Section 1509.5.1 which were deleted because they were out of context in regard to the provisions of the section which addressed towers, spires, domes, and cupolas.

1509.7.2 Bulkheads. It is proposed to treat bulkheads like penthouses as we believe was intended by Section 1509.2.3 where bulkheads are currently referred to. We eliminated bulkheads from that section since it specifically addresses penthouses. In this way we keep the section clean and then simply reference it and require bulkheads to be constructed to meet those requirements as if they were penthouses. Looking at the definition for "Bulkhead" in Webster's dictionary, the most likely meaning within the context of Section 1509 is "a projecting framework with a sloping door giving access to a cellar stairway or a shaft."

1509.7.3 Dormers. This is where Exception 7 of Section 1509.2.4 was relocated after it was deleted from that section addressing penthouses since it was clearly out of context.

1509.7.4 Fences. It is our best judgment that fences should be treated as mechanical equipment screens since they are similar structures and can be considered similar in fire hazard. It should be noted that they are mentioned in Exception 6 to Section 1509.2.4 for penthouses which was deleted, again, as being out of context.

1509.7.5 Flagpoles. These requirements are taken from the last sentence of Section 1509.2.3 for penthouses which was deleted as being out of context.

In summary, it is readily obvious after delving into Section 1509 that it is very disjointed and inconsistent and utilizes terminology and language that is not consistent with the rest of the code. It appears to be, as it most likely is, an amalgam of the three legacy code requirements for rooftop structures which was put together without a lot of detailed evaluation or review. Since Trespa North America, Ltd. manufactures products that are used in many of these applications, we have come across many projects where Section 1509 has been attempted to be applied but without much success. It is extremely difficult to determine what the true intent is of many of the requirements, especially those that do not specifically address penthouses. We have tried our best to clarify and reformat this section to make it clearer to understand, easier to read and interpret, and, hopefully, more effectively enforced and applied. We hope that the Committee will give this comprehensive revision to Section 1509 serious and in-depth consideration so that we can fix it for the 2012 IBC, remembering that we only have one chance to get it corrected before the next edition is published.

Cost Impact: The proponent shall indicate one of the following regarding the cost impact of the code change proposal: The code change proposal will not increase the cost of construction.

ICCFILENAME: Thornberry-S1-1509

Public Hearing Results

Committee Action: Disapproved

Committee Reason: The committee recognized the need to improve this section and acknowledged the efforts of the proponents. Based on the testimony provided and the number of attempted modifications, the proposal needs additional refinement before it can be approved. The committee also expressed concerns that some of the wall and screening requirements for the penthouses would be more stringent that the walls of the building below. There was an uncomfortable mixture of materials and fire resistance ratings. The various fire separation distances appeared inconsistent as did the variety of height limits.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Rick Thornberry, PE, The Code Consortium, Inc., representing, Alcan Composites USA, Inc. and Jesse Beitel, Hughes Associates, Inc., representing Trespa North America. Ltd, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

1509.2 Penthouses. Penthouses in compliance with Sections 1509.2.1 through 1509.2.5 shall be considered as a portion of the story directly below the roof deck on which such penthouses are located. All other penthouses shall be considered as an additional story of the building.

1509.2.1 Height above roof deck. Penthouses constructed on buildings of other than Type I construction shall not exceed 18 feet (5486 mm) in height above the roof deck as measured to the average height of the roof of the penthouse.

Exceptions:

1. Where used to enclose tanks or elevators that travel to the roof level, penthouses shall be permitted to have a maximum height of 28 feet (8534 mm) above the roof deck.
2. Penthouses located on the roof of buildings of Type I construction shall not be limited in height.

1509.2.2 Area limitation. The aggregate area of penthouses and other enclosed rooftop structures shall not exceed one-third the area of the supporting roof deck. Such penthouses and other enclosed rooftop structures shall not be required to be included in determining the building area or number of stories as regulated by Section 503.1. The area of such penthouses shall not be included in determining the fire area specified in Section 901.7.

1509.2.3 Use limitations. Penthouses shall not be used for purposes other than the shelter of mechanical or electrical equipment, tanks, or vertical shaft openings in the roof assembly.

1509.2.4 Weather protection. Provisions such as louvers, louver blades or flashing shall be made to protect the mechanical and electrical equipment and the building interior from the elements.

1509.2.5 Type of construction. Penthouses shall be constructed with walls, floors and roof as required for the type of construction of the building on which such penthouses are built.

Exceptions:

1. On buildings of Type I construction, the exterior walls and roofs of penthouses with a fire separation distance greater than 5 feet (1524 mm) and less than 20 feet (6096 mm) shall be permitted to have not less than a 1-hour fire resistance-rating. The exterior walls and roofs of penthouses with a fire separation distance of 20 feet (6096 mm) or greater shall not be required to have a fire-resistance rating.
2. On buildings of Type I construction two stories or less in height above grade plane or Type II construction, the exterior walls and roofs of penthouses with a fire separation distance greater than 5 feet (1524 mm) and less than 20 feet (6096 mm) shall be permitted to have not less than a 1-hour fire-resistance-rating or a lesser fire-resistance rating as required by Table 602 and be constructed of fire-retardant-treated wood. The exterior walls and roofs of penthouses with a fire separation distance of 20 feet (6096 mm) or greater shall be permitted to be constructed of fire-retardant-treated wood and shall not be required to have a fire-resistance rating. Interior framing and walls shall be permitted to be constructed of fire retardant treated wood.
3. On buildings of Type III, IV or V construction, the exterior walls of penthouses with a fire separation distance greater than 5 feet (1524 mm) and less than 20 feet (6096 mm) shall be permitted to have not less than a 1-hour fire-resistance-rating or a lesser fire-resistance rating as required by Table 602. On buildings of Type III, IV or VA construction, the exterior walls of penthouses with a fire separation distance of 20 feet (6096 mm) or greater shall be permitted to be of Type IV ~~construction or shall be constructed of~~ or noncombustible construction or fire-retardant-treated wood and shall not be required to have a fire-resistance rating.
4. ~~On buildings of Type III or IV construction, penthouses constructed of noncombustible materials or fire-retardant-treated wood, housing only mechanical equipment, and located with a fire separation distance not less than 20 feet (6096 mm) shall be permitted and shall not be required to be fire-resistance-rated.~~

1509.3 Tanks. Tanks having a capacity of more than 500 gallons (2 m^3) located on the roof deck of a building shall be supported on masonry, reinforced concrete, steel or Type IV construction provided that, where such supports are located in the building above the lowest story, the support shall be fire-resistance rated as required for Type IA construction.

1509.3.1 Valve and drain. In the bottom or on the side near the bottom of the tank, a pipe or outlet fitted with a suitable quick opening valve for discharging the contents in an emergency into a drain shall be provided.

1509.3.2 Location. Tanks shall not be placed over or near a stairway or an elevator shaft, unless there is a solid roof or floor underneath the tank.

1509.3.3 Tank cover. Unenclosed tanks shall have covers sloping toward the perimeter of the tanks.

1509.4 Cooling towers. Cooling towers located on the roof deck of a building and greater than 250 square feet (23.2 m^2) in base area or greater than 15 feet (4572 mm) in height above the roof deck, as measured to the highest point on the cooling tower, where the roof is greater than 50 feet

(15 240 mm) in height above grade plane shall be constructed of noncombustible materials. The base area of cooling towers shall not exceed one-third the area of the supporting roof deck.

Exception: Drip boards and the enclosing construction shall be permitted to be wood not less than 1 inch (25 mm) nominal thickness, provided the wood is covered on the exterior of the tower with noncombustible material.

1509.5 Towers, spires, domes and cupolas. Towers, spires, domes and cupolas shall be of a type of construction having fire-resistance ratings not less than required for the building on top of which such tower, spire, dome or cupola is built. Towers, spires, domes and cupolas greater than 85 feet (25 908 mm) in height above grade plane as measured to the highest point on such structures, and either greater than 200 square feet (18.6 m^2) in horizontal area or used for any purpose other than a belfry or an architectural embellishment, shall be constructed of and supported on Type I or II construction.

1509.5.1 Noncombustible construction required. Towers, spires, domes and cupolas greater than 60 feet (18 288 mm) in height above the highest point at which such structure contacts the roof as measured to the highest point on such structure, or that exceeds 200 square feet (18.6 m^2) in area at any horizontal section, or which is intended to be used for any purpose other than a belfry or architectural embellishment, or is located on the top of a building greater than 50 feet (1524 mm) in building height shall be constructed of and supported by noncombustible materials and shall be separated from the building below by construction having a fire-resistance rating of not less than 1.5 hours with openings protected in accordance with Section 712. Such structures located on the top of a building greater than 50 feet (15240 mm) in building height shall be supported by noncombustible construction.

1509.5.2 Towers and spires. Enclosed towers and spires shall have exterior walls constructed as required for the building on top of which such towers and spires are built. The roof covering of spires shall not be less than the same class of roof covering required for the building on top of which the spire is located.

1509.6 Mechanical equipment screens. Mechanical equipment screens shall be constructed of the materials specified for the exterior walls in accordance with the type of construction of the building. Where the fire separation distance is greater than 5 feet (1524 mm), mechanical equipment screens shall not be ~~without being~~ required to comply with the fire-resistance rating requirements.

1509.6.1 Height limitations. Mechanical equipment screens shall not exceed 18 feet (5486 mm) in height above the roof deck, as measured to the highest point on the mechanical equipment screen~~, and the highest point on the mechanical equipment screen, as measured to grade plane, shall not exceed the maximum building height allowed for the building by other provisions of this code~~.

Exception: Where located on buildings of Type IA construction, the height of mechanical equipment screens shall not be limited.

1509.6.2 Types I, II, III, and IV construction. Regardless of the requirements in Section 1509.6, mechanical equipment screens shall be permitted to be constructed of combustible materials where located on the roof decks of building of Type I, II, III, or IV construction in accordance with any one of the following limitations:

1. The fire separation distance shall not be less than 20 feet (6096 mm) and the height of the mechanical equipment screen above the roof deck shall not exceed 4 feet (1219 mm) as measured to the highest point on the mechanical equipment screen.
2. The fire separation distance shall not be less than 20 feet (6096 mm) and the mechanical equipment screen shall be constructed of fire-retardant-treated wood complying with Section 2302.2 for exterior installation.
3. ~~The materials~~ Where exterior wall covering panels are used, the panels shall have a flame spread index of 25 or less when tested in the minimum and maximum thicknesses intended for use with each face tested independently in accordance with ASTM E 84 or UL 723~~, the facings~~. The panels shall be tested in the minimum and maximum thicknesses intended for use in accordance with, and shall comply with the acceptance criteria of, NFPA 285~~,~~ and ~~the facings~~ shall be installed as tested ~~but without any substrates or wall assemblies~~. Where the panels are tested as part of an exterior wall assembly in accordance with NFPA 285, the panels shall be installed on the face of the mechanical equipment screen supporting structure in the same manner as they were installed on the tested exterior wall assembly.

1509.6.3 Type V construction. The height of mechanical equipment screens located on the roof decks of buildings of Type V construction, as measured from grade plane to the highest point on the mechanical equipment screen, shall be permitted to exceed the maximum building height allowed for the building by other provisions of this code where complying with any one of the following limitations, provided the fire separation distance is greater than 5 feet (1524 mm):

1. where the fire separation distance is not less than 20 feet (6096 mm), the height above grade plane of the mechanical equipment screen shall not exceed 4 feet (1219 mm) more than the maximum building height allowed,
2. the mechanical equipment screen shall be constructed of noncombustible materials,
3. the mechanical equipment screen shall be constructed of fire-retardant-treated wood complying with Section 2302.2 for exterior installation, or
4. where fire separation distance is not less than 20 feet (6096 mm), the mechanical equipment screen shall be constructed of materials having a flame spread index of 25 or less when tested in the minimum and maximum thicknesses intended for use with each face tested independently in accordance with ASTM E 84 or UL 723.

1509.7 Other rooftop structures. Rooftop structures not regulated by Sections 1509.2 through 1509.6 shall comply with Section 1509.7.1 through 1509.7.5 as applicable.

1509.7.1 Aerial supports. Aerial supports shall be constructed of noncombustible materials.

Exception: Aerial supports not greater than 12 feet (3658 mm) in height as measured from the roof deck to the highest point on the aerial supports shall be permitted to be constructed of combustible materials.

1509.7.2 Bulkheads. Bulkheads used for the shelter of mechanical or electrical equipment or vertical shaft openings in the roof assembly shall comply with Section 1509.2 as penthouses. Bulkheads used for any other purpose shall be considered as an additional story of the building.

1509.7.3 Dormers. Dormers shall be of the same type of construction as required for the roof in which such dormers are located or the exterior walls of the building.

1509.7.4 Fences. Fences and similar structures shall comply with Section 1509.6 as mechanical equipment screens.

1509.7.5 Flagpoles. Flagpoles and similar structures shall not be required to be constructed of noncombustible materials and shall not be limited in height or number.

1502.1 General.

MECHANICAL EQUIPMENT SCREEN. A rooftop structure<u>, not covered by a roof,</u> used to aesthetically conceal plumbing, electrical or mechanical equipment from view.

PENTHOUSE. An enclosed, unoccupied rooftop structure used for sheltering mechanical and electrical equipment, tanks, elevators and related machinery, and vertical shaft openings.

ROOF DECK. The flat or sloped surface constructed on top of the exterior walls of a building or other supports for the purpose of enclosing the story below, or sheltering an area, to protect it from the elements, not including its supporting members or vertical supports.

ROOFTOP STRUCTURE A structure erected on top of the roof deck or on top of any part of a building.

Commenter's Reason: We have submitted this Public Comment with the sincere hope that the revisions we have included herein will satisfy the concerns expressed during the Public Hearings by several members of the IBC General Code Development Committee so that this much needed improvement to Section 1509 Rooftop Structures can be approved as revised during the ICC Final Action Hearings and incorporated into the 2012 edition of the IBC. As we all know, this is the only opportunity we will have to fix this rather confusing section to make it more user friendly and code enforceable for inclusion in the 2012 IBC. Otherwise we will have to wait another three years for one more opportunity during the next three year code development cycle for the publication of the 2015 IBC.

At any rate, we have also worked with the ICC Tri-Chapter Code Committee (which represents the ICC East Bay, Peninsula, and Monterey Bay Chapters) in further revising this Code Change Proposal to address their issues and concerns in providing for a comprehensive yet reasonable overhaul of the requirements for rooftop structures which are questionable at best in the current code. In fact, the ICC Tri-Chapter Code Committee has another Public Comment to their Code Change Proposal S26-09/10 which tries to make some minor yet significant changes to this section which they have also found to be very confusing and difficult to interpret and enforce.

The revisions proposed in this Public Comment further clarify the original rewrite and make it more internally consistent, as well as simplified to some extent. Some of the more conservative and restrictive requirements have been somewhat relaxed to satisfy some of the concerns expressed by members of the ICC Tri-Chapter Code Committee and members of the IBC General Code Development Committee for establishing reasonable minimum requirements for regulating rooftop structures.

Otherwise, we stand on our original Reason Statement for this Code Change Proposal which has clearly indicated what we've done to make these extensive and comprehensive revisions to Section 1509 and how they interrelate with the current code provisions, as well as with each other, to provide for a more systematic set of requirements for the various types of rooftop structures found on buildings. We truly believe that the revisions made in this Public Comment, if approved by the Class A voting members, will result in a much better set of requirements for rooftop structures than we currently have. Although this rewrite may not be perfect, it is certainly significantly better than what we have now. Therefore, we strongly urge the Class A voting members to overturn the Committee's recommendation for disapproval and approve this Public Comment which will result in approval as revised of Code Change S27-09/10.

Final Action: AS AM AMPC____ D

S29-09/10
1510.3

<u>Proposed Change as Submitted</u>

Proponent: Mike Ennis representing Single Ply Roofing Industry (SPRI, Inc.)

Revise as follows:

1510.3 Recovering versus replacement. New roof coverings shall not be installed without first removing all existing layers of roof coverings down to the roof deck where any of the following conditions occur:

1. Where the existing roof or roof covering is water soaked or has deteriorated to the point that the existing roof or roof covering is not adequate as a base for additional roofing.
2 Where the existing roof covering is wood shake, slate, clay, cement or asbestos-cement tile.
3. Where the existing roof has two or more applications of any type of roof covering.

Exceptions:

1. Complete and separate roofing systems, such as standing-seam metal roof systems, that are designed to transmit the roof loads directly to the building's structural system and that do not rely on existing roofs and roof coverings for support, shall not require the removal of existing roof coverings.

2. Metal panel, metal shingle and concrete and clay tile roof coverings shall be permitted to be installed over existing wood shake roofs when applied in accordance with Section 1510.4.
3. The application of a new protective coating over an existing spray polyurethane foam roofing system shall be permitted without tear-off of existing roof coverings.
4. <u>The application of a new single-ply membrane directly over an existing roofing system shall be permitted without tear-off of the existing roof coverings except where the existing roof or roof covering is water soaked or has deteriorated to the point that the existing roof or roof covering is not adequate as a base for additional roofing.</u>

Reason: A layer of single-ply membrane is very lightweight, adding approximately 1/3 of a pound per square foot to the existing structure. The single-ply membrane can be used as a reflective layer to reduce rooftop temperatures, thus providing a cooling benefit for the building. The cooling benefits of reflective roof systems are recognized by the energy codes. This exception will allow for a cost effective method for increasing the energy efficiency of the building while providing excellent waterproofing protection. A single layer of membrane will also provide the same function and benefit as a new protective coating over an existing spray polyurethane foam roofing system, which is currently allowed as an exception under Section 1510.3, Exception 3.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: ENNIS-S2-1510.3

Public Hearing Results

Committee Action: Disapproved

Committee Reason: The proposed exception is not necessary because the existing recovering versus replacement requirement already allows this. Furthermore, it would be a loophole to conditions 2 and 3.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Mike Ennis, Single Ply Roofing Industry (SPRI), requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

1510.3 Recovering versus replacement. New roof coverings shall not be installed without first removing all existing layers of roof coverings down to the roof deck where any of the following conditions occur:

1. Where the existing roof or roof covering is water soaked or has deteriorated to the point that the existing roof or roof covering is not adequate as a base for additional roofing.
2. Where the existing roof covering is wood shake, slate, clay, cement or asbestos-cement tile.
3. Where the existing roof has two or more applications of any type of roof covering.

Exceptions:

1. Complete and separate roofing systems, such as standing-seam metal roof systems, that are designed to transmit the roof loads directly to the building's structural system and that do not rely on existing roofs and roof coverings for support, shall not require the removal of existing roof coverings.
2. Metal panel, metal shingle and concrete and clay tile roof coverings shall be permitted to be installed over existing wood shake roofs when applied in accordance with Section 1510.4.
3. The application of a new protective coating over an existing spray polyurethane foam roofing system shall be permitted without tear-off of existing roof coverings.
4. <u>For existing low-slope (roof slope < 2:12) roofs with two applicants of any type of roof covering</u> ~~The~~ <u>the</u> application of a new single-ply membrane directly over an existing roofing system shall be permitted without tear-off of the existing roof coverings ~~except where the existing roof or roof covering is water soaked or has deteriorated to the point that the existing roof or roof covering is not adequate as a base for additional roofing~~.

Commenter's Reason: The intent of the original code change proposal was to provide an exemption to the requirement contained in Condition 3 of Section 1510.3 that the existing roof must be torn off if there are two or more applications of any type of roof covering, The exemption would be for an additional layer of single-ply roof membrane because it is lightweight, provides a cost-effective means of returning the roof to watertight condition, and can reduce the energy consumption of the building.

The modifications are proposed to address the following comments made at the code change hearings:

1) The proposed exception is not necessary because the existing recovering vs. replacement requirement already allows this.

Section 1510.3 Recovering vs. replacement does not allow for the installation of an additional layer if the existing already contains two layers of an existing roof. The original proposal included the wording of condition 1 of Section 1510.3 to emphasis the importance of not recovering over an existing roof that is water soaked. This caused confusion as to the intent of the proposed exception. Removing this language from the exception and including specific language describing when the exception is to be allowed clarifies the intent.

2) This exception would provide a loophole to conditions 2 and 3 of Section 1510.3.

The proposed modification directs the exception to existing low slope (roof slope <2:12) roof assemblies. This removes the potential of providing a loophole to condition 2 of Section 1510.3. The intent is to provide an exception to condition 3 of Section 1510.3.

3) Concern was expressed regarding the wind uplift and fire resistance of the resulting system by installing a new single ply membrane over an existing roof.

Manufacturers of singe ply roof membrane systems have conducted testing in accordance with the requirements of the International Building Code to evaluate the wind uplift and fire resistance of roof recovery assemblies. Recover assemblies must meet the requirements of the International Building Code.

4) How many additional layers of single ply roof membrane would be allowed?

The proposed modification limits the exception to roofs with a maximum of two existing applications of roof covering.

Final Action: AS AM AMPC____ D

S34-09/10
1603.1.5

<u>Proposed Change as Submitted</u>

Proponent: Kevin Moore, PE, SE, SECB and Edwin Huston, PE, SE, SECB, representing National Council of Structural Engineers Associations

Revise as follows:

1603.1.5 Earthquake design data. The following information related to seismic design loads shall be shown, regardless of whether seismic loads govern the design of the lateral-force-resisting system of the building:

1. Seismic importance factor, *I*, and *occupancy category.*
2. Mapped spectral response accelerations, S_S and S_1.
3. *Site class.*
4. Spectral response coefficients, S_{DS} and S_{D1}.
5. *Seismic design category.*
6. Basic seismic-force-resisting system(s).
7. Design base shear.
8. Seismic response coefficient(s), C_S.
9. Response modification factor(s), *R*.
10. Analysis procedure used.
11. <u>Applicable horizontal structural irregularities.</u>
12. <u>Applicable vertical structural irregularities.</u>

Reason: Structural irregularities (defined in ASCE-7 section 12.3) can result in restrictions on building height, prohibition of certain configurations, increased design forces, additional analytical requirements, restriction of permissible analytical procedures, greater building separations, or additional detailing requirements for certain structural elements. It is often not evident whether one or more irregularities are applicable to a structure, because many of them require structural analysis to determine their applicability. This information is useful for building officials, plan checkers, peer reviewers, and for structural engineers in future building additions and/or alterations.

Cost Impact: This proposal will not increase the cost of construction.

ICCFILENAME: MOORE-HUSTON-S2-1603.1.5

<u>Public Hearing Results</u>

Committee Action: **Disapproved**

Committee Reason: The proposal to include horizontal and vertical irregularities in the seismic data required for construction documents was judged to be too burdensome. This information is not as imperative as the other data that is currently required. Architectural design changes would affect this, requiring the information to be revised. It is recognized that the existence of certain irregularities matter more than others. Therefore, it would be preferable to focus on specific irregularities and this could be achieved in the public comment phase.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment :

Kevin Moore, PE, SE, SECB, representing the National Council of Structural Engineers Association (NCSEA); Steven Winkel, FAIA, PE, representing the Federal Emergency Management Agency, BSSC Code Resource Support Committee (FEMA/BSSC CRSC), request Approval as Modified by this Public Comment.

Modify the proposal as follows:

1603.1.5 Earthquake design data. The following information related to seismic design loads shall be shown, regardless of whether seismic loads govern the design of the lateral-force-resisting system of the ~~building~~ structure:

1. Seismic importance factor, *I*, and *occupancy category.*
2. Mapped spectral response accelerations, *SS* and *S1*.
3. *Site class.*
4. Spectral response coefficients, *SDS* and *SD1*.
5. *Seismic design category.*
6. Basic seismic-force-resisting system(s).
7. Design base shear.
8. Seismic response coefficient(s), *CS*.
9. Response modification factor(s), *R*.
10. Analysis procedure used.
11. Where a structure is classified as irregular, identify structural irregularity type(s) in accordance with Tables 12.3-1 and 12.3-2 of ASCE 7.

~~11. Applicable horizontal structural irregularities.~~

~~12. Applicable vertical structural irregularities.~~

Commenter's Reason: An awareness of what structural irregularities are applicable to a structure facilitates quicker plan reviews for building officials (and other reviewers) by increasing the understanding of expected structural response and specific detailing requirements. It also aids designers of future renovations for the same reasons.

All irregularities are important because they represent undesirable aspects of structures that, if ignored, increase the seismic hazard. This information is arguably more important than parameters currently required by Section 1603.1.5 because, in many cases, it cannot be verified without detailed analysis. (In contrast, mapped acceleration parameters are easily verified and not structure dependent, and seismic importance factor is implied because it is dependent on occupancy/risk category.)

Knowledge of applicable structural irregularities is critical to understand the expected seismic response of a structure and the detailing requirements that arise because of them. For example, if a structure contains a discontinuity in the lateral-force-resisting system, then the supporting element is required to be designed for special load combinations. Acknowledging the irregularity in the construction documents is an indication that the condition has been considered in the design. More important, if this proposal is successful, a lack of acknowledgement may indicate that the irregularity has not been considered in the design and should result in an important review comment.

Committee commentary on proposal EB22 alludes to the importance of knowing when irregularities have been created or modified by the renovation of an existing building. This proposal would flag the existence of irregularities for future renovations, which benefits both designers and reviewers.

Reporting these irregularities is not burdensome. Calculations and detailing are required regardless, and late design changes do not excuse the design professional from incorporating requirements into the analysis or design. Requiring the design professional to report structural irregularities facilitates plan review, informs designers of renovations, and helps ensure that design professionals consider irregularities in their design.

In the charging language, the word "building" is proposed to be changed to "structure" to correlate with the intent that the data listed in Section 1603.1.5 apply to structures, in general -not just buildings.

Final Action: AS AM AMPC____ D

S39-09/10
Table 1604.5

Proposed Change as Submitted

Proponent: David R. Badger PE, CBO, Virginia Tech, representing self.

Revise as follows:

TABLE 1604.5
OCCUPANCY CATEGORY OF BUILDINGS AND OTHER STRUCTURES

OCCUPANCY CATEGORY	NATURE OF OCCUPANCY
III	Buildings and other structures that represent a substantial hazard to human life in the event of failure, including but not limited to: • Buildings and other structures whose primary occupancy is public assembly with an occupant load greater than 300. • Buildings and other structures containing elementary school, secondary school or day care facilities with an occupant load greater than 250. ~~• Buildings and other structures containing adult education facilities, such as colleges and universities, with an occupant load greater than 500.~~ • <u>Buildings and other structures used for the education of adults who are either above the 12th grade or not in a formal educational system; where the teaching is done in classroom settings with an occupant load density equal to or greater than that required for educational classroom areas per Table 1004.1.1; and the aggregate occupant load of all classrooms exceeds 500.</u> • Group I-2 occupancies with an occupant load of 50 or more resident patients but not having surgery or emergency treatment facilities. • Group I-3 occupancies. • Any other occupancy with an occupant load greater than 5,000[a]. • Power-generating stations, water treatment facilities for potable water, waste water treatment facilities and other public utility facilities not included in Occupancy Category IV. • Buildings and other structures not included in Occupancy Category IV containing sufficient quantities of toxic or explosive substances to be dangerous to the public if released.

(Portions of table not shown do not change)
(No change to footnote)

Reason: The general language of 1604.5 is ambiguous and misleading. This problem is well recognized, and there have been several proposals to rewrite major portions of this in recent code change cycles. Although a general overhaul of this section is needed, there is a specific problem that needs to be addressed immediately. There is one phrase in Table 1604.5 that is routinely being misinterpreted, resulting in hidden costs which are extremely high, and completely unnecessary. It is a problem primarily for colleges and universities, has been a problem for many years, and must be corrected.

Under 1604.5 the phrase "*Buildings and other structures containing adult education facilities, such as colleges and universities*" is very easily interpreted to require <u>any</u> building on a college or university campus with an occupant load over 500 to be classified as Occupancy Category III, regardless of use. The phrase is so poorly written, it is difficult to not read it this way. The perceived connection to "adult education facilities" occurs simply because the building is located on a college or university campus; not because there is an educational function occurring within the building.

For example, a research laboratory building with 600 occupants located in an industrial research park clearly would be classified under Occupancy Category II. If the exact same building was placed on a university campus, the Occupancy Category should not change. But in fact, many design professionals and code officials would classify the building as Category III since it now sits on campus. A check of several local structural engineering firms confirmed that every one of them interprets 1604.5 as requiring an Occupancy Category III for any building on campus with an occupant load greater than 500. This is very likely occurring on a national level as well. But this is not the intent of 1604.5.
Occupancy Category III addresses the extra risk associated with the presence of a large number of occupants concentrated in small areas, such as classrooms or lecture halls. There is nothing special about the act of teaching that warrants a Category III classification. The only reason it is referenced in 1604.5 is that teaching is usually done in groups, and it is the people in those groups to be protected. University laboratory and office buildings, with no classrooms, should not be subject to the 500 occupant threshold. The occupant load threshold for a Category III classification for a lab building is 5,000 occupants, not 500. Classification is a function of the building occupancy and not the property upon which the building sits.
The proposed new language clarifies the intent of the current regulation in three ways.

It emphasizes that it is the specific use of the building to be evaluated. Reference is made to both higher education, and a catch-all for any other adult educational building, to ensure that a broad scope of coverage is established.
Since the IBC does not define a "classroom," the proposed change uses the basis for occupant load calculations as a handle to indentify spaces to be included in the analysis. Classrooms are calculated at 20 SF per person and this sets the benchmark for "high" occupant densities. Educational spaces with "low" densities such as teaching labs and vocational areas, at 50 SF per person, would not be included in the analysis. There are non-educational uses identified in Table 1004.1.1 which are also at 50 SF per person, and these are not subject to the 500 occupant threshold. Therefore, if the principle is to be applied consistently, this threshold should not apply to low density educational occupancies. Spaces with

densities higher than a classroom will normally be classified as assembly space, but it's possible that a classroom could have a density greater than 20, so this potential is also addressed with the phrase "or greater than."

Since the specific risk being addressed occurs only in the classrooms, it is appropriate to use the summation of the occupant loads of just these rooms as the basis for the analysis, and not the total building occupant load. The limit should apply to those people associated with the higher risk, and should not include other general occupants of the building.

Cost Impact: The change would result in a major savings by minimizing the probability of future misapplication of this section. The cost from this problem isn't immediately apparent; it is buried in the structural engineer's calculations and the resulting overdesign. A recent project cost analysis for a 54,000 square foot laboratory building identified a **$1.2 million savings** ($22.71 / gsf) by changing the Occupancy Category from III to II, as shown in the following.

VBI III Conceptual Estimate on Cost Premium for Category III Construction vs Category II						
Description	**Qty**		**Unit Cost**		**Total**	**Comments**
Increase concrete reinforcing by 40%	147	ton	$ 2,500	/ton	$ 367,000	
Increase perimeter beam size by 20%	28	cyd	$ 1,200	/cyd	$ 33,333	
Increase for pre-cast concrete panel	10,056	sf	$ 4.00	/sf	$ 40,224	
Increase CMU wall reinforcing by 30%	2.93	ton	$ 2,500	/ton	$ 7,313	
Increase grout fill by 30%	88	cyd	$ 175	/cyd	$ 15,381	
Increase for Hokie Stone connections	13,600	sf	$ 10.00	/sf	$ 136,000	
Impact on roof screen	150.00	ton	$ 4,000	/ton	$ 400,000	
Increase for metal panel connections	1,103	sf	$ 3.00	/sf	$ 3,309	
Impact on curtain wall due to wind loading increase	15,935	sf	$ 5.00	/sf	$ 79,675	
Impact on acoustical ceiling supports	23,970	sf	$ 1.50	/sf	$ 35,955	
Impact on elevators and shaft						Possibility?
Impact on MEP for seismic supports	54,000	sf	$ 2.00	/sf	$ 108,000	Equipment associated changes need further discussion
					$1,226,190	
					$ 22.71	/gsf

$1.2 million was saved on just one building. Given how prevalent this misinterpretation is likely being made on colleges and universities nationwide, the net potential savings by correcting the problem is enormous.

ICCFILENAME: DUBE-S1-1604.4

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The intent to clarify adult education facilities in Occupancy Category III of Table 1604.5 is valid, but the proposal does not recognize the nature of occupancy. The phrase "formal educational system" is not defined which could lead to non uniform application. As worded, it suggests the building has to have classrooms and the classroom occupant load must be greater than 500. This differs from the current provision. If a public comment is submitted wording such as "aggregate classroom occupant load" may be more appropriate.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

David R. Badger, representing self, requests Approval as Modified by this Public Comment.

Replace proposal as follows:

TABLE 1604.5
OCCUPANCY CATEGORY OF BUILDINGS AND OTHER STRUCTURES

OCCUPANCY CATEGORY	NATURE OF OCCUPANCY
III	Buildings and other structures that represent a substantial hazard to human life in the event of failure, including but not limited to: • Buildings and other structures whose primary occupancy is public assembly with an occupant load greater than 300. • Buildings and other structures containing elementary school, secondary school or day care facilities with an occupant load greater than 250. ~~• Buildings and other structures containing adult education facilities, such as colleges and universities, with an occupant load greater than 500.~~ • Group I-2 occupancies with an occupant load of 50 or more resident patients but not having surgery or emergency treatment facilities. • Group I-3 occupancies. • Any other occupancy with an occupant load greater than 5,000[a]. • Power-generating stations, water treatment facilities for potable water, waste water treatment facilities and other public utility facilities not included in Occupancy Category IV. • Buildings and other structures not included in Occupancy Category IV containing sufficient quantities of toxic or explosive substances to be dangerous to the public if released.

(Portions of table not shown do not change)
(No change to footnote)

Commenter's Reason:

1. The current reference to "adult education facilities" in Chapter 16 is an archaic remnant from older versions of the codes and recommended standards.
2. No other section in the IBC, outside of Chapter 16, has ever contained special provisions just for "adult education facilities."
3. "Adult education facility," "college" and "university" are terms that are not defined in the IBC. Using nothing but these open-ended terms as the sole basis to define something within Occupancy Category III is a serious problem. This category has requirements that can be extremely expensive to meet, and as currently written it is hard to understand what it really means.
4. The IBC recognizes the special needs for occupants in educational settings, but they only apply to the 12th grade down. Adults in educational occupancies do not require the special assistance during a building emergency that high school and elementary school students do. Adults are able to make independent decisions and act accordingly; this concept should not be abandoned in Chapter 16.
5. In the 2003 FEMA / NEHRP Provisions, the problem has already been corrected – there is no longer any reference to "adult educational facilities." Educational facilities are included, but only apply up to 12th grade, which is consistent with the general intent of the non-structural concepts of the IBC.
6. The elimination of "adult education facilities" from the list in 1604.5 will not create any gaps in scope of coverage for this section. Nothing needs to be put back in its place after it is eliminated from the table. The higher risk occupancies that do warrant Occupancy Category III are still in the table, and not affected by this change.
7. College and university buildings with a primary occupancy of large classrooms and lecture halls are already regulated as assembly occupancies with an occupant load limit of 300, above which they are Occupancy Category III.
8. The provision for "adult education facilities" in 1604.5 is vague, ambiguous, and wide open for different interpretations with potentially huge, but unnecessary, cost to owners. Building officials are currently in an unreasonable position of trying to interpret the intent of a very significant code requirement, without it having any relation to the rest of the code or any definitions to use. This provision needs to be eliminated.

Final Action: AS AM AMPC____ D

S40-09/10
Table 1604.5, 1705.3.3, 1707.7

Proposed Change as Submitted

Proponent: Philip Brazil, PE, SE, representing self

Revise as follows:

TABLE 1604.5
OCCUPANCY CATEGORY OF BUILDINGS AND OTHER STRUCTURES

OCCUPANCY CATEGORY	NATURE OF OCCUPANCY
III	Buildings and other structures that represent a substantial hazard to human life in the event of failure, including but not limited to: Buildings and other structures whose primary occupancy is public assembly with an occupant load greater than 300 Buildings and other structures containing elementary school, secondary school or day care facilities with an occupant load greater than 250 Buildings and other structures containing adult education facilities, such as colleges and universities, with an occupant load greater than 500 Group I-2 occupancies with an occupant load of 50 or more resident patients but not having surgery or emergency treatment facilities Group I-3 occupancies Any other occupancy with an occupant load greater than 5,000 [a] Power-generating stations, water treatment for potable water, waste water treatment facilities and other public utility facilities not included in Occupancy Category IV Buildings and other structures not included in Occupancy Category IV containing ~~sufficient~~ quantities of toxic or explosive ~~substances~~ materials that: Exceed maximum allowable quantities per control area as given in Table 307.1(1) or 307.1(2) or per outdoor control area in accordance with the *International Fire Code*; and Are sufficient to ~~be dangerous~~ pose a threat to the public if released [b]
IV	Buildings and other structures designated as essential facilities, including but not limited to: Group I-2 occupancies having surgery or emergency treatment facilities Fire, rescue, ambulance and police stations and emergency vehicle garages Designated earthquake, hurricane or other emergency shelters Designated emergency preparedness, communications, and operations centers and other facilities required for emergency response Power-generating stations and other public utility facilities required as emergency backup facilities for Occupancy Category IV structures Buildings and other structures containing quantities of highly toxic materials ~~as defined by Section 307 where the quantity of the material~~ that: Exceed~~s~~ ~~the~~ maximum allowable quantities ~~of~~ per control area as given in Table 307.1(2) or per outdoor control area in accordance with the *International Fire Code*; and Are sufficient to pose a threat to the public if released [b] Aviation control towers, air traffic control centers and emergency aircraft hangars Buildings and other structures having critical national defense functions Water storage facilities and pump structures required to maintain water pressure for fire suppression

(Portions of table not shown remain unchanged))

(No change to footnote a)

b. Where approved by the building official, the classification of buildings and other structures as Occupancy Category III or IV based on their quantities of toxic, highly toxic or explosive materials is permitted to be reduced to Occupancy Category II, provided it can be demonstrated by a hazard assessment in accordance with Section 1.5.2 of ASCE 7 that a release of the toxic, highly toxic or explosive materials is not sufficient to pose a threat to the public.

1705.3.3 Seismic Design Category C. The following additional systems and components in structures assigned to Seismic Design Category C:

1. ~~Heating, ventilating and air-conditioning (HVAC)~~ Ductwork ~~containing~~ designed to carry hazardous materials and anchorage of such ductwork.
2. Piping systems ~~and mechanical units containing flammable, combustible or highly toxic~~ designed to carry hazardous materials and their associated mechanical units.
3. Anchorage of electrical equipment used for emergency or standby power systems.

1707.7 Mechanical and electrical components. Special inspection for mechanical and electrical equipment shall be as follows:

1. Periodic special inspection is required during the anchorage of electrical equipment for emergency or standby power systems in structures assigned to Seismic Design Category C, D, E or F;
2. Periodic special inspection is required during the ~~installation of~~ anchorage of other electrical equipment in structures assigned to Seismic Design Category E or F;
3. Periodic special inspection is required during the installation and anchorage of piping systems ~~intended~~ designed to carry ~~flammable, combustible or highly toxic contents~~ hazardous materials and their associated mechanical units in structures assigned to Seismic Design Category C, D, E or F;
4. Periodic special inspection is required during the installation and anchorage of ~~HVAC~~ ductwork ~~that will contain~~ designed to carry hazardous materials in structures assigned to Seismic Design Category C, D, E or F; and
5. Periodic special inspection is required during the installation and anchorage of vibration isolation systems in structures assigned to Seismic Design Category C, D, E or F where the construction documents require a nominal clearance of 1/4 inch (6.4 mm) or less between the equipment support frame and restraint.

Reason: The purpose for this proposal is to clarify the determination of occupancy category and the requirements for special inspection where hazardous materials are present. It was prepared in conjunction with ASCE 7 Proposal GPSC-5R2, which was approved by the General Subcommittee on March 1, 2009 and is being balloted by the Main Committee (Second Main Committee Ballot on General Requirements). It is expected that the Main Committee will approve the proposal.

Table 1604.5 currently classifies buildings and other structures containing certain quantities of toxic, highly toxic or explosive materials as Occupancy Category III or IV. The Category III classification applies to toxic and explosive materials and the threshold for the classification is subjective: quantities sufficient to be dangerous to the public if released. The Category IV classification applies to highly toxic materials and the threshold is objective: quantities exceeding the maximum allowable quantities of Table 307.1(2). Table 307.1(2) specifies maximum allowable quantities per control area for hazardous materials posing a health hazard.

Explosive materials are classified as posing a “physical hazard.” Toxic and highly toxic materials are classified as posing a “health hazard.” Materials that pose a physical hazard or a health hazard are classified as “hazardous materials.” Refer to IBC Section 307.2 and IFC Section 2702.1 for definitions of these terms. The maximum quantities per control area are given in IBC Table 307.1(1) and IFC Table 2703.1.1(1) for hazardous materials posing a physical hazard and IBC Table 307.1(2) and IFC Table 2703.1.1(2) for hazardous materials posing a health hazard. The maximum quantities per outdoor control area are given in IFC Table 2703.1.1(3) for hazardous materials posing a physical hazard and IFC Table 2703.1.1(4) for hazardous materials posing a health hazard,.

A “control area” is defined in Section 307.2 as a space “within a building where quantities of hazardous materials not exceeding the maximum allowable quantities per control area are stored, used or handled.” The effect of this definition on a Category IV classification is that it is limited to quantities of highly toxic materials within buildings. Not considered in the classification are quantities per “outdoor control area,” which is defined in Section 2702.1 of the *International Fire Code* (IFC) as “an outdoor area that contains hazardous materials in amounts not exceeding the maximum allowable quantities of (IFC) Table 2703.1.1(3) (e.g., explosive materials) or Table 2703.1.1(4) (e.g., toxic and highly toxic materials).”

The intent in classifying buildings and other structures containing certain quantities of toxic, highly toxic or explosive materials as Occupancy Category III or IV is to reduce the potential for catastrophic release of these hazardous materials resulting from the failure of a building or structure (or a component conveying or supporting the materials and supported by a building or structure) to resist the structural demands of a design event, such as an earthquake. The required classification is limited to toxic, highly toxic and explosive materials because they pose the most serious threat to the general public if released. The threat being addressed is related to large-scale impacts on the general public, which can be characterized as global (e.g., beyond the boundaries of the site where the building or structure is located) rather than local (e.g., within those same boundaries).

Table 1604.5 currently classifies the building or structure as Occupancy Category III based on a subjective threshold but as Occupancy Category IV based on an objective threshold. This proposal revises the thresholds for both classifications so that two conditions are met for classification as Occupancy Category III or IV and they are summarized below. These revised thresholds are more consistent with the global threat discussed above. Similar thresholds are found in Table 1-1 of ASCE 7-10.

1. The quantities exceed maximum allowable quantities per control area within buildings or structures or per outdoor control area for outdoor areas; and

2. The quantities are sufficient to pose a threat to the public if released.

The first condition has the effect of exempting buildings or portions thereof from being classified as Occupancy Category III or IV except where they are classified as Group H. Where the quantities of hazardous materials in the control areas of a building or portion thereof are less than the maximum allowable quantities per control area, the occupancy classifications without considering the presence of hazardous materials are not affected by their presence. The first condition has the effect of exempting such buildings or portions thereof because the small quantities of hazardous materials permitted in occupancies other than Group H do not generally pose a global threat.

The second condition is subjective but the global threat posed by toxic, highly toxic and explosive materials is not easily quantified. Footnote (b) is added to Table 1604.5 permitting classification as Occupancy Category II for a building or structure otherwise classified as Occupancy Category III or IV, provided a hazard assessment in accordance with Section 1.5.2 of ASCE 7 is performed and it is demonstrated that a release of the toxic, highly toxic or explosive materials is not sufficient to pose a threat to the public. Refer to Section 1.5.2 and Commentary Section C1.5.2 of ASCE 7 for further information.

In Table 1604.5, a reference to IBC Table 307.1(1) is specified as well as Table 307.1(2). This is because explosive materials pose a physical hazard as discussed above but toxic and highly toxic materials pose a health hazard.

Also in Table 1604.5, maximum allowable quantities per outdoor control area are specified as well as maximum allowable quantities per control area. Hazardous materials pose physical or health hazards not only from being located in buildings but also from being located in structures not generally considered as buildings, such as tanks, towers, bins, hoppers, silos and similar structures. ASCE 7-10 distinguishes between "building structures" (e.g., buildings) and "nonbuilding structures." Refer to Chapter 11 of ASCE 7-10 for definitions of these terms.

In conjunction with Chapter 13 of ASCE 7-10 and the revisions to Table 1604.5 in this proposal, Sections 1705.3.3 and 1707.7 are also revised. All instances of terms related to hazardous materials in the structural chapters (Chapter 16 through 23) in the 2009 IBC are found in these sections. In Item #1 of Section 1705.3.3 and Item #4 of Section 1707.7, "HVAC" is deleted because HVAC ducts typically convey environmental air, not hazardous materials. At items in both sections, the change to "designed to carry" is for consistency with Chapter 13 of ASCE 7-10. The other revisions are either editorial or are intended to make the intent more clear.

Although Section 1705.3.3 is being modified in this proposal, the deletion of this section is the subject of a separate proposal. Should both proposals be approved by the ICC membership, it is not the intent of the proponent to retain Section 1705.3.3 in the 2012 IBC for the purpose of modifying the section in accordance with this proposal.

Cost Impact: The code change proposal will not increase the cost of construction.

FILENAME: Brazil-S1-1604.5

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: This code change provides clarification on the Table 1604.5 Occupancy Category determination where hazardous materials are a factor. Referring to the maximum allowable quantities per control area for the hazardous material tables is an improvement.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Philip Brazil, PE, SE, representing self, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

TABLE 1604.5
CLASSIFICATION OF BUILDINGS AND OTHER STRUCTURES FOR IMPORTANCE FACTORS

OCCUPANCY CATEGORY [a]	NATURE OF OCCUPANCY
III	Buildings and other structures that represent a substantial hazard to human life in the event of failure, including but not limited to: Buildings and other structures whose primary occupancy is public assembly with an occupant load greater than 300 Buildings and other structures containing elementary school, secondary school or day care facilities with an occupant load greater than 250 Buildings and other structures containing adult education facilities, such as colleges and universities, with an occupant load greater than 500 Group I-2 occupancies with an occupant load of 50 or more resident patients but not having surgery or emergency treatment facilities Group I-3 occupancies Any other occupancy with an occupant load greater than 5,000 [a] Power-generating stations, water treatment for potable water, waste water treatment facilities and other public utility facilities not included in Occupancy Category IV Buildings and other structures not included in Occupancy Category IV containing quantities of toxic or explosive materials that: Exceed maximum allowable quantities per control area as given in Table 307.1(1) or 307.1(2) or per outdoor control area ~~in accordance with~~ <u>as given in Table 2703.1(3) or 2703.1(4) of</u> the *International Fire Code*; and Are sufficient to pose a threat to the public if released [b]
IV	Buildings and other structures designated as essential facilities, including but not limited to: Group I-2 occupancies having surgery or emergency treatment facilities Fire, rescue, ambulance and police stations and emergency vehicle garages Designated earthquake, hurricane or other emergency shelters Designated emergency preparedness, communications, and operations centers and other facilities required for emergency response Power-generating stations and other public utility facilities required as emergency backup facilities for Occupancy Category IV structures Buildings and other structures containing quantities of highly toxic materials that: Exceed maximum allowable quantities per control area as given in Table 307.1(2) or per outdoor control

OCCUPANCY CATEGORY [a]	NATURE OF OCCUPANCY
	area ~~in accordance with~~ as given in Table 2703.1(3) or 2703.1(4) of the *International Fire Code*; and Are sufficient to pose a threat to the public if released [b] . Aviation control towers, air traffic control centers and emergency aircraft hangars . Buildings and other structures having critical national defense functions . Water storage facilities and pump structures required to maintain water pressure for fire suppression

(Portions of table not shown remain unchanged)

(No change to footnotes)

(Portions of proposal not shown remain unchanged)

Commenter's Reason: The purpose for the public comment is to improve the references to the International Fire Code in Table 1604.5 for the determination of the maximum quantities per outdoor control area of toxic, explosive and highly toxic materials. This is done by adding references to IFC Tables 2703.1(3) and 2703.1(4) where the maximum quantities per outdoor control area are specified. This is also being done for consistency with the references to IBC Tables 307.1(1) and 307.1(2) in Table 1604.5 for the determination of the maximum quantities per control area of the same materials. The corresponding tables in the IFC are Tables 2703.1(1) and 2703.1(2). These tables are more fully discussed in the first four paragraphs of the Reason accompanying the original proposal.

Final Action: AS AM AMPC____ D

S44-09/10
1604.8.2, 1613.7

Proposed Change as Submitted

Proponent: Philip Brazil, PE, SE, Reid Middleton, Inc., representing self, Jim Rossberg, SEI of ASCE, representing self

1. Revise as follows:

1604.8.2 Structural walls. Walls that provide vertical load bearing resistance or lateral shear resistance for a portion of the structure shall be anchored to the roof and to all floors~~, roofs~~ and ~~other structural elements~~ members that provide lateral support for the wall or that are supported by the wall. ~~Such anchorage shall provide a positive direct connection~~ The connections shall be capable of resisting the horizontal forces specified in ~~this chapter but not less than the minimum strength design horizontal force specified in~~ Section ~~11.7.3~~ 1.4.4 of ASCE 7~~, substituted for "*E*" in the load combinations of Section 1605.2 or 1605.3~~ for walls of structures assigned to Seismic Design Category A and to Section 12.11 of ASCE 7 for walls of all other structures. Concrete and masonry walls shall be designed to resist bending between anchors where the anchor spacing exceeds 4 feet (1219 mm). Required anchors in masonry walls of hollow units or cavity walls shall be embedded in a reinforced grouted structural element of the wall. See Section 1609 for wind design requirements and see Section 1613 for earthquake design requirements.

2. Delete without substitution:

~~**1613.7 ASCE 7, Section 11.7.5.** Modify ASCE 7, Section 11.7.5 to read as follows:~~

> ~~**11.7.5 Anchorage of walls.** Walls shall be anchored to the roof and all floors and members that provide lateral support for the wall or that are supported by the wall. The anchorage shall provide a direct connection between the walls and the roof or floor construction. The connections shall be capable of resisting the forces specified in Section 11.7.3 applied horizontally, substituted for E in the load combinations of Section 2.3 or 2.4.~~

.

Reason:
(BRAZIL)-The purpose for this proposal is to delete a revision to ASCE 7-05 that will no longer be needed because a similar revision will have been incorporated into the 2010 edition of ASCE 7. Section 1604.8.2 is also revised for consistency with this and other related revisions to ASCE 7. These are being accomplished by ASCE 7 Proposal GPSC-2R2, which was approved by the General Subcommittee on March 1, 2009 and is being balloted by the Main Committee (Item #2 of the Second Main Committee Ballot on General Requirements); and by ASCE 7 Proposal SSC TC-4-CH14-07-R1, which was approved by the Seismic Subcommittee on May 15, 2009 and is being balloted by the Main Committee (Item #1 of the Seventh Main Committee Ballot on Seismic Provisions). It is expected that the Main Committee will approve both proposals.
(ROSSBERG)- This provision has been considered and approved by the Seismic Subcommittee of ASCE 7 for inclusion into the 2010 edition of ASCE 7 hence with the adoption of ASCE 7-10 by reference this provision becomes duplicative. As of the submission date of this code change, the ASCE 7 Standards Committee is completing the committee balloting portion of the 2010 edition of ASCE/SEI 7. The document is designated ASCE/SEI 7-10 *Minimum Design Loads for Buildings and Other Structures* and it is expected that it will be completed and available for purchase prior to the ICC Final Action Hearings in May of 2010 . Any person interested in obtaining a public comment copy of ASCE/SEI 7-10 may do so by contacting the proponent at jrossberg@asce.org.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: Brazil-Rossberg-S23-1604.8.2

Public Hearing Results

Committee Action: Approved as Modified

Modify the proposal as follows:

1604.8.2 Structural walls. Walls that provide vertical load bearing resistance or lateral shear resistance for a portion of the structure shall be anchored to the roof and to all floors and members that provide lateral support for the wall or that are supported by the wall. The connections shall be capable of resisting the horizontal forces specified in Section 1.4.4 of ASCE 7 for walls of structures assigned to Seismic Design Category A and to Section 12.11 of ASCE 7 for walls of structures assigned to all other ~~structures~~ seismic design categories. ~~Concrete and masonry walls shall be designed to resist bending between anchors where the anchor spacing exceeds 4 feet (1219 mm).~~ Required anchors in masonry walls of hollow units or cavity walls shall be embedded in a reinforced grouted structural element of the wall. See Section 1609 for wind design requirements and see Section 1613 for earthquake design requirements.

Committee Reason: The proposal removes an ASCE 7 modification in Section 1613.7 that will not be needed, since it will be addressed in the next edition of the standard. It also revises the requirements for anchoring walls to diaphragms for clarity and makes reference to appropriate requirements in ASCE 7. The modification reflects further updates made in the ASCE 7 development process.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Gary J. Ehrlich, PE, National Association of Home Builders, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

1604.8.2 Structural walls. Walls that provide vertical load bearing resistance or lateral shear resistance for a portion of the structure shall be anchored to the roof and to all floors and members that provide lateral support for the wall or that are supported by the wall. The connections shall be capable of resisting the horizontal forces specified in Section 1.4.4 of ASCE 7 for walls of structures assigned to Seismic Design Category A and to Section 12.11 of ASCE 7 for walls of structures assigned to all other seismic design categories. Required anchors in masonry walls of hollow units or cavity walls shall be embedded in a reinforced grouted structural element of the wall. See Section 1609 for wind design requirements and see Section 1613 for earthquake design requirements.

Exceptions:

1. Light-frame wood walls not exceeding 15 pounds per square foot (718 N/m^2) in weight, designed and constructed in accordance with Section 2304 or Section 2308, shall be deemed to comply with the provisions of this section.
2. Cold-formed steel walls not exceeding 15 pounds per square foot (718 N/m^2) in weight, designed and constructed in accordance with Section 2210, shall be deemed to comply with the provisions of this section.
3. In structures assigned to Seismic Design Category A, B, or C, light-frame wood or cold-formed steel walls with stone or masonry veneer, not exceeding 48 pounds per square foot (2298 N/m^2) in weight, designed and constructed in accordance with Section 2304, Section 2308, or Section 2210, shall be deemed to comply with the provisions of this section.

Commenter's Reason: The purpose of this public comment is to provide exemptions for light-frame wood and cold-formed steel walls constructed using prescriptive fastener schedules from the new minimum connection requirements in the IBC and ASCE 7.

NAHB generally supported the removal of the longstanding, overly conservative 280 lb/ft and $400S_{ds}$ minimum anchorage requirements from the IBC and ASCE 7, and their replacement with improved procedures for out-of-plate anchorage of walls. However, the old provisions were only applied to concrete and masonry walls. The new provisions apply to all wall systems, including wood and cold-formed steel stud walls. In Seismic Design Category A, the new provisions require a "check" of 20% of the horizontal load on the wall or 5psf. In Seismic Design Category B and C, the new provisions would now require connections for stud walls to be checked for seismic loading based on the design accelerations, in addition to the wind loading (including the 10psf minimum exterior wall load) they would normally be designed for.

Requiring these additional design checks for light-frame walls is unjustified. It can be clearly shown that the seismic component of the connection check will never govern for the three cases detailed above. To illustrate this, two charts which accompanied the ASCE 7-10 proposal are included below:

Comparison of anchorage forces

All walls single story without parapet; force calculated at the roof

Four levels of S_{DS} compared:

	SDCat B		SDCat C		SDCat D		SDCat E	
	S_{DS} =	0.20	S_{DS} =	0.40	S_{DS} =	1.00	S_{DS} =	1.50
	near middle of category		near middle of category		on the plateau		mod. close to fault	

All comparisons are for importance factor = 1.0

	Flexible diaphragm, 100 foot span								
10	280	100	280	100	400	200	600	300	120
15	280	150	280	150	400	300	600	450	180
20	280	200	280	200	400	400	600	600	240
25	280	250	280	250	500	500	750	750	300
30	280	300	280	300	600	600	900	900	360

We are concerned about the potential for some plan reviewers to require checks for all of the standard prescriptive connections covered by the standard wood and cold-formed steel fastener schedules. Also, we note that small design firms and sole practitioners are already struggling with trying to balance the demands of today's complex codes with limited project budgets and aggressive schedules. They do not need the code to require more burdensome and unnecessary design requirements.

Final Action: AS AM AMPC____ D

S57-09/10-PART I
Table 1607.1

Proposed Change as Submitted

Proponent: Philip Brazil, PE, SE, representing self

Part I—IBC Structural

Revise as follows:

TABLE 1607.1
MINIMUM UNIFORMLY DISTRIBUTED LIVE LOADS, L_o, AND
MINIMUM CONCENTRATED LIVE LOADS [g]

OCCUPANCY OR USE	UNIFORM (psf)	CONCENTRATED (lbs.)
27. Residential		
One- and two-family dwellings		
Uninhabitable attics without storage [i]	10	
Uninhabitable attics with ~~limited~~ storage [i, j, k]	20	
Habitable attics and sleeping areas [k]	30	–
All other areas	40	
Hotels and multiple-family dwellings		
Private rooms and corridors serving them	40	
Public rooms and corridors serving them	100	

(No changes to the remaining Table not shown)

(No change to footnotes a through h)

I. Uninhabitable attics without storage are those where the maximum clear height between the joist and rafter is less than 42 inches, or where there are not two or more adjacent trusses with ~~the same~~ web configurations capable of ~~containing a~~ accommodating an assumed rectangle 42 inches ~~high~~ in height by ~~2 feet wide~~ 24 inches in width, or greater, ~~located~~ within the plane of the trusses. ~~For attics without storage~~, This live load need not be assumed to act concurrently with any other live load requirements.

j. ~~For~~ Uninhabitable attics with ~~limited~~ storage ~~and constructed with trusses, this live load need only be applied to those portions of the bottom chord~~ are those where the maximum clear height between the joist and rafter is 42 inches or greater, or where there are two or more adjacent trusses with ~~the same~~ web configurations ~~containing a~~ capable of accommodating an assumed rectangle 42 inches ~~high~~ in height by ~~2 feet wide~~ 24 inches in width, or greater, ~~located~~ within the plane of the trusses. ~~The rectangle shall fit between the top of the bottom chord and the bottom of any other truss member, provided that each of the following criteria is met~~

At the trusses, the live load need only be applied to those portions of the bottom chords where both of the following conditions are met:

i. The attic area is accessible ~~by a pull-down stairway or framed opening in accordance with Section 1209.2~~ from an opening not less than 20 inches in width by 30 inches in length that is located where the clear height in the attic is a minimum of 30 inches; and
ii. The slopes of the truss ~~shall have a~~ bottom chords ~~pitch less than 2:12~~ are no greater than 2 units vertical to 12 units horizontal.
~~iii.~~ The remaining portions of the bottom chords ~~of trusses~~ shall be designed for ~~the greater of actual imposed dead load or 10 psf,~~ a uniformly distributed ~~over the entire span~~ concurrent live load of not less than 10 lb/ft^2.

k. Attic spaces served by ~~a fixed stair~~ stairways other than pull-down type shall be designed to support the minimum live load specified for habitable attics and sleeping rooms.

(No change to footnote l).

Reason: The purpose for this proposal is to correlate the IBC and IRC with the 2010 edition of ASCE 7. The need for correlation is due to ASCE 7 Proposal LLSC-LL-9, which has been approved by the Live Load Subcommittee and is being balloted by the Main Committee (Item #5 of the Second Main Committee Ballot on Live/Dead Load Provisions). It is expected that the Main Committee will approve the proposal.
The changes are seen as largely editorial. In Footnotes (i) and (j), the threshold that is based on a 24-inch by 42-inch rectangular is changed to an assumed condition (rather than an actual one), which is considered more appropriate for a building code requirement.
In Footnote (j), the reference to “a pull-down stairway or framed opening in accordance with Section 1209.2” is replaced with minimum opening dimensions that are consistent with IBC Section 1209.2 on openings to attic areas. These dimensions are objective and considered more appropriate for a building code requirement, whereas “pull-down stairway” and “framed opening” are considered vague and subject to a wide variation in interpretation.

In Footnote (k), the reference to a “fixed stair” is changed to “stairways other than pull-down type” in conjunction with the deletion of “pull-down type stairway” in Footnote (j) and for consistency with the definitions of “stair” and “stairway” in Section 1002.1. These definitions apply to all instances of the terms throughout the IBC. “Stair” is a “change in elevation consisting of one or more risers.” “Stairway” is “one or more flights of stairs…with the necessary landings and platforms connecting them to form a continuous and uninterrupted passage form one level to another” and is the better choice for the footnote. The change will revise the footnote to better convey its intent: require an otherwise uninhabitable attic to be designed for live loads specified for habitable attics where the attic is served by a stairway that could enable it become occupiable. The current threshold of “fixed stair” before design for live loads specified for habitable attics is required is considered vague and subject to a wide variation in interpretation.

In Table 1607.1 and Footnote (j), “limited” at uninhabitable attics with storage is considered superfluous and is deleted. The three categories of uninhabitable attics without storage, uninhabitable attics with storage and habitable attics are sufficiently clear to account for all design conditions. Retaining “limited” begs the question: what is an uninhabitable attic with more than limited storage?

Cost Impact: The code change proposal will not increase the cost of construction.

FILENAME: Brazil-S3-T1607.1

Public Hearing Results

PART I- IBC STRUCTURAL
Committee Action: Approved as Modified

Modify the proposal as follows:

TABLE 1607.1
MINIMUM UNIFORMLY DISTRIBUTED LIVE LOADS, L_o, AND MINIMUM CONCENTRATED LIVE LOADS [g]

(No change to footnotes a through h)

I. Uninhabitable attics without storage are those where the maximum clear height between the joists and rafters is less than 42 inches, or where there are not two or more adjacent trusses with web configurations capable of accommodating an assumed rectangle 42 inches in height by 24 inches in width, or greater, within the plane of the trusses. This live load need not be assumed to act concurrently with any other live load requirements.

j. Uninhabitable attics with storage are those where the maximum clear height between the joists and rafters is 42 inches or greater, or where there are two or more adjacent trusses with web configurations capable of accommodating an assumed rectangle 42 inches in height by 24 inches in width, or greater, within the plane of the trusses.

~~At the trusses,~~ The live load need only be applied to those portions of the joists or bottom chords where all ~~both~~ of the following conditions are met:

i. The attic area is accessible from an opening not less than 20 inches in width by 30 inches in length that is located where the clear height in the attic is a minimum of 30 inches; and

ii. The slopes of the joists or truss bottom chords are no greater than 2 units vertical to 12 units horizontal.

The remaining portions of the joists or bottom chords shall be designed for a uniformly distributed concurrent live load of not less than 10 lb/ft^2.

(Portions of proposal not shown are unchanged)

Committee Reason: This proposal makes editorial clarifications to Table 1607.1 footnotes that relate to attic live loads. These changes correspond to updates in the next edition of the ASCE 7 load standard. The modification clarifies the applicability of the uninhabitable attic with storage live load.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Larry Wainright, Qualtim, Inc, representing Structural Building Components Association (SBCA), and Philip Brazil, PE, SE, representing self, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

TABLE 1607.1
MINIMUM UNIFORMLY DISTRIBUTED LIVE LOADS, L_o, AND MINIMUM CONCENTRATED LIVE LOADS [g]

(No change to footnotes a through h)

I. Uninhabitable attics without storage are those where the maximum clear height between the joists and rafters is less than 42 inches, or where there are not two or more adjacent trusses with web configurations capable of accommodating an assumed rectangle 42 inches in height by 24 inches in width, or greater, within the plane of the trusses. This live load need not be assumed to act concurrently with any other live load requirements.

j. Uninhabitable attic~~s~~ areas with storage are those where the maximum clear height between the joist~~s~~ and rafter~~s~~ is 42 inches or greater, or where there are two or more adjacent trusses with web configurations capable of accommodating an assumed rectangle 42 inches in height by 24 inches in width, or greater, within the plane of the trusses.

The live load need only be applied to those portions of the joists or bottom chords where all of the following conditions are met:

i. The attic area is accessible from an opening not less than 20 inches in width by 30 inches in length that is located where the clear height in the attic is a minimum of 30 inches; and

ii. The slop~~es~~ of the joists or truss bottom chords is ~~are~~ no greater than 2 units vertical to 12 units horizontal.

The remaining portions of the joists or bottom chords shall be designed for a uniformly distributed non-concurrent live load of not less than 10 lb/ft^2.

(Portions of proposal not shown are unchanged)

Commenter's Reason: In speaking with the original proponent of the change to this section, the requirement for the 10 PSF live load on those portions of the bottom chords not serving as storage areas was intended to reflect the requirement to provide a 10 PSF load per Table 1607.1, for uninhabitable attics without storage. However, footnote "i" clearly indicates that this is a non-concurrent load (intended for occasional access for maintenance). Current truss design methodology also treats this 10 PSF non-storage load as a non-concurrent maintenance load. Furthermore, the intent was to coordinate with ASCE 7-10, Table 4-1. ASCE 7-10 has since been out for public comment and this wording was changed to reflect the intended non-concurrent loading. Therefore, non-storage areas of the joists or truss bottom chords should be loaded for the maintenance load non-concurrent with other live loads.

Final Action: AS AM AMPC____ D

S57-09/10-PART II
IRC Table R301.5

Proposed Change as Submitted

Proponent: Philip Brazil, PE, SE, representing self

Part II: IRC

Revise as follows:

TABLE R301.5
MINIMUM UNIFORMLY DISTRIBUTED LIVE LOADS
(in pounds per square foot)

USE	LIVE LOAD
Uninhabitable attics without storage [b]	10
Uninhabitable attics with ~~limited~~ storage [b, g]	20
Habitable attics and attics served with fixed stairs	30

(No changes to the remaining Table not shown)

(No change to footnote a)

b. Uninhabitable attics without storage are those where the maximum clear height between the joist and rafter is less than 42 inches, or where there are not two or more adjacent trusses with ~~the same~~ web configurations capable of ~~containing a~~ accommodating an assumed rectangle 42 inches ~~high~~ in height by ~~2 feet wide~~ 24 inches in width, or greater, ~~located~~ within the plane of the trusses. ~~For attics without storage,~~ This live load need not be assumed to act concurrently with any other live load requirements.

(No change to footnotes c through f)

g. ~~For~~ Uninhabitable attics with ~~limited~~ storage ~~and constructed with trusses, this live load need be applied only to those portions of the bottom chord~~ are those where the maximum clear height between the joist and rafter is 42 inches or greater, or where there are two or more adjacent trusses with ~~the same~~ web configurations ~~containing a~~ capable of accommodating an assumed rectangle 42 inches ~~high or greater~~ in height by ~~2 feet wide~~ 24 inches in width, or greater, ~~located~~ within the plane of the trusses. ~~The rectangle shall fit between the top of the bottom chord and the bottom of any other truss member, provided that each of the following criteria is met~~

At the trusses, the live load need only be applied to those portions of the bottom chords where all of the following conditions are met:

1. The attic area is accessible ~~by a pull-down stairway or framed opening in accordance with Section R807.1~~ from an opening not less than 20 inches in width by 30 inches in length that is located where the clear height in the attic is a minimum of 30 inches.
2. The slopes of the truss ~~has a~~ bottom chords ~~pitch less than 2:12~~ are no greater than 2 units vertical to 12 units horizontal.
3. Required insulation depth is less than the bottom chord member depth.

The remaining portions of the bottom chords ~~of trusses meeting the above criteria for limited storage~~ shall be designed for ~~the greater of the actual imposed dead load or 10 psf,~~ a uniformly distributed ~~over the entire span~~ concurrent live load of not less than 10 lb/ft^2.

(No change to footnote h)

Reason: The purpose for this proposal is to correlate the IBC and IRC with the 2010 edition of ASCE 7. The need for correlation is due to ASCE 7 Proposal LLSC-LL-9, which has been approved by the Live Load Subcommittee and is being balloted by the Main Committee (Item #5 of the Second Main Committee Ballot on Live/Dead Load Provisions). It is expected that the Main Committee will approve the proposal.

The changes are seen as largely editorial. In Footnotes (i) and (j), the threshold that is based on a 24-inch by 42-inch rectangular is changed to an assumed condition (rather than an actual one), which is considered more appropriate for a building code requirement.
In Footnote (j), the reference to “a pull-down stairway or framed opening in accordance with Section 1209.2” is replaced with minimum opening dimensions that are consistent with IBC Section 1209.2 on openings to attic areas. These dimensions are objective and considered more appropriate for a building code requirement, whereas “pull-down stairway” and “framed opening” are considered vague and subject to a wide variation in interpretation.

In Footnote (k), the reference to a “fixed stair” is changed to “stairways other than pull-down type” in conjunction with the deletion of “pull-down type stairway” in Footnote (j) and for consistency with the definitions of “stair” and “stairway” in Section 1002.1. These definitions apply to all instances of the terms throughout the IBC. “Stair” is a “change in elevation consisting of one or more risers.” “Stairway” is “one or more flights of stairs…with the necessary landings and platforms connecting them to form a continuous and uninterrupted passage form one level to another” and is the better choice for the footnote. The change will revise the footnote to better convey its intent: require an otherwise uninhabitable attic to be designed for live loads specified for habitable attics where the attic is served by a stairway that could enable it become occupiable. The current threshold of “fixed stair” before design for live loads specified for habitable attics is required is considered vague and subject to a wide variation in interpretation.

In Table 1607.1 and Footnote (j), “limited” at uninhabitable attics with storage is considered superfluous and is deleted. The three categories of uninhabitable attics without storage, uninhabitable attics with storage and habitable attics are sufficiently clear to account for all design conditions. Retaining “limited” begs the question: what is an uninhabitable attic with more than limited storage?

Cost Impact: The code change proposal will not increase the cost of construction.

(No change to footnote a)
b. Uninhabitable attics without storage are those where the maximum clear height between the joists and rafters is less than 42 inches, or where there are not two or more adjacent trusses with web configurations capable of accommodating an assumed rectangle 42 inches in height by 24 inches in width, or greater, within the plane of the trusses. This live load need not be assumed to act concurrently with any other live load requirements.
(No change to footnotes c through f)
g. Uninhabitable attics with limited storage are those where the maximum clear height between the joists and rafters is 42 inches or greater, or where there are two or more adjacent trusses with web configurations capable of accommodating an assumed rectangle 42 inches in height by 24 inches in width, or greater, within the plane of the trusses.

~~At the trusses,~~ The live load need only be applied to those portions of the joists or bottom chords where all of the following conditions are met:

1. The attic area is accessible from an opening not less than 20 inches in width by 30 inches in length that is located where the clear height in the attic is a minimum of 30 inches.
2. The slopes of the joists or truss bottom chords are no greater than 2 units vertical to 12 units horizontal.
3. Required insulation depth is less than the joist or bottom chord member depth.

The remaining portions of the joists or bottom chords shall be designed for a uniformly distributed concurrent live load of not less than 10 lb/ft^2.
(No change to footnote h)

Committee Reason: This change adds clarity to the code and correlates with ASCE 7-10. The modification clarifies that Note g applies to joists as well as truss bottom chords. Also, the modification retains the term "limited storage".

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Larry Wainright, Qualtim, Inc, representing Structural Building Components Association (SBCA), and Philip Brazil, PE, SE, representing self, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

TABLE R301.5
MINIMUM UNIFORMLY DISTRIBUTED LIVE LOADS
(in pounds per square foot)

g. Uninhabitable attics with limited storage are those where the maximum clear height between the joists and rafters is 42 inches or greater, or where there are two or more adjacent trusses with web configurations capable of accommodating an assumed rectangle 42 inches in height by 24 inches in width, or greater, within the plane of the trusses.

The live load need only be applied to those portions of the joists or bottom chords where all of the following conditions are met:

1. The attic area is accessible from an opening not less than 20 inches in width by 30 inches in length that is located where the clear height in the attic is a minimum of 30 inches.
2. The slopes of the joists or truss bottom chords are no greater than 2 units vertical to 12 units horizontal.
3. Required insulation depth is less than the joist or bottom chord member depth.

The remaining portions of the joists or bottom chords shall be designed for a uniformly distributed non-concurrent live load of not less than 10 lb/ft^2.

(Portions of proposal not shown remain unchanged)

Commenter's Reason: In speaking with the original proponent of the change to this section, the requirement for the 10 PSF live load on those portions of the bottom chords not serving as storage areas was intended to reflect the requirement to provide a 10 PSF load per Table R301.5, footnote "b" for uninhabitable attics without storage. However, footnote b clearly indicates that this is a non-concurrent load (intended for occasional access for maintenance). Current truss design methodology also treats this 10 PSF non-storage load as a non-concurrent maintenance load. Furthermore, the intent was to coordinate with ASCE 7-10, Table 4-1. ASCE 7-10 has since been out for public comment and this wording was changed to reflect the intended non-concurrent loading. Therefore, non-storage areas of the joists or truss bottom chords should be loaded for the maintenance load non-concurrent with other live loads.

Final Action: AS AM AMPC____ D

S60-09/10
1605.2.1, Table 1607.1, 1607.9.1, 1607.9.1.4, 1607.9.2, 1607.11.2.2

Proposed Change as Submitted

Proponent: Philip Brazil, PE, SE, Reid Middleton, Inc., representing self

1. Revise as follows:

1605.2.1 Basic load combinations. Where strength design or load and resistance factor design is used, structures and portions thereof shall resist the most critical effects from the following combinations of factored loads:

$1.4\ (D + F)$	**(Equation 16-1)**
$1.2\ (D + F + T) + 1.6\ (L + H) + 0.5\ (L_r \text{ or } S \text{ or } R)$	**(Equation 16-2)**
$1.2\ D + 1.6\ (L_r \text{ or } S \text{ or } R) + (f_1\ L \text{ or } 0.8\ W)$	**(Equation 16-3)**
$1.2\ D + 1.6\ W + f_1\ L + 0.5\ (L_r \text{ or } S \text{ or } R)$	**(Equation 16-4)**
$1.2\ D + 1.0\ E + f_1\ L + f_2\ S$	**(Equation 16-5)**
$0.9\ D + 1.6\ W + 1.6\ H$	**(Equation 16-6)**
$0.9\ D + 1.0\ E + 1.6\ H$	**(Equation 16-7)**

where:

f_1 = 1 for floors in ~~places of public~~ assembly areas and recreational uses (see Table 1607.1), for live loads, L, in excess of 100 pounds per square foot (4.79 kN/m^2), and for ~~parking~~ floors in passenger vehicle garages ~~live load~~; and

= 0.5 for other live loads, L.

f_2 = 0.7 for roof configurations (such as saw tooth) that do not shed snow off the structure; and

= 0.2 for other roof configurations.

Exception: Where other factored load combinations are specifically required by the provisions of this code, such combinations shall take precedence.

c. Design in accordance with the ICC 300.
m. Live load reduction is not permitted unless specific exceptions of Section 1607.9 apply.

(Footnotes not shown are unchanged)

1607.9.1 General. Subject to the limitations of Sections 1607.9.1.1 through ~~1607.9.1.4~~ 1607.9.1.3 and Table 1607.1, members for which a value of $K_{LL} A_T$ is 400 square feet (37.16 m^2) or more are permitted to be designed for a reduced live load in accordance with the following equation:

$$L = L_o\left[0.25 + \frac{15}{\sqrt{K_{LL}A_T}}\right]$$ **(Equation 16-22)**

$$\text{In SI: } L = L_o\left[0.25 + \frac{4.57}{\sqrt{K_{LL}A_T}}\right]$$

where:

L = Reduced design live load per square foot (meter) of area supported by the member.
L_o = Unreduced design live load per square foot (meter) of area supported by the member (see Table 1607.1).
K_{LL} = Live load element factor (see Table 1607.9.1).
A_T = Tributary area, in square feet (square meters).

L shall not be less than 0.50 L_o for members supporting one floor and L shall not be less than 0.40 L_o for members supporting two or more floors.

2. Delete without substitution:

~~**1607.9.1.4 Group A occupancies.** Live loads of 100 psf (4.79 kN/m^2) and at areas where fixed seats are located shall not be reduced in Group A occupancies.~~

3. Revise as follows:

1607.9.2 Alternate floor live load reduction. As an alternative to Section 1607.9.1 and subject to the limitations of Table 1607.1, floor live loads are permitted to be reduced in accordance with the following provisions. Such reductions shall apply to slab systems, beams, girders, columns, piers, walls and foundations.

~~1.~~ ~~A reduction shall not be permitted in Group A occupancies.~~
~~2~~ 1. A reduction shall not be permitted when the live load exceeds 100 psf (4.79 kN/m^2) except that the design live load for members supporting two or more floors is permitted to be reduced by 20 percent.

Exception: For uses other than storage, where approved, additional live load reductions shall be permitted where shown by the registered design professional that a rational approach has been used and that such reductions are warranted.

~~3~~ 2. A reduction shall not be permitted in passenger vehicle parking garages except that the live loads for members supporting two or more floors are permitted to be reduced by a maximum of 20 percent.
~~4~~ 3. For live loads not exceeding 100 psf (4.79 kN/m^2), the design live load for any structural member supporting 150 square feet (13.94 m^2) or more is permitted to be reduced in accordance with Equation 16-23.
~~5~~ 4. For one-way slabs, the area, *A*, for use in Equation 16-23 shall not exceed the product of the slab span and a width normal to the span of 0.5 times the slab span.

$R = 0.08\,(A - 150)$ **(Equation 16-23)**
For SI: $R = 0.861\,(A - 13.94)$

Such reduction shall not exceed the smallest of:

1. 40 percent for horizontal members,
2. 60 percent for vertical members, or
3. *R* as determined by the following equation:

$R = 23.1\,(1 + D / L_o)$ **(Equation 16-24)**

where:

A = Area of floor supported by the member, square feet (m^2).
D = Dead load per square foot (m^2) of area supported.
L_o = Unreduced live load per square foot (m^2) of area supported.
R = Reduction in percent.

1607.11.2.2 Special-purpose roofs. Roofs used for promenade purposes, roof gardens, assembly purposes or other special purposes, and marquees, shall be designed for a minimum live load, L_o, as specified in Table 1607.1. Such live loads are permitted to be reduced in accordance with Section 1607.9. ~~Live loads of 100 psf or more at areas of roofs classified as Group A occupancies shall not be reduced.~~

Reason: The purpose for this proposal is to correlate the IBC with the 2010 edition of ASCE 7. The need for correlation is due to ASCE 7 Proposals LLSC-LL9 and LLSC-LL11, which were approved by the Live Load Subcommittee and are being balloted by the Main Committee (Items #5 and #6 of the Second Main Committee Ballot on Live/Dead Load Provisions). It is expected that the Main Committee will approve the proposals.

The proposal focuses on correlating the IBC with changes to the provisions of ASCE 7-10 where reduction of live loads at floors and occupied roofs is restricted or prohibited. The applicable provisions in the IBC are currently located in Section 1607.9. Reduction of live loads is typically permitted except for live loads exceeding 100 psf, in passenger vehicle garages, and in Group A occupancies where the live load is 100 psf or where fixed seats are located. There are exceptions for members supporting two or more floors where the live load exceeds 100 psf or in passenger vehicle garages but the reduction is limited to 20 percent. The corresponding provisions in ASCE 7-05 are nearly identical except that Group A occupancies are identified as assembly occupancies.

The proposal adds a footnote to Table 1607.1 that prohibits live load reduction “unless specific exceptions of Section 1607.9 apply.” The footnote is specified at each use or occupancy in Table 1607.1 where live load reduction is to be restricted. With the addition of this footnote, Table 1607.1 will contain limitations on live load reduction and references to Table 1607.1 are added to Sections 1607.9.1 and 1607.9.2 to correlate with the footnote. Section 1607.9.1.4 (basic live load reduction), Item #1 of Section 1607.9.2 (alternative live load reduction), and the last sentence of Section 1607.11.2.2, on Group A occupancies are deleted because their purpose is supplanted by the changes to Table 1607.1. Sections 1607.9.1.2 and 1607.9.1.3 (basic live load reduction) and Items #2 and #3 of Section 1607.9.2 (alternative live load reduction) are retained because they specify exceptions to Section 1607.9 that the proposed footnote of Table 1607.1 references.

These changes will clarify where live load reduction is prohibited or restricted by effectively specifying the requirement at each applicable use or occupancy in Table 1607.1 and they will align the applicable provisions of IBC Section 1607 with the corresponding provisions in Chapter 4 of ASCE 7-10. The change will also eliminate reliance on occupancy classification (Group A), which is not related to structural design but to fire- and life-safety regulations, for determination of whether live load reduction is permitted.

The proposal also consolidates several separately listed items in Table 1607.1 into a single category of recreational use and will align the table with Table 4-1 of ASCE 7-10. This is seen as simplifying the data in the table by grouping similar uses together. With respect to this consolidation, Section 1607.9.1.4 (basic live load reduction) and Item #1 of Section 1607.9.2 (alternative live load reduction) currently prohibit live load reduction in areas of Group A occupancies as noted above. IBC Section 303.1 lists bowling alleys, dance halls, gymnasiums, and pool and billiard parlors as Group A-3 occupancies; arenas and skating rinks as Group A-4 occupancies; and bleachers, grandstands and stadiums as Group A-5 occupancies.

Skating rinks are deleted from Table 1607.1 rather than being an item under "recreational uses" in Table 1607.1 because it is not listed in Table 4-1 of ASCE 7 and it conflicts with Table C4-1 of ASCE-7, which specifies uniform live loads of 250 psf for ice skating rinks and 100 psf for roller skating rinks.

The application of a value of 1.0 for f_1 in Section 1605.2.1 is revised for consistency with the other changes in this proposal. The notation for "L" is added to make it clear that roof live load, L_r, is not intended.

This proposal was prepared in conjunction with a proposal to editorially correlate IBC Section 1607 with Chapter 4 of ASCE 7-10 and is intended to further revise Section 1607 without any overlapping or conflicting changes between the two proposals.

A separate proposal also revises Item 4 of Table 1607.1 with respect to the live loads. These revisions are not repeated in this proposal but, should both proposals be approved by the membership, the proponent intends that Footnote (m) be specified for the uniform live loads at stages and platforms.

A separate proposal also revises Item 29 of Table 1607.1 in conjunction with correlating the IBC with changes to the provisions of ASCE 7-10 where reduction of live loads at floors and occupied roofs is restricted or prohibited. These revisions are not repeated in this proposal but, should both proposals be approved by the membership, the proponent intends that Footnote (m) be specified for the uniform live load at roofs used for assembly purposes but that all other changes to Item 29 in this proposal be disregarded.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: Brazil-S45-T1607.1

Public Hearing Results

This code change was contained in the errata posted on the ICC website. Please go to http://www.iccsafe.org/cs/codes/Pages/09-10ProposedChanges.aspx.

Committee Action: Approved as Modified

Modify the proposal as follows:

1605.2.1 Basic load combinations. Where strength design or load and resistance factor design is used, structures and portions thereof shall resist the most critical effects from the following combinations of factored loads:

$1.4 (D + F)$	**(Equation 16-1)**
$1.2 (D + F + T) + 1.6 (L + H) + 0.5 (L_r \text{ or } S \text{ or } R)$	**(Equation 16-2)**
$1.2 D + 1.6 (L_r \text{ or } S \text{ or } R) + (f_1 L \text{ or } 0.8 W)$	**(Equation 16-3)**
$1.2 D + 1.6 W + f_1 L + 0.5 (L_r \text{ or } S \text{ or } R)$	**(Equation 16-4)**
$1.2 D + 1.0 E + f_1 L + f_2 S$	**(Equation 16-5)**
$0.9 D + 1.6 W + 1.6 H$	**(Equation 16-6)**
$0.9 D + 1.0 E + 1.6 H$	**(Equation 16-7)**

where:

f_1 = 1 for ~~floors in~~ places of public assembly~~,~~ ~~areas and recreational uses (see Table 1607.1), for~~ live loads~~, L,~~ in excess of 100 pounds per square foot (4.79 kN/m^2), and ~~for floors in passenger vehicle~~ parking garages; and
= 0.5 for other live loads~~, L~~.

f_2 = 0.7 for roof configurations (such as saw tooth) that do not shed snow off the structure; and
= 0.2 for other roof configurations.

Exception: Where other factored load combinations are specifically required by the provisions of this code, such combinations shall take precedence.

(Portions of proposal not shown are unchanged)

Committee Reason: This proposal correlates the reduction of live loads at floors and occupied roofs with comparable provisions in the next edition of ASCE 7 load standard. The modification rolls back portions of the proposed revisions to the basic allowable load combination notes that were deemed unnecessary.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Edwin Huston, National Council of Structural Engineers Associations (NCSEA), representing NCSEA Code Advisory Subcommittee – General Requirements Subcommittee, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

TABLE 1607.1
MINIMUM UNIFORMLY DISTRIBUTED LIVE LOADS, *Lo*, AND MINIMUM CONCENTRATED LIVE LOADS [g]

OCCUPANCY OR USE	UNIFORM (psf)	CONCENTRATED (lbs.)
23. Recreational uses:		
Bowling alleys, poolrooms and similar uses	75 [m]	
Dance halls and ballrooms	100 [m]	
Gymnasiums	100 [m]	
Reviewing stands, grandstands and bleachers	100 [c, m]	
Stadiums and arenas with fixed seats (fastened to floor)	60 [c, m]	
Roller skating rinks	100 [m]	
Ice skating rinks	250 [m]	

(Portions of table not shown are unchanged)

c. Design in accordance with the ICC 300.
m. Live load reduction is not permitted unless specific exceptions of Section 1607.9 apply.

(Portions of proposal not shown are unchanged)

Commenter's Reason: The proponent of S60 did a good job of aligning Table 1607.1 with the revisions in Chapter 4 of ASCE 7-10. However, S60 removed Line 33, Skating Rinks and the 100 psf uniform live load, because they are only listed in the commentary of ASCE 7. The classification of Skating Rink has been in the IBC since its inception. NCSEA believes it should still be in the Building Code. Unlike ASCE 7, the IBC doesn't have a commentary to Table 1607.1 for suggestions of other loads.

At the Code Development Hearings in Baltimore, NCSEA provided a floor amendment to add Skating Rinks back in, but opposing testimony pointed out that ASCE 7 has different live loads for Roller Skating Rinks (100 psf) and Ice Skating Rinks (250 psf). Thus our Floor Modification would disagree with ASCE 7 and could be unsafe. This Public Comment restores the 100 psf for (Roller) Skating Rinks to the IBC and adds the ASCE 7 Commentary load of 250 psf for (Ice) Skating Rinks.

NCSEA urges your acceptance of this public comment to S35-09/10. Thank you.

Final Action: AS AM AMPC____ D

S63-09/10
202

Proposed Change as Submitted

Proponent: Edwin Huston, National Council of Structural Engineers Associations- Code Advisory Committee - General Requirements Subcommittee

Revise text as follows:

SECTION 202
DEFINITIONS

AWNING. An architectural projection that provides weather protection, identity or decoration and is partially or wholly supported by the building to which it is attached. An *awning* is comprised of a lightweight frame structure over which a covering is attached.

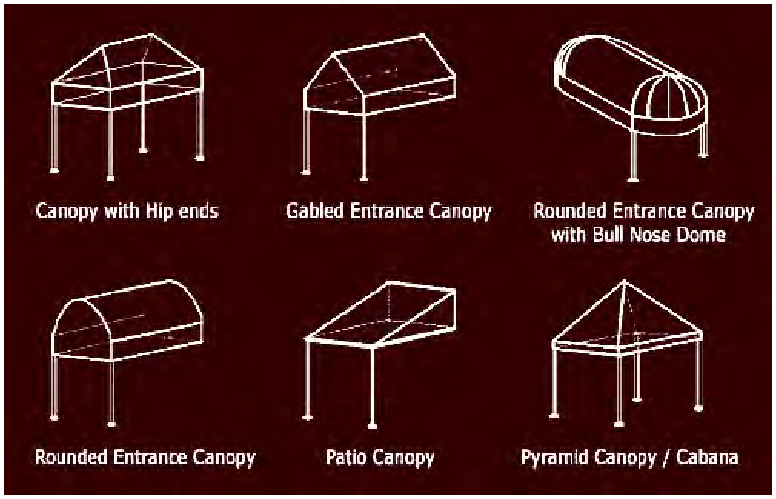
CANOPY. A permanent structure or architectural projection of rigid construction over which a covering is attached that provides weather protection, identity or decoration. ~~,~~ A canopy is permitted to ~~and shall~~ be structurally independent or supported by attachment to a building ~~on one end and by not less than one stanchion on the outer end~~ <u>on one or more sides</u>. Canopies shall be sloped more than 25 degrees from the horizontal or so constructed so as to inhibit access other than for maintenance functions.

<u>**CORNICE.** A projection at the top of a wall or a projecting element over an architectural feature, such as a doorway. Portions of a cornice which are sloped less than 25 degrees from the horizontal and are less than 10 feet (3.05 m) above the ground, more than 10 feet (3.05 m) below an adjacent roof, or located less than 10 feet (3.05 m) from operable openings above or adjacent to the level of the cornice, shall be designed for the live load from Table 1607.1.</u>

MARQUEE. A permanent roofed structure attached to and supported by the building <u>on one or more sides</u> ~~and~~ that ~~projects into the public right-of-way~~ <u>has a top surface which is sloped less than 25 degrees from the horizontal</u>. <u>A marquee shall be less than 10 feet (3.05 m) above the ground, more than 10 feet (3.05 m) below an adjacent roof, or located less than 10 feet (3.05 m) from operable openings above or adjacent to the level of the marquee.</u>

Reason: The current definitions for Awning, canopy and marquee are not adequate.

Lightweight, fabric covered, frame structures also have stanchion(s), in which case the awning definition would not apply. This doesn't make them canopies. Awnings are listed in Table 1607.1, Item 11 with a live load of 5 psf.



Architectural projections of rigid construction over which a covering is attached don't always have stanchion(s). If they do not, they are not defined in the IBC. What if, instead of a stanchion, the canopy cantilevers from the building, or has a hanger rod, chain or cable suspension system?

Copywrited MMP

Cornices are not defined in the IBC, yet they are listed in Table 1607.1, Item 11 with a live load of 60 psf.

Currently, a Marquee must project over the public right-of-way. It is listed in Table 1607.1, Item 24 with a live load of 75 psf. If it doesn't project over the public right-of-way, what is it and what live load should it be designed for? The chapter-by-chapter synopsis for Chapter 32 on page xii of the 2009 IBC notes that "steps, columns, awnings, canopies, marquees, signs, windows, balconies and similar architectural features above grade" can all encroach into the public right-of-way. This effectively negates the definition of a marquee.

With these problems, the definitions in the IBC are not enforceable.

The definition of an "Awing" is retained. However, it can now have a stanchion. The proposed definition, which is tied to a 5 psf live load in Table 1607.1, is now keyed to the lightweight frame structure.

The definition of a "Canopy" is retained. However, instead of relying on a stanchion for its defining characteristic, it is defined by its permanent, rigid construction and its function of providing weather protection, identity or decoration.

From the position of structural engineers, architects and building officials, these definitions need to be able to be tied to Table 1607.1. The proposed revisions do this and include a discernable intent to allow for better code interpretation for other, undefined situations.

That is, when the canopy is like a roof, it is designed for 20 psf, like a roof structure. If a canopy, marquee or cornice has a reasonably flat surface, and is accessible, such as by a short ladder or an operable opening, so that the public might be inclined to get onto it, then it should be designed for a more robust live load.

Cost Impact: This code change proposal will not increase the cost of construction.

ICCFILENAME: HUSTON-S2-202

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The proposed definitions should not contain requirements. The committee encourages a public comment modifying the definitions of cornice.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Edwin Huston, National Council of Structural Engineers Associations (NCSEA), representing NCSEA Code Advisory Subcommittee – General Requirements Subcommittee, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

SECTION 202 DEFINITIONS:

AWNING. An architectural projection that provides weather protection, identity or decoration and is partially or wholly supported by the building to which it is attached. An awning is comprised of a lightweight frame structure over which a covering is attached

CANOPY. A permanent structure or architectural projection of rigid construction over which a covering is attached that provides weather protection, identity or decoration.~~,~~ A canopy is permitted to be structurally independent or supported by attachment to a building on one or more sides. ~~Canopies shall be sloped more than 25 degrees from the horizontal or so constructed so as to inhibit access other than for maintenance functions~~.

CORNICE. A projecting horizontal ~~projection at the top of a wall or a projecting~~ molded element located at or near the top of an architectural feature. ~~element over an architectural feature, such as a doorway. Portions of a cornice which are sloped less than 25 degrees from the horizontal and are less than 10 feet (3.05 m) above the ground, more than 10 feet (3.05 m) below an adjacent roof, or located less than 10 feet (3.05 m) from operable openings above or adjacent to the level of the cornice, shall be designed for the live load from Table 1607.1.~~

MARQUEE. A ~~permanent roofed structure attached to and supported by the building on one or more sides~~ canopy that has a top surface which is sloped less than 25 degrees from the horizontal and is ~~A marquee shall be less than 10 feet above the ground, more than 10 feet below an adjacent roof, or~~ located less than 10 feet (3.05 m) from operable openings above or adjacent to the level of the marquee.

Commenter's Reason: The ICC Structural Committee urged NCSEA to modify S63 and bring it back in a Public Comment and stated that these definitions needed to be updated. NCSEA has worked with AIA and others to address the points raised in the Code Development Hearings.

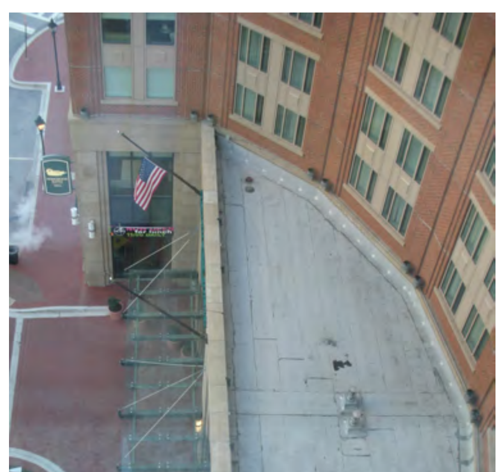
The Current IBC definitions of awning, canopy and marquee are not adequate. Lightweight, fabric covered frame structures also have stanchion(s), in which case the awning definition would not apply. This doesn't make them canopies. Awnings are listed in Table 1607.1, Item 11 with a live load of 5 psf.

Architectural projections of rigid construction over which a covering is attached don't always have stanchion(s). If they do not, they are not defined in the IBC. What if, instead of a stanchion, the canopy cantilevers from the building, or has a hanger rod, chain or cable suspension system?

Cornices are not defined in the IBC, yet they are listed in Table 1607.1, Item 11 with a live load of 60 psf.

Currently, a Marquee must project over the public right-of-way. It is listed in Table 1607.1, Item 24 with a live load of 75 psf. If it doesn't project over the public right-of-way, what is it and what live load should it be designed for? The chapter-by-chapter synopsis for Chapter 32 on page xii of the 2009 IBC notes that "steps, columns, awnings, canopies, marquees, signs, windows, balconies and similar architectural features above grade" can all encroach into the public right-of-way. This effectively negates the definition of a marquee.

The photo at the right was taken during the Code Development Hearings in Baltimore at a nearby hotel which had a Marquee that would not meet the current definition of a Marquee because it is not "project into the public right of way". However, access would be available from the operable windows of the adjacent rooms.



Prior to the Code Development Hearings in Baltimore, Paul McCartney and his band preformed in New York City while standing on the marquee of the Ed Sullivan Theater on July 15, 2009. Access was presumably through the operable windows which can be seen in the background. There are also historic photographs taken on VE day in New York City that show scores of people on marquees looking down on the thousands of people in the streets.

With these problems, the definitions in the IBC are not enforceable.

In this Public Comment, the definition of an "Awing" is retained. However, it can now have a stanchion. The proposed definition, which is tied to a 5 psf live load in Table 1607.1, is now keyed to the lightweight frame structure. The definition of a "Canopy" is retained. However, instead of relying on a stanchion for its defining characteristic, it is defined by its permanent, rigid construction and its function of providing weather protection, identity or decoration.

From the position of structural engineers, architects and building officials, these definitions need to be able to be tied to Table 1607.1. The proposed revisions do this and include a discernable intent to allow for better code interpretation for other, undefined situations.

That is, when the canopy is like a roof, it is designed for 20 psf, like a roof structure. If a canopy is accessible, such as by an operable opening, so that the public might be inclined to get onto it, then it should be designed for a more robust live load.

NCSEA urges your acceptance of this public comment to S63-09/10. Thank you.

Final Action: AS AM AMPC____ D

S70-09/10

1607.6, 1607.6.1, 1607.6.2-1607.6.5 (New), Table 1607.6

Proposed Change as Submitted

Proponent: Edwin Huston, National Council of Structural Engineers Associations- Code Advisory Committee - General Requirements Subcommittee

1. Delete and Substitute as follows:

~~**1607.6 Truck and bus garages.** Minimum live loads for garages having trucks or buses shall be as specified in Table 1607.6, but shall not be less than 50 psf (2.40 kN/m2), unless other loads are specifically justified and *approved* by the *building official*. Actual loads shall be used where they are greater than the loads specified in the table.~~

~~**1607.6.1 Truck and bus garage live load application.** The concentrated load and uniform load shall be uniformly distributed over a 10-foot (3048 mm) width on a line normal to the centerline of the lane placed within a 12-foot-wide (3658 mm) lane. The loads shall be placed within their individual lanes so as to produce the maximum stress in each structural member. Single spans shall be designed for the uniform load in Table 1607.6 and one simultaneous concentrated load positioned to produce the maximum effect. Multiple spans shall be designed for the uniform load in Table 1607.6 on the spans and two simultaneous concentrated loads in two spans positioned to produce the maximum negative moment effect. Multiple span design loads, for other effects, shall be the same as for single spans.~~

1607.6 Heavy Vehicle Loads. Structures or portions of structures which are subject to heavy vehicle loads shall be designed for the loads from Section 1607.6.1.

1607.6.1 Truck and bus loads. Where any structure does not have provisions to restrict access for trucks and buses that exceed the weight limitations set forth in Table 1607.1 footnote a, those portions of the structure subject to such loads shall be designed using the vehicular live loads, including consideration of impact and fatigue, in accordance with the codes and specifications required by the jurisdiction having authority for the design and construction of the roadways and bridges in the same location of the structure.

2. Add new text as follows:

1607.6.2 Fire truck loading. Where fire department access requires travel over or loading of a structure by fire department vehicles or similar emergency vehicles, the structure shall be designed for the greater of the following loads:

1607.6.2.1 Fire truck operational loads. The actual operational loads (including out rigger reactions and contact areas) of the vehicles as stipulated and / or approved by the local Fire Department or Building Official having jurisdiction for the structure.

1607.6.2.2 Truck and bus loads. The live loading required by section 1607.6.1.

1607.6.3 Truck and bus garages. Garages designed specifically to allow trucks or buses that exceed the weight limitations for passenger vehicles as set forth in Table 1607.1 footnote a, shall be designed using the vehicular live loads, per the Codes and Specifications required by the jurisdiction having authority for the design and construction of the roadways and bridges in the same location of the structure. (Note: design for impact and fatigue in a garage is not required).

Exception: The design live loads and load placement are allowed to be determined using the actual vehicle weights for the vehicles allowed onto the garage floors, provided such loads and placement are based on rational engineering principles and are approved by the Building Official, but shall not be less than 50 psf (this live load shall not be reduced).

1607.6.4 Forklifts and moveable equipment. Where a structure is intended to have forklifts or other moveable equipment present, the structure shall be designed for the total vehicle load and the individual wheel loads for the anticipated vehicles as specified by the owner of the facility. These loads shall be posted per Section 1607.6.5.

1607.6.4.1 Impact and fatigue. Due to the nature of the operations of a facility with forklifts and other moveable equipment, impact loads and fatigue loading must be considered in the design of the supporting structure. This must include consideration for relative stiffness and differential deflections between adjacent framing members; positive and negative moments induced by a moving live load; effects of multiple vehicle loads in the same vicinity; and the punching shear on a slab based on the actual contact area of the wheel loads for the specific vehicle to be used. For the purposes of design, the vehicle and wheel loads shall be increased by 30 percent to account for impact.

1607.6.5 Posting. The maximum weight of the vehicles allowed into or on a garage or other structure shall be conspicuously posted by the owner in accordance with Section 106.1.

3. Delete without substitution:

~~TABLE 1607.6~~
~~UNIFORM AND CONCENTRATED LOADS~~

~~LOADING CLASSa~~	~~UNIFORM LOAD (pounds/linear foot of lane)~~	~~CONCENTRATED LOAD (pounds)b~~	
		~~For moment design~~	~~For shear design~~
~~H20-44 and HS20-44~~	~~640~~	~~18,000~~	~~26,000~~
~~H15-44 and HS15-44~~	~~480~~	~~13,500~~	~~19,500~~

~~For SI: 1 pound per linear foot = 0.01459 kN/m, 1 pound = 0.004448 kN, 1 ton = 8.90 kN.~~

~~a. An H loading class designates a two-axle truck with a semitrailer. An HS loading class designates a tractor truck with a semitrailer. The numbers following the letter classification indicate the gross weight in tons of the standard truck and the year the loadings were instituted.~~

~~b. See Section 1607.6.1 for the loading of multiple spans.~~

Reason: The current Section 1607.6 Truck and bus garages, is addressing truck and bus loads in garages only and does not give direction for heavy vehicle loads in other conditions outside of a "garage". The current section lists loading criteria that appears to be extracted from the live load section from the AASHTO (American Association of State Highway and Transportation Officials) Code. AASHTO is not a referenced standard in the IBC. The current section however does not give other critical loading criteria such as spacing of the concentrated loads or impact requirements. Buildings designed for repair or storage may need to be designed for higher levels of loading than are currently prescribed by Table 1607.6 due to tighter spacing requirements This new section clarifies that for conditions where heavy highway type vehicles have access onto a structure, then that structure will need to be designed using the same code and requirements that the roadways in that jurisdiction are designed under. This loading may in fact be the loading from AASHTO, or the loading for other elements such as lids of large detention tanks or utility vaults. It will likely vary from one Jurisdiction to another. Thus the RDP should consult with the Jurisdiction for design loads for these special conditions. The new language also gives criteria for addressing other heavy vehicle loads (Fire trucks and forklifts), which is currently absent in the current code, and is only mentioned under Section 1607.2 Loads not specified.

Cost Impact: This code change proposal will not increase the cost of construction.

ICCFILENAME: HUSTON-S7-1607.6

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The proposal would provide necessary clarifications of provisions for heavy vehicle loading. Proposed requirements for emergency vehicles need work and it is hoped this can be accomplished in the public comment phase.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Edwin Huston, National Council of Structural Engineers Associations (NCSEA), representing NCSEA Code Advisory Subcommittee – General Requirements Subcommittee, requests Approval as Modified by this Public Comment.

Replace proposal as follows:

~~**1607.6 Truck and bus garages.** Minimum live loads for garages having trucks or buses shall be as specified in Table 1607.6, but shall not be less than 50 psf (2.40 kN/m2), unless other loads are specifically justified and *approved* by the *building official*. Actual loads shall be used where they are greater than the loads specified in the table.~~

~~**1607.6.1 Truck and bus garage live load application.** The concentrated load and uniform load shall be uniformly distributed over a 10-foot (3048 mm) width on a line normal to the centerline of the lane placed within a 12-foot-wide (3658 mm) lane. The loads shall be placed within their individual lanes so as to produce the maximum stress in each structural member. Single spans shall be designed for the uniform load in Table 1607.6 and one simultaneous concentrated load positioned to produce the maximum effect. Multiple spans shall be designed for the uniform load in Table 1607.6 on the spans and two simultaneous concentrated loads in two spans positioned to produce the maximum negative moment effect. Multiple span design loads, for other effects, shall be the same as for single spans.~~

~~**TABLE 1607.6**~~
~~**UNIFORM AND CONCENTRATED LOADS**~~

1607.6 Heavy vehicle loads. Floors and other surfaces that are intended to support vehicle loads greater than a 10,000 pound gross vehicle weight rating shall comply with Sections 1607.6.1 through 1607.6.5.

1607.6.1 Loads. Where any structure does not restrict access for vehicles that exceed a 10,000 pounds gross vehicle weight rating, those portions of the structure subject to such loads shall be designed using the vehicular live loads, including consideration of impact and fatigue, in accordance with the codes and specifications required by the Jurisdiction having authority for the design and construction of the roadways and bridges in the same location of the structure.

1607.6.2 Fire truck and emergency vehicles. Where a structure or portions of a structure are accessed and loaded by fire department access vehicles and other similar emergency vehicles, the structure shall be designed for the greater of the following loads:

1. The actual operational loads, including out rigger reactions and contact areas of the vehicles as stipulated and approved by the Building Official, or

2. The live loading specified in Section 1607.6.1.

1607.6.3 Heavy vehicle garages. Garages designed to accommodate vehicles that exceed a 10,000 pound gross vehicle weight rating, shall be designed using the live loading specified by Section 1607.6.1. For garages the design for impact and fatigue is not required.

Exception: The vehicular live loads and load placement are allowed to be determined using the actual vehicle weights for the vehicles allowed onto the garage floors, provided such loads and placement are based on rational engineering principles and are approved by the Building Official, but shall not be less than 50 psf. This live load shall not be reduced.

1607.6.4 Forklifts and moveable equipment. Where a structure is intended to have forklifts or other moveable equipment present, the structure shall be designed for the total vehicle or equipment load and the individual wheel loads for the anticipated vehicles as specified by the owner of the facility. These loads shall be posted per Section 1607.6.5.

1607.6.4.1 Impact and fatigue. Impact loads and fatigue loading shall be considered in the design of the supporting structure. For the purposes of design, the vehicle and wheel loads shall be increased by 30 percent to account for impact.

1607.6.5 Posting. The maximum weight of the vehicles allowed into or on a garage or other structure shall be posted by the owner in accordance with Section 106.1.

Commenter's Reason: The current Section 1607.6 Truck and bus garages, addresses truck and bus loads in garages only and does not give direction for heavy vehicle loads in other conditions outside of a "garage". The current section lists loading criteria that appears to be extracted from the live load section from the AASHTO (American Association of State Highway and Transportation Officials) Code. AASHTO is not a referenced standard in the IBC. The current section however does not give other critical loading criteria such as spacing of the concentrated loads or impact requirements. Buildings designed for repair or storage may need to be designed for higher levels of loading than are currently prescribed by Table 1607.6 due to tighter spacing requirements This new section clarifies that for conditions where heavy highway type vehicles have access onto a structure, then that structure will need to be designed using the same code and requirements that the roadways in that jurisdiction are designed under. This loading may in fact be the loading from AASHTO, or the loading for other elements such as lids of large detention tanks or utility vaults. It will likely vary from one Jurisdiction to another. Thus the RDP should consult with the Jurisdiction for design loads for these special conditions. The new language also gives criteria for addressing other heavy vehicle loads such as Fire trucks and forklifts, which is currently absent in the current code, and is only mentioned under Section 1607.2 Loads not specified.

Final Action: AS AM AMPC____ D

1012.1, 1013.1, 1013.1.1, 1602.1, Table 1607.1, 1607.7, 1607.7.1, 1607.7.1.1, 1607.7.1.2, 1607.7.2, 1607.7.3

Proposed Change as Submitted

Proponent: Philip Brazil, PE, SE, Reid Middleton, Inc., representing self

1. Add new definitions as follows:

1602.1 Definitions. The following words and terms shall, for the purposes of this chapter, have the meanings shown herein.

GRAB BAR SYSTEM. A bar and associated anchorages and attachments to the structural system for the support of body weight in locations such as toilets, showers and tub enclosures.

GUARDRAIL SYSTEM. A system of components, including anchorages and attachments to the structural system, near open sides of an elevated surface for the purpose of minimizing the possibility of a fall from the elevated surface by people, equipment or material.

HANDRAIL SYSTEM. A rail grasped by hand for guidance and support, and associated anchorages and attachments to the structural system.

2. Revise as follows:

1602.1 Definitions. The following words and terms shall, for the purposes of this chapter, have the meanings shown herein.

VEHICLE BARRIER SYSTEM. A system of ~~building~~ components, including anchorages and attachments to the structural system, near open sides of a garage floor or ramp or building walls that act as restraints for vehicles.

TABLE 1607.1
MINIMUM UNIFORMLY DISTRIBUTED LIVE LOADS, L_o, AND MINIMUM CONCENTRATED LIVE LOADS[g]

OCCUPANCY OR USE	UNIFORM (psf)	CONCENTRATED (lbs.)
19. Handrail, guardrail and grab bar systems ~~Handrails, guards and grab bars~~	See Section 1607.7	

(Portions of table not shown remain unchanged)

1607.7 Loads on handrails, ~~guards~~ guardrail, grab bars, seats and vehicle barrier systems. ~~Handrails~~ Handrail, ~~guards~~ guardrail, grab bar ~~bars~~, accessible seat ~~seats~~, accessible bench ~~benches~~ and vehicle barrier systems shall be designed and constructed to the structural loading conditions set forth in this section.

1607.7.1 Handrails and ~~guards~~ guardrail systems. Handrail ~~Handrails~~ and ~~guards~~ guardrail systems shall be designed to resist a load of 50 plf (0.73 kN/m) applied in any direction at the top ~~and to transfer this load through the supports to the structure~~. Glass handrail ~~assemblies~~ and ~~guards~~ guardrail systems shall also comply with Section 2407.

Exceptions:

1. For one- and two-family dwellings, only the single concentrated load required by Section 1607.7.1.1 shall be applied.
2. In Group I-3, F, H and S occupancies, for areas that are not accessible to the general public and that have an occupant load less than 50, the minimum load shall be 20 pounds per foot (0.29 kN/m).

1607.7.1.1 Concentrated load. Handrail ~~Handrails~~ and ~~guards~~ guardrail systems shall be able to resist a single concentrated load of 200 pounds (0.89 kN), applied in any direction at any point along the top~~, and to transfer this load through the supports to the structure~~. This load need not be assumed to act concurrently with the loads specified in Section 1607.7.1.

1607.7.1.2 Components. Intermediate rails (all those except the handrail), balusters and panel fillers shall be designed to withstand a horizontally applied normal load of 50 pounds (0.22 kN) on an area equal to 1 square foot ($0.093m^2$), including openings and space between rails. Reactions due to this loading are not required to be superimposed with those of Section 1607.7.1 or 1607.7.1.1.

1607.7.2 Grab bar~~s~~, shower seat~~s~~ and dressing room bench seat~~s~~ systems. Grab bar ~~bars~~, shower seat ~~seats~~ and dressing room bench seat systems shall be designed to resist a single concentrated load of 250 pounds (1.11 kN) applied in any direction at any point.

1607.7.3 Vehicle barrier systems. Vehicle barrier systems for passenger vehicles shall be designed to resist a single load of 6,000 pounds (26.70 kN) applied horizontally in any direction to the barrier system ~~and shall have anchorage or attachment capable of transmitting this load to the structure~~. For design of the system, two loading conditions shall be analyzed. The first condition shall apply the load at a height of 1 foot, 6 inches (457 mm) above the floor or ramp surface. The second loading condition shall apply the load at 2 feet, 3 inches (686 mm) above the floor or ramp surface. The more severe load condition shall govern the design of the vehicle barrier ~~restraint~~ system. The load shall be assumed to act on an area not to exceed 1 square foot ($305 mm^2$), and is not required to be assumed to act concurrently with any handrail or guardrail system loadings specified in Section 1607.7.1. Garages accommodating trucks and buses shall be designed in accordance with an approved method that contains provision for traffic railings.

1012.1 Where required. *Handrails* for *stairways* and *ramps* shall be adequate in strength and attachment in accordance with Section 1607.7 for handrail systems. *Handrails* required for *stairways* by Section 1009.12 shall comply with Sections 1012.2 through 1012.9. *Handrails* required for *ramps* by Section 1010.8 shall comply with Sections 1012.2 through 1012.8.

1013.1 Where required. *Guards* shall be located along open-sided walking surfaces, including *mezzanine*s, *equipment platforms*, *stairs*, *ramps* and landings that are located more than 30 inches (762 mm) measured vertically to the floor or grade below at any point within 36 inches (914 mm) horizontally to the edge of the open side. *Guards* shall be adequate in strength and attachment in accordance with Section 1607.7 for guardrail systems.

Exception: *Guards* are not required for the following locations:

1. On the loading side of loading docks or piers.
2. On the audience side of stages and raised platforms, including steps leading up to the stage and raised platforms.
3. On raised stage and platform floor areas, such as runways, ramps and side stages used for entertainment or presentations.
4. At vertical openings in the performance area of stages and platforms.
5. At elevated walking surfaces appurtenant to stages and platforms for access to and utilization of special lighting or equipment.
6. Along vehicle service pits not accessible to the public.
7. In assembly seating where *guards* in accordance with Section 1028.14 are permitted and provided.

1013.1.1 Glazing. Where glass is used to provide a *guard* or as a portion of the *guard* system, the *guard* shall also comply with Section 2407. Where the glazing provided does not meet the strength and attachment requirements of Section 1607.7 for guardrail systems, complying *guards* shall also be located along glazed sides of open-sided walking surfaces.

Reason: The purpose for this proposal is to correlate the IBC with the 2010 edition of ASCE 7. The need for correlation is due to ASCE 7 Proposal LLSC-LL9, which was approved by the Live Load Subcommittee and is being balloted by the Main Committee (Item #5 of the Second Main Committee Ballot on Live/Dead Load Provisions). It is expected that the Main Committee will approve the proposal.

This proposal takes into account the definitions of “guard” and “handrail” in the IBC by limiting the applicability of the proposed definitions in this proposal to Chapter 16, whereas the definitions of “guard” and “handrail” apply throughout the IBC. The definitions in this proposal will establish grab bar, guardrail and handrail systems as structural systems that are required to resist structural design loads and transfer these loads to the supporting structure. This will contrast with guards and handrails whose definitions are primarily utilized in code provisions related to egress and accessibility.

All instances of “guard” in the structural chapters, and all references to Section 1607.7 in the nonstructural chapters, of the 2009 IBC are included in this proposal.

This proposal was prepared in conjunction with a proposal to editorially correlate IBC Section 1607 with Chapter 4 of ASCE 7-10 and is intended to further revise Section 1607 without any overlapping or conflicting changes between the two proposals.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: Brazil-S25-1607.7

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The proposed terminology, in trying to distinguish the structural requirements from means of egress requirements, is itself potentially confusing. The currently used term is guard and there's no reason to change it to guardrail.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Scott Beard, City of Tacoma, WA, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

1013.1 (IFC [B]1013.1) Where required. Guards shall be located along open-sided walking surfaces, including mezzanines, equipment platforms, stairs, ramps and landings that are located more than 30 inches (762 mm) measured vertically to the floor or grade below at any point within 36 inches (914 mm) horizontally to the edge of the open side. Guards shall be adequate in strength and attachment in accordance with Section 1607.7 for guard~~rail~~ systems.

(no proposed changes to exceptions)

1013.1.1 (IFC [B]1013.1.1) Glazing. Where glass is used to provide a guard or as a portion of the guard system, the guard shall also comply with Section 2407. Where the glazing provided does not meet the strength and attachment requirements in Section 1607.7 for guard~~rail~~ systems, complying guards shall also be located along glazed sides of open-sided walking surfaces.

1602.1 Definitions. The following words and terms shall, for the purposes of this chapter, have the meanings shown herein.

GUARD~~RAIL~~ SYSTEM. A system of components, including anchorages and attachments to the structural system, near open sides of an elevated surface for the purpose of minimizing the possibility of a fall from the elevated surface by people, equipment or material.

TABLE 1607.1
MINIMUM UNIFORMLY DISTRIBUTED LIVE LOADS, L_o, AND MINIMUM CONCENTRATED LIVE LOADS [g]

OCCUPANCY OR USE	UNIFORM (psf)	CONCENTRATED (lbs.)
19. Handrail, guard~~rail~~ and grab bar systems	See Section1607.7	

(Portions of table and footnotes not shown remain unchanged)

1607.7 Loads on handrail, guard~~rail~~, grab bar, seat and vehicle barrier systems. Handrail, guard~~rail~~, grab bar, accessible seat, accessible bench and vehicle barrier systems shall be designed and constructed to the structural loading conditions set forth in this section.

1607.7.1 Handrail and guard~~rail~~ systems. Handrail and guard~~rail~~ systems shall be designed to resist a load of 50 plf (0.73 kN/m) applied in any direction at the top. Glass handrail and guard~~rail~~ systems shall also comply with Section 2407.

Exceptions:
1. For one- and two-family dwellings, only the single concentrated load required by Section 1607.7.1.1 shall be applied.
2. In Group I-3, F, H and S occupancies, for areas that are not accessible to the general public and that have an occupant load less than 50, the minimum load shall be 20 pounds per foot (0.29 kN/m).

1607.7.1.1 Concentrated load. Handrail and guard~~rail~~ systems shall be ~~able~~ designed to resist a single concentrated load of 200 pounds (0.89 kN), applied in any direction at any point along the top, and to transfer this load through the supports to the structure. This load need not be assumed to act concurrently with the loads specified in Section 1607.7.1.

1607.7.2 Grab bar, shower seat and dressing room bench seat systems. Grab bar, shower seat and dressing room bench seat systems shall be designed to resist a single concentrated load of 250 pounds (1.11 kN) applied in any direction at any point on the grab bar or seat to produce the maximum load effects.

1607.7.3 Vehicle barrier systems. Vehicle barrier systems for passenger vehicles shall be designed to resist a single load of 6,000 pounds (26.70 kN) applied horizontally in any direction to the barrier system. For design of the system, two loading conditions shall be analyzed. The first condition shall apply the load at a height of 1 foot, 6 inches (457 mm) above the floor or ramp surface. The second loading condition shall apply the load at 2 feet, 3 inches (686 mm) above the floor or ramp surface. The more severe load condition shall govern the design of the vehicle barrier system and shall have anchorage or attachment capable of transmitting this load to the structure. The load shall be assumed to act on an area not to exceed 1 square foot (305 mm^2), and is not required to be assumed to act concurrently with any handrail or guard~~rail~~ system loadings specified in Section 1607.7.1. Garages accommodating trucks and buses shall be designed in accordance with an approved method that contains provision for traffic railings.

Commenter's Reason: The public comment completes the correlation of the provisions of the IBC with the corresponding provisions in ASCE 7-10 and adjusts "guardrail system" from ASCE 7-10 to "guard system" for compatibility with the provisions for guards in the IBC.

Public Comment 2:

Philip Brazil, P.E., S.E., representing self, requests Approval as Modified by this Public Comment.

Replace the proposal with the following:

406.2.3 Guards. Guards shall be provided in accordance with Section 1013. Guards serving as vehicle barriers ~~systems~~ shall comply with Sections 406.2.4 and 1013.

406.2.4 Vehicle barriers ~~systems~~. Vehicle barriers ~~systems~~ not less than 2 feet 9 inches (835 mm) high shall be placed at the ends of drive lanes, and at the end of parking spaces where the vertical distance to the ground or surface directly below is greater than 1 foot (305 mm). Vehicle barriers ~~systems~~ shall comply with the loading requirements of Section 1607.7.3.

406.3.3 Construction. Open parking garages shall be of Type I, II or IV construction. Open parking garages shall meet the design requirements of Chapter 16. For vehicle barriers ~~systems~~, see Section 406.2.4.

1602.1 Definitions. The following words and terms shall, for the purposes of this chapter, have the meanings shown herein.

~~**GUARD.** See Section 1002.1.~~

VEHICLE BARRIER ~~SYSTEM~~. A component or a system of ~~building~~ components near open sides of a garage floor or ramp or building walls that act as restraints for vehicles.

TABLE 1607.1
MINIMUM UNIFORMLY DISTRIBUTED LIVE LOADS, L_o, AND MINIMUM CONCENTRATED LIVE LOADS [g]

OCCUPANCY OR USE	UNIFORM (psf)	CONCENTRATED (lbs.)
19. Handrails, guards and grab bars	See Section	1607.7
38. Vehicle barriers ~~systems~~	See Section	1607.7.3

1607.7 Loads on handrails, guards, grab bars, seats and vehicle barriers ~~systems~~. Handrails, guards, grab bars, accessible seats, accessible benches and vehicle barriers ~~systems~~ shall be designed and constructed to the structural loading conditions set forth in this section.

1607.7.1 Handrails and guards. Handrails and guards shall be designed to resist a linear load of 50 plf (0.73 kN/m) ~~applied in any direction at the top and to transfer this load through the supports to the structure~~ in accordance with Section 4.5.1 of ASCE 7. Glass handrail assemblies and guards shall also comply with Section 2407.

Exceptions:
1. For one- and two-family dwellings, only the single concentrated load required by Section 1607.7.1.1 shall be applied.
2. In Group I-3, F, H and S occupancies, for areas that are not accessible to the general public and that have an occupant load less than 50, the minimum load shall be 20 pounds per foot (0.29 kN/m).

1607.7.1.1 Concentrated load. Handrails and guards shall also be ~~able~~ designed to resist a ~~single~~ concentrated load of 200 pounds (0.89 kN)~~, applied in any direction at any point along the top, and to transfer this load through the supports to the structure. This load need not be assumed to act concurrently with the loads specified in Section 1607.7.1~~ in accordance with Section 4.5.1 of ASCE 7.

1607.7.1.2 Components. Intermediate rails (all those except the handrail), balusters and panel fillers shall be designed to ~~withstand~~ resist a ~~horizontally applied normal~~ concentrated load of 50 pounds (0.22 kN) ~~on an area equal to 1 square foot (0.093m^2), including openings and space between rails. Reactions due to this loading are not required to be superimposed with those of Section 1607.7.1 or 1607.7.1.1~~ in accordance with Section 4.5.1 of ASCE 7.

1607.7.2 Grab bars, shower seats and dressing room bench seats. Grab bars, shower seats and dressing room bench seats ~~systems~~ shall be designed to resist a single concentrated load of 250 pounds (1.11 kN) applied in any direction at any point on the grab bar or seat to produce the maximum load effects.

1607.7.3 Vehicle barriers ~~systems~~. Vehicle barriers ~~systems~~ for passenger vehicles shall be designed to resist a ~~single~~ concentrated load of 6,000 pounds (26.70 kN) ~~applied horizontally in any direction to the barrier system and shall have anchorage or attachment capable of transmitting this load to the structure. For design of the system, two loading conditions shall be analyzed. The first condition shall apply the load at a height of 1 foot, 6 inches (457 mm) above the floor or ramp surface. The second loading condition shall apply the load at 2 feet, 3 inches (686 mm) above the floor or ramp surface. The more severe load condition shall govern the design of the barrier restraint system. The load shall be assumed to act on an area not to exceed 1 square foot (305 mm^2), and is not required to be assumed to act concurrently with any handrail or guard loadings specified in Section 1607.7.1~~ in accordance with Section 4.5.3 of ASCE 7. Garages accommodating trucks and buses shall be designed in accordance with an approved method that contains provision for traffic railings.

Commenter's Reason: Based on the Committee's reason for disapproval, this public comment revises the current provisions in the IBC to be a combination of scoping requirements in the IBC with references to the corresponding technical requirements in ASCE 7-10.
The cross-reference to the definition of "guard" in Section 1602.1 is deleted because a cross-reference already exists in Section 202 and a repetition of it in Section 1602.1 serves no functional purpose. Also, there is no similar cross-reference in Section 1602.1 to the definition of "handrail" in Section 1002.1.

The term for "vehicle barrier system" in Section 1602.1 is changed to "vehicle barrier" for consistency with the defined terms of "guard" and "handrail" in Section 1002.1. All references to "vehicle barrier system" in the IBC are included in this public comment and are also changed to "vehicle barrier." The definition for "vehicle barrier system" in Section 1602.1 is also changed for consistency with the definition of "guard," which is a "building component or a system of building components…" but it is also changed to a component or a system of components…" for consistency with changes to the definition of "vehicle barrier system" in Proposal S31-09/10-AS ("a system of components…").

The provisions in Section 1607.7 are typically revised in this public comment to be scoping requirements and references to technical requirements except for Section 1607.7.2. In this case, scoping and technical requirements are included because corresponding Section 4.5.2 of ASCE 7-10 is limited to grab bars.

Final Action: AS AM AMPC____ D

S77-09/10

1607.9, 1607.9.1.5, 1607.11.2, 1607.11.2.1, 1607.11.2.2, Table 1607.1

<u>Proposed Change as Submitted</u>

Proponent: Philip Brazil, PE, SE, Reid Middleton, Inc., representing self

1. Revise as follows:

1607.9 Reduction in live loads. Except for uniform live loads at roofs, all other minimum uniformly distributed live loads, L_o, in Table 1607.1 are permitted to be reduced in accordance with Section 1607.9.1 or 1607.9.2. ~~Roof~~ <u>U</u>niform live loads~~, other than special purpose roofs of Section 1607.11.2.2~~ <u>at roofs</u> are permitted to be reduced in accordance with Section 1607.11.2. ~~Roof uniform live loads of special purpose roofs are permitted to be reduced in accordance with Section 1607.9.1 or 1607.9.2~~.

~~**1607.9.1.5 Roofs members.** Live loads of 100 psf (4.79 kN/m^2) or less shall not be reduced for roof members except as specified in Section 1607.11.2.~~

1607.11.2 ~~Reduction in roof live loads~~ <u>General</u>. The minimum uniformly distributed live loads of roofs and marquees, L_o, in Table 1607.1 are permitted to be reduced in accordance with Section 1607.11.2.1 or 1607.11.2.2.

1607.11.2.1 ~~Flat, pitched and curved~~ <u>Ordinary</u> roofs<u>, awnings and canopies</u>. Ordinary flat, pitched and curved roofs, and awnings and canopies other than of fabric construction supported by lightweight rigid skeleton structures, are permitted to be designed for a reduced <u>uniformly distributed</u> roof live load<u>, L_r,</u> as specified in the following equations or other controlling combinations of loads in Section 1605, whichever produces the greater load.

In structures such as greenhouses, where special scaffolding is used as a work surface for workers and materials during maintenance and repair operations, a lower roof load than specified in the following equations shall not be used unless approved by the building official. Such structures shall be designed for a minimum roof live load of 12 psf (0.58 kN/m^2).

$L_r = L_o R_1 R_2$ **(Equation 16-25)**

where: $12 \leq L_r \leq 20$

For SI: $L_r = L_o R_1 R_2$

where: $0.58 \leq L_r \leq 0.96$

L_r = Reduced live load per square foot (m^2) of horizontal projection in pounds per square foot (kN/m^2).

The reduction factors R_1 and R_2 shall be determined as follows:

$R_1 = 1$ for $A_t \leq 200$ square feet (18.58 m^2) **(Equation 16-26)**

$R_1 = 1.2 - 0.001 A_t$ for 200 square feet < A_t < 600 square feet **(Equation 16-27)**

For SI: $1.2 - 0.011\,A_t$ for 18.58 square meters < A_t < 55.74 square meters

R_1 = 0.6 for $A_t \geq$ 600 square feet (55.74 m^2) **(Equation 16-28)**

where:

A_t = Tributary area (span length multiplied by effective width) in square feet (m^2) supported by any structural member, and

R_2 = 1 for $F \leq 4$ **(Equation 16-29)**

R_2 = $1.2 - 0.05\,F$ for $4 < F < 12$ **(Equation 16-30)**

R_2 = 0.6 for $F \geq 12$ **(Equation 16-31)**

where:

F = For a sloped roof, the number of inches of rise per foot (for SI: F = 0.12 x slope, with slope expressed as a percentage), or for an arch or dome, rise-to-span ratio multiplied by 32.

1607.11.2.2 ~~Special-purpose roofs~~ Roof areas serving occupancy functions. Areas of roofs ~~used for promenade purposes,~~ that serve occupancy functions, such as roof gardens, or for assembly ~~purposes~~ or other ~~special~~ similar purposes, and marquees~~, shall be designed for a minimum live load, L_o, as specified in Table 1607.1. Such live loads~~ are permitted to ~~be~~ have their uniformly distributed live loads reduced in accordance with Section 1607.9. Live loads of 100 psf or more at areas of roofs classified as Group A occupancies shall not be reduced.

TABLE 1607.1
MINIMUM UNIFORMLY DISTRIBUTED LIVE LOADS, L_o, AND MINIMUM CONCENTRATED LIVE LOADS [g]

OCCUPANCY OR USE	UNIFORM (psf)	CONCENTRATED (lbs.)
29. Roofs:		
All roof surfaces subject to maintenance workers		300

All other occupancies		300
All roof surfaces subject to maintenance workers		300

(Portions of Table not show, remain unchanged)

Reason This proposal was prepared in conjunction with a proposal to editorially correlate IBC Section 1607 with the provisions of Chapter 4 of ASCE 7-10 related to floor live load reduction. This proposal focuses on editorial correlation for roof live load reduction and is intended to further align IBC Section 1607 with Chapter 4 of ASCE 7-10 without any overlapping or conflicting changes between the two proposals. The changes in this proposal are seen as largely editorial.

The items under "roofs" in Table 1607.1 are reorganized to align them with Section 1607.11.2 on the reduction of live loads at roofs. Section 1607.11.2 permits reductions in uniform live loads at roofs and marquees "in accordance with Section 1607.11.2.1 or 1607.11.2.2." These sections, in turn, refer to items under "roofs" in Table 1607.1 except for marquees, which are separately listed in the table. The reorganization of the items under "roofs" is intended to reduce confusion over the applicability of roof live load reduction at "ordinary flat, pitched and curved roofs" in Section 1607.11.2.1, which applies to roofs that do not serve an occupancy function but are susceptible to loads from maintenance workers, and at roofs that serve an occupancy function in Section 1607.11.2.2, which are the structural equivalent of floors. Section 1607.11.2.1 also applies to awnings and canopies and the title of the section is changed accordingly. Table 1607.1 is reorganized so that it aligns with these sections.

The changes to Section 1607.9 and the deletion of Section 1607.9.1.5 eliminate superfluous text. Section 1607.9 provides the charging text for reduction of uniformly distributed live loads at floors. The changes retain the reference to Section 1607.11.2 on roof live load reduction but delete the text referring to special purpose roofs in favor of the charging text in Section 1607.11.2.

Section 1607.11.2.2 is changed to align it with the corresponding provisions in Section 4.8.2 of ASCE 7-10. Section 4.9.2 of ASCE 7-05 currently specifies roofs "that have an occupancy function" but the title of the section is "special purpose roofs." The proponent is requesting the title be changed to "roof areas serving an occupancy function" in Section 4.8.2 of ASCE 7-10 and IBC Section 1607.11.2.2 is changed accordingly. Section 4.8.2 of ASCE 7-10 specifies roof gardens and areas used for "assembly or other similar purposes" as examples of roof areas that serve occupancy functions. Section 4.9.2 of ASCE 7-05 is similar. Table 4-1 of ASCE 7-05, however, lists roofs used for promenade purposes along with roofs used for roof gardens or for assembly or other special purposes. This listing of roofs used for promenade purposes is deleted in Table 4-1 of ASCE 7-10 and IBC Table 1607.1 is changed accordingly.

The proponent is requesting "other special purposes" be changed to "other similar purposes" in Section 4.8.2 and Table 4-1 of ASCE 7-10 in conjunction with the requested change in the title of Section 4.8.2 from "special purpose roofs" to "roof areas serving an occupancy function." IBC Section 1607.11.2.2 and Table 1607.1 are changed accordingly. Note that the uniform live load at roofs used for other special purposes in Table 4-1 of ASCE 7-05 and 2009 IBC Table 1607.1, and at other similar areas of roofs serving an occupancy function in IBC Table 1607.1 of this proposal, is not specified in favor of a footnote specifying appropriate loads as approved by the authority having jurisdiction (ASCE 7) or building official (IBC) and is not affected by this proposal.

Footnotes (g) and (l) to Table 1607.1 are revised for consistency with the changes to Section 1607.11.2.2 above. The deletion in Footnote (g) also eliminates a superfluous cross-reference.

A separate proposal correlates the IBC with changes to the provisions of ASCE 7-10 where reduction of live loads at floors and occupied roofs is restricted or prohibited. That proposal adds Footnote (m) to "100 psf" at "roofs used for assembly purposes" in the item for roofs in Table 1607.1. The addition of the footnote is not repeated in this proposal but, should this proposal and the proposal adding the footnote be approved by the membership, the proponent intends that Footnote (m) be specified with "100 psf" at "assembly areas" under "roofs serving an occupancy function" in the item for roofs in Table 1607.1.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: Brazil-S14-1607.9

Public Hearing Results

Committee Action: **Approved as Modified**

Modify the proposal as follows:

TABLE 1607.1
MINIMUM UNIFORMLY DISTRIBUTED LIVE LOADS, L_o, AND MINIMUM CONCENTRATED LIVE LOADS [g]

OCCUPANCY OR USE	UNIFORM (psf)	CONCENTRATED (lbs.)
29. Roofs:		
All roof surfaces subject to maintenance workers		300
Awnings and canopies:		
Fabric construction supported by a lightweight rigid skeleton structure	5 nonreduceable	
All other construction	20	
Ordinary flat, pitched, and curved roofs (not serving an occupancy function)	20	
Primary roof members, exposed to a work floor:		
Single panel point of lower chord of roof trusses or any point along primary structural members supporting roofs over manufacturing, storage warehouses, and repair garages		2,000
All other occupancies		300
Roofs serving an occupancy function:		
Roof gardens	~~60~~ 100	
Assembly areas	100	
All other similar areas	Note l	Note l

(Portions of Table not show, remain unchanged)

Portions of proposal not shown are unchanged

Committee Reason: By deleting duplicate text and reorganizing the roof live load requirements, this code change clarifies this portion of the code. The modification reverses the reorganization of Table 1607.1 in item 2 and also restores roof live loads that were not intended to be included in this code change.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Maureen Traxler, City of Seattle Department of Planning & Development, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

1607.11.2.2 Occupiable roof ~~Roof~~ areas ~~serving occupancy functions~~. Areas of roofs that ~~serve occupancy functions~~ are occupiable, such as roof gardens, or for assembly or other similar purposes, and marquees are permitted to have their uniformly distributed live loads reduced in accordance with Section 1607.9. Live loads of 100 psf or more at areas of roofs classified as Group A occupancies shall not be reduced.

TABLE 1607.1
MINIMUM UNIFORMLY DISTRIBUTED LIVE LOADS, *Lo*, AND MINIMUM CONCENTRATED LIVE LOADS[g]

OCCUPANCY OR USE	UNIFORM (psf)	CONCENTRATED (lbs.)
29. Roofs:		
All roof surfaces subject to maintenance workers		300
Awnings and canopies<u>:</u>		
Fabric construction supported by a lightweight rigid skeleton structure	5 nonreduceable	
All other construction	20	
Ordinary flat, pitched, and curved roofs (~~not serving an occupancy function~~ <u>that are not occupiable</u>)	20	
Primary roof members, exposed to a work floor:		
Single panel point of lower chord of roof trusses or any point along primary structural members supporting roofs over manufacturing, storage warehouses, and repair garages		2,000
All other occupancies		300
<u>Occupiable roofs</u> ~~Roofs~~ serving an occupancy function:		
Roof gardens	100	
Assembly areas	100	
All other similar areas	Note l	Note l

(Portions of Table not show, remain unchanged)

l. Areas of <u>occupiable</u> roofs ~~serving an occupancy function~~, other than roof gardens and assembly areas, shall be designed for appropriate loads as approved by the building official.

(Portions of proposal not shown remain unchanged)

Commenter's Reason: This proposed modification more clearly states where the roof live loads are intended to be used. "Serving an occupancy function" is not clear—"occupancy function" is not defined, and the phrase is not used elsewhere in the Code. It could be construed to apply to roofs that are accessory to an occupancy (i.e., they "serve" the "occupancy"). The loads for roofs "serving an occupancy function" are intended to apply when the roof can be occupied, not just when it's accessory to another space.

Final Action: AS AM AMPC____ D

S81-09/10
1607.13

<u>Proposed Change as Submitted</u>

Proponent: Stephen Kerr, PE, SE, representing self

Revise as follows:

1607.13 Interior walls and partitions. Interior walls and partitions that exceed 6 feet (1829 mm) in height, including their finish materials, shall have adequate strength to resist the loads to which they are subjected but not less than a horizontal load of 5 psf (0.240 kN/m^2). <u>For the purposes of calculating deflection, the loading of this section shall be treated as a wind load in accordance with Table 1604.3.</u>

> **Exception:** Fabric partitions complying with Section 1607.13.1 shall not be required to resist the minimum horizontal load of 5 psf (0.240 kN/m^2)

Reason: Currently, Table 1604.3 does not have deflection limits for Live Loads on Interior walls. The 5.0 psf requirement in section 1607.13 is classified as a live load and would not require a deflection check. Under the legacy Uniform Building Code this load was treated as an "other load" and was required to meet the defection limits identical to those in IBC Table 1604.3. To avoid confusion for walls, and to require deflection checks on interior walls, the proposed code change is necessary.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: KERR-S3-1607.13

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The proposed wording creates confusion as to why the specified partition live load should be considered a wind load when used in Table 1604.3 for determining allowable deflections. It would be preferable to state the deflection limit prescriptively or fix the table. A public comment is encouraged.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Don Allen, Steel Framing Alliance, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

1607.13 Interior walls and partitions. Interior walls and partitions that exceed 6 feet (1829 mm) in height, including their finish materials, shall have adequate strength to resist the loads to which they are subjected but not less than a horizontal load of 5 psf (0.240 kN/m^2). ~~For the purposes of calculating deflection, the loading of this section shall be treated as a wind load in accordance with Table 1604.3.~~

Exception: Fabric partitions complying with Section 1607.13.1 shall not be required to resist the minimum horizontal load of 5 psf (0.240 kN/m^2).

TABLE 1604.3
DEFLECTION LIMITS[a, b, c, h, i]

CONSTRUCTION	*L*	*S* or W [f]	*D* + *L*[d, g]
Roof members:[e]			
Supporting plaster ceiling	*l*/360	*l*/360	*l*/240
Supporting nonplaster ceiling	*l*/240	*l*/240	*l*/180
Not supporting ceiling	*l*/180	*l*/180	*l*/120
Floor members	*l*/360	—	*l*/240
Exterior walls and interior partitions:			
<u>With plaster or stucco finishes</u>	<u>*l*/360</u>	<u>*l*/360</u>	—
With <u>other</u> brittle finishes	<u>*l*/240</u>	*l*/240	—
With flexible finishes	<u>*l*/120</u>	*l*/120	—
Farm buildings	—	—	*l*/180
Greenhouses	—	—	*l*/120

b. Interior partitions not exceeding 6 feet in height and flexible, folding and portable partitions are not governed by the provisions of this section. The ~~deflection criterion for interior partitions is based on the~~ horizontal load defined in Section 1607.13<u> is permitted to be multiplied by 0.7 for the purpose of determining deflection limits herein</u>.

(No change to footnotes a and c through i)

Commenter's Reason: The IBC does not give deflection limits for Live Loads on Interior walls. Although historically treated as a wind load, the 5.0 psf requirement in section 1607.13 is classified as a live load and does not require a deflection check. Under the Uniform Building Code this 5.0 psf was treated as an "other load" and interior partitions were required to meet L/120 for flexible finishes and L/240 for brittle finishes. This code change is needed to fix an error which permits interior walls to be designed without deflection checks.

The additional language in footnote B would make the interior wall requirements consistent with the exterior wall requirements in footnote F: walls use the load combinations in section 1605 for strength checks, and use a 0.7 load factor for deflection checks. This is a conservative application of chapter C, Appendix C (entitled *Serviceability Considerations*) of the ASCE 7-05 commentary. ASCE 7-05 section CC.1.2 includes the following: "Use of the factored wind load in checking serviceability is excessively conservative. The load combination with an annual probability of 0.05 of being exceeded, which can be used for checking short-term effects, is D + 0.5L + 0.7W." Note that this proposed load factor would not apply to other loads on partitions, such as earthquake loads.

This public comment is in response to the committee action on proposal S81, which specifically encouraged a public comment and suggested fixing table 1604.3. This also addresses the additional line for stucco and plaster added to this table by S35-09/10.

Public Comment 2:

Edwin Huston, National Council of Structural Engineers Association (NCSEA), representing NCSEA Code Advisory Subcommittee – General Requirements Subcommittee, request Approval as Modified by this Public Comment.

Modify the proposal as follows:

1607.13 Interior walls and partitions. Interior walls and partitions that exceed 6 feet (1829 mm) in height, including their finish materials, shall have adequate strength and stiffness to resist the loads to which they are subjected but not less than a horizontal load of 5 psf (0.240 kN/m^2). ~~For the purposes of calculating deflection, the loading of this section shall be treated as a wind load in accordance with Table 1604.3.~~

Exception: Fabric partitions complying with Section 1607.13.1 shall not be required to resist the minimum horizontal load of 5 psf (0.240 kN/m^2).

TABLE 1604.3
DEFLECTION LIMITS[a, ~~b,~~ c, h, i]

CONSTRUCTION	*L*	*S* or W[f]	*D* + *L*[d, g]
Roof members:[e]			
Supporting plaster ceiling	*l*/360	*l*/360	*l*/240
Supporting nonplaster ceiling	*l*/240	*l*/240	*l*/180
Not supporting ceiling	*l*/180	*l*/180	*l*/120
Floor members	*l*/360	—	*l*/240
Exterior walls ~~and interior partitions~~:			
With brittle finishes	—	*l*/240	—
With flexible finishes	—	*l*/120	—
Interior partitions:[b]			
With other brittle finishes	*l*/240		
With flexible finishes	*l*/120		
Farm buildings	—	—	*l*/180
Greenhouses	—	—	*l*/120

(No change to footnotes)

Commenter's Reason: Currently, Table 1604.3 does not have deflection limits for Live Loads on Interior walls. The 5.0 psf requirement in Section 1607.13 is classified as a live load and would not require a deflection check. Under the legacy Uniform Building Code this load was treated as an "other load" and was required to meet the defection limits identical to those in IBC Table 1604.3. To avoid confusion for walls, and to require deflection checks on interior walls, the proposed code change is necessary.

Under the original S81 proposal the intent was to reference the deflection criteria by reclassifying the 5.0psf load as a wind load and using the deflection criteria in the S or W column of Table 1604.3. The proponent understands that this wording may create unwanted confusion. To eliminate the possible confusion, the new item will add the defection criteria in Table 1604.3 for Live Loads on interior partitions.

The ICC Structural Committee urged the proponent to develop a Public Comment and in fact, Mr. Cole Graveen, a member of the ICC Structural Committee worked with the proponent and with NCSEA to correct this issue through this Public Comment.

Final Action: AS AM AMPC____ D

S83-09/10

1602.1, 1608.3 (new), 1611.2

Proposed Change as Submitted

Proponent: Philip Brazil, PE, SE, Reid Middleton, Inc., representing self

1. Add new definition as follows:

1602.1 Definitions. The following words and terms shall, for the purposes of this chapter, have the meanings shown herein.

SUSCEPTIBLE BAY. A roof or portion thereof with (1) a slope less than 1/4-inch per foot (0.0208 rad), or (2) where water will be impounded upon it, in whole or in part, and the secondary drainage system is functional but the primary drainage system is not functional. A roof surface with a slope of 1/4-inch per foot (0.0208 rad) or greater towards points of free drainage is not a susceptible bay.

2. Add new text as follows:

1608.3 Ponding instability. Susceptible bays of roofs shall be evaluated for ponding instability in accordance with Section 7.11 of ASCE 7.

3. Revise as follows:

1611.2 Ponding instability. ~~For~~ Susceptible bays of roofs ~~with a slope less than 1/4 inch per foot [1.19 degrees (0.0208 rad)], the design calculations~~ shall ~~include verification of~~ be investigated by structural analysis to ensure that they possess adequate stiffness to preclude progressive deflection in accordance with Section 8.4 of ASCE 7.

Reason: The purpose for the proposal is to correlate the IBC with the 2010 edition of ASCE 7. The need for correlation is due to an ASCE 7 proposal on ponding instability, which was approved by the Snow/Rain Subcommittee and is being balloted by the Main Committee (Item #3 of the ASCE 7 Third Main Committee Ballot on Snow and Rain Provisions). It is expected that the Main Committee will approve the proposal.

Susceptible bays of roofs are required to meet the technical provisions of ASCE 7-10 for precluding progressive deflection. A "susceptible bay" is defined in Section 8.4 of ASCE 7-10 and this definition is being added to the IBC. Having a definition of "susceptible bay" in the IBC will provide a technical basis for determining which bays of a roof are susceptible bays and, thus, are required to meet the technical provisions of ASCE 7-10 for them. All bays of roofs other than susceptible bays are not required to meet these technical provisions.

Without the definition, the IBC will be without effective charging text. IBC Sections 1608.3 and 1611.2 rely on the determination of which bays are susceptible bays in order to determine the need to comply with the applicable provisions of ASCE 7. That determination is not possible unless a definition of "susceptible bay" is included in the IBC.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: Brazil-S37-1602.1

Public Hearing Results

Committee Action: **Approved as Modified**

Modify the proposal as follows:

SUSCEPTIBLE BAY. A roof or portion thereof with (1) a slope less than 1/4-inch per foot (0.0208 rad), or (2) ~~where~~ on which water ~~will be~~ is impounded upon it, in whole or in part, and the secondary drainage system is functional but the primary drainage system is ~~not functional~~ blocked. A roof surface with a slope of 1/4-inch per foot (0.0208 rad) or greater towards points of free drainage is not a susceptible bay.

1611.2 Ponding instability. Susceptible bays of roofs shall be ~~investigated by structural analysis to ensure that they possess adequate stiffness to preclude progressive deflection~~ evaluated for ponding instability in accordance with Section 8.4 of ASCE 7.

(Portions of proposal not shown are unchanged)

Committee Reason: This code change enhances the safety of roofs by correlating the IBC with the ponding instability provisions of ASCE 7. In addition to covering portions of roofs with a slope up to ¼ inch per foot, it also addresses greater slopes that do not drain to a point of free drainage. The modification reflects further updates made in the ASCE 7 development process.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Homer Maiel, PE., CBO., City of San Jan Jose, representing ICC Tri-Chapter (Peninsula, East Bay, Monterey Chapters), requests Disapproval.

Commenter's Reason: The wording of the proposed new definition for "*Susceptible Bay*", approved as part of the floor modification of item S83 contains very confusing wording that will certainly result in uneven or incorrect application and enforcement. This commenter considered submitting a public comment proposing alternative wording, however, it is impossible to know from the original submittal exactly what was intended, or how to fix it, therefore this public comment is recommending disapproval.

The structural implications (potential collapse) of water ponding on roof surfaces is a longstanding and very important safety issue that must have clear and unambiguous rules for both the design professional and the code enforcement community. The current code Section 1611.2 Ponding instability, achieves that goal because it is a clearly written and easily understood provision that applies to all roofs with a slope less than ¼ inch per foot. We are aware that the proposed new definition is derived from the final ballot draft of ASCE 7-10, but we do not agree that placing confusing language into the building code is an appropriate solution to achieving desired consistency of structural provisions, nor to achieve the important protection the code should provide from ponding induced roof collapses.

The difficulty with new definition is specifically located in its item 2), where it attempts to define portions of roofs that are not sloped less than ¼ inch per foot that must additionally comply with Section 8.4 of ASCE 7. The statement: "*A roof or portion thereof …2) on which water is impounded upon it, in whole or in part, and the secondary drainage system is functional but the primary drainage system is blocked*" is very poorly worded and is simply unclear regarding the intended scope of application.

While it is reasonably clear that the definition intends to address a condition where water ponding occurs due to the the blockage of one or more primary roof drains, the actual extent of what portions of the roof become a *susceptible bay* is anything but clear. As currently written, one could easily conclude that because when any primary drain is blocked water will pond up to the level of the secondary drain serving that portion of the roof, then each and every roof area where water cannot freely drain over an edge becomes a *susceptible bay*. If that was the intent, there certainly must be a better way to explain it. Additional enforcement and design application questions that will arise from the current definition include:

How deep must the water be to trigger this definition? Using the wording "*in whole or in part*" would imply any depth above zero. If that was intended, then even if a secondary drain is a scupper, or a roof edge, and is only 1 inch higher than the inlet of the primary drain, that roof area where the water ponds only one inch deep is still a *susceptible bay*.

Was there a minimum ponding depth threshold considered when drafting this change within the ASCE 7 committee? If there was, why is that depth not included in the definition? If no minimum depth was considered, what substantiation was provided to justify that any depth above zero when a primary drain is blocked creates the susceptible bay that requires additional design analysis?

While the final sentence of the definition appears to be clear, does a "*point of free drainage"* occur where the roof has a slightly raised edge at its perimeter, as is a common construction practice, or only when the flow of water is totally unimpeded on a slope of at least ¼ inch per foot to, and over, that edge?

Final Action: AS AM AMPC____ D

S84-09/10

1602, 1609.1.2.2-1710.3

Proposed Change as Submitted

Proponent: Jim Rossberg, SEI of ASCE, representing self

1. Add new text as follows:

SECTION 1602
DEFINITIONS AND NOTATIONS

NOTATIONS.

V_{asd} = nominal design wind speed (3-sec gust), miles per hour (mph) (km/hr) where applicable.

V_{ult} = ultimate design wind speeds (3-sec gust), miles per hour (mph) (km/hr) determined from Figures 1609A, 1609B, or 1609C or ASCE 7.

2. Revise as follows:

1603.1 General. Construction documents shall show the size, section and relative locations of structural members with floor levels, column centers and offsets dimensioned. The design loads and other information pertinent to the structural design required by Sections 1603.1.1 through 1603.1.9 shall be indicated on the *construction documents*.

> **Exception:** *Construction documents* for buildings constructed in accordance with the *conventional light-frame construction* provisions of Section 2308 shall indicate the following structural design information:
>
> 1. Floor and roof live loads.
> 2. Ground snow load, P_g.
> 3. ~~Basic~~ Ultimate design wind speed, V_{ult} , (3-second gust), miles per hour (mph) (km/hr) and nominal design wind speed, V_{asd}, as determined in accordance with Section 1609.3.1 and wind exposure.
> 4. *Seismic design category* and *site class*.
> 5. Flood design data, if located in *flood hazard areas* established in Section 1612.3.
> 6. Design load-bearing values of soils.

1603.1.4 Wind design data. The following information related to wind loads shall be shown, regardless of whether wind loads govern the design of the lateral-force-resisting system of the building:

1. ~~Basic~~ Ultimate design wind speed, V_{ult}, (3-second gust), miles per hour (km/hr) and nominal design wind speed, V_{asd} , as determined in accordance with Section 1609.3.1.
2. Wind importance factor, *I*, and *occupancy category*.

3. Wind exposure. Where more than one wind exposure is utilized, the wind exposure and applicable wind direction shall be indicated.
4. The applicable internal pressure coefficient.
5. Components and cladding. The design wind pressures in terms of psf (kN/m_2) to be used for the design of exterior component and cladding materials not specifically designed by the *registered design professional*

TABLE 1604.3
DEFLECTION LIMITS[a,b,c,h,i]
(No change to table)

(No change to footnotes a-e)
f. The wind load is permitted to be taken as 0.42 ~~0.7~~ times the "component and cladding" loads for the purpose of determining deflection limits herein.
(No change to footnotes g-i)

1605.2.1 Basic load combinations. Where strength design or *load and resistance factor design* is used, structures and portions thereof shall resist the most critical effects from the following combinations of factored loads:

$1.4 (D+F)$	**(Equation 16-1)**
$1.2(D + F + T) + 1.6(L + H) + 0.5 (L_r \text{ or } S \text{ or } R)$	**(Equation 16-2)**
$1.2D + 1.6(L_r \text{ or } S \text{ or } R) + (f_1L \text{ or } \cancel{0.8W}\ \underline{0.5W})$	**(Equation 16-3)**
$1.2D + \cancel{1.6}\ \underline{1.0}W + f_1L + 0.5(L_r \text{ or } S \text{ or } R)$	**(Equation 16-4)**
$1.2D + 1.0E + f_1L + f_2S$	**(Equation 16-5)**
$0.9D + \cancel{1.6}\ \underline{1.0}W + 1.6H$	**(Equation 16-6)**
$0.9D + 1.0E + 1.6H$	**(Equation 16-7)**

where:

f_1 = 1 for floors in places of public assembly, for live loads in excess of 100 pounds per square foot (4.79 kN/m^2), and for parking garage live load, and
= 0.5 for other live loads.
f_2 = 0.7 for roof configurations (such as saw tooth) that do not shed snow off the structure, and
= 0.2 for other roof configurations.

Exception: Where other factored load combinations are specifically required by the provisions of this code, such combinations shall take precedence.

1605.3.1 Basic load combinations. Where *allowable stress design* (working stress design), as permitted by this code, is used, structures and portions thereof shall resist the most critical effects resulting from the following combinations of loads:

$D+F$	**(Equation 16-8)**
$D+H+F+ L + T$	**(Equation 16-9)**
$D+H+F+ (L_r \text{ or } S \text{ or } R)$	**(Equation 16-10)**
$D + H + F + 0.75(L + T) + 0.75 (L_r \text{ or } S \text{ or } R)$	**(Equation 16-11)**
$D+H+F+(\underline{0.6}W \text{ or } 0.7E)$	**(Equation 16-12)**
$D + H + F + 0.75(\underline{0.6}W \text{ or } 0.7E) + 0.75L + 0.75 (L_r \text{ or } S \text{ or } R)$	**(Equation 16-13)**
$0.6D + \underline{0.6}W+H$	**(Equation 16-14)**

$0.6D + 0.7E + H$ **(Equation 16-15)**

Exceptions:

1. Crane hook loads need not be combined with roof live load or with more than three-fourths of the snow load or one-half of the wind load.
2. Flat roof snow loads of 30 psf (1.44 kN/m^2) or less and roof live loads of 30 psf or less need not be combined with seismic loads. Where flat roof snow loads exceed 30 psf (1.44 kN/m^2), 20 percent shall be combined with seismic loads.

1605.3.2 Alternative basic load combinations. In lieu of the basic load combinations specified in Section 1605.3.1, structures and portions thereof shall be permitted to be designed for the most critical effects resulting from the following combinations. When using these alternative basic load combinations that include wind or seismic loads, allowable stresses are permitted to be increased or load combinations reduced where permitted by the material chapter of this code or the referenced standards. For load combinations that include the counteracting effects of dead and wind loads, only two-thirds of the minimum dead load likely to be in place during a design wind event shall be used. Where wind loads are calculated in accordance with Chapters 26 through 31 ~~Chapter 6~~ of ASCE 7, the coefficient . in the following equations shall be taken as 0.78 ~~1.3~~. For other wind loads, shall be taken as 1. When using these alternative load combinations to evaluate sliding, overturning and soil bearing at the soil-structure interface, the reduction of foundation overturning from Section 12.13.4 in ASCE 7 shall not be used. When using these alternative basic load combinations for proportioning foundations for loadings, which include seismic loads, the vertical seismic *load effect*, E_v, in Equation 12.4-4 of ASCE 7 is permitted to be taken equal to zero.

$D + L + (L_r \text{ or } S \text{ or } R)$ **(Equation 16-16)**

$D + L + (\omega W)$ **(Equation 16-17)**

$D + L + \omega W + S/2$ **(Equation 16-18)**

$D + L + S + \omega W/2$ **(Equation 16-19)**

$D + L + S + E/1.4$ **(Equation 16-20)**

$0.9D + E/1.4$ **(Equation 16-21)**

Exceptions:

1. Crane hook loads need not be combined with roof live loads or with more than three-fourths of the snow load or one-half of the wind load.
2. Flat roof snow loads of 30 psf (1.44 kN/m^2) or less and roof live loads of 30 psf or less need not be combined with seismic loads. Where flat roof snow loads exceed 30 psf (1.44 kN/m^2), 20 percent shall be combined with seismic loads.

1609.1.1 Determination of wind loads. Wind loads on every building or structure shall be determined in accordance with Chapters 26 to 30 ~~6~~ of ASCE 7 ~~or provisions of the alternate all-heights method in Section 1609.6~~. The type of opening protection required, the ~~basic~~ ultimate design wind speed, V_{ult}, and the exposure category for a site is permitted to be determined in accordance with Section 1609 or ASCE 7. Wind shall be assumed to come from any horizontal direction and wind pressures shall be assumed to act normal to the surface considered.

Exceptions:

1. Subject to the limitations of Section 1609.1.1.1, the provisions of ICC 600 shall be permitted for applicable Group R-2 and R-3 buildings.
2. Subject to the limitations of Section 1609.1.1.1, residential structures using the provisions of the AF&PA WFCM.
3. Subject to the limitations of Section 1609.1.1.1, residential structures using the provisions of AISI S230.
4. Designs using NAAMM FP 1001.
5. Designs using TIA-222 for antenna-supporting structures and antennas.
6. Wind tunnel tests in accordance with Chapter 31 ~~Section 6.6~~ of ASCE 7~~, subject to the limitations in Section 1609.1.1.2~~.

The wind speeds in Figure 1609A, 1609B and 1609C are ultimate design wind speeds, V_{ult}, and shall be converted in accordance with Section 1609.3.1 to nominal design wind speeds, V_{asd}, when the provisions of the standards referenced in Exceptions 1 through 5 are used.

4. Delete without substitution as follows:

~~**1609.1.1.2 Wind tunnel test limitations.** The lower limit on pressures for main wind-force-resisting systems and components and cladding shall be in accordance with Sections 1609.1.1.2.1 and 1609.1.1.2.2.~~

~~**1609.1.1.2.1 Lower limits on main wind-force-resisting system.** Base overturning moments determined from wind tunnel testing shall be limited to not less than 80 percent of the design base overturning moments determined in accordance with Section 6.5 of ASCE 7, unless specific testing is performed that demonstrates it is the aerodynamic coefficient of the building, rather than shielding from other structures, that is responsible for the lower values.~~
~~The 80-percent limit shall be permitted to be adjusted by the ratio of the frame load at critical wind directions as determined from wind tunnel testing without specific adjacent buildings, but including appropriate upwind roughness, to that determined in Section 6.5 of ASCE 7.~~

~~**1609.1.1.2.2 Lower limits on components and cladding.** The design pressures for components and cladding on walls or roofs shall be selected as the greater of the wind tunnel test results or 80 percent of the pressure obtained for Zone 4 for walls and Zone 1 for roofs as determined in Section 6.5 of ASCE 7, unless specific testing is performed that demonstrates it is the aerodynamic coefficient of the building, rather than shielding from nearby structures, that is responsible for the lower values. Alternatively, limited tests at a few wind directions without specific adjacent buildings, but in the presence of an appropriate upwind roughness, shall be permitted to be used to demonstrate that the lower pressures are due to the shape of the building and not to shielding.~~

5. Revise as follows:

1609.1.2 Protection of openings. In *wind-borne debris regions*, glazing in buildings shall be impact resistant or protected with an impact-resistant covering meeting the requirements of an *approved* impact-resistant standard or ASTM E 1996 and ASTM E 1886 referenced herein as follows:

1. Glazed openings located within 30 feet (9144 mm) of grade shall meet the requirements of the Large Missile Test of ASTM E 1996.
2. Glazed openings located more than 30 feet (9144 mm) above grade shall meet the provisions of the small missile test of ASTM E 1996.

Exceptions:

1. Wood structural panels with a minimum thickness of 7/16 inch (11.1 mm) and maximum panel span of 8 feet (2438 mm) shall be permitted for opening protection in one- and two-story buildings classified as Group R-3 or R-4 occupancy. Panels shall be precut so that they shall be attached to the framing surrounding the opening containing the product with the glazed opening. Panels shall be predrilled as required for the anchorage method and shall be secured with the attachment hardware provided. Attachments shall be designed to resist the components and cladding loads determined in accordance with the provisions of ASCE 7, with corrosion-resistant attachment hardware provided and anchors permanently installed on the building. Attachment in accordance with Table 1609.1.2 with corrosion-resistant attachment hardware provided and anchors permanently installed on the building is permitted for buildings with a mean roof height of 45 feet (13 716 mm) or less where V_{asd} determined in accordance with Section 1609.3.1 ~~wind speeds do~~ does not exceed 140 mph (63 m/s).
2. Glazing in *Occupancy Category* I buildings as defined in Section 1604.5, including greenhouses that are occupied for growing plants on a production or research basis, without public access shall be permitted to be unprotected.
3. Glazing in *Occupancy Category* II, III or IV buildings located over 60 feet (18 288 mm) above the ground and over 30 feet (9144 mm) above aggregate surface roofs located within 1,500 feet (458 m) of the building shall be permitted to be unprotected.

6. Add new text as follows:

1609.1.2.2. Modifications to ASTM E 1996. Section 6.2.2 of ASTM E 1996 shall be modified as follows:

6.2.2 Unless otherwise specified, select the wind zone based on the strength design wind speed, V_{ult}, as follows:
6.2.2.1 *Wind Zone 1* - 130 mph ≤ ultimate design wind speed, V_{ult} < 140 mph.
6.2.2.2 *Wind Zone 2* - 140 mph ≤ ultimate design wind speed, V_{ult} < 150 mph at greater than 1.6 km (one mile) from the coastline. The coastline shall be measured from the mean high water mark.
6.2.2.3 *Wind Zone 3* - ultimate design wind speed, V_{ult} ≥ 150 mph, or the ultimate design wind speed, V_{ult} ≥ 140 mph and within 1.6 km (one mile) of the coastline. The coastline shall be measured from the mean high water mark.

7. Revise as follows:

1609.2 Definitions. The following words and terms shall, for the purposes of Section 1609, have the meanings shown herein.

HURRICANE-PRONE REGIONS. Areas vulnerable to hurricanes defined as:

1. The U. S. Atlantic Ocean and Gulf of Mexico coasts where the ~~basic~~ ultimate design wind speed, V_{ult}, for Occupancy Category II buildings is greater than 115 ~~90~~ mph (40 m/s) and
2. Hawaii, Puerto Rico, Guam, Virgin Islands and American Samoa.

WIND-BORNE DEBRIS REGION. Areas within ~~Portions of~~ *hurricane- prone regions* located: ~~that are~~

1. W~~w~~ithin 1 mile (1.61 km) of the coastal mean high water line where the ~~basic~~ ultimate design wind speed V_{ult} is 130 ~~110 mph~~ (48 m/s) or greater; or
2. In areas ~~portions of *hurricane-prone regions*~~ where the ~~basic~~ ultimate design wind speed is V_{ult} 140 ~~120~~ mph (53 m/s) or greater~~; or Hawaii.~~

For Occupancy Category II buildings and structures and Occupancy Category III buildings and structures, except health care facilities, the windborne debris region shall be based on Figure 1609b. For Occupancy Category IV buildings and structures and Occupancy Category III health care facilities, the windborne debris region shall be based on Figure 1609c.

8. Add new definitions as follows:

1609.2 Definitions.

WIND SPEED, V_{ult}. Ultimate design wind speeds.

WIND SPEED, V_{asd}. Nominal design wind speeds.

9. Revise as follows:

1609.3 Basic wind speed. The ~~basic~~ ultimate design wind speed V_{ult}, in mph, for the determination of the wind loads shall be determined by ~~Figure 1609~~ Figures 1609A, 1609B and 1609C. The ultimate design wind speed, V_{ult}, for use in the design of Occupancy Category II buildings and structures shall be obtained from Figure 1609A. The ultimate design wind speed, V_{ult}, for use in the design of Occupancy Category III and IV buildings and structures shall be obtained from Figure 1609B. The ultimate design wind speed, V_{ult}, for use in the design of Occupancy Category I buildings and structures shall be obtained from Figure 1609C. ~~Basic~~ The ultimate design wind speed, V_{ult}, for the special wind regions indicated, near mountainous terrain and near gorges shall be in accordance with local jurisdiction requirements. ~~Basic~~ The ultimate design wind speeds, V_{ult}, determined by the local jurisdiction shall be in accordance with Section 26.5.1 ~~6.5.4~~ of ASCE 7.

In nonhurricane-prone regions, when the ~~basic~~ ultimate design wind speed, V_{ult}, is estimated from regional climatic data, the ~~basic~~ ultimate design wind speed, V_{ult}, shall be ~~not less than the wind speed associated with an annual probability of 0.02 (50-year mean recurrence interval), and the estimate shall be adjusted for equivalence to a 3-second gust wind speed at 33 feet (10 m) above ground in Exposure Category C. The data analysis shall be performed~~ determined in accordance with Section 26.5.3 ~~6.5.4.2~~ of ASCE 7.

10. Delete and substitute as follows:

~~**FIGURE 1609**~~
~~**BASIC WIND SPEED (3-SECOND GUST)**~~

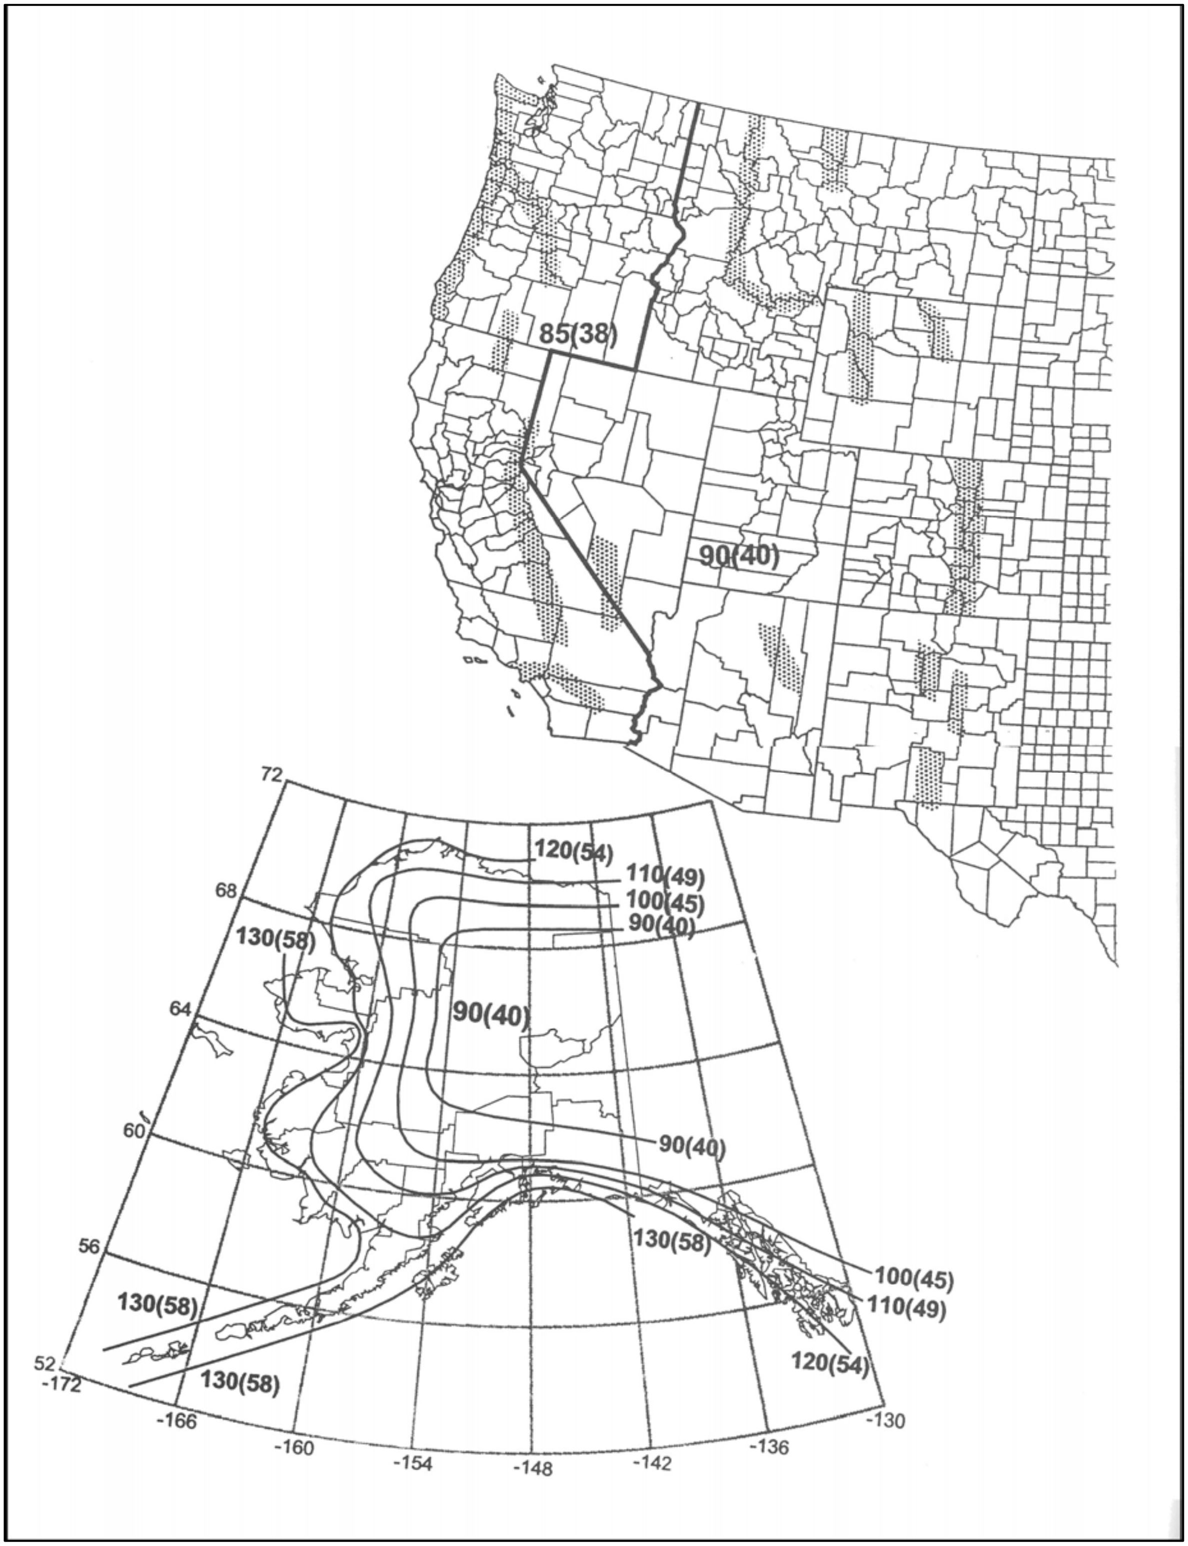

FIGURE 1609A
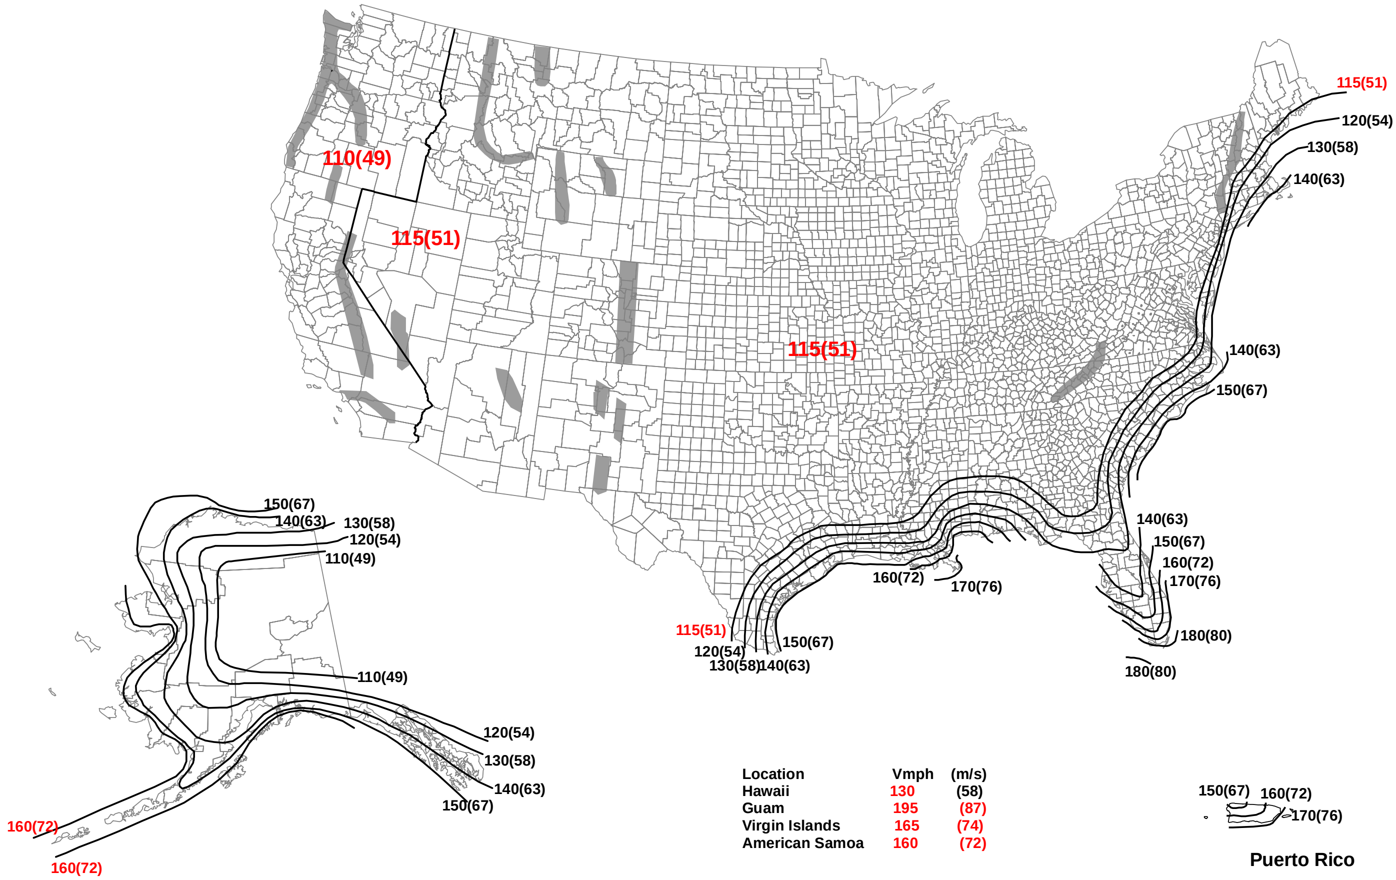
ULTIMATE DESIGN WIND SPEEDS, V_{ULT}, FOR OCCUPANCY CATEGORY II BUILDINGS AND OTHER STRUCTURES



Notes:
1. Values are nominal design 3-second gust wind speeds in miles per hour (m/s) at 33 ft (10m) above ground for Exposure C category.
2. Linear interpolation between contours is permitted.
3. Islands and coastal areas outside the last contour shall use the last wind speed contour of the coastal area.
4. Mountainous terrain, gorges, ocean promontories, and special wind regions shall be examined for unusual wind conditions.
5. Wind speeds correspond to approximately a 7% probability of exceedance in 50 years.

Location	V mph	(m/s)
Hawaii - <u>Special Wind Region Statewide</u>	130	(58)
Guam	195	(87)
Virgin Islands	165	(74)

11. Revise as follows:

1609.3.1 Wind speed conversion. When required, the ~~3-second gust basic~~ ultimate design wind speeds of Figure 1609A, B and C shall be converted to nominal design wind speeds, V_{asd}, ~~fastest-mile wind speeds, V_{fm}~~, using Table 1609.3.1 or Equation 16-32.

$$\cancel{V_{fm} = \frac{V_{3S} - 10.5}{1.05}}$$ **(Equation 16-32)**

~~where:~~

~~V_{3S} = 3-second gust basic wind speed from Figure 1609.~~

$V_{asd} = V_{ult}\sqrt{0.6}$

Where:
V_{asd} = nominal design wind speed applicable to methods specified in Exceptions 1 through 5 of Section 1609.1.1
V_{ult} = ultimate design wind speeds determined from Figures 1609A, 1609B, or 1609C

12. Delete and substitute as follows:

~~TABLE 1609.3.1~~
~~EQUIVALENT BASIC WIND SPEEDS~~[~~a,b,c~~]

~~V_{3S}~~	~~85~~	~~90~~	~~100~~	~~105~~	~~110~~	~~120~~	~~125~~	~~130~~	~~140~~	~~145~~	~~150~~	~~160~~	~~170~~

~~For SI: 1 mile per hour = 0.44 m/s.~~
~~a. Linear interpolation is permitted.~~
~~b. *V3S* is the 3-second gust wind speed (mph).~~
~~c. *Vfm* is the fastest mile wind speed (mph).~~

TABLE 1609.3.1
WIND SPEED CONVERSIONS[a,b,c]

V_{ul}	100	110	120	130	140	150	160	170	180	190	200
V_{asd}	78	85	93	101	108	116	124	132	139	147	155

a. Linear interpolation is permitted
b. V_{asd} = nominal design wind speed applicable to methods specified in Exceptions 1 through 5 of Section 1609.1.1
c. V_{ult} = ultimate design wind speeds determined from Figures 1609A, 1609B, or 1609C

13. Revise as follows:

1609.4.2 Surface roughness categories. A ground surface roughness within each 45-degree (0.79 rad) sector shall be determined for a distance upwind of the site as defined in Section 1609.4.3 from the categories defined below, for the purpose of assigning an exposure category as defined in Section 1609.4.3.

Surface Roughness B. Urban and suburban areas, wooded areas or other terrain with numerous closely spaced obstructions having the size of single-family dwellings or larger.

Surface Roughness C. Open terrain with scattered obstructions having heights generally less than 30 feet (9144 mm). This category includes flat open country~~,~~ and grasslands~~, and all water surfaces in *hurricane-prone regions*~~.

Surface Roughness D. Flat, unobstructed areas and water surfaces ~~outside *hurricane-prone regions*~~. This category includes smooth mud flats, salt flats and unbroken ice.

1609.4.3 Exposure categories. An exposure category shall be determined in accordance with the following:

Exposure B. For buildings with a mean roof height of less than or equal to 30 feet, Exposure B shall apply where the ground surface roughness ~~condition~~, as defined by Surface Roughness B, prevails in the upwind direction for a distance of at least 1,500 feet (457 m). For buildings with a mean roof height greater than 30 feet, Exposure B shall apply where Surface Roughness B prevails in the upwind direction for a distance of at least 2,600 feet (792 m) or 20 times the height of the building, whichever is greater.

~~**Exception:** For buildings whose mean roof height is less than or equal to 30 feet (9144 mm), the upwind distance is permitted to be reduced to 1,500 feet (457 m).~~

Exposure C. Exposure C shall apply for all cases where Exposures B or D do not apply.

Exposure D. Exposure D shall apply where the ground surface roughness, as defined by Surface Roughness D, prevails in the upwind direction for a distance of at least 5,000 feet (1524 m) or 20 times the height of the building, whichever is greater. Exposure D shall also apply where the ground surface roughness immediately upwind of the site is B or C, and the site is within a distance of 600 feet (183 m) or 20 times the building height, whichever is greater, from an exposure D condition as defined in the previous sentence. ~~Exposure D shall extend inland from the shoreline for a distance of 600 feet (183 m) or 20 times the height of the building, whichever is greater.~~

1609.5.3 Rigid tile. Wind loads on rigid tile roof coverings shall be determined in accordance with the following equation:

$$M_a = q_h C_L b L L_a [1.0 - GC_p] \qquad \textbf{(Equation 16-33)}$$

$$\text{For SI: } M_a = \frac{q_h C_L b L L_a \left[1.0 - GC_p\right]}{1{,}000}$$

where:

b	=	Exposed width, feet (mm) of the roof tile.
CL	=	Lift coefficient. The lift coefficient for concrete and clay tile shall be 0.2 or shall be determined by test in accordance with Section 1716.2.
GC_p	=	Roof pressure coefficient for each applicable roof zone determined from Chapter 30 ~~6~~ of ASCE 7. Roof coefficients shall not be adjusted for internal pressure.
L	=	Length, feet (mm) of the roof tile.
L_a	=	Moment arm, feet (mm) from the axis of rotation to the point of uplift on the roof tile. The point of uplift shall be taken at 0.76*L* from the head of the tile and the middle of the exposed width. For roof tiles with nails or screws (with or without a tail clip), the axis of rotation shall be taken as the head of the tile for direct deck application or as the top edge of the batten for battened applications. For roof tiles fastened only by a nail or screw along the side of the tile, the axis of rotation shall be determined by testing. For roof tiles installed with battens and fastened only by a clip near the tail of the tile, the moment arm shall be determined about the top edge of the batten with consideration given for the point of rotation of the tiles based on straight bond or broken bond and the tile profile.
Ma	=	Aerodynamic uplift moment, feet-pounds (N-mm) acting to raise the tail of the tile.
q_h	=	Wind velocity pressure, psf (kN/m^2) determined from Section 27.3.2 ~~6.5.10~~ of ASCE 7.

Concrete and clay roof tiles complying with the following limitations shall be designed to withstand the aerodynamic uplift moment as determined by this section.

1. The roof tiles shall be either loose laid on battens, mechanically fastened, mortar set or adhesive set.
2. The roof tiles shall be installed on solid sheathing which has been designed as components and cladding.
3. An underlayment shall be installed in accordance with Chapter 15.
4. The tile shall be single lapped interlocking with a minimum head lap of not less than 2 inches (51 mm).
5. The length of the tile shall be between 1.0 and 1.75 feet (305 mm and 533 mm).
6. The exposed width of the tile shall be between 0.67 and 1.25 feet (204 mm and 381 mm).
7. The maximum thickness of the tail of the tile shall not exceed 1.3 inches (33 mm).
8. Roof tiles using mortar set or adhesive set systems shall have at least two-thirds of the tile's area free of mortar or adhesive contact.

14. Delete without substitution:

~~**1609.6 Alternate all-heights method.** The alternate wind design provisions in this section are simplifications of the ASCE 7 Method 2—Analytical Procedure.~~

~~**1609.6.1 Scope.** As an alternate to ASCE 7 Section 6.5, the following provisions are permitted to be used to determine the wind effects on regularly shaped buildings, or other structures that are regularly shaped, which meet all of the following conditions:~~

1. ~~The building or other structure is less than or equal to 75 feet (22 860 mm) in height with a height-to-leastwidth ratio of 4 or less, or the building or other structure has a fundamental frequency greater than or equal to 1 hertz.~~
2. ~~The building or other structure is not sensitive to dynamic effects.~~
3. ~~The building or other structure is not located on a site for which channeling effects or buffeting in the wake of upwind obstructions warrant special consideration.~~
4. ~~The building shall meet the requirements of a simple diaphragm building as defined in ASCE 7 Section 6.2, where wind loads are only transmitted to the main wind-force-resisting system (MWFRS) at the diaphragms.~~

5. ~~For open buildings, multispan gable roofs, stepped roofs, sawtooth roofs, domed roofs, roofs with slopes greater than 45 degrees (0.79 rad), solid free-standing walls and solid signs, and rooftop equipment, apply ASCE 7 provisions.~~

~~**1609.6.1.1 Modifications.** The following modifications shall be made to certain subsections in ASCE 7: in Section 1609.6.2, symbols and notations that are specific to this section are used in conjunction with the symbols and notations in ASCE 7 Section 6.3.~~

~~**1609.6.2 Symbols and notations.** Coefficients and variables used in the alternate all-heights method equations are as follows:~~

~~*Cnet*~~	~~=~~	~~Net-pressure coefficient based on *Kd* [(*G*) (*Cp*) – (*GCpi*)], in accordance with Table 1609.6.2(2).~~
~~*G*~~	~~=~~	~~Gust effect factor for rigid structures in accordance with ASCE 7 Section 6.5.8.1.~~
~~*Kd*~~	~~=~~	~~Wind directionality factor in accordance with ASCE 7 Table 6-4.~~
~~*Pnet*~~	~~=~~	~~Design wind pressure to be used in determination of wind loads on buildings or other structures or their components and cladding, in psf (kN/m2).~~
~~*qs*~~	~~=~~	~~Wind stagnation pressure in psf (kN/m2) in accordance with Table 1609.6.2(1).~~

~~**1609.6.3 Design equations.** When using the alternate all-heights method, theMWFRS,and components and cladding of every structure shall be designed to resist the effects of wind pressures on the building envelope in accordance with Equation 16-34.~~

~~*Pnet* = *qsKzCnet* [*IKzt*]~~ ~~**(Equation 16-34)**~~

~~Design wind forces for theMWFRSshall not be less than 10 psf (0.48 kN/m2) multiplied by the area of the structure projected on a plane normal to the assumed wind direction (see ASCE 7 Section 6.1.4 for criteria). Design net wind pressure for components and cladding shall not be less than 10 psf (0.48 kN/m2) acting in either direction normal to the surface.~~

~~**1609.6.4 Design procedure.** The MWFRS and the components and cladding of every building or other structure shall be designed for the pressures calculated using Equation 16-34.~~

~~**1609.6.4.1 Main wind-force-resisting systems.** The MWFRS shall be investigated for the torsional effects identified in ASCE 7 Figure 6-9.~~

~~**1609.6.4.2 Determination of *Kz* and *Kzt*.** Velocity pressure exposure coefficient, *Kz,* shall be determined in accordance with ASCE 7 Section 6.5.6.6 and the topographic factor, *Kzt*, shall be determined in accordance with ASCE 7 Section 6.5.7.~~

1. ~~For the windward side of a structure, *Kzt* and *Kz* shall be based on height *z*.~~
2. ~~For leeward and sidewalls, and for windward and leeward roofs, *Kzt* and *Kz* shall be based on mean roof height *h*.~~

~~**1609.6.4.3 Determination of net pressure coefficients, *Cnet*.** For the design of the MWFRS and for components and cla~~dding, the sum of the internal and external net pressure shall be based on the net pressure coefficient, *Cnet*.

1. ~~The pressure coefficient, *Cnet*, for walls and roofs shall be determined from Table 1609.6.2(2).~~
2. ~~Where *Cnet* has more than one value, the more severe wind load condition shall be used for design.~~

~~**1609.6.4.4 Application of wind pressures.** When using the alternate all-heights method, wind pressures shall be applied simultaneously on, and in a direction normal to, all building envelope wall and roof surfaces.~~

~~**1609.6.4.4.1 Components and cladding.**Wind pressure for each component or cladding element is applied as follows using *Cnet* values based on the effective wind area, *A*, contained within the zones in areas of discontinuity of width and/or length "a," "2a" or "4a" at: corners of roofs and walls; edge strips for ridges, rakes and eaves; or field areas onwalls or roofs as indicated in figures in tables in ASCE 7 as referenced in Table 1609.6.2(2) in accordance with the following:~~

1. ~~Calculated pressures at local discontinuities acting over specific edge strips or corner boundary areas.~~
2. ~~Include "field" (Zone 1, 2 or 4, as applicable) pressures applied to areas beyond the boundaries of the areas of discontinuity.~~

~~3. Where applicable, the calculated pressures at discontinuities (Zones 2 or 3) shall be combined with design pressures that apply specifically on rakes or eave overhangs.~~

15. Revise as follows:

1405.14 Vinyl siding. Vinyl siding conforming to the requirements of this section and complying with ASTM D 3679 shall be permitted on exterior walls of buildings located in areas where ~~the~~ V_{asd} as determined in accordance with Section 1609.3.1 ~~basic wind speed specified in Chapter 16~~ does not exceed 100 miles per hour (45 m/s) and the *building height* is less than or equal to 40 feet (12 192 mm) in Exposure C. Where construction is located in areas where ~~the~~ V_{asd} as determined in accordance with Section 1609.3.1 ~~basic wind speed~~ exceeds 100 miles per hour (45 m/s), or building heights are in excess of 40 feet (12 192 mm), tests or calculations indicating compliance with Chapter 16 shall be submitted. Vinyl siding shall be secured to the building so as to provide weather protection for the exterior walls of the building.

1504.5 Edge securement for low-slope roofs. Low-slope membrane roof system metal edge securement, except gutters, shall be designed and installed for wind loads in accordance with Chapter 16 and tested for resistance in accordance with ANSI/SPRI ES-1, except ~~the basic~~ V_{ult} wind speed shall be determined from Figure 1609A, 1609B, or 1609C as applicable.

TABLE 1504.8
MAXIMUM ALLOWABLE MEAN ROOF HEIGHT PERMITTED FOR BUILDINGS WITH AGGREGATE ON THE ROOF IN AREAS OUTSIDE A HURRICANE-PRONE REGION

V_{asd} determined in accordance with Section 1609.3.1 ~~BASIC WIND SPEED FROM FIGURE 1609 (mph)b~~	MAXIMUM MEAN ROOF HEIGHT (ft)a,c		
	Exposure category

(Portions of Table not shown, remain unchanged)

1705.4 Wind resistance. The statement of special inspections shall include wind requirements for structures constructed in the following areas:

1. In wind Exposure Category B, where ~~the~~ V_{asd} as determined in accordance with Section 1609.3.1 ~~3-second-gust basic wind speed~~ is 120 miles per hour (mph) (52.8 m/s) or greater.
2. In wind Exposure Category C or D, where ~~the~~ V_{asd} as determined in accordance with Section 1609.3.1 ~~3-second- gust basic wind speed~~ is 110 mph (49 m/s) or greater.

1706.1 Special inspections for wind requirements. *Special inspections* itemized in Sections 1706.2 through 1706.4, unless exempted by the exceptions to Section 1704.1, are required for buildings and structures constructed in the following areas:

1. In wind Exposure Category B, where ~~the~~ V_{asd} as determined in accordance with Section 1609.3.1 ~~3-second-gust basic wind speed~~ is 120 miles per hour (52.8 m/sec) or greater.
2. In wind Exposure Categories C or D, where ~~the~~ V_{asd} as determined in accordance with Section 1609.3.1 ~~3-second-gust basic wind speed~~ is 110 mph (49 m/sec) or greater.

1710.3 Structural observations for wind requirements. Structural observations shall be provided for those structures sited where ~~the~~ V_{asd} as determined in accordance with Section 1609.3.1 ~~basic wind speed~~ exceeds 110 mph (49 m/sec) ~~determined from Figure 1609~~, where one or more of the following conditions exist:

1. The structure is classified as *Occupancy Category* III or IV in accordance with Table 1604.5.
2. The *building height* of the structure is greater than 75 feet (22 860 mm).
3. When so designated by the *registered design professional* responsible for the structural design.
4. When such observation is specifically required by the *building official*.

2109.1.1 Limitations. The use of empirical design of masonry shall be limited as noted in Section 5.1.2 of TMS 402/ACI 530/ASCE 5. The use of dry-stacked, surface-bonded masonry shall be prohibited in *Occupancy Category* IV structures. In buildings that exceed one or more of the limitations of Section 5.1.2 of TMS 402/ACI 530/ASCE 5,

masonry shall be designed in accordance with the engineered design provisions of Section 2101.2.1, 2101.2.2 or 2101.2.3 or the foundation wall provisions of Section 1807.1.5.
Section 5.1.2.2 of TMS 402/ACI 530/ASCE 5 shall be modified as follows:

5.1.2.2 *Wind* – Empirical requirements shall not apply to the design or construction of masonry for buildings, parts of buildings, or other structures to be located in areas where V_{asd} as determined in accordance with Section 1609.3.1 of the *International Building Code* exceeds 110 mph.

TABLE 2304.6.1
MAXIMUM V_{asd} determined in accordance with Section 1609.3.1
~~BASIC WIND SPEED~~ (mph) (3-SECOND GUST) PERMITTED FOR
WOOD STRUCTURAL PANEL WALL SHEATHING USED TO RESIST WIND PRESSURESa,b,c

MINIMUM NAIL		MINIMUM WOOD STRUCTURAL PANEL SPAN RATING	MINIMUM NOMINAL PANEL THICKNESS (inches)	MAXIMUM WALL STUD SPACING (inches)	PANEL NAIL SPACING		MAXIMUM V_{asd} DETERMINED IN ACCORDANCE WITH SECTION 1609.3.1 ~~WIND SPEED (MPH)~~		
							Wind exposure category		
Size	Penetration (inches)				Edges (inches o.c.)	Field (inches o.c.)	B	C	D

(Portions of Table not shown, remain unchanged)

a. Panel strength axis shall be parallel or perpendicular to supports. Three-ply plywood sheathing with studs spaced more than 16 inches on center shall be applied with panel strength axis perpendicular to supports.
b. The table is based on wind pressures acting toward and away from building surfaces in accordance with Section 30.7 ~~6.4.2.2~~ ofASCE7. Lateral requirements shall be in accordance with Section 2305 or 2308.
c. Wood structural panels with span ratings ofwall-16 orwall-24 shall be permitted as an alternate to panels with a 24/0 span rating. Plywood siding rated 16 o.c. or 24 o.c. shall be permitted as an alternate to panels with a 24/16 span rating.Wall-16 and plywood siding 16 o.c. shall be used with studs spaced a maximum of 16 inches o.c.

2308.2 Limitations. Buildings are permitted to be constructed in accordance with the provisions of *conventional light-frame construction*, subject to the following limitations, and to further limitations of Sections 2308.11 and 2308.12.

1. Buildings shall be limited to a maximum of three *stories above grade plane*. For the purposes of this section, for buildings in *Seismic Design Category* D or E as determined in Section 1613, cripple stud walls shall be considered to be a *story*.

   Exception: Solid blocked cripplewalls not exceeding 14 inches (356 mm)in height need not be considered a *story*.

2. Maximum floor-to-floor height shall not exceed 11 feet, 7 inches (3531 mm). Bearing wall height shall not exceed a stud height of 10 feet (3048 mm).
3. Loads as determined in Chapter 16 shall not exceed the following:
   3.1. Average dead loads shall not exceed 15 psf (718 N/m^2) for combined roof and ceiling, exterior walls, floors and partitions.

   Exceptions:

   1. Subject to the limitations of Sections 2308.11.2 and 2308.12.2, stone or masonry veneer up to the lesser of 5 inches (127 mm) thick or 50 psf (2395 N/m^2) and installed in accordance with Chapter 14 is permitted to a height of 30 feet (9144 mm) above a noncombustible foundation, with an additional 8 feet (2438 mm) permitted for gable ends.
   2. Concrete or masonry fireplaces, heaters and chimneys shall be permitted in accordance with the provisions of this code.

   3.2. Live loads shall not exceed 40 psf (1916 N/m^2) for floors.
   3.3. Ground snow loads shall not exceed 50 psf (2395 N/m^2).

4. V_{asd} as determined in accordance with Section 1609.3.1 ~~Wind speeds~~ shall not exceed 100 miles per hour (mph) (44 m/s) (3-second gust).

   Exception: V_{asd} as determined in accordance with Section 1609.3.1 ~~Wind speeds~~ shall not exceed 110 mph (48.4 m/s) (3-second gust) for buildings in Exposure Category B that are not located in a *hurricane-prone region*.

5. Roof trusses and rafters shall not span more than 40 feet (12 192 mm) between points of vertical support.
6. The use of the provisions for *conventional light-frame construction* in this section shall not be permitted for *Occupancy Category* IV buildings assigned to *Seismic Design Category* B, C, D, E or F, as determined in Section 1613.
7. *Conventional light-frame construction* is limited in irregular structures in *Seismic Design Category* D or E, as specified in Section 2308.12.6.

2308.2.1 Basic wind speed greater than 100 mph (3-second gust). Where the V_{asd} as determined in accordance with Section 1609.3.1 ~~basic wind speed~~ exceeds 100 mph (3-second gust), the provisions of either AF&PAWFCM, or the ICC 600 are permitted to be used. Wind speeds in Figure 1609A, 1609B, and 1609C shall be converted in accordance with Section 1609.3.1 for use with AF&PAWFCM or ICC 600.

TABLE 2308.10.1
REQUIRED RATING OF APPROVED UPLIFT CONNECTORS (pounds)[a,b,c,e,f,g,h,I]

V_{asd} determined in accordance with Section 1609.3.1 ~~**BASIC WIND SPEED (3-second gust)**~~	**ROOF SPAN (feet)**							**OVERHANGS (pounds/feet)d**
	12	**20**	**24**	**28**	**32**	**36**	**40**	**OVERHANGS (pounds/feet)[d]**

(Portions of Table not shown, remain unchanged)

For SI: 1 inch = 25.4 mm, 1 foot = 304.8 mm, 1 mile per hour = 1.61 km/hr, 1 pound = 0.454 Kg, 1 pound/foot = 14.5939 N/m.

a. The uplift connection requirements are based on a 30-foot mean roof height located in Exposure B. For ExposureC orD and for other mean roof heights, multiply the above loads by the adjustment coefficients below.

	Mean Roof Height (feet)									
EXPOSURE	**15**	**20**	**25**	**30**	**35**	**40**	**45**	**50**	**55**	**60**
B	**1.00**	**1.00**	**1.00**	**1.00**	**1.05**	**1.09**	**1.12**	**1.16**	**1.19**	**1.22**
C	**1.21**	**1.29**	**1.35**	**1.40**	**1.45**	**1.49**	**1.53**	**1.56**	**1.59**	**1.62**
D	**1.47**	**1.55**	**1.61**	**1.66**	**1.70**	**1.74**	**1.78**	**1.81**	**1.84**	**1.87**

b. he uplift connection requirements are based on the framing being spaced 24 inches on center. Multiply by 0.67 for framing spaced 16 inches on center and multiply by 0.5 for framing spaced 12 inches on center.
c. The uplift connection requirements include an allowance for 10 pounds of dead load.
d. The uplift connection requirements do not account for the effects of overhangs. The magnitude of the above loads shall be increased by adding the overhang loads found in the table. The overhang loads are also based on framing spaced 24 inches on center. The overhang loads given shall be multiplied by the overhang projection and added to the roof uplift value in the table.
e. The uplift connection requirements are based upon wind loading on end zones as defined in Figure 28.6.3 ~~6-2~~ of ASCE 7. Connection loads for connections located a distance of 20 percent of the least horizontal dimension of the building from the corner of the building are permitted to be reduced by multiplying the table connection value by 0.7 and multiplying the overhang load by 0.8.
f. For wall-to-wall and wall-to-foundation connections, the capacity of the uplift connector is permitted to be reduced by 100 pounds for each full wall above. (For example, if a 500-pound rated connector is used on the roof framing, a 400-pound rated connector is permitted at the next floor level down).
g. Interpolation is permitted for intermediate values of V_{asd} ~~basic wind speeds~~ and roof spans.
h. The rated capacity of approved tie-down devices is permitted to include up to a 60-percent increase for wind effects where allowed by material specifications.

CHAPTER 35
REFERENCED STANDARDS

ASCE/SEI
American Society of Civil Engineers/Structural Engineering Institute
1801 Alexander Bell Drive
Reston, VA 20191-440

7-10 ~~7-05~~ Minimum Design Loads for Buildings and Other Structures ~~including Supplements No. 1 and 2, excluding Chapter 14 and Appendix 11A.~~

Reason: The purpose of ths proposal is to update and coordinate the provisions of the 2012 IBC with those of the 2010 edition of ASCE 7 for the determination of wind loads. Although consisting of 30 small parts, the underlying reason for this change is to adopt into the 2012 IBC the new wind speed maps that have been adopted into ASCE 7.

Over the past 10 years, new data and research has been performed that indicates that the hurricane wind speeds provided in the current maps of the IBC-09 and ASCE-05 are too conservative and need to be adjusted downward. Significantly more hurricane data have become available thereby allowing for substantial improvements in the hurricane simulation model that is used to create the wind speed maps.
These new data have resulted in an improved representation of the hurricane wind field, including the modeling of the sea-land transition and the hurricane boundary layer height; new models for hurricane weakening after landfall; and an improved statistical model for the Holland *B* parameter which controls the wind pressure relationship. The new hurricane hazard model yields hurricane wind speeds that are lower than those given in ASCE 7-05 and IBC-09 even though the overall rate of intense storms (as defined by central pressure) produced by the new model is increased compared to those produced by the hurricane simulation model used to develop previous maps.

In preparing the new maps, the ASCE 7 standards committee decided to use multiple ultimate event or strength design maps in conjunction with a wind load factor of 1.0 for strength design – for allowable stress design, the factor was reduced from 1.0 to 0.6. Several factors that are important to an accurate wind load standard led to this decision:

(i) An ultimate event or strength design wind speed map makes the overall approach consistent with that used in seismic design in that they both map ultimate events and use a load factor of 1.0 for strength design.

(ii) Utilizing different maps for the different Occupancy Categories eliminates the problems associated with using "importance factors" that vary with category. The difference in the importance factors in hurricane prone and non-hurricane prone regions for Category I structures prompted many questions and have been removed from ASCE 7-10.

(iii) The use of multiple maps eliminates the confusion associated with the recurrence interval associated with the existing map - the map was not a uniform fifty year return period map. This therefore created a situation where the level of safety provided for within the overall design was not consistent along the hurricane coast.

Utilizing the new wind speed maps and integrating their use into the IBC necessitated the introduction of the terms V_{ult} and V_{asd} to be associated with the "ultimate" design wind speed and the "nominal" design wind speed. Because of the number of different provisions which use the wind speed map to "trigger" different requirements it was necessary to modify the conversion section (1609.3.1) so that those provisions were not changed. The terms "ultimate design wind speed" and "nominal design wind speed" were incorporate in numerous locations to aid in drawing the users attention to the different types of wind speeds – similar to what was done with the change from fastest mile to 3-second gust wind speeds.

Beyond the adoption of the new strength design wind speed maps, the 2010 edition of ASCE 7 also includes a new simplified method for use in the determination of wind loads for buildings up to 160' in height. In addition, the wind load calculation provisions have been removed from Chapter 6 of ASCE 7 and been reorganized into 6 separate chapters (26 thru 31) for the sake of clarity and ease of use. This of course necessitated multiple coordination revisions with the IBC text.

ASCE/SEI 7 has been a referenced standard of the IBC since its inception and as such it is well known to the building community. ASCE/SEI 7 is published and maintained by the Structural Engineering Institute of the American Society of Civil Engineers (SEI/ASCE). The document is a nationally recognized consensus standard developed in full compliance with the ASCE *Rules for Standards Committees*. The ASCE standards process is fully accredited by the American National Standards Institute (ANSI).

As of the submission date of this code change, the ASCE 7 Standards Committee is completing the committee balloting portion of the 2010 edition of ASCE/SEI 7. The document is designated ASCE/SEI 7-10 *Minimum Design Loads for Buildings and Other Structures* and it is expected that it will be completed and available for purchase prior to the ICC Final Action Hearings in May of 2010 . Any person interested in obtaining a public comment copy of ASCE/SEI 7-10 may do so by contacting the proponent at jrossberg@asce.org .

Cost Impact: The overall, national cost impact is believed to be neutral.

ICCFILENAME: ROSSBERG-S1-1602 NOTATIONS

Public Hearing Results

Committee Action: **Approved as Modified**

Modify the proposal as follows:

1609.6 Alternate all-heights method. The alternate wind design provisions in this section are simplifications of the ASCE 7 Directional Procedure.

1609.6.1 Scope. As an alternate to ASCE 7 Chapters 27 and 30, the following provisions are permitted to be used to determine the wind effects on regularly shaped buildings, or other structures that are regularly shaped, which meet all of the following conditions:

1. The building or other structure is less than or equal to 75 feet (22 860 mm) in height with a height-to-least width ratio of 4 or less, or the building or other structure has a fundamental frequency greater than or equal to 1 hertz.
2. The building or other structure is not sensitive to dynamic effects.
3. The building or other structure is not located on a site for which channeling effects or buffeting in the wake of upwind obstructions warrant special consideration.
4. The building shall meet the requirements of a simple diaphragm building as defined in ASCE 7 Section 26.2, where wind loads are only transmitted to the main wind-force-resisting system (MWFRS) at the diaphragms.
5. For open buildings, multispan gable roofs, stepped roofs, sawtooth roofs, domed roofs, roofs with slopes greater than 45 degrees (0.79 rad), solid free-standing walls and solid signs, and rooftop equipment, apply ASCE 7 provisions.

1609.6.1.1 Modifications. The following modifications shall be made to certain subsections in ASCE 7: in Section 1609.6.2, symbols and notations that are specific to this section are used in conjunction with the symbols and notations in ASCE 7 Section 26.3.

1609.6.2 Symbols and notations. Coefficients and variables used in the alternate all-heights method equations are as follows:

C_{net} = Net-pressure coefficient based on K_d [(G) (Cp) – (GC_{pi})], in accordance with Table 1609.6.2.

G = Gust effect factor for rigid structures in accordance with ASCE 7 Section 26.9.3.
K_d = Wind directionality factor in accordance with ASCE 7 Table 26-6.
P_{net} = Design wind pressure to be used in determination of wind loads on buildings or other structures or their components and cladding, in psf (kN/m^2).

TABLE 1609.6.2
NET PRESSURE COEFFICIENTS, C_{NET}[a,b]

STRUCTURE OR PART THEREOF	DESCRIPTION		C_{net} FACTOR			
1. Main Wind Force Resisting Frames and Systems	WALLS:		Enclosed		Partially Enclosed	
			+ Internal Pressure	- Internal Pressure	+ Internal Pressure	- Internal Pressure

For SI: 1 foot = 304.8 mm, 1 square foot = 0.0929 m^2, 1 degree = 0.0175 radians

a. Linear interpolation between values in the table is permitted.

b. Some C_{net} values have been grouped together. Less conservative results may be obtained by applying ASCE 7 provisions.

1609.6.3 Design equations. When using the alternate all-heights method, the MWFRS, and components and cladding of every structure shall be designed to resist the effects of wind pressures on the building envelope in accordance with Equation 16-34.

$P_{net} = 0.00256V^2 K_z C_{net} K_{zt}$ **(Equation 16-34)**

Design wind forces for the MWFRS shall not be less than 16 psf (0.77 kN/m^2) multiplied by the area of the structure projected on a plane normal to the assumed wind direction (see ASCE 7 Section 27.4.7 for criteria). Design net wind pressure for components and cladding shall not be less than 16 psf (0.77 kN/m^2) acting in either direction normal to the surface.

1609.6.4 Design procedure. The MWFRS and the components and cladding of every building or other structure shall be designed for the pressures calculated using Equation 16-34.

1609.6.4.1 Main wind-force-resisting systems. The MWFRS shall be investigated for the torsional effects identified in ASCE 7 Figure 27.4.6.

1609.6.4.2 Determination of K_z and K_{zt}. Velocity pressure exposure coefficient, K_z, shall be determined in accordance with ASCE 7 Section 27.3.1 and the topographic factor, K_{zt}, shall be determined in accordance with ASCE 7 Section 26.8.

1. For the windward side of a structure, K_{zt} and K_z shall be based on height *z*.
2. For leeward and sidewalls, and for windward and leeward roofs, K_{zt} and K_z shall be based on mean roof height *h*.

1609.6.4.3 Determination of net pressure coefficients, C_{net}. For the design of the MWFRS and for components and cladding, the sum of the internal and external net pressure shall be based on the net pressure coefficient, C_{net}.

1. The pressure coefficient, C_{net}, for walls and roofs shall be determined from Table 1609.6.2.
2. Where C_{net} has more than one value, the more severe wind load condition shall be used for design.

1609.6.4.4 Application of wind pressures. When using the alternate all-heights method, wind pressures shall be applied simultaneously on, and in a direction normal to, all building envelope wall and roof surfaces.

1609.6.4.4.1 Components and cladding. Wind pressure for each component or cladding element is applied as follows using C_{net} values based on the effective wind area, *A*, contained within the zones in areas of discontinuity of width and/or length "a," "2a" or "4a" at: corners of roofs and walls; edge strips for ridges, rakes and eaves; or field areas on walls or roofs as indicated in figures in tables in ASCE 7 as referenced in Table 1609.6.2 in accordance with the following:

1. Calculated pressures at local discontinuities acting over specific edge strips or corner boundary areas.
2. Include "field" (Zone 1, 2 or 4, as applicable) pressures applied to areas beyond the boundaries of the areas of discontinuity.
3. Where applicable, the calculated pressures at discontinuities (Zones 2 or 3) shall be combined with design pressures that apply specifically on rakes or eave overhangs.

(Portions of proposal not shown are unchanged)

Committee Reason: This code change updates the IBC wind load requirements for consistency with the next edition of the ASCE 7 load standard. The modification retains the current IBC alternative procedure with necessary corrections to the ASCE 7 references. A public comment is recommended to further coordinate the IBC with ASCE 7

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Modify the proposal as follows:

1609.1.2.2. Modifications to ATM E 1996. Section 6.2.2 of ASTM E 1996 shall be modified as follows:

6.2.2 Unless otherwise specified, select the wind zone based on the basic wind speed as follows:
6.2.2.1 *Wind Zone 1* - 130 mph ≤ basic wind speed < 140 mph, and Hawaii.
6.2.2.2 *Wind Zone 2* - 140 mph ≤ basic wind speed < 150 mph at greater than 1.6 km (one mile) from the coastline. The coastline shall be measured from the mean high water mark.
~~6.2.2.3 *Wind Zone 3* - basic wind speed ≥ 150 mph, or basic wind speed ≥ 140 mph and within 1.6 km (one mile) of the coastline. The coastline shall be measured from the mean high water mark.~~
6.2.2.3 *Wind Zone 3*—150 mph (58 m/s) ≤ basic wind speed ≤160 mph (63 m/s), or 140 mph (54 m/s) ≤ basic wind speed ≤160 mph (63 m/s) and within 1.6 km (one mile) of the coastline. The coastline shall be measured from the mean high water mark.
6.2.2.4 *Wind Zone 4*—basic wind speed >160 mph (63 m/s).

Commenter's Reason: The purpose of the modification proposed in this public comment is simply to correlate the wind zones in the 2009 Edition of ASTM E 1996 with the new wind speed maps in ASCE 7-10 as proposed in S84-09/10. During the preparation of the original code change, an older version of ASTM E 1996 which didn't include Wind Zone 4 or slight changes to Wind Zone 3 that is reflected in ASTM e 1996-09. Approval of S84-09/10 as modified by this public comment is needed so that the delineation of the wind zones are modified consistently by this section in the IBC.

Public Comment 2:

Jerremy John Barbera, Structural Engineers Association of Washington (SEAW), representing SEAW Wind Engineering Committee, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

1605.3.2 Alternative basic load combinations. In lieu of the basic load combinations specified in Section 1605.3.1, structures and portions thereof shall be permitted to be designed for the most critical effects resulting from the following combinations. When using these alternative basic load combinations that include wind or seismic loads, allowable stresses are permitted to be increased or load combinations reduced where permitted by the material chapter of this code or the referenced standards. For load combinations that include the counteracting effects of dead and wind loads, only two-thirds of the minimum dead load likely to be in place during a design wind event shall be used. Where wind loads are calculated in accordance with Chapters 26 through 31 of ASCE 7, the coefficient ω in the following equations shall be taken as ~~0.78~~ 1.3. For other wind loads ω, shall be taken as 1. When using these alternative load combinations to evaluate sliding, overturning and soil bearing at the soil-structure interface, the reduction of foundation overturning from Section 12.13.4 in ASCE 7 shall not be used. When using these alternative basic load combinations for proportioning foundations for loadings, which include seismic loads, the vertical seismic *load effect*, *Ev, i*n Equation 12.4-4 of ASCE 7 is permitted to be taken equal to zero.

$D + L + \underline{0.6}\cancel{(}\omega W\cancel{)}$ **(Equation 16-17)**
$D + L + \underline{0.6}\omega W + S/2$ **(Equation 16-18)**
$D + L + S + \underline{0.6}\omega W/2$ **(Equation 16-19)**

(Equations not shown are unchanged)

(Portions of proposal not shown are unchanged)

Commenter's Reason: As the proponent of S84 pointed out in the reason statement, the ASCE 7 wind maps are changing to a strength-based set of maps. The two sets of allowable stress based load combinations in 1605.3.1 and 1605.3.2 need to have a 0.6 load factor applied to wind loads to account for this change. The proponent made such a change to the load combinations in 1605.3.1. In 1605.3.2, the proponent made a similar change by changing the ω factor from 1.3 to 1.3 * 0.6 = 0.78. While numerically correct, this change is not transparent and will lead to confusion on the part of users. This public comment will align the two sets of allowable stress load combinations so that this new load factor is evident.

Public Comment 3:

Edwin Huston, National Council of Structural Engineers Associations (NCSEA), representing NCSEA Code Advisory Subcommittee – General Requirements Subcommittee, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

1605.3.2 Alternative basic load combinations. In lieu of the basic load combinations specified in Section 1605.3.1, structures and portions thereof shall be permitted to be designed for the most critical effects resulting from the following combinations. When using these alternative basic load combinations that include wind or seismic loads, allowable stresses are permitted to be increased or load combinations reduced where permitted by the material chapter of this code or the referenced standards. For load combinations that include the counteracting effects of dead and wind loads, only two-thirds of the minimum dead load likely to be in place during a design wind event shall be used. When using allowable stresses which have been increased or load combinations which have been reduced as permitted by the material chapter of this code or the referenced standards, where wind loads are calculated in accordance with Chapters 26 through 31 of ASCE 7, the coefficient ω in the following equations shall be taken as ~~0.78~~ 1.3. For other wind loads ω, shall be taken as 1. When allowable stresses have not been increased or load combinations have not been reduced as permitted by the material chapter of this code or the referenced standards ω, shall be taken as 1. When using these alternative load combinations to evaluate sliding, overturning and soil bearing at the soil-structure interface, the reduction of foundation overturning from Section 12.13.4 in ASCE 7 shall not be used. When using these alternative basic load combinations for proportioning foundations for loadings, which include seismic loads, the vertical seismic *load effect*, *Ev, i*n Equation 12.4-4 of ASCE 7 is permitted to be taken equal to zero.

$D + L + \underline{0.6}\cancel{(}\omega W\cancel{)}$ **(Equation 16-17)**
$D + L + \underline{0.6}\omega W + S/2$ **(Equation 16-18)**
$D + L + S + \underline{0.6}\omega W/2$ **(Equation 16-19)**

(Equations not shown are unchanged)

(Portions of proposal not shown are unchanged)

Commenter' Reason: The ASCE 7 wind maps are changing to a strength based set of maps. The two sets of allowable stress based load combinations in 1605.3.1 and 1605.3.2 need to have a 0.6 load factor applied to wind loads to account for this change. The proponent made such a change to the load combinations in 1605.3.1.

In testimony at the Code Development Hearings in Baltimore, the CRSC noted that the load combination of 1605.3.2 is often used when a geotechnical consultant permitted a one-third stress increase. Geotechnical consultants routinely do allow this stress increase, but not all geotechnical consultants allow it, so Section 1605.3.2 is not always used with a one-third stress increase. If no stress increase is used, the ω factor in 1605.3.2, should be taken as unity. This Public Comment will address the cases when a one-third stress increase is not provided or permitted and provide for the proper use of the load combinations in Section 1605.3.2 for those cases.

NCSEA urges your acceptance of this public comment to S84-09/10. Thank you.

Final Action: AS AM AMPC____ D

S90-09/10
1609.1.2.2, Chapter 35

Proposed Change as Submitted

Proponent: John Woestman, The Kellen Company, representing the Door Safety Council (DSC)

1. Add new text as follows:

1609.1.2.2 Side-hinged doors. Side-hinged door glazed opening protection for wind-borne debris shall meet the requirements of an *approved* impact-resistant standard or ANSI A250.13.

(Renumber remaining sections)

2. Add standard to Chapter 35 as follows:

ANSI
A250.13-08 Testing and Rating of Severe Windstorm Resistant Components for Swinging Door Assemblies

Reason: This proposal helps resolve performance and code compliance issues when exterior side-hinged door openings are comprised of components from multiple sources and include interchangeable elements (ie: doors, frames, hinging and latching hardware, etc.).

This proposed change allows an alternative method to demonstrate performance to impact-resistant requirements for side-hinged door openings by requiring components to be tested to ANSI A250.13-2008. ANSI A250.13 contains language that prescribes how components are to be selected to create complete door openings expected to perform equivalently to door assemblies tested to ASTM E 1996 / E 1886 for impact resistance.

Through the ANSI standards development process stake-holders comprising most major manufacturing associations, testing and certification organizations, specifiers, code officials and end users, developed a national standard for a component-based approach to testing for windstorm resistance of swinging door openings. The test procedures used in this standard represent the most severe requirements found in the windstorm resistance standards referenced in today's building codes. These procedures are designed to isolate the loads, conditions and critical performance requirements that a particular component is subjected to in full assembly tests and duplicate these specific conditions. Using a combination of worst-case scenario design and safety factors, this standard is designed to provide a component rating that relates directly to the component's ability to withstand the conditions that occur in full assembly tests.

Prior to releasing the current revision of ANSI A250.13, validation tests of the large missile impact test specified by ASTM E1886/E1996 were conducted through Intertek Testing Services, a Nationally Recognized Test Laboratory. The study was conducted to quantify the energy that would tend to shear the latch bolt in assembly tests and compare it to the energy delivered to the latch bolt in the ANSI A250.13 component test procedure which uses a relatively rigid fixture and a pendulum type impactor. The impact energy applied to the test sample was varied and the actual energy imparted to the lock and hinge was measured. The component text fixture is more efficient at transferring the energy applied to the system into the test samples than the ASTM E1996 assembly test fixture. This results in higher impact energy at the lock or hinge. For example, only 4% of the impact energy applied in the ASTM E1996 test transfers to the lock. Whereas, 15% of the impact energy is delivered to the lock mounted in the A250.13 test fixture.

Results demonstrated that this test specified in ANSI A250.13 for latches was indeed much more severe (approximately 3.75 times more) than the exposure provided in door assembly tests conducted per ASTM E1996 and similar wind borne debris impact tests. The current impact test requirements of ANSI A250.13 were therefore adjusted to be two times more severe (maintaining a 2 times safety factor) to the current requirements of ASTM E1996.

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: A review of the standard(s) proposed for inclusion in the code, ANSI A250 13-08, for compliance with ICC criteria for referenced standards given in Section 3.6 of Council Policy #CP 28 will be posted on the ICC website on or before September 24, 2009.

ICCFILENAME: WOESTMAN-S1-1609.1.2.2

Public Hearing Results

Note: The following analysis was not in the Code Change monograph but was published on the ICC website at http://www.iccsafe.org/cs/codes/Documents/2009-10cycle/ProposedChanges/Standards-Analysis.pdf :

Analysis: Review of proposed new standard ANSI A250.12 indicated that, in the opinion of ICC Staff, the standard complies with ICC standards criteria.

Committee Action: **Approved as Submitted**

Committee Reason: With the addition of ANSI A250.12 to regulate the parts of a side-hinged door, there will be at least a requirement for their testing. It can be better to have tests on each part of the assembly. This component approach is not a novel idea, but is something that is done all the time. There is a consensus standard and it's a good option to have in the code.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Jeff Inks, Window and Door Manufacturers Association, requests Disapproval.

Commenter's Reason: After subsequent consideration of the Structural Committee's approval of this code change proposal, WDMA believes it should be disapproved.

While as the committee pointed out in their reason for approving the proposal, the "*component approach is not a novel idea*," it has not evolved to the point that it can be relied upon to the extent intended by this proposal which is to ensure side-hinged door assemblies constructed of components that have been tested, but not together as an assembly, are compliant with the performance requirements for these assemblies in wind borne debris regions. ANSI 250.13 allows substitutions that go far beyond what is allowed in the ASTM E-1996 standard.

While we are also supportive of the concept, more guidance should be in place with respect to component substitution and the extent to which it can be safely employed in the construction of assemblies that are not tested as assemblies. That guidance should be available before provisions such as those proposed by S90 are approved for the code.

Public Comment 2:

Julie Ruth, JRuth Code Consulting, representing American Architectural Manufacturers Association, requests Disapproval.

Commenter's Reason: S90 would require glazed opening protection in side hinged doors to meet the requirements of an approved impact resistant standard, or ANSI A250.13. Since glazed opening protections are already required to meet the requirements of an approved impact resistant standard elsewhere in Section 1609.1.2, the net effect of S90 would be to permit the alternate use of ANSI A250.13 to determine the impact resistance of components of side hinged doors rather than testing complete systems as required by other impact resistance standards.

It has been AAMA's experience that the testing and rating of individual components of a fenestration assembly, without testing a full assembly to establish a baseline, does not provide adequate information on the performance of the resultant assembly under load. This is as true for resistance to impact load as it is for resistance to design wind pressure.

During the testimony on S90 at the code development hearings in Baltimore, the proponents of S90 pointed to the fact that the standard requires the door slab to be stiffened prior to testing, to more fully impart the impact load onto the hardware that is securing the door slab into the opening. While such stiffening may in fact provide a more meaningful test of the hardware, it almost certainly does not give an accurate view of the performance of the door slab itself. There is also some question as to whether the most appropriate test for the hardware is in fact also the most appropriate for the door slab. Perhaps two different test methods, or two different methods of preparing the test assembly, should be used.

AAMA also has a concern that sections 9.1.1 and 9.1.2 of ANSI A250.13 permit alternate means of testing glazing in impact rated doors. Section 9.1.1 specifies that the glazing is to be tested in the largest size that can accommodate the glazing system. Section 9.1.2 permits the glazing system to be tested as part of door assemblies that are defined elsewhere in the standard, which are not required to include glazing in the largest size that can be accommodated. The members of the AAMA Door Council know from years of testing that these glazing options will react differently in different door slab and framing systems (assemblies). Therefore, permitting alternate means of testing the glazing options will not result in consistent test results, or consistent product performance.

Finally, it should be noted that validation test data from proponents of ANSI A250.13 has not been made available for review. Confirmation of the validity of a proposed new testing and rating method, either through peer review, round robin testing, or some other method of verifying the validity of the results, is the hallmark of meaningful standards development. The need for it should not be dismissed or lightly set aside.

Considering the importance of impact protection in maintaining the integrity of the building envelope, it is prudent that building codes remain conservative in their approach to specifying the means of qualifying impact protective products. Allowing a method such as A250.13, that does not require a full assembly test, is not a conservative approach. We urge disapproval of the use of this method, as provided for in S90.

Public Comment 3:

Larry J. Tanner P.E., Texas Tech University, representing Wind Sciences & Engineering Center, Debris Impact Test Laboratory, requests Disapproval.

Commenter's Reason: The ANSI A250 Standard, along with the ASTM 1886/1996 standards, were developed to prevent the proliferation of envelope perforations and the resulting inundation of rainwater from hurricane events. Evidence from hurricane investigations has revealed that indeed buildings designed to these standards performed better than buildings without said protection. However, it should be understood and specifically included in technical specifications by the manufacturers and advertisements to the consumers, that such products are intended only for non-catastrophic property protection from rainwater inundation and not for the protection of building occupants (Life Safety). I was a coauthor of both FEMA 320 and FEMA 361 which utilize Tornado and Hurricane Saferoom Design Wind Speed Maps. Never were the above referenced ANSI and ASTM standards considered suitable for FEMA 320 Saferooms or FEMA 361 Community Shelters.

Specifics to the proposed changes to the ANSI A250.13-2008 Standard:

1. From a quantitative standpoint the "stiffness theory" appears reasonable; however laboratory tests have proven otherwise. Texas Tech University has been the leading "storm debris impact researcher" for over 35 years. Tests on door assemblies have proven that success or failure from wind pressures and debris impacts is unique to the door (or window unit) and the hardware components installed. A heavily constructed door absorbs little energy and directs most of the energy to the attaching components and has proven to fail components that previously passed on other less massive doors. Lighter constructed doors can bend excessively and either pull out locking bolts or cause bolting bending and ultimate failure. Doors passing the impact tests must have a unique set of hardware that matches the door performance, thus doors are rated as a complete assembly, inclusive of frame, door(s), hinging, and locking hardware. Window lites in doors compromise the strength of the door and present another set of unique circumstances which require the unit to be rated as a complete assembly. Window unit performance is unique to the opening size, frame type, and the glazing. The elasticity of the glazing is a function of size and type. Based on size, some glazing is so elastic that it bounces

out of the frame. Smaller is not always better; some glazing will destroy the framing system and be pushed out. Thus, the only way to predict window behavior under impact is by full scale testing in the laboratory in "as specified and installed" condition.

2. Though these Standards were developed for "envelope" protection to reduce rainwater intrusion, these components that are now rated as "Hurricane Tested" are now being used in hardened "Hurricane Shelters" which are intended to protect lives. This is the result of misleading specification sheets, and uninformed dealers and consumers.

3. The "component rating" system does not consider the size of doors or glazed openings; the stiffness of doors with various sizes of lites, nor the quantity of hinges or latches required per size to carry the loads.

4. The Standard requires the component to be rated by ultimate load, but there is no guidance regarding the "assembly rating" based upon mixture of components with various ratings.

5. The Standard does not require engineering review or oversight.

6. According to the Test Procedure stated in Section 5.2.2, the impact energy should be 350 foot-pounds. However, for hinges, Section 6.1.1.2 and Latching Hardware, Section 7.1.1.3, the impact kinetic energy has been reduced to 125 foot-pounds. I understand the "stiffness" theory of the test fixture and product configuration, but this assumes that every laboratory will have the same fixtures and the same laboratory conditions.

7. The wind speed range has changed from 110-150 mph for the 2003 Standard to 110-170 mph for the 2008 Standard, but the test loads and impact criteria has not changed.

8. The impact location 6" above the floor on Figure 4, page 6 is unrealistic. In researching most all of the severe tornadoes and hurricanes since 1989, I have never seen an impact lower than 2.5 feet on a vertical surface.

9. Although there is not the opportunity at this time, to prevent the misuse of these products as describe above, I would suggest that the title of the standard be changed to: *Testing and Rating of Windstorm Resistant Components for Swinging Doors for Non-Life Safety Uses.*

Public Comment 4:

Gordon Thomas P.E., representing self, requests Disapproval.

Commenter's Reason: The ANSI A250.13 standard is a component rating standard not an assembly design standard. By referencing a component standard in the code, it would allow any non-engineering professional to inappropriately assemble components into an unqualified door assembly.

In addition, the proponent's *Reason Statement* for S90 contained the following statement regarding ANSI A250.13;

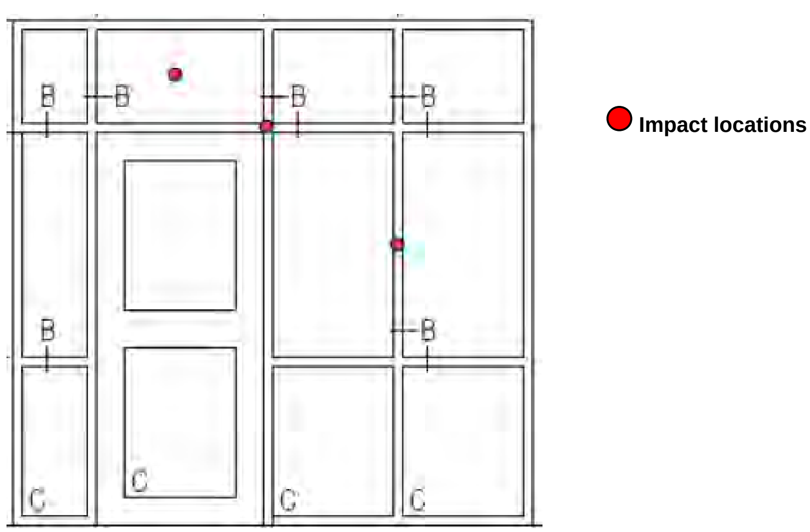
"The test procedures used in this standard represent the most severe requirements found in the windstorm resistance standards referenced in today's building codes."

As a Professional Engineer with extensive experience in design, testing and analysis of debris impact-resistant opening protectives, I have researched this claim and have concluded that this is not an accurate statement. Please consider the following facts;

ANSI A250.13 Section 6.1.1.2 – Hinges, and Section 7.1.1.3 – Latching Hardware, have impact energy requirements reduced to 125 foot-pounds. This represents a 64% reduction from the 350 foot-pounds impact energy requirements of the Florida Building Code or ASTM 1996.

The 2003 edition of A250.13 defined its scope as hurricanes with wind speeds of 110 to 150 MPH. The 2008 edition has expanded its scope to encompass wind speeds up to 170 MPH, while reducing impact energy requirements and the safety factor in section 6.1.3.1

ANSI A250.13 - 2008 section 10.1 prohibits missile impacts to framing members of glazed transom / sidelite openings, as is typically conducted under ASTM 1996, ICC 500 or Florida Building Code protocol TAS 201 testing. A graphic comparison of impact test methods follows;



Florida Building Code - TAS 201
6.3.2.2 When testing any specimen with more than one component, in addition to complying with the impacts required by Section 1626.2 of the Florida Building Code, the framing member connecting these components shall be impacted at one half the span of such member with the large missile at a speed indicated in Section 1626.2.4 of the Florida Building Code.

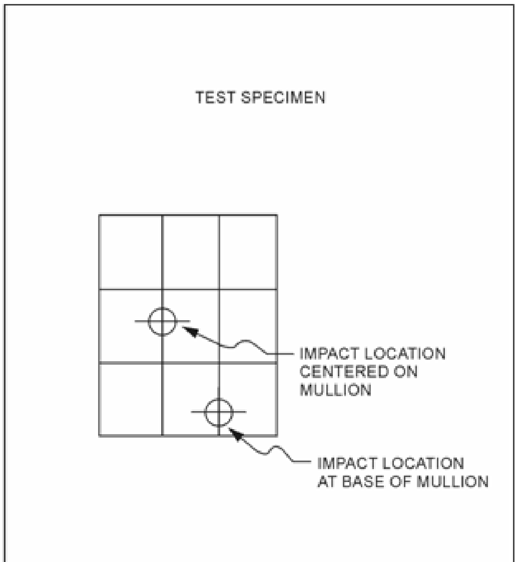


Figure 804.9.4-2

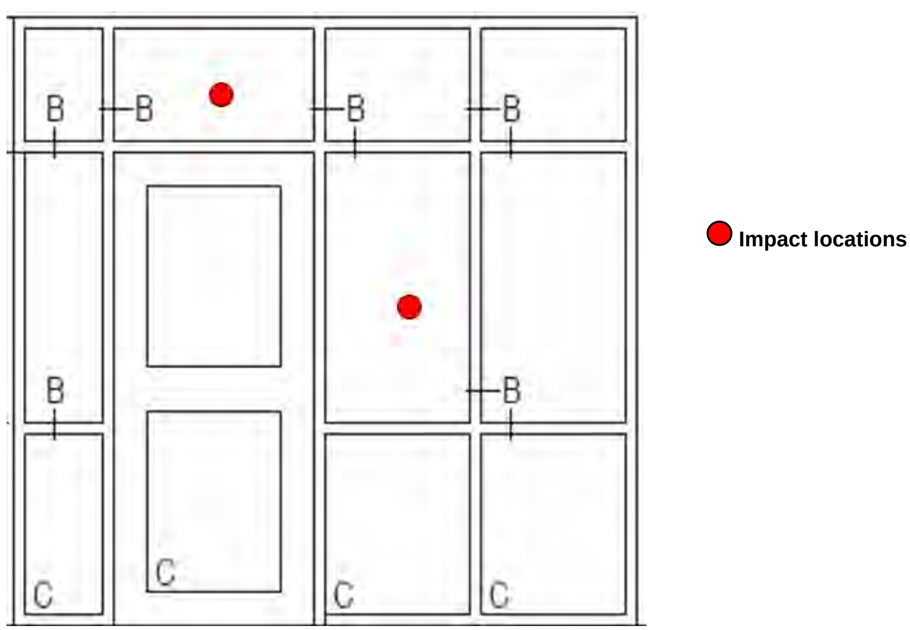
ICC 500

804.9.4 Windows and other Glazed Openings. All window assemblies and other glazed openings shall be impacted in the center of the smallest glazed section, and at one interface corner as detailed in Figure 804.9.4-1. Where interior mullions or other glazed section joints and/or latches are present, additional impacts shall be applied on these features as shown in Figure 804.9.4-2.



ANSI A 250.13
Sidelights and / or Transoms
10.1 Sidelights and/or transoms shall be tested with doors, to the largest total size (maximum area, height and width) to be rated. Testing shall be performed per ASTM E1886 and ASTM E1996 with the impacts applied only to the glazed portion of the assembly

Two similar proposals (S83 and S143 -07/08) to add ANSI A250.13 were disapproved in the last cycle by vote of the membership on September 20, 2008 at the Final Action Hearings in Minneapolis, MN

The Standard does not require engineering calculations validating openings configured from components, leaving the Plans Examiner or AHJ with the responsibility to do so, or the liability for not doing so

The October 30, 2009 issue of ANSI Standards Action identifies for public comment changes made to the A250.13 standard *after the approval of the document*. This matter is still open and pending with ANSI, subject to further review by the ANSI Board of Standards Review

Final Action: AS AM AMPC____ D

S94-09/10

1612.6 (New), Chapter 35

Proposed Change as Submitted

Proponent: Michael Mahoney, Federal Emergency Management Agency, representing the National Tsunami Hazard Mitigation Program

1. Add a new text as follows:

1612.6 Tsunami-generated flood hazard. Construction within a Tsunami Hazard Inundation Zone shall be in accordance with this section.

1612.6.1 Definitions. The following words and terms shall, for the purposes of this section, have the meanings shown herein.

TSUNAMI HAZARD INUNDATION MAP. A map that designates the extent of inundation by a design event tsunami which is developed and provided to a community by either the State or the National Atmospheric and Oceanic Administration (NOAA) under the National Tsunami Hazard Mitigation Program, using NOAA mapping criteria.

TSUNAMI HAZARD INUNDATION ZONE. The area anticipated to be flooded or inundated by a design event tsunami as identified on a community's Tsunami Hazard Inundation Map.

1612.6.2 Establishment of Tsunami Hazard Inundation Zone. Where a community has adopted a Tsunami Hazard Inundation Map, that map shall be used to establish a community's Tsunami Hazard Inundation Zone.

1612.6.3 Construction within the Tsunami Hazard Inundation Zone. Buildings and structures designated Occupancy Category III or IV in accordance with Section 1604.5 shall be prohibited within a Tsunami Hazard Inundation Zone.

> **Exception:** A vertical evacuation tsunami refuge shall be permitted to be located in a Tsunami Hazard Inundation Zone provided it is constructed in accordance with FEMA P646.

2. Add standard to Chapter 35 as follows:

Federal Emergency Management Agency
P646- 08 *Guidelines for Design of Structures for Vertical Evacuation from Tsunamis*

Reason: For coastal communities subject to tsunami waves, where the either the State or the National Oceanic and Atmospheric Administration (NOAA) have provided a Tsunami Hazard Inundation Map and that community has adopted that Map, the Map specifies a Tsunami Hazard Inundation Zone. This Zone is subject to inundation in a design event tsunami, which can result in significant damage. Most of these maps are deterministic in nature, using historical and best available scientific data, and it is currently difficult to assign a specific probability to the design event used for mapping purposes. However, given the potentially serious life safety risk presented to structures within this zone, this is sufficient justification to limit the presence of high hazard and high occupancy structures within the Zone.

Cost Impact: The potential cost impact would be requiring new high hazard and high occupancy structures to be located outside the Tsunami Inundation Zone. Given that this land is further away from the shore and therefore normally less expensive, the cost impact is believed to be minimal.

Analysis: A review of the standard(s) proposed for inclusion in the code, FEMA P646-08, for compliance with ICC criteria for referenced standards given in Section 3.6 of Council Policy #CP 28 will be posted on the ICC website on or before September 24, 2009.

ICCFILENAME: MAHONEY-S2-1612.6 NEW

Public Hearing Results

Note: The following analysis was not in the Code Change monograph but was published on the ICC website at http://www.iccsafe.org/cs/codes/Documents/2009-10cycle/ProposedChanges/Standards-Analysis.pdf :

Analysis: Review of proposed new standard, FEMA P646, indicated that, in the opinion of ICC Staff, the standard did not comply with ICC standards criteria, Section 3.6.2(1) Mandatory language, 3.6.3(2) Consensus process.

Committee Action: Approved as Modified

Modify the proposal as follows:

~~**1612.6 Tsunami-generated flood hazard.** Construction within a Tsunami Hazard Inundation Zone shall be in accordance with this section.~~

APPENDIX L
TSUNAMI-GENERATED FLOOD HAZARD

L101.1 General. The purpose of this appendix is to provide tsunami regulatory criteria for those communities that have a tsunami hazard and have elected to develop and adopt a map of their tsunami hazard inundation zone.

~~**1612.6.1**~~ **L101.2 Definitions.** The following words and terms shall, for the purposes of this ~~section~~ appendix, have the meanings shown herein.

TSUNAMI HAZARD INUNDATION MAP. A map that designates the extent of inundation by a design event tsunami which is developed and provided to a community by either the State or the National Atmospheric and Oceanic Administration (NOAA) under the National Tsunami Hazard Mitigation Program, using NOAA mapping criteria.

TSUNAMI HAZARD INUNDATION ZONE. The area anticipated to be flooded or inundated by a design event tsunami as identified on a community's Tsunami Hazard Inundation Map.

~~**1612.6.2**~~ **L101.3 Establishment of Tsunami Hazard Inundation Zone.** Where a community has adopted a Tsunami Hazard Inundation Map, that map shall be used to establish a community's Tsunami Hazard Inundation Zone.

~~**1612.6.3**~~ **L101.4 Construction within the Tsunami Hazard Inundation Zone.** Buildings and structures designated Occupancy Category III or IV in accordance with Section 1604.5 shall be prohibited within a Tsunami Hazard Inundation Zone.

> **Exception:** A vertical evacuation tsunami refuge shall be permitted to be located in a Tsunami Hazard Inundation Zone provided it is constructed in accordance with FEMA P646.

(Portions of proposal not shown are unchanged)

Committee Reason: This code change provides a good start, giving guidance on tsunami hazards. The modification places the provisions In an appendix, making them available for jurisdictions to adopt them.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Michael Mahoney, FEMA, representing National Tsunami Hazard Mitigation Program, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

APPENDIX L
TSUNAMI-GENERATED FLOOD HAZARD

L101.1 General. The purpose of this appendix is to provide tsunami regulatory criteria for those communities that have a tsunami hazard and have elected to develop and adopt a map of their tsunami hazard inundation zone.

L101.2 Definitions.

TSUNAMI HAZARD ~~INUNDATION~~ ZONE MAP. A map adopted by the community that designates the extent of inundation by a design event tsunami. This map shall be based the tsunami inundation map which is developed and provided to a community by either the applicable State agency or the National Atmospheric and Oceanic Administration (NOAA) under the National Tsunami Hazard Mitigation Program, ~~using NOAA mapping criteria~~ but shall be permitted to utilize a different probability or hazard level.

TSUNAMI HAZARD ~~INUNDATION~~ ZONE. The area ~~anticipated to be~~ vulnerable to being flooded or inundated by a design event tsunami as identified on a community's Tsunami Hazard ~~Inundation~~ Zone Map.

L101.3 Establishment of Tsunami Hazard ~~Inundation~~ Zone. Where applicable, if a community has adopted a Tsunami Hazard ~~Inundation~~ Zone Map, that map shall be used to establish a community's Tsunami Hazard ~~Inundation~~ Zone.

L101.4 Construction within the Tsunami Hazard ~~Inundation~~ Zone. Construction of structures designated Occupancy Category III and IV as specified under Section 1604.5 shall be prohibited within a Tsunami Hazard ~~Inundation~~ Zone.

Exceptions:

1. A vertical evacuation tsunami refuge shall be permitted to be located in a Tsunami Hazard ~~Inundation~~ Zone provided it is constructed in accordance with FEMA P646.
2. Community critical facilities shall be permitted to be located within the Tsunami Hazard Zone when such a location is necessary to fulfill their function, providing suitable structural and emergency evacuation measures have been incorporated..

Commenter's Reason: A subsequent review by the State representatives to the National Tsunami Hazard Mitigation Program (NTHMP) generated several comments, which have been condensed into this single public comment. The most significant of these was that the Tsunami Inundation Maps developed by either the State or the National Oceanic and Atmospheric Administration (NOAA) are generally worst case deterministic maps for emergency evacuation purposes. Those maps may be too severe for the purposes of this appendix, so the language in M101.2 has been modified to decouple the Tsunami Inundation Map from the Tsunami Hazard Zone Map referenced in this appendix so that a community can select a map using a more appropriate hazard level. A second comment was that some communities may have a situation where critical facilities may need to be located in the Tsunami Hazard Zone. Exception #2 was added for this situation, but only if evacuation measures have been incorporated.

Final Action: AS AM AMPC____ D

S97-09/10-PART I

1613.5.1, Figure 1613.5(1) - Figure 1613.5(14)

Proposed Change as Submitted

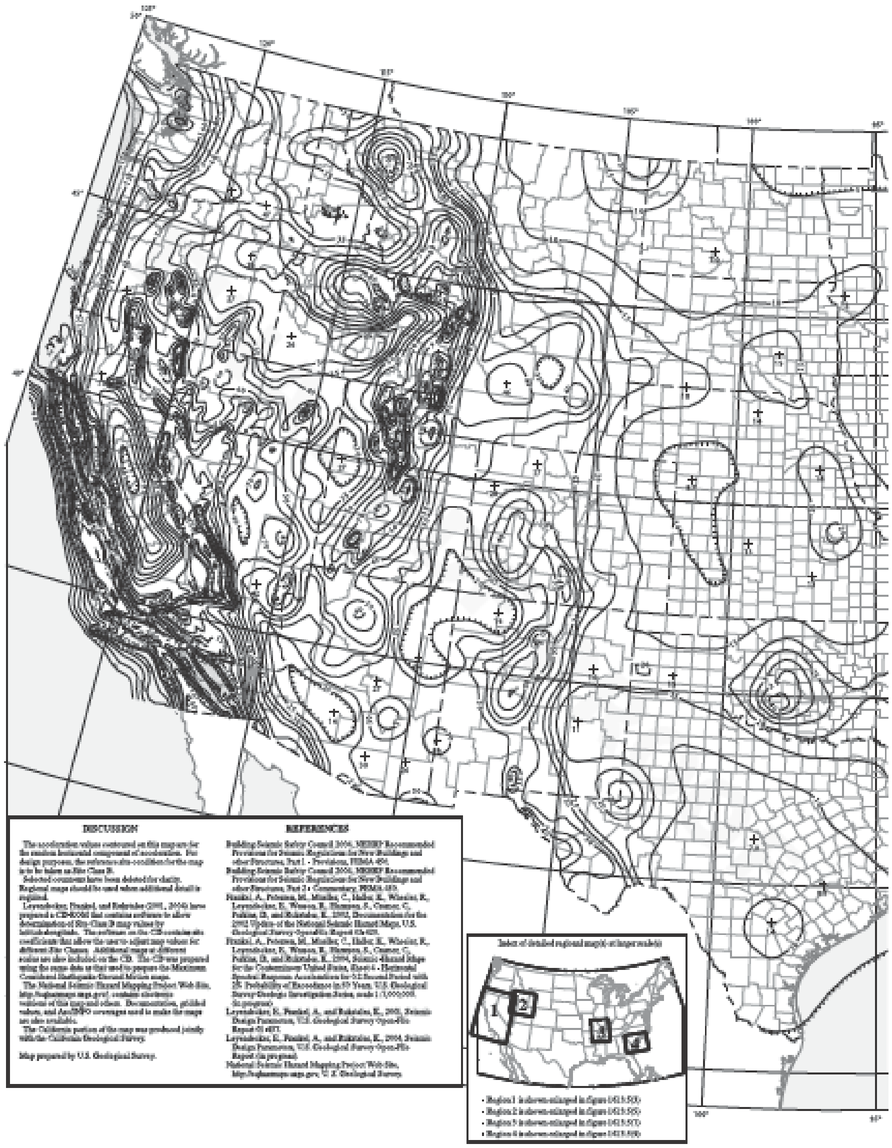
Proponent: Steven Winkel, FAIA, PE, Kelly Cobeen, PE, SE, and J. Daniel Dolan, PhD, PE, Building Seismic Safety Council (BSSC) of the National Institute of Building Sciences, representing the Federal Emergency Management Agency/BSSC Code Resource Support Committee

PART I – IBC STRUCTURAL

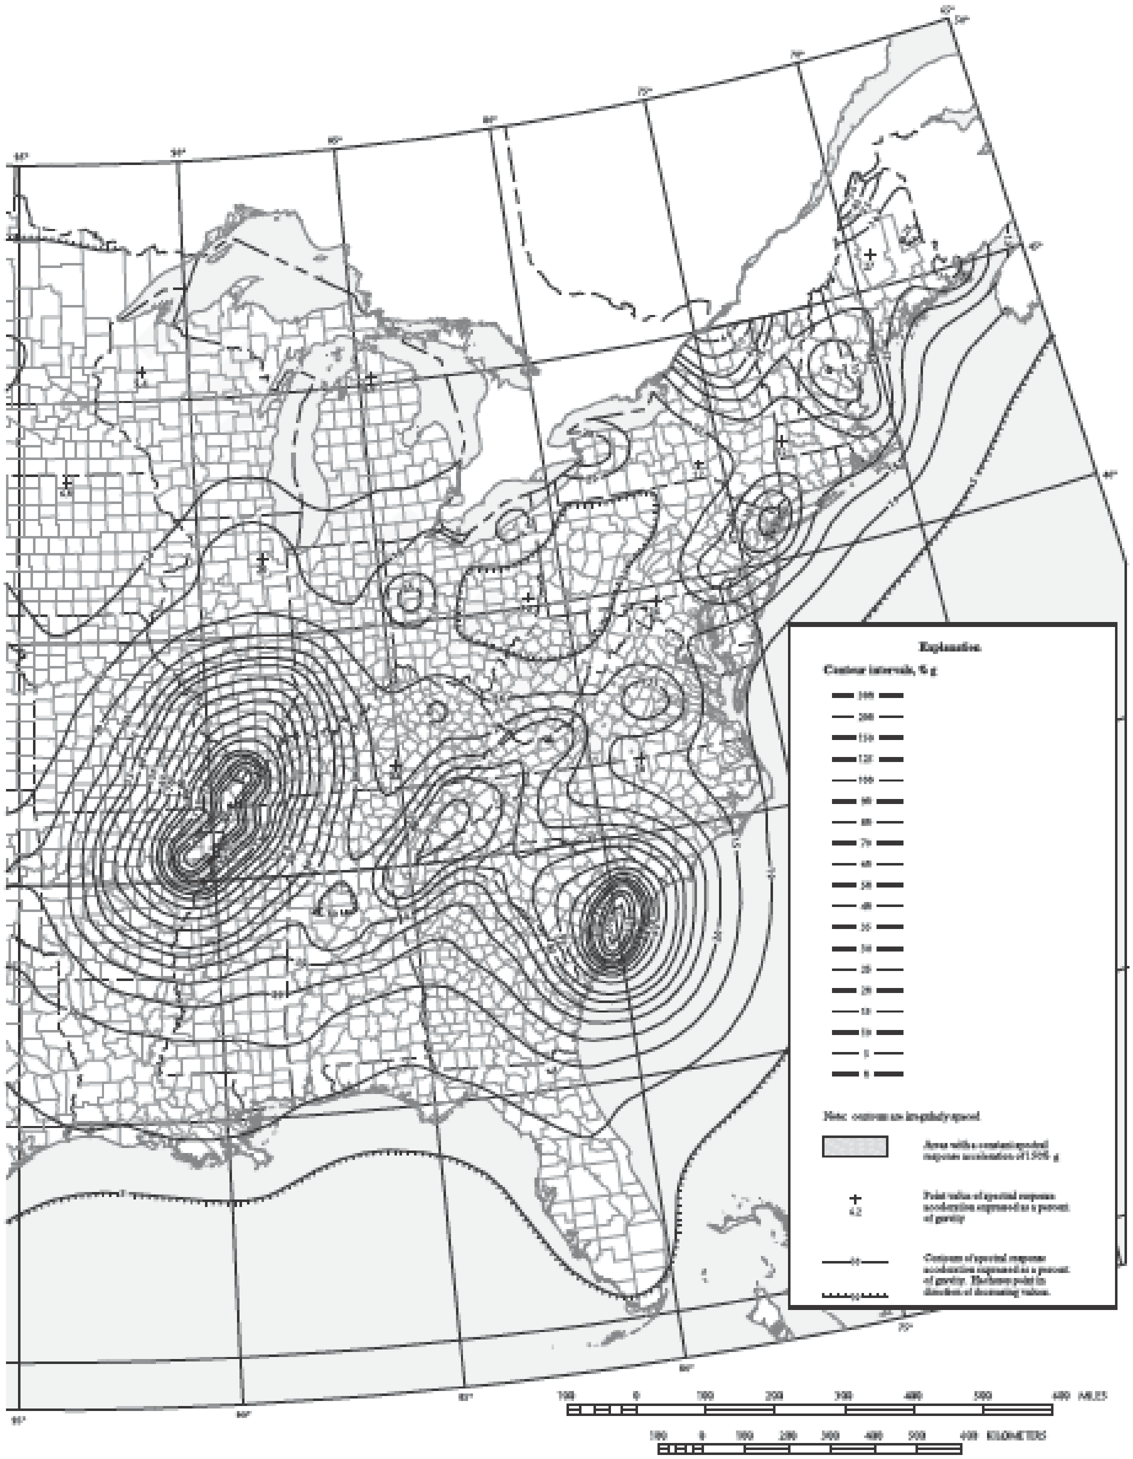
Revise as follows:

1613.5.1 Mapped Acceleration Parameters. The parameters S_S and S_1 shall be determined from the 0.2 and 1 s spectral response accelerations shown on Figures 1613.5(1) and 1613.5(2) ~~through 1613.5(14), respectively~~. Where S_1 is less than or equal to 0.04 and S_S is less than or equal to 0.15, the structure is permitted to be assigned to Seismic Design Category A.

2. Delete and substitute as follows:



~~FIGURE 1613.5(1)~~
~~MAXIMUM CONSIDERED EARTHQUAKE GROUND MOTION FOR THE CONTERMINOUS UNITED STATES OF 0.2 SEC SPECTRAL RESPONSE ACCELERATION (5% OF CRITICAL DAMPING), SITE CLASS B~~



~~**FIGURE 1613.5(1)-continued**~~
~~**MAXIMUM CONSIDERED EARTHQUAKE GROUND MOTION FOR THE CONTERMINOUS UNITED STATES OF 0.2 SEC SPECTRAL RESPONSE ACCELERATION (5% OF CRITICAL DAMPING), SITE CLASS B**~~

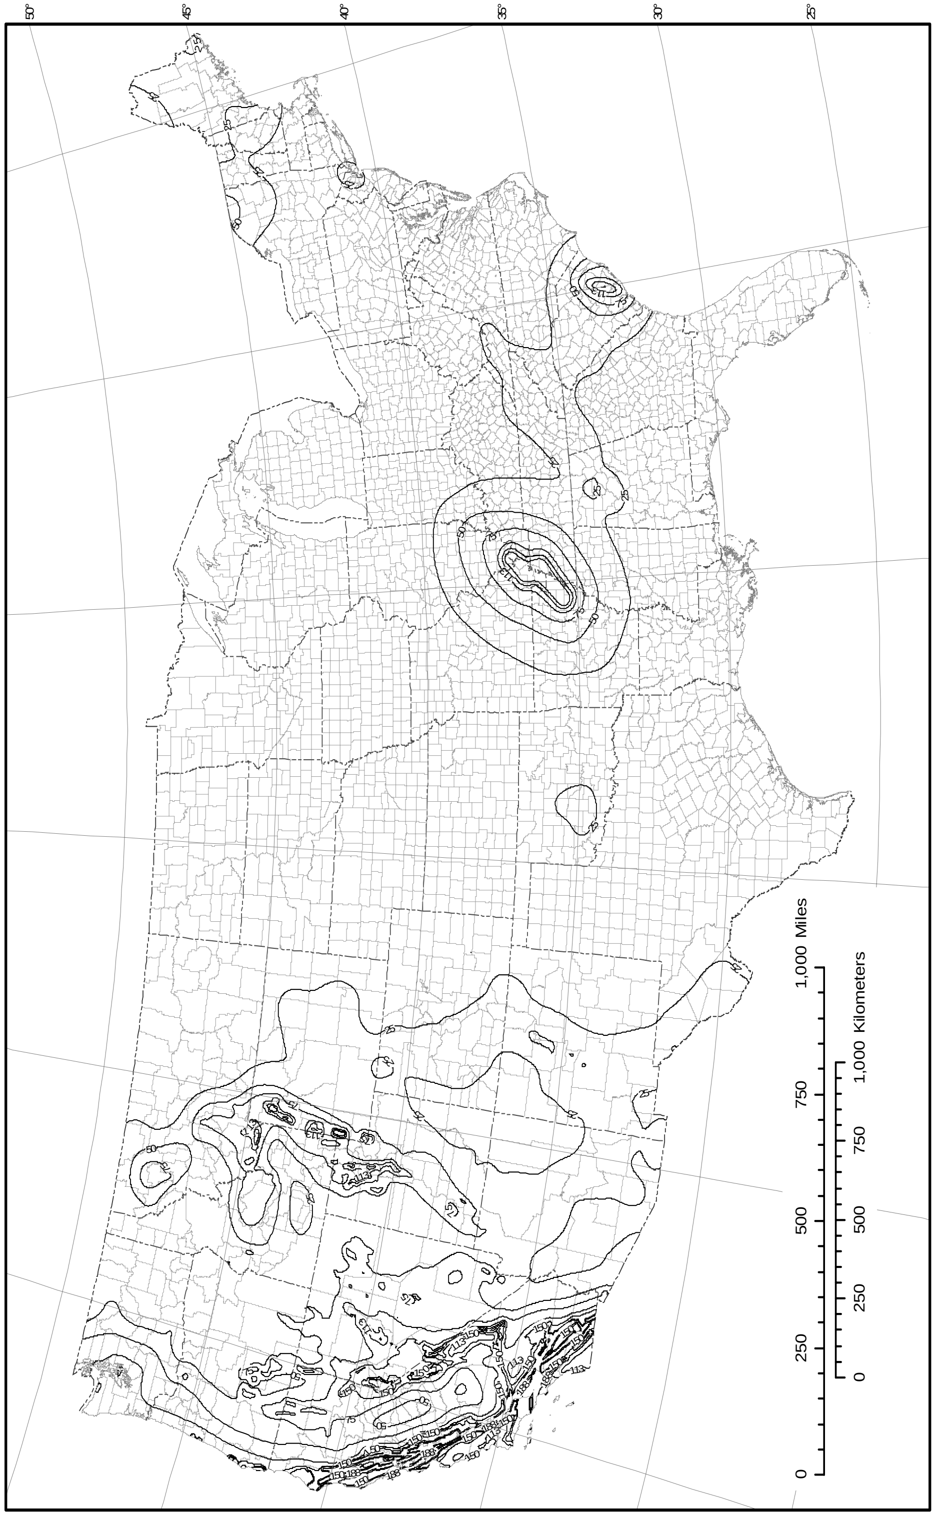


FIGURE 1613.5(1)
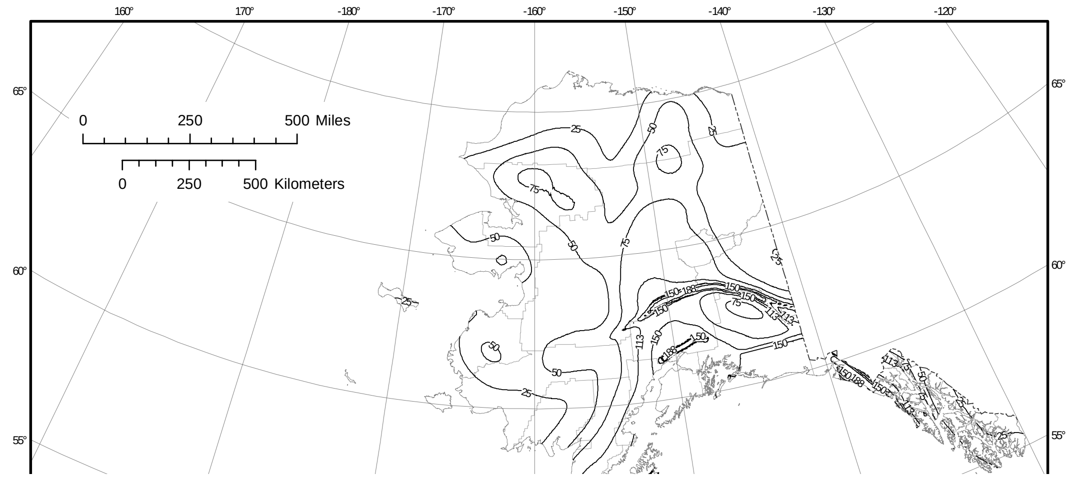
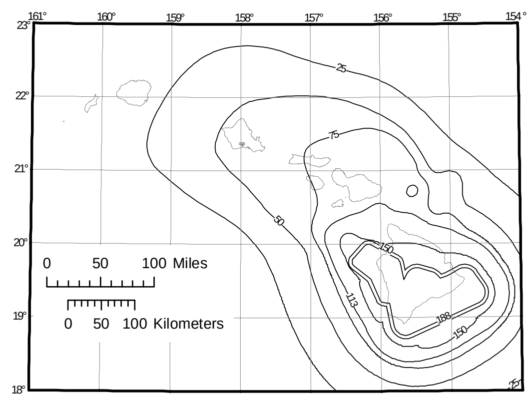
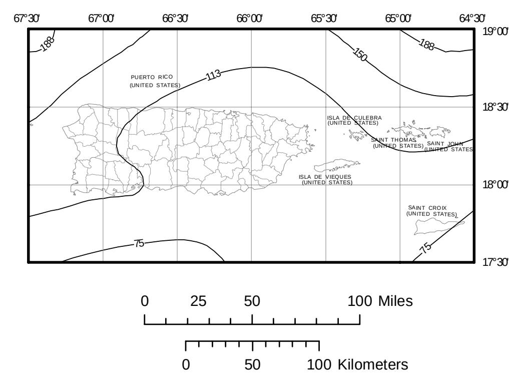
MAXIMUM CONSIDERED EARTHQUAKE (MCE) GROUND MOTION OF 0.2 S SPECTRAL RESPONSE ACCELERATION (5% OF CRITICAL DAMPING), SITE CLASS B



Contours are in units of %g





Notes:

Maps prepared by United States Geological Survey (USGS) in collaboration with the Federal Emergency Management Agency funded work of the Building Seismic Safety Council (BSSC) and with the American Society of Civil Engineers (ASCE) 7 Seismic Subcommittee.

Ground motion values contoured on these maps incorporate risk-targeted and deterministic ground motions and a factor of 1.1 for the maximum direction of 0.2 s spectral response acceleration. As such, they are different from those on the uniform-hazard-based 2008 USGS National Seismic Hazard Maps posted at http://earthquake.usgs.gov/research/hazmaps/.

Larger, more detailed versions of these maps are not provided because it is recommended that a corresponding USGS web tool at http://earthquake.usgs.gov/research /hazmaps/design/ be used to determine the mapped value for specific locations.

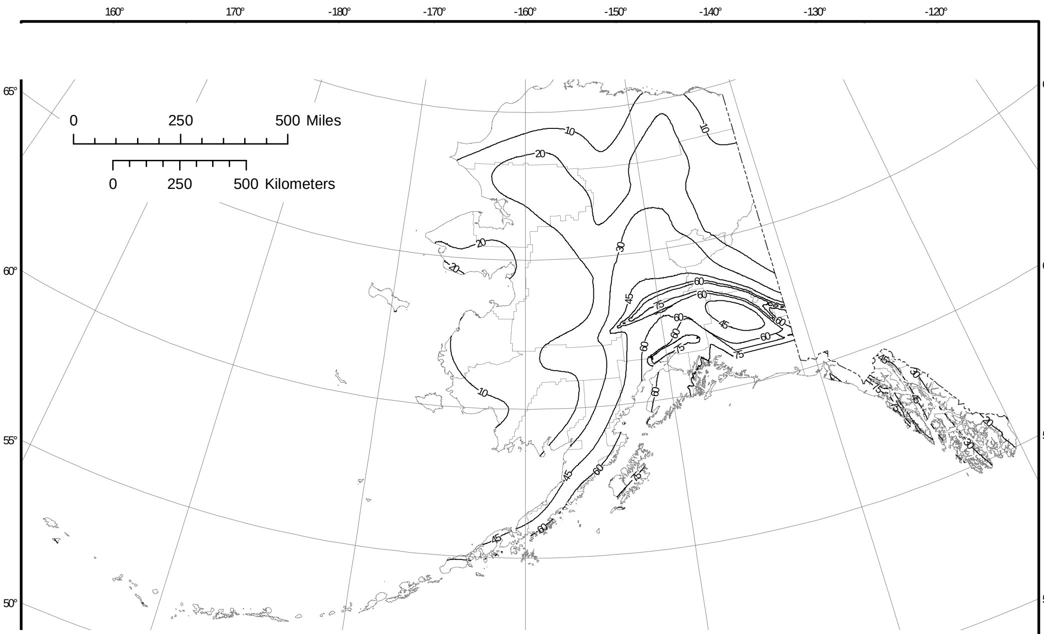
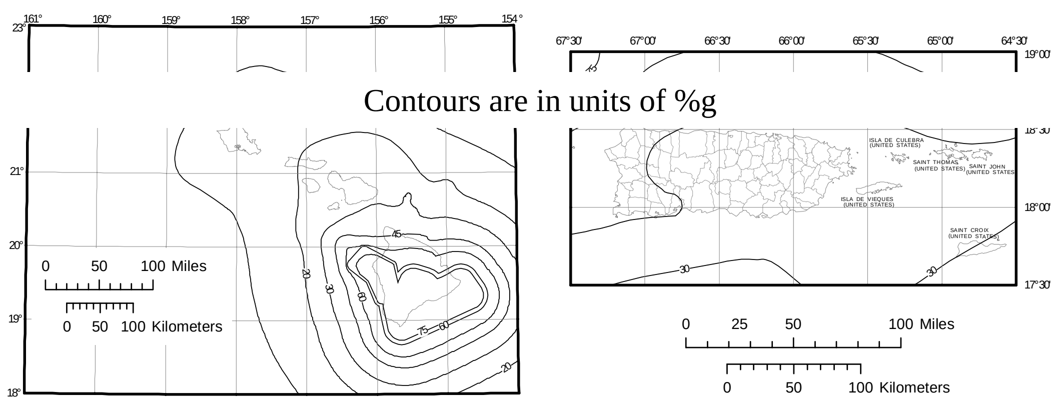
MAXIMUM CONSIDERED EARTHQUAKE (MCE) GROUND MOTION OF 1 S SPECTRAL RESPONSE ACCELERATION (5% OF CRITICAL DAMPING), SITE CLASS B



Contours are in units of %g



Contours are in units of %g

Notes:

Maps prepared by United States Geological Survey (USGS) in collaboration with the Federal Emergency Management Agency funded work of the Building Seismic Safety Council (BSSC) and with the American Society of Civil Engineers (ASCE) 7 Seismic Subcommittee.

Ground motion values contoured on these maps incorporate risk-targeted and deterministic ground motions and a factor of 1.3 for the maximum direction of 1.0 s spectral response acceleration. As such, they are different from those on the uniform-hazard-based 2008 USGS National Seismic Hazard Maps posted at http://earthquake.usgs.gov/research/hazmaps/.

Larger, more detailed versions of these maps are not provided because it is recommended that a corresponding USGS web tool at http://earthquake.usgs.gov/research /hazmaps/design/ be used to determine the mapped value for specific locations.

FIGURE 1613.5(2) (CONTINUED)
MAXIMUM CONSIDERED EARTHQUAKE (MCE) GROUND MOTION OF 1 S SPECTRAL RESPONSE ACCELERATION (5% OF CRITICAL DAMPING), SITE CLASS B

Delete Figures 1613.5(3) through 1613.5(14) without substitution.

Reason: PART I**-** This proposal incorporates updated earthquake ground motion maps that reflect the 2008 maps developed by the United States Geological Survey (USGS) National Seismic Hazard Mapping Project as well as technical changes adopted for the 2009 *NEHRP Recommended Seismic Provisions for New Buildings and Other Structures* (FEMA P750), which was developed by the Building Seismic Safety Council with funding from the Federal Emergency Management Agency. Both projects are part of federal National Earthquake Hazard Reduction Program's (NEHRP) ongoing efforts to make the most current earthquake hazard information available to the building codes. If this code change is not moved forward, the ground motion maps in the IBC will reflect superseded seismic hazard information.

The 2008 USGS seismic hazard maps incorporate new information on earthquake sources and ground motion prediction equations including the new Next Generation Attenuation (NGA) relations. The ground motion maps proposed for the IBC further incorporate technical changes adopted for the 2009 *NEHRP Provisions* that include use of: (1) risk-targeted ground motions, (2) maximum direction ground motions, and (3) near-source 84th percentile ground motions.

The proposed ground motion maps for the IBC also reflect a current draft proposal for change to the ASCE 7 (Minimum Design Loads for Buildings and other Structures) standard update process. Under normal circumstances, ASCE 7 would adopt ground motion map related changes drawn from the most current edition of the *NEHRP Recommended Seismic Provisions* prior to incorporation of the maps into the IBC*;* however, the recent changes to the ICC code development process and schedule have made it necessary to submit this working version of the ASCE 7 proposal in an effort to provide the regulatory community with the most up-to-date information available. It should be understood that, to the extent possible, this proposal will be updated to reflect any modifications to maps, maps titles or other Section 1613 content made during the ASCE 7 consensus standard process so the consistency between ASCE 7 and the IBC is maintained. In the NEHRP update process the title for these maps was revised from "Maximum Considered Earthquake (MCE) Ground Motions" to "Risk-Targeted Earthquake (RTE) Ground Motions." This proposal retains the MCE terminology because it is retained in the working version of the ASCE 7 proposal.

This proposal also reduces the number of printed maps to appear in the IBC from 14 to 2. Twelve of the maps included in earlier editions of the IBC provided enlargements of portions of two maps that covered the entire United States; this proposal eliminates the enlargements. This is being recommended because the maps printed in former editions of the IBC, while generally illustrative of the earthquake hazard, could not to be read clearly enough to provide exact design values for specific building sites. Those in need of precise design values can easily obtain them from a USGS web site (http://earthquake.usgs.gov/research/hazmaps/design/index.php) using the longitude and latitude of the building site, obtained from GPS mapping programs or web sites.

Detailed descriptions of changes made for the 2009 *NEHRP Recommended Seismic Provisions* are available at www.bssconline.org under the explanation of changes made for the 2009 edition of the *Provisions.*

Cost Impact: The new maps may lower costs in some locations but may increase them in others.

ICCFILENAME: WINKEL-COBEEN-S1-1613.1

Public Hearing Results

PART I- IBC STRUCTURAL
Committee Action: Approved as Modified

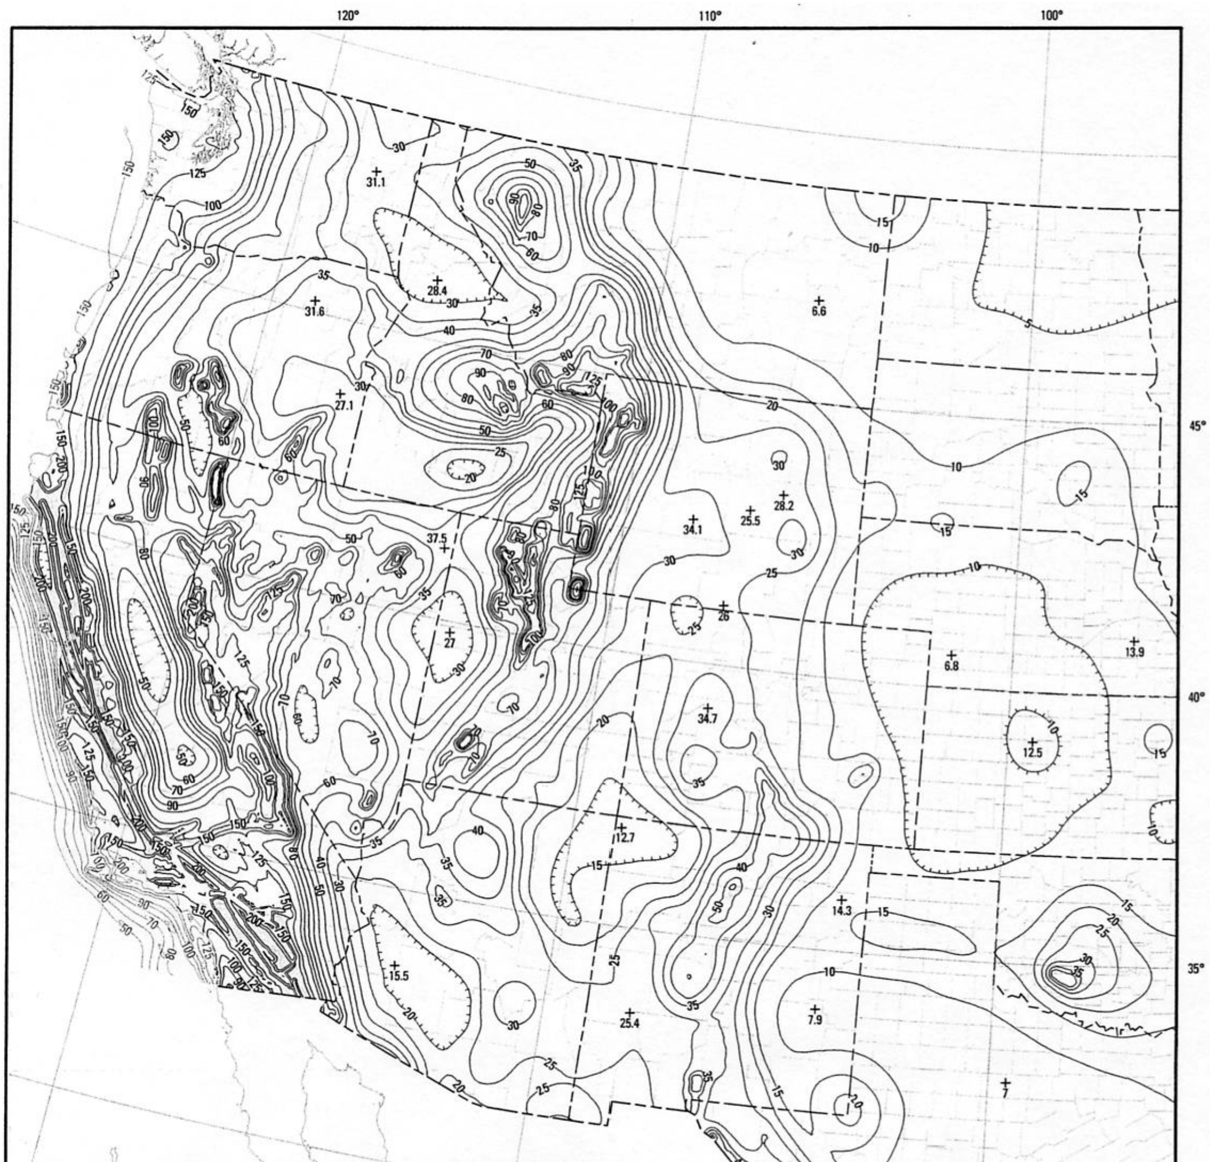
Modify the proposal as follows:

1613.2 Definitions. The following words and terms shall, for the purposes of this section, have the meanings shown herein.

MAXIMUM CONSIDERED EARTHQUAKE GROUND MOTION (MCE$_R$). The most severe earthquake effects considered by this code.

(No changes to definitions not shown)

1613.5.1 Mapped Acceleration Parameters. The parameters S_S and S_1 shall be determined from the 0.2 and 1 s spectral response accelerations shown on Figures 1613.5(1) ~~and 1613.5(2)~~ through 1613.5(6). Where S_1 is less than or equal to 0.04 and S_S is less than or equal to 0.15, the structure is permitted to be assigned to Seismic Design Category A.



DISCUSSION

Maps prepared by United States Geological Survey (USGS) in collaboration with the Federal Emergency Management Agency (FEMA)-funded Building Seismic Safety Council (BSSC) and the American Society of Civil Engineers (ASCE). The basis is explained in commentaries prepared by BSSC and ASCE and in the references.

Ground motion values contoured on these maps incorporate:

- a target risk of structural collapse equal to 1% in 50 years based upon a generic structural fragility
- a factor of 1.1 to adjust from a geometric mean to the maximum response regardless of direction
- deterministic upper limits imposed near large, active faults, which are taken as 1.8 times the estimated median response to the characteristic earthquake for the fault (1.8 is used to represent the 84th percentile response), but not less than 150% g.

As such, the values are different from those on the uniform-hazard 2008 USGS National Seismic Hazard Maps posted at http://earthquake.usgs.gov/hazmaps.

Larger, more detailed versions of these maps are not provided because it is recommended that the corresponding USGS web tool (http://earthquake.usgs.gov/designmaps or http://content.seinstitute.org) be used to determine the mapped value for a specified location.

DISCUSSION

Maps prepared by United States Geological Survey (USGS) in collaboration with the Federal Emergency Management Agency (FEMA)-funded Building Seismic Safety Council (BSSC) and the American Society of Civil Engineers (ASCE). The basis is explained in commentaries prepared by BSSC and ASCE and in the references given below.

Ground motion values contoured on these maps incorporate:

- a target risk of structural collapse equal to 1% in 50 years based upon a generic structural fragility
- deterministic upper limits imposed near large, active faults, which are taken as 1.8 times the estimated median response to the characteristic earthquake for the fault (1.8 is used to represent the 84th percentile response), but not less than 150 and 60% g for 0.2 and 1.0 sec, respectively.

As such, the values are different from those on the uniform-hazard 1998 USGS National Seismic Hazard Maps for Hawaii posted at http://earthquake.usgs.gov/hazmaps.

Larger, more detailed versions of these maps are not provided because it is recommended that the corresponding USGS web tool (http://earthquake.usgs.gov/designmaps or http://content.seinstitute.org) be used to determine the mapped value for a specified location.

Committee Reason: This proposal incorporates the latest USGS ground motion maps. The modification updates the map titles and provides reformatted versions of the maps with no technical changes. It also separates areas outside the conterminous United States, on individual maps.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Steven Winkel, FAIA, PE, and Kelly Cobeen, PE, SE, representing the Federal Emergency Management Agency/Building Seismic Safety Council Code Resource Support Committee (FEMA/BSSC CRSC) and James Rossberg, PE, representing the American Society of Civil Engineers (ASCE),request Approval as Modified by this Public Comment.

Further modify the proposal as follows:

1613.2 Definitions. The following words and terms shall, for the purposes of this section, have the meanings shown herein.

RISK-TARGETED MAXIMUM CONSIDERED EARTHQUAKE (MCE_R). GROUND MOTION ~~(MCE_R).~~ RESPONSE ACCELERATIONS The most severe earthquake effects considered by this code, determined for the orientation that results in the largest maximum response to horizontal ground motions and, with adjustment for targeted risk.

(No changes to definitions not shown)

FIGURE 1613.5(1)
RISK-TARGETED MAXIMUM CONSIDERED EARTHQUAKE (MCE_R) GROUND MOTION RESPONSE ACCELERATIONS ~~(MCE_R)~~ FOR THE CONTERMINOUS UNITED STATES OF 0.2 SECOND SPECTRAL RESPONSE ACCELERATION (5% OF CRITICAL DAMPING), SITE CLASS B

FIGURE 1613.5(6)
RISK-TARGETED MAXIMUM CONSIDERED EARTHQUAKE (MCE_R) GROUND MOTION RESPONSE ACCELERATIONS ~~(MCE_R)~~ FOR PUERTO RICO, CULEBRA, VIEQUES, ST. THOMAS, ST. JOHN AND ST. CROIX OF 0.2 AND 1 SECOND SPECTRAL RESPONSE ACCELERATION (5% OF CRITICAL DAMPING), SITE CLASS B

(Portions of proposal not shown remain unchanged)

Commenter's Reason: In the original submittal, the reason stated that this code change would be modified if required to correlate with modifications to the maps being adopted into ASCE 7. This modification changes the map titles and definition to coordinate with ASCE 7 wording. This change is editorial; there is no technical change.

Public Comment 2:

James Bela, Oregon Earthquake Awareness, requests Disapproval.

Commenter's Reason: The Commenter asks DISAPPROVAL, because the proposals [Part I- IBC STRUCTURAL; PART II- IRC B/E] were:

(a) neither adequately nor correctly justified by the committee, but were let-in without a proper checking of their content and credentials, *simply* because they were "the latest USGS ground motion maps."

(b) inclusive of *changes* in Mapped Spectral Response Acceleration contour values from previous code editions that were *not* specifically made clear (along with the impact of those changes on seismic design parameters).

(c) inclusive of changes resulting from applying Next Generation Attenuation (NGA) relationships that reduced design spectral response acceleration by up to 25% in some earthquake prone regions of the country, despite a clear lack of consensus for this change from the USGS Ground Motion Mapping Workshop participants.

(d) inclusive of a so-called "target risk of structural collapse equal to 1% in 50 years based upon a generic structural fragility" that is arbitrary, ambiguous and a major departure from all previous codes. This is particularly "dangerous" to public safety (because the specified target risk is the same probability as considered for the May 2008 Wenchuan Earthquake in China—where that earthquake *disproved* all the assumptions underlying the formulation of the USGS Seismic Hazard Maps (and killed more than 80,000 people); and

(e) introduces a new term $\underline{MCE_R}$ as a "MAXIMUM CONSIDERED EARTHQUAKE GROUND MOTION" – that is anything but an earthquake ground motion! This will introduce unnecessary confusion and complication into the code--in particular, problems in relating to earlier code editions for continuity.

The USGS Seismic Hazard Maps have been, and continue to be, too *unstable* as a basis for seismic design. We are introducing "yo-yo" tectonics into the seismic design codes, such that there is no longer *continuity* in our system of what to do to keep the earthquakes from attacking you! Engineers cannot develop experience and hone valuable judgement skills, if the code continues to be a moving target.

For the wholesale changes proposed here (where seismic hazard has become whatever input parameters people can come up with . . . from NGA, GPS strain monitoring, new faults and so-called slip rates, Risk mumbo-jumbo, generic fragility curves); the new spectral response acceleration maps should have first been produced in the same manner as the previous code editions - then a comparison of results could have been made with proposed applications of the new map. This is necessary for a *reality check* as to the reasonableness of adopting something "new" for "newness" sake, where it might weaken or reduce long accepted minimum standards for protecting the public safety.

These new maps should have provided a city-by-city comparison of old map design values with the "latest" to be considered values. Otherwise, there is no telling how the public safety is being impacted. *Documentation of the discussions, votes taken, and specific explanations and justifications for these changes should have been provided to the committee and to the public*. A code change proponent must be held accountable to justify these changes (and also clearly define these same) to the committee from which approval is sought. Giving a weblink to a telephone book of information is unacceptable for a public process.

These "latest" maps are unsafe at any parameter, because they are not anchored to a stable earthquake design methodology. The only stable basis for earthquake design provisions that truly protect publics safety is to link them to a consideration of the maximum potential earthquake size (or Magnitude) from a specific fault. For example, earthquake design within 15 miles of a M 6 active fault, and within 25 miles of a M 7 or greater active faults should incorporate design provisions against that eventuality, regardless of complex methodologies of applied mathematics (to calculate earthquake probabilities and risk). These methods entice our code provisions to sink ever lower, because they too often *perceive* the likelihood of an earthquake to be too rare to be taken seriously.

SEISMIC DESIGN CATEGORIES -- SITE CLASS D

Reason: This proposal reflects new seismic hazard data developed by the U.S. Geological Survey (USGS) as part of its National Seismic Hazard Mapping Project and related technical changes developed by the Building Seismic Safety Council's (BSSC) Seismic Design Procedures Reassessment Group (SDPRG) as part of its work for the Federal Emergency Management Agency (FEMA).

The USGS and the FEMA-funded SDPRG worked together to update the seismic design maps and procedures for the 2009 edition of the NEHRP (National Earthquake Hazards Reduction Program) Recommended Seismic Provisions for New Building and Other Structures. The products of this collaboration are new design maps that appear in the 2009 *Provisions* and a similar version that is proposed for inclusion in ASCE 7-10. Although the terminology used in the *Provisions* is slightly different from that proposed for ASCE 7-10, the substance of the mapping changes is the same for both. The new design maps are based on USGS updates to their seismic hazard data and ground motion attenuation formulas as well as the SDPRG's use of risk-targeted ground motions, maximum direction ground motions, and near-source 84th percentile ground motions.

Code updates to the seismic maps and seismic resistant design requirements normally are drawn from ASCE 7 (*Minimum Design Loads for Buildings and Other Structures*) which is, in turn, based on the *NEHRP Recommended Provisions*. This proposal reflects material developed under the 2009 *NEHRP Recommended Provisions* as presented in the current draft proposal for ASCE 7-10. The ICC code change submittal schedule makes it necessary to submit this working version with the understanding that it will be updated to the extent possible to reflect any modifications made by ASCE 7. Note that the maps included in this proposal are based on the maps proposed for inclusion in the IBC. If this code change is not moved forward, the IRC will retain superseded seismic hazard mapping information, thereby potentially being in conflict with the IBC.

These new IRC maps are different from earlier versions in that the division between Seismic Design Categories D2 and E has been changed from 118% g to 125% g. The 125% g contour would have been used in earlier maps but the mapping technology then available for drawing the IRC maps did not permit this to be done. The result of this change and the improved seismic hazard data generated by the USGS over the past 10 years is that the geographic region affected by the Seismic Design Category E designation is smaller. This occurs primarily in the region around Charleston, South Carolina, but is also evident in Seismic Design Category E regions in other parts of the United States. As noted above, maps developed on the same basis have been proposed for the IBC which will allow engineers to design components of the building that are outside of the scope of the IRC with compatible seismic loads.

Cost Impact: This proposal will not increase the cost of construction and will reduce the cost in some regions.

ICCFILENAME: WINKEL-COBEEN-S2-1613.5.1

Public Hearing Results

PART II- IRC B/E
Committee Action: **Approved as Submitted**

Committee Reason: This change brings the latest and improved Seismic Maps into the code. This will correlate the maps with the IBC and ASCE 7-10. One benefit of the new map is that some Seismic Design Category E regions will be smaller in area. This will result in some previous Seismic Design Category E structures to now be Seismic Design Category D structures.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

James Bela, Oregon Earthquake Awareness, requests Disapproval.

Commenter's Reason: See S97-09/10-Part I

Final Action: AS AM AMPC____ D

S108-09/10

1613.8 (New), Appendix L (New)

Proposed Change as Submitted

Proponent: Robert E. Bachman, SE, Robert E Bachman Consulting Structural Engineers, representing The Consortium of Organizations for Strong-Motion Observation Systems

Add new text as follows:

1613.8 Earthquake-recording instrumentations. For earthquake-recording instrumentations, see Appendix L.

APPENDIX L

EARTHQUAKE RECORDING INSTRUMENTATIONS

SECTION L101
GENERAL

L101.1 General. Every building located where the 1-second spectral response acceleration, S_1, in accordance with Section 1613.5 is greater than 0.40 that either 1) exceeds six stories above grade plane with an aggregate floor area of 60,000 square feet (5574 m^2) or more, or 2) exceeds 10 stories above grade plane regardless of floor area, shall be provided with not less than three approved recording accelerographs.

The accelerographs shall be interconnected for common start and common timing.

L 101.2 Location. As a minimum, instruments shall be located at the lowest level, midheight, and near the top of the building. Each instrument shall be located so that access is maintained at all times and is unobstructed by room contents. A sign stating MAINTAIN CLEAR ACCESS TO THIS INSTRUMENT shall be posted in a conspicuous location.

L 101.3 Maintenance. Maintenance and service of the instrumentation shall be provided by the owner of the building, subject to the approval of the building official. Data produced by the instrument shall be made available to the building official on request.

Reason: Earthquake Recording Instrumentation measurements provide fundamental information needed to cost effectively improve the seismic performance of buildings. The wording of the added Section is taken from Section 1652 and Appendix Chapter 16, Division II of the 1997 UBC. When the IBC was created, this section was apparently inadvertently not included. The code change proposal is intended to correct this oversight. The proposed change only covers instrumentation in newly constructed buildings. This proposal was submitted in the last cycle as a mandatory requirement in Chapter 1613. The Structural Committee suggested it be resubmitted as a non-mandatory Appendix during this cycle.

Cost Impact: Because this is an optional Appendix, this change will only have a cost impact in Jurisdictions in which it is adopted. In Jurisdictions where it is adopted, the cost impact will depend on whether similar ordinances are already in place. If ordinances are already in place, the cost impact will be negligible. For jurisdictions that adopt where ordinances are not in place, the cost impact, would be very small (less than 0.1% of the cost of the new construction) and only apply to very few structures in the high areas of seismic activity.

ICCFILENAME: Bachman-S1-1613.8-App L

Public Hearing Results

Committee Action: **Approved as Modified**

Modify the proposal as follows:

~~**1613.8 Earthquake-Recording Instrumentations.** For earthquake-recording instrumentations, see Appendix L.~~

L101.1 General. Every structure ~~building~~ located where the 1-second spectral response acceleration, S_1, in accordance with Section 1613.5 is greater than 0.40 that either 1) exceeds six stories in height ~~above grade plane~~ with an aggregate floor area of 60,000 square feet (5574 m^2) or more, or 2) exceeds ten ~~10~~ stories in height ~~above grade plane~~ regardless of floor area, shall be equipped ~~provided~~ with not less than three approved recording accelerographs. The accelerographs shall be interconnected for common start and common timing.

~~The accelerographs shall be interconnected for common start and common timing.~~

L 101.2 Location. As a minimum, instruments shall be located at the lowest level, mid-height, and near the top of the structure ~~building~~. Each instrument shall be located so that access is maintained at all times and is unobstructed by room contents. A sign stating "MAINTAIN CLEAR ACCESS TO THIS INSTRUMENT" in one inch block letters shall be posted in a conspicuous location.

L 101.3 Maintenance. Maintenance and service of the instrumentation shall be provided by the owner of the structure ~~building, subject to the approval of the building official~~. Data produced by the instrument shall be made available to the building official on request.

Maintenance and service of the instruments shall be performed annually by an approved testing agency. The owner shall file with the building official a written report from an approved testing agency certifying that each instrument has been serviced and is in proper working condition. This report shall be submitted when the instruments are installed and annually thereafter. Each instrument shall have affixed to it an externally visible tag specifying the date of the last maintenance or service and the printed name and address of the testing agency.

(Portions of the proposal not shown are unchanged.)

Committee Reason: An appendix chapter on earthquake recording instrumentation is an important addition to the IBC for those jurisdictions that have typically adopted such provisions. The data collected is valuable in understanding how earthquakes affect structures. The modification removes an unnecessary reference to the appendix from Chapter 16. "Building" has been appropriately changed to the more general term, "structure". The reference to the building official's approval was removed from the section on maintenance since this would be difficult to enforce after a certificate of occupancy is issued. Other changes are consistent with similar requirements in the LA City Building Code.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

James Bela, Oregon Earthquake Awareness, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

1613.8 Earthquake Recording Instrumentation. For earthquake-recording instrumentations, see Appendix L.

L101.1 General. Every ~~structure~~ building located where the 1-second spectral response acceleration, S_1, in accordance with Section 1613.5 is greater than 0.40, or lies within 15 miles distance of an active fault with a maximum potential earthquake M 6 or above, or lies within 25 miles distance of an active fault with a maximum potential earthquake M 7 or above; and that either 1) exceeds six stories in height with an aggregate floor area of 60,000 square feet (5574 m^2) or more, or 2) exceeds ten stories in height regardless of floor area, shall be equipped with not less than three approved recording accelerographs. The accelerographs shall be interconnected for common start and common timing.

L 101.2 Location. As a minimum, instruments shall be located at the lowest level, mid-height, and near the top of the ~~structure~~ building. Each instrument shall be located so that access is maintained at all times and is unobstructed by room contents. A sign stating "MAINTAIN CLEAR ACCESS TO THIS INSTRUMENT" in one inch block letters shall be posted in a conspicuous location.

L 101.3 Maintenance. Maintenance and service of the instrumentation shall be provided by the owner of the ~~structure~~ building, subject to the approval of the building official. Data produced by the instrument shall be made available to the building official on request.

Maintenance and service of the instruments shall be performed annually by an approved testing agency. The owner shall file with the building official a written report from an approved testing agency certifying that each instrument has been serviced and is in proper working condition. This report shall be submitted when the instruments are installed and annually thereafter. Each instrument shall have affixed to it an externally visible tag specifying the date of the last maintenance or service and the printed name and address of the testing agency.

(Portions of the proposal not shown are unchanged)

Commenter's Reason: The 1-second spectral response acceleration contours are interesting, but their locations are yo-yoing around with each new addition of the maps; so that are not reliable over time. An earthquake will occur on a fault, and it is the proximity of a building to an earthquake source that determines its actual experience to ground shaking in a real earthquake. This additional charging language fills this hole in locations, particularly in the western U.S. where there are active faults; but the sum total of all contributing faults is not enough to give 1-second contours of 0.40g.

The term building is as used in the city of Los Angeles strong motion accelerograph language. We have building officials, building codes, building permits, building maintenance, Building Owners and Managers Associations . . . so everyone is pretty clear what a "building" actually is. Maybe, for example, an airplane hangar is more of a structure, than it is a building?

Final Action: AS AM AMPC____ D

S111-09/10
1702.1

Proposed Change as Submitted

Proponent: Philip Brazil, PE, SE, Reid Middleton, Inc., representing self

Revise as follows:

1702.1 General. The following words and terms shall, for the purposes of this chapter and as used elsewhere in this code, have the meanings shown herein.

SPECIAL INSPECTION, CONTINUOUS. The ~~full-time~~ observation of construction or work requiring special inspection by an approved special inspector who is continuously present in the area when and where the construction or work is being performed.

SPECIAL INSPECTION, PERIODIC. The ~~part-time or intermittent~~ observation of construction or work requiring special inspection by an approved special inspector who is intermittently present in the area when and where the construction or work ~~has been or~~ is being performed ~~and at the completion of the work~~.

Reason: The purpose for this proposal is to adjust the definitions for "continuous special inspection" and "periodic special inspection" for consistency with the requirements for special inspection elsewhere in Chapter 17. These requirements typically specify special inspections as either continuous or periodic. The only means in the IBC for determining what is required of a special inspector to perform continuous or periodic special inspection is their respective definitions in Section 1702.1. The definitions should be such that the special inspector is able to arrive at the site in time to observe the construction or work sufficiently to enable a determination of whether the construction complies with applicable requirements in the building code and its reference standards and is in accordance with the approved construction documents.

The definitions need to account for two primary aspects of special inspection: extent and frequency. Frequency can be seen as the number of times a special inspector inspects; extent can be seen as the degree to which a special inspector inspects. Neither can be comprehensively accounted for in a definition and this proposal does not attempt to do so. However, adjustments to the definitions are proposed to improve their correlation with the extent and frequency assumed for the special inspections where continuous or periodic special inspection is specified.
In both definitions, "construction" is added before "work" for consistency with the same phrase in Section 110.1 on inspections by the building official. Also in both definitions, "when" is added before "where" to indicate that the special inspector is expected be in the area while the work is being performed, not before or after the work is being performed, which is possible with the current definitions.

In the definition of periodic special inspection, "has been" is deleted so that the definition is silent on whether performing special inspections after the construction or work is completed constitutes periodic special inspection. It is conceivable that certain special inspection are possible after completion of the construction or work but this should be agreed upon by all affected parties, including, but not limited to, the owner or owner's representative, contractor, special inspector and the building official. Retaining "has been" in the definition, however, implies that special inspection after the construction or work is completed always constitutes periodic special inspection and there are certain special inspections identified as periodic elsewhere in Chapter 17 for which such inspection may not be sufficient.

Also in the definition of periodic special inspection, "at the completion of work" is deleted. Where periodic special inspection is warranted, whether the special inspector is present "at the completion of work" is irrelevant. An intermittent presence permits time gaps between actions or observations by the special inspector, which includes a period of time between the last action or observation by the special inspector and the completion of the work. Where this is not considered to be a sufficient presence by the special inspector, periodic special inspection is not warranted.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: Brazil-S41-1702.1

Public Hearing Results

Committee Action: Disapproved

Committee Reason: There was concern over striking "at the completion of the work" from the definition of periodic special inspection. The proposed revisions should be reconciled with S115 – 09/10

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Philip Brazil, P.E., S.E., Reid Middleton, Inc., representing self; D. Kirk Harman, P.E., The Harman Group, representing the National Council of Structural Engineers Associations (NCSEA) Code Advisory Committee, Quality Assurance and Special Inspection Subcommittee; Jonathan Siu, P.E., S.E., City of Seattle, Department of Planning and Development, representing self; John Silva, P.E., S.E., Hilti North America, representing self, request Approval as Modified by this Public Comment.

Modify the proposal as follows:

1702.1 General. The following words and terms shall, for the purposes of this chapter and as used elsewhere in this code, have the meanings shown herein.

SPECIAL INSPECTION. Inspection ~~as herein required of the materials, installation, fabrication, erection or placement of components and connections~~ of construction requiring ~~special~~ the expertise of an *approved* special inspector in order to ensure compliance with this code and the *approved construction documents* ~~and referenced standards (see Section 1704)~~.

~~SPECIAL INSPECTION, CONTINUOUS~~ Continuous special inspection. ~~The observation of construction or work requiring~~ *Special inspection* by ~~an *approved*~~ the special inspector who is continuously present ~~in the area~~ when and where the ~~construction or~~ work to be inspected is being performed.

~~SPECIAL INSPECTION, PERIODIC~~ Periodic special inspection. ~~The observation of construction or work requiring~~ *Special inspection* by ~~an *approved*~~ the special inspector who is intermittently present ~~in the area when and~~ where the ~~construction or~~ work to be inspected has been or is being performed.

Commenter's Reason: The original proposal modified the definitions of "special inspection, continuous" and "special inspection, periodic" but, based on comments at the code development hearings, it was recognized that some of the objectives in submitting the proposal would be better served by also considering the definition of "special inspection," which is being done in this public comment.

The proposed revisions to these definitions recognize that a definition is inherently nonmandatory and can be nothing more than an explanation of the meaning for a word or phrase. One purpose for the revisions in this public comment is so that these definitions provide this explanation.

The proposed revisions also recognize what these definitions can not do and that is to explain the meaning of "inspection." The IBC does not contain a definition of "inspection" deferring to dictionaries for an explanation. Therefore, the definition of "special inspection" should explain what it means for an inspection to be "special" and should not also explain the meaning of "inspection." Also, the definitions of continuous special inspection and periodic special inspection should explain what it means for a special inspection to be "continuous" or "periodic" and should not also explain the meaning of "special inspection."

In the definition of “special inspection,” inspection of the “materials, installation, fabrication, erection or placement of components and connections” is replaced by inspection of “construction” because they are related to the meaning of “inspection,” not to what it means for an inspection to be “special.” A list of this sort is also inappropriate because it is not comprehensive and implies that actions other than those listed are not special inspections.

In the definition of “special inspection,” “special” is deleted before “expertise” because specifying expertise is sufficient to denote the role of the special inspector in the definition of special inspection: provide expertise. If “special” were to remain, it would imply that a special inspector with the expertise to ensure compliance would not be conducting a special inspection unless his or her expertise is “special” and would raise the question of what is necessary for an individual’s expertise to be special in order to qualify as special expertise.

In the definition of “special inspection,” “this code” is added because an essential part of special inspection by a special inspector is compliance with the building code as well as the approved construction documents. There are requirements in the building code relevant to the performance of the special inspector’s duties that may not appear in the approved construction documents.

In the definition of “special inspection,” “and referenced standards (see Section 1704)” is deleted because specifying them is redundant and can lead to conflicts with the building code. According to IBC Section 102.4, referenced standards are a mandatory “part or the requirements of this code to the prescribed extent of each such reference. Where differences occur between provisions of this code and referenced codes and standards, the provisions of this code shall apply.” Specifying “referenced standards” but not “this code” conflicts with Section 102.4 in that the referenced standards apply rather than the building code where there are conflicts between them and the building code, and the referenced standards apply to their full extent rather than to their prescribed extent.

Adding “approved special inspector” to the definition of “special inspection,” and deleting “approved” from the definitions of continuous special inspection and periodic special inspection is seen as editorial because whether a special inspector is approved is not related to the distinction between “continuous” and “periodic.”

The definitions of “special inspection, continuous” and “special inspection, periodic” are adjusted to be sub-definitions of “special inspection” because the purpose in defining them should be to explain what it means for a special inspection to be “continuous” or “periodic.”

In the sub-definitions of “continuous special inspection” and “periodic special inspection,” deleting “the observation of construction or work” is seen as editorial because it is redundant given the adjustment of the current definitions to be sub-definitions that explain what it means for a special inspection to be “continuous” or “periodic” (see above).

In the sub-definitions, the addition in the original proposal of “construction or” before “work” is removed and “to be inspected” is added after “work” in this public comment to establish the distinction between “inspection of construction” in the definition of special inspection and “work to be inspected” by the special inspector in the sub-definitions. Thus, “special inspection” is a process involving the actions of a special inspector and the continuous special inspection” or “periodic special inspection” are the actions of a special inspector. With the addition of “to be inspected,” the deletion in the original proposal of “and at the completion of work” in the sub-definition of “periodic special inspection,” is now seen as editorial because it is redundant given the obvious assumption that a special inspector will complete the work to be inspected. This is also being done for consistency with similar terminology in Section 1704.1.

In the sub-definitions, deleting “in the area” is seen as editorial because it is redundant given the text explaining that the special inspector is present “where the work to be inspected is being performed.” Obviously, the special inspector is “in the area” when he or she is at “the work to be inspected.”

The deletion in the original proposal of “has been” before “or is being performed” is restored in the sub-definition of “periodic special inspection” to distinguish between periodic special inspection that could be delayed until after material installation but before the materials are covered (e.g., reinforcing steel after installation but before concrete placement), and continuous special inspection that typically can’t be delayed until after material installation (e.g., concrete placement). Also, the addition in the original proposal of “when and” before “where” is removed from the sub-definition of “periodic special inspection” but is retained in the sub-definition of “continuous special inspection” so that “has been” does not conflict with “intermittently present” (avoids “intermittently present when…the work…has been…performed”).

Finally, the original proposal and this public comment were submitted, in part, because of the apparent belief by some individuals that the current definition of continuous special inspection intends inspection by a special inspector who is continuously present the entire time construction requiring special inspection is occurring even to the extent of expecting a special inspector be continuously present to observe the actions of each worker involved in the construction (i.e., 100 welders would require 100 special inspectors). This is not the intent of the definition nor is it the purpose for continuous special inspection, which is intended to provide a level of quality assurance sufficient to ensure that public safety in the built environment is achieved. For any construction project, the extent of special inspection and the frequency of special inspections can not be reliably determined except through an agreement between the owner, contractor, special inspector and the building official before construction begins on the scope of work for the special inspector. Chapter 17 of the International Building Code does not specify extent or frequency except through the definitions of continuous and periodic special inspection and the revisions to the definitions in this public comment will not change that.

Final Action: AS AM AMPC____ D

S113-09/10
1702.1

Proposed Change as Submitted

Proponent: D. Kirk Harman, The Harman Group, representing The National Council of Structural Engineers Associations (NCSEA) Code Advisory Committee, Quality Assurance and Special Inspection Subcommittee

Add new definition as follows:

1702.1 General. The following words and terms shall, for the purposes of this chapter and as used elsewhere in this code, have the meanings shown herein.

SPECIAL INSPECTOR. An individual qualified in accordance with Section 1704.1 of this code, employed or retained by the *approved agency* and assigned to execute the *special inspections* or tests required by the statement of special inspections.

Reason: The term Special Inspector is used many times throughout the chapter but is currently not defined. Approved Agency is defined as the entity that provides inspection but the inspections are actually accomplished by the "special inspector". Both should be defined.

Cost Impact: This proposal will not increase the cost of construction.

ICCFILENAME: Harman-S1-1702.1

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The proposed definition is not needed since Section 1704.1 currently contains this information.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Philip Brazil, P.E., S.E., Reid Middleton, Inc., representing self; D. Kirk Harman, P.E., The Harman Group, representing the National Council of Structural Engineers Associations (NCSEA) Code Advisory Committee, Quality Assurance and Special Inspection Subcommittee; Jonathan Siu, P.E., S.E., City of Seattle, Department of Planning and Development, representing self; John Silva, P.E., S.E., Hilti North America, representing self, request Approval as Modified by this Public Comment.

Modify the proposal as follows:

SPECIAL INSPECTOR. ~~An individual~~ A qualified ~~in accordance with Section 1704.1 of this code,~~ person employed or retained by ~~the~~ an *approved agency* and ~~assigned to execute the *special inspections* or tests required by the statement of special inspections~~ *approved* by the *building official* as having the competence necessary to inspect a particular type of construction requiring *special inspection*.

1704.1 General. Where application is made for construction as described in this section, the owner or the *registered design professional in responsible charge* acting as the owner's agent shall employ one or more *approved agencies* to perform inspections during construction on the types of work listed under Section 1704. These inspections are in addition to the inspections specified in Section 110.
~~The special inspector shall be a qualified person who shall demonstrate competence, to the satisfaction of the *building official*, for the inspection of the particular type of construction or operation requiring *special inspection*.~~ The *registered design professional in responsible charge* and engineers of record involved in the design of the project are permitted to act as the *approved agency* and their personnel are permitted to act as the special inspector for the work designed by them, provided ~~those personnel meet the qualification requirements of this section to the satisfaction of the *building official*~~ they qualify as *special inspectors*.
The special inspector shall provide written documentation to the building official demonstrating his or her competence and relevant experience or training. Experience or training shall be considered relevant when the documented experience or training is related in complexity to the same type of *special inspection* activities for projects of similar complexity and material qualities. These qualifications are in addition to qualifications specified in other sections of this code.

Exceptions:

1. *Special inspections* are not required for ~~work~~ construction of a minor nature or as warranted by conditions in the jurisdiction as *approved* by the *building official*.
2. *Special inspections* are not required for building components unless the design involves the practice of professional engineering or architecture as defined by applicable state statutes and regulations governing the professional registration and certification of engineers or architects.
3. Unless otherwise required by the *building official*, *special inspections* are not required for Group U occupancies that are accessory to a residential occupancy including, but not limited to, those listed in Section 312.1.

Commenter's Reason: This public comment addresses the concern of the Committee that the definition is not needed because Section 1704.1 currently contains the information in the proposed definition. The text from Section 1704.1 that is replaced by the definition is deleted. The definition is also revised to be consistent with the text in Section 1704.1 that it replaces. In addition, "work" is changed to "construction" in Exception #1 of Section 1704.1 for consistency with the public comment on Proposal S111-09/10, which distinguishes between "inspection of construction" in the definition of special inspection and "work to be inspected" by the special inspector in the sub-definitions of "continuous special inspection" and "periodic special inspection."

Note that the first paragraph of Section 1704.1 currently requires the owner, or the registered design professional in responsible charge acting as the owner's agent, to employ one or more approved agencies, not special inspectors, to perform the necessary special inspections; and the second paragraph of Section 1704.1 requires the special inspector to "demonstrate competence, to the satisfaction of the building official, for the inspection of the particular type of construction or operation requiring special inspection." This proposal defines a "special inspector" as "employed or retained by an approved agency" for consistency with the first paragraph of Section 1704.1 and also as "approved by the building official as having the competence necessary to inspect a particular type of construction requiring special inspection" for consistency with the second paragraph of Section 1704.1.

Final Action: AS AM AMPC____ D

S118-09/10
1704.1

Proposed Change as Submitted

Proponent: Gary J. Ehrlich, PE, representing National Association of Home Builders

Revise as follows:

1704.1 General. Where application is made for construction as described in this section, the owner or the *registered design professional in responsible charge* acting as the owner's agent shall employ one or more *approved agencies* to perform inspections during construction on the types of work listed under Section 1704. These inspections are in addition to the inspections identified in Section 110.

The special inspector shall be a qualified person who shall demonstrate competence, to the satisfaction of the *building official*, for the inspection of the particular type of construction or operation requiring *special inspection*. The *registered design professional in responsible charge* and engineers of record involved in the design of the project are permitted to act as the *approved agency* and their personnel are permitted to act as the special inspector for the work designed by them, provided those personnel meet the qualification requirements of this section to the satisfaction of the *building official*. The special inspector shall provide written documentation to the building official demonstrating their competence and relevant experience or training. Experience or training shall be considered relevant when the documented experience or training is related in complexity to the same type of *special inspection* activities for projects of similar complexity and material qualities. These qualifications are in addition to qualifications specified in other sections of this code.

Exceptions:

1. *Special inspections* are not required for work of a minor nature or as warranted by conditions in the jurisdiction as *approved* by the *building official*.
2. *Special inspections* are not required for building components unless the design involves the practice of professional engineering or architecture as defined by applicable state statutes and regulations governing the professional registration and certification of engineers or architects.
3. Unless otherwise required by the *building official*, *special inspections* are not required for Group U occupancies that are accessory to a residential occupancy including, but not limited to, those listed in Section 312.1.
4. Special inspections are not required for portions of structures designed and constructed in accordance with the conventional light-frame construction provisions of Section 2308.

Reason: The purpose of this proposal is to add an exemption from third-party special inspections for portions of wood-frame dwellings or other simple wood-frame structures constructed under prescriptive provisions within the International Building Code (IBC). Without this exception, a building official may require a builder to contract with a third-party inspector, with the expense passed on to the homeowner.

A change made to the IBC during the 2006-07 Code Development Cycle (S31-06/07) struck the exemption for Residential R-3 structures, and now subjects one- and two-family dwellings and townhouses designed under the IBC to the requirements for special inspections. These inspections are in addition to the standard inspections performed by the building department. Also, other structures classified as R-3 occupancies (group homes, day care) will be subject to these special inspections for all elements of their construction. As justification for the original code change, the proponent claimed R 3 structures often contain complicated roof truss systems, structural steel framing, reinforced masonry and other complex elements or unusual construction materials and methods requiring the qualifications and experience of a special inspector.

But, IBC Section 1704.1.1 exempts the registered design professional from needing to prepare, and the permit applicant from needing to submit, a statement of special inspections for structures designed and constructed per Section 2308. This clearly implies that structures built under Section 2308 do not need special inspections for any element, including the wood wall framing, roof and floor trusses, concrete or masonry foundations, and any miscellaneous masonry or steel framing inside the structure. In a structure designed to the conventional construction provisions, these elements are not likely to be as complex as those in a fully-engineered structure.

Building departments are more than capable of reviewing and inspecting these simple structures. In the case of items such as trusses and miscellaneous steel framing that may occur in a structure otherwise designed using conventional construction provisions, shop drawings will be submitted to the building official for their review and use in inspections. The building department does not need a special inspector to do their work for them in reviewing and inspecting these structures and elements.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: Ehrlich-S1-1704 1

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The wording of the proposed exception in Section 1704.1 is potentially confusing, specifically the reference to "portions of structures". Furthermore, the reference solely to section 2308 would be too narrow since it would not include other types of light-frame construction.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Gary J. Ehrlich, PE, National Association of Home Builders; Bonnie Manley, PE, AISI, representing Steel Framing Alliance; Larry Wainright, Qualtim, Inc., representing Structural Building Components Association (SBCA); Philip Brazil, PE, SE, Reid Middleton, Inc., representing self, request Approval as Modified by this Public Comment.

Modify the proposal as follows:

1704.1 General. Where application is made for construction as described in this section, the owner or the *registered design professional in responsible charge* acting as the owner's agent shall employ one or more *approved agencies* to perform inspections during construction on the types of work listed under Section 1704. These inspections are in addition to the inspections identified in Section 110.

The special inspector shall be a qualified person who shall demonstrate competence, to the satisfaction of the *building official*, for the inspection of the particular type of construction or operation requiring *special inspection*. The *registered design professional in responsible charge* and engineers of record involved in the design of the project are permitted to act as the *approved agency* and their personnel are permitted to act as the special inspector for the work designed by them, provided those personnel meet the qualification requirements of this section to the satisfaction of the *building official*. The special inspector shall provide written documentation to the building official demonstrating their competence and relevant experience or training. Experience or training shall be considered relevant when the documented experience or training is related in complexity to the same type of *special inspection* activities for projects of similar complexity and material qualities. These qualifications are in addition to qualifications specified in other sections of this code.

Exceptions:

1. *Special inspections* are not required for work of a minor nature or as warranted by conditions in the jurisdiction as *approved* by the *building official*.
2. *Special inspections* are not required for building components unless the design involves the practice of professional engineering or architecture as defined by applicable state statutes and regulations governing the professional registration and certification of engineers or architects.
3. Unless otherwise required by the *building official*, *special inspections* are not required for Group U occupancies that are accessory to a residential occupancy including, but not limited to, those listed in Section 312.1.
4. Special inspections are not required for portions of structures designed and constructed in accordance with the <u>cold formed steel light-frame construction provisions of Section 2210.7 or the </u>conventional light-frame construction provisions of Section 2308.

1704.1.1 Statement of special inspections. The applicant shall submit a statement of *special inspections* prepared by the *registered design professional in responsible charge* in accordance with Section 107.1 as a condition for issuance. This statement shall be in accordance with Section 1705.

Exceptions:

1. A statement of *special inspections* is not required for <u>portions of </u>structures designed and constructed in accordance with the <u>cold formed steel light-frame construction provisions of Section 2210.7 or the </u>conventional <u>light frame </u>construction provisions of Section 2308.
2. The statement of *special inspections* is permitted to be prepared by a qualified person *approved* by the *building official* for construction not designed by a *registered design professional*.

Commenter's Reason: At the Public Hearing in Baltimore, a floor modification was offered by the Steel Framing Alliance to add a reference to Section 2210.7 for construction of cold-formed steel light-frame structures using the prescriptive provisions of AISI S230. The modification was ruled out-of-order, leading to disapproval of the proposal. The IBC Structural Committee strongly indicated their desire to have the proposed Exception #4 to Section 1704.1 incorporate the floor modification.

In addition to providing the desired reference in Exception #4 of Section 1704.1, this public comment also makes the corresponding change in Exception #1 of Section 1704.1.1 to exempt cold-formed steel light frame construction from the requirement for a statement of special inspections. Furthermore, Exception #1 is amended to apply only to those <u>portions</u> of structures constructed using prescriptive methods. This clarifies that special inspections would still be required for those portions not designed and constructed using prescriptive method, e.g. deep foundations, helical piers, or structural steel.

Final Action: AS AM AMPC____ D

S121-09/10
1704.3-1704.3.3.3, Table 1704.3

Proposed Change as Submitted

Proponent: Bonnie Manley, American Iron and Steel Institute, representing American Institute of Steel Construction

1. Revise as follows:

1704.3 Steel construction. The *special inspections* for steel elements of buildings and structures shall be as required in this Section ~~by Section 1704.3 and Table 1704.3~~.

Exception~~s~~:

~~1.~~ *Special inspection* of the steel fabrication process shall not be required where the fabricator does not perform any welding, thermal cutting or heating operation of any kind as part of the fabrication process. In such cases, the fabricator shall be required to submit a detailed procedure for material control that demonstrates the fabricator's ability to maintain suitable records and procedures such that, at any time during the fabrication process, the material specification~~,~~ and grade ~~and mill test reports~~ for the main stress-carrying elements are capable of being determined. Mill test reports shall be identifiable to the main stress-carrying elements when required by the approved construction documents.

~~2. The special inspector need not be continuously present during welding of the following items, provided the materials, welding procedures and qualifications of welders are verified prior to the start of the work; periodic inspections are made of the work in progress and a visual inspection of all welds is made prior to completion or prior to shipment of shop welding.~~

~~2.1. Single-pass fillet welds not exceeding 5/16 inch (7.9 mm) in size.~~
~~2.2. Floor and roof deck welding.~~
~~2.3. Welded studs when used for structural diaphragm.~~
~~2.4. Welded sheet steel for cold-formed steel members.~~
~~2.5. Welding of stairs and railing systems.~~

1704.3.1 Structural steel. Special inspection for structural steel shall be in accordance with the quality assurance inspection requirements of AISC 360.

1704.3.2 Steel construction other than structural steel. Special inspection for steel construction other than structural steel shall be in accordance with Table 1704.3 and this section.

~~**1704.3.1**~~ **1704.3.2.1 Welding.**Welding inspection and welding inspector qualification shall be in accordance with this section.

~~**1704.3.1.1 Structural steel.** Welding inspection and welding inspector qualification for structural steel shall be in accordance with AWS D1.1.~~

~~**1704.3.1.2**~~ **1704.3.2.1.1 Cold-formed steel.** Welding inspection and welding inspector qualification for cold-formed steel floor and roof decks shall be in accordance with AWS D1.3.

~~**1704.3.1.3**~~ **1704.3.2.1.2 Reinforcing steel.** Welding inspection and welding inspector qualification for reinforcing steel shall be in accordance with AWS D1.4 and ACI 318.

2. Delete without substitution:

~~**1704.3.2 Details.** The special inspector shall perform an inspection of the steel frame to verify compliance with the details shown on the *approved construction documents*, such as bracing, stiffening, member locations and proper application of joint details at each connection.~~

~~**1704.3.3 High-strength bolts.** Installation of high-strength bolts shall be inspected in accordance with AISC 360.~~

~~**1704.3.3.1 General.** While the work is in progress, the special inspector shall determine that the requirements for bolts, nuts,washers and paint; bolted parts and installation and tightening in such standards are met. For boltsrequiring pretensioning, the special inspector shall observe the preinstallation testing and calibration procedures when such procedures are required by the installation method or by project plans or specifications; determine that all plies of connected materials have been drawn together and properly snugged and monitor the installation of bolts to verify that the selected procedure for installation is properly used to tighten bolts. For joints required to be tightened only to the snug-tight condition, the special inspector need only verify that the connected materials have been drawn together and properly snugged.~~

~~**1704.3.3.2 Periodic monitoring.** Monitoring of bolt installation for pretensioning is permitted to be performed on a periodic basis when using the turn-of-nut method with matchmarking techniques, the direct tension indicator method or the alternate design fastener (twist-off bolt) method. Joints designated as snug tight need be inspected only on a periodic basis.~~

~~**1704.3.3.3 Continuous monitoring.** Monitoring of bolt installation for pretensioning using the calibrated wrench method or the turn-of-nut method without matchmarking shall be performed on a continuous basis.~~

3. Revise as follows:

~~**1704.3.4**~~ **1704.3.2.2 Cold-formed steel trusses spanning 60 feet or greater.** Where a cold-formed steel truss clear span is 60 feet (18 288 mm) or greater, the special inspector shall verify that the temporary installation restraint/bracing and the permanent individual truss member restraint/bracing are installed in accordance with the *approved* truss submittal package.

TABLE 1704.3
REQUIRED VERIFICATION AND INSPECTION OF STEEL CONSTRUCTION OTHER THAN STRUCTURAL STEEL

VERIFICATION AND INSPECTION	CONTINUOUS	PERIODIC	REFERENCED STANDARD[a]	IBC REFERENCE

For SI: 1 inch = 25.4 mm.

a. Where applicable, see also Section 1707.1, Special inspection for seismic resistance.

Reason: The 2010 edition of ANSI/AISC 360, *Specification for Structural Steel Buildings,* incorporates a new Chapter N, which addresses comprehensive quality control and quality assurance requirements for all structural steel construction. These requirements are similar in nature to those that were incorporated into the 2005 edition of AISC 341, Appendix Q. Those AISC 341 requirements are currently referenced in the 2009 edition of the IBC, Sections 1707 and 1708 for special inspection requirements in high-seismic applications. AISC 360-10, Chapter N provisions provide the foundation for the quality control and quality assurance requirements for general structural steel construction, with AISC 341-10, Chapter I (previously contained in AISC 341-05, Appendix Q) extending specific requirements to high-seismic applications.

AISC 360, Chapter N covers quality control requirements on the part of the structural steel fabricator and erector, as well as quality assurance requirements on the part of the owners inspecting and or testing agents. While AISC 360 addresses the total quality aspects of the structural steel project, the inspection requirements of the Quality Assurance Inspector can be equated to those specified for the Special Inspector under IBC Chapter 17.

The present Section 1704.3 addresses all forms of steel construction. The majority of the requirements in this section and Table 1704.3 pertain to structural steel construction. However, there are a few items which refer to cold-formed steel construction and rebar welding, which are not covered by AISC 360. The current special inspection requirements for structural steel as covered in Section 1704.3 and Table 1704.3 are recommended for deletion by this proposal; and, instead, a direct reference is made to the more detailed requirements of AISC 360, Chapter N. Requirements for special inspection of other forms of steel construction are left in a separate section of Section 1704.3.2, and in a reduced Table 1704.3, *Steel Construction Other than Structural Steel*.

Specifically, the topics currently in IBC Section 1704.3 are covered in AISC 360, Chapter N as follows:

Section 1704.3, Exception 2: The structural steel items are covered in AISC 360, Section N5.5. As for the cold formed steel exception applicable to roof and floor deck, it really is not correct and is recommended for deletion. Shop welding is typically used for a multi-skin closed cell deck, which would be a violation of the AWS D1.3 requirement that arc spot is only valid for deck to underlying structural members (D1.3, Clause 1.5.4). Multi-skin deck within itself appears to fall outside of the code itself and requires direct qualification by the manufacturer of their processes, potentially through testing rather than calculations. In reality, cold formed steel deck is sufficiently covered in Section 1704.3.2.1.1, Table 1704.3, and the reference to AWS D1.3.

Section 1704.3.2: AISC 360, Section N5.8.

Section 1704.3.3: AISC 360, Section N5.7(3)

Additionally, the topics currently in IBC Table 1704.3 are covered as in AISC 360, Chapter N as follows:

Table 1704.3, Item 1: AISC 360, Section N5.7 and Table N5.7-1.

Table 1704.3, Item 2: AISC 360, Section N5.7

Table 1704.3, Item 3a: AISC 360, Section N3.2 requires that the MTRs, as well as numerous other documents be made available for EOR review.

Table 1704.3, Item 4: AISC 360, Section N5.5 and Table N5.5-1

Table 1704.3, Item 5: AISC 360, Section N5.5
Table 1704.3, Item 6: AISC 360, Section N5.8

Also, Section 1704.3, Exception 1 is retained and modified to clarify the requirements. Often in practice, the "representative mill test reports" are supplied as described in the AISC Code of Standard practice. The added sentence on mill test reports allows for traceability when required by the construction documents, and defers to AISC 360 in other cases.

Please note, public review drafts of the 2010 AISC documents can be found on the AISC website (www.aisc.org). The public review period for AISC 360-10 is currently scheduled for 8/14/09 through 9/28/09 and the public review period for AISC 341-10 is currently scheduled for 9/11/09 through 10/26/09. It is anticipated that the 2010 editions of both AISC 360 and AISC 341 will be technically complete by the end of October 2009, with ANSI approval in March 2010 and publication in August 2010.

Cost Impact: There is no anticipated impact on the cost of construction.

ICCFILENAME: Manley-S13-1704.3

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: This proposal makes use of the more comprehensive inspection requirements for structural steel by referencing AISC 360 quality assurance inspections. Replacing the IBC provisions with this reference is similar to the reference to AISC 341 for steel seismic systems.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Steven Winkel, FAIA, PE, and Kelly Cobeen, PE, SE, representing the Federal Emergency Management Agency/Building Seismic Safety Council Code Resource Support Committee (FEMA/BSSC CRSC) and Bonnie Manley, PE, representing the American Institute of Steel Construction (AISC), request Approval as Modified by this Public Comment.

Modify the proposal as follows:

1704.3 Steel construction. The *special inspections* for steel elements of buildings and structures shall be as required in this Section.

> **Exception:** *Special inspection* of the steel fabrication process shall not be required where the fabricator does not perform any welding, thermal cutting or heating operation of any kind as part of the fabrication process. In such cases, the fabricator shall be required to submit a detailed procedure for material control that demonstrates the fabricator's ability to maintain suitable records and procedures such that, at any time during the fabrication process, the material specification and grade for the main stress-carrying elements are capable of being determined. Mill test reports shall be identifiable to the main stress-carrying elements when required by the approved construction documents.

1704.3.1 Structural steel. Special inspection for structural steel shall be in accordance with the quality assurance inspection requirements of AISC 360.

1704.3.2 Steel Construction other than structural steel. Special inspection for steel construction other than structural steel shall be in accordance with Table 1704.3 and this section.

1704.3.2.1 Welding. Welding inspection and welding inspector qualification shall be in accordance with this section.

1704.3.2.1.1 Cold-formed steel. Welding inspection and welding inspector qualification for cold-formed steel floor and roof decks shall be in accordance with AWS D1.3.

1704.3.2.1.2 Reinforcing steel. Welding inspection and welding inspector qualification for reinforcing steel shall be in accordance with AWS D1.4 and ACI 318.

1704.3.2.1.3 Other steel construction. Hot-rolled steel construction, other than structural steel covered in Section 1704.3.1, that has been designated in the statement of special inspections by the registered design professional in responsible charge as requiring special inspection, shall be subject to the welding inspection requirements of AWS D1.1. The welding shall be inspected on a periodic basis. As a minimum, such construction shall include H-piles and stair and railing systems.

1704.3.2.2 Cold-formed steel trusses spanning 60 feet or greater. Where a cold-formed steel truss clear span is 60 feet (18 288 mm) or greater, the special inspector shall verify that the temporary installation restraint/bracing and the permanent individual truss member restraint/bracing are installed in accordance with the *approved* truss submittal package.

TABLE 1704.3
REQUIRED VERIFICATION AND INSPECTION OF STEEL CONSTRUCTION OTHER THAN STRUCTURAL STEEL

VERIFICATION AND INSPECTION	CONTINUOUS	PERIODIC	REFERENCED STANDARD[a]	IBC REFERENCE
1. Material verification cold-formed steel deck:				
a. Identification markings to conform to ASTM standards specified in the approved construction documents.	—	X	Applicable ASTM material standards	
b. Manufacturers' certified test reports.	—	X		
2. Inspection of welding: a. Cold-formed steel deck:				
1) Floor and roof deck welds.	—	X	AWS D1.3	
b. Reinforcing steel:				
1) Verification of weldability of reinforcing steel other than ASTM A 706.	—	X	AWS D1.4 or ACI 318: Section 3.5.2	—
2) Reinforcing steel-resisting flexural and axial forces in intermediate and special moment frames, and boundary elements of special reinforced concrete shear walls and shear reinforcement.	X	—		
3) Shear reinforcement.	X	—		
4) Other reinforcing steel.	—	X		

For SI: 1 inch = 25.4 mm.
a. Where applicable, see also Section 1707.1, special inspection for seismic resistance

Commenter's Reason: Proposal S121-09/10, as originally written, inadvertently deleted a narrow sub-set of hot-rolled structural steel items that are intended to be covered by the special inspection requirements of IBC Chapter 17 but that fall outside the defined scope of AISC 360. Specifically, the scope of AISC 360 states the following in Section A1:

> The *Specification for Structural Steel Buildings*, hereafter referred to as the Specification, shall apply to the design of the *structural steel* system, where the steel elements are defined in the AISC *Code of Standard Practice for Steel Buildings and Bridges*, Section 2.1.

In addition, the AISC 360 glossary defines structural steel as follows:

> *Structural steel.* Steel elements as defined in Section 2.1 of the AISC *Code of Standard Practice for Steel Buildings and Bridges*.

In contrast, the 2009 IBC does not specifically define "structural steel." Rather, Chapter 22, *Steel*, includes definitions for *Cold Formed Steel Construction, Steel Joist,* and *Structural Steel Member*. The definition of *Structural Steel Member* is as follows:

> STEEL MEMBER, STRUCTURAL. Any steel structural member of a building or structure consisting of a rolled steel structural shape other than cold-formed steel, or steel joist members.

And, IBC-09, Section 2205, *Structural Steel*, references AISC 360 for the "…design, fabrication and erection of structural steel for buildings and structures..." (2205.1).

However, IBC-09, Section 1704.3, Exception 2 includes welding special inspection requirements for steel construction other than steel deck and reinforcing steel that is not purely defined as "structural steel," such as stair and railing systems. The deletion of this exception by Proposal S121-09/10 removed these necessary special inspection requirements.

This public comment reinstitutes the welding special inspection for such elements, when identified in the statement of special inspection by the design professional in responsible charge. In practice, structural engineers often use the provisions of AISC 360 to design steel members using hot-rolled steel shapes, plates, and bars that resist loads and forces, even when such members do not meet AISC's definition of structural steel. Rather than continue to use AISC 360 outside of its intended scope, this comment references AWS D1.1 and specifies "periodic" frequency for the welding inspection, which is consistent with the provisions inadvertently deleted by S121. The minimum list of steel elements includes both H-piles and stair and railing systems. The inclusion of steel H-piles is consistent with the requirements of Table 1704.8, *Required Verification and Inspection of Driven Deep Foundation Elements*, Item 5.

Public Comment 2:

Alan Robinson, SE and Art Dell, PE, representing Structural Engineers Association of California, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

1704.3 Steel construction. The *special inspections* for steel elements of buildings and structures shall be as required in this Section.

> **Exception:** *Special inspection* of the steel fabrication process shall not be required where the fabricator does not perform any welding, thermal cutting or heating operation of any kind as part of the fabrication process. In such cases, the fabricator shall be required to submit a detailed procedure for material control that demonstrates the fabricator's ability to maintain suitable records and procedures such that, at any time during the fabrication process, the material specification and grade for the main stress-carrying elements are capable of being determined. Mill test reports shall be identifiable to the main stress-carrying elements when required by the approved construction documents.

1704.3.1 Structural steel. Special inspection for structural steel shall be in accordance with the quality assurance inspection requirements of AISC 360.

> **Exception:** The special inspection for complete and partial penetration groove welds, multipass fillet welds, and fillet welds greater than 5/16 inch (7.9 mm) shall be continuous *special inspection* as defined in this code.

1704.3.2 Steel Construction other than structural steel. Special inspection for steel construction other than structural steel shall be in accordance with Table 1704.3 and this section.

1704.3.2.1 Welding. Welding inspection and welding inspector qualification shall be in accordance with this section.

1704.3.2.1.1 Cold-formed steel. Welding inspection and welding inspector qualification for cold-formed steel floor and roof decks shall be in accordance with AWS D1.3.

1704.3.2.1.2 Reinforcing steel. Welding inspection and welding inspector qualification for reinforcing steel shall be in accordance with AWS D1.4 and ACI 318.

1704.3.2.2 Cold-formed steel trusses spanning 60 feet or greater. Where a cold-formed steel truss clear span is 60 feet (18 288 mm) or greater, the special inspector shall verify that the temporary installation restraint/bracing and the permanent individual truss member restraint/bracing are installed in accordance with the *approved* truss submittal package.

TABLE 1704.3
REQUIRED VERIFICATION AND INSPECTION OF STEEL CONSTRUCTION OTHER THAN STRUCTURAL STEEL

VERIFICATION AND INSPECTION	CONTINUOUS	PERIODIC	REFERENCED STANDARD[a]	IBC REFERENCE
1. Material verification cold-formed steel deck:				
a. Identification markings to conform to ASTM standards specified in the approved construction documents.	—	X	Applicable ASTM material standards	
b. Manufacturers' certified test reports.	—	X		
2. Inspection of welding: a. Cold-formed steel deck:				
1) Floor and roof deck welds.	—	X	AWS D1.3	
b. Reinforcing steel:				
1) Verification of weldability of reinforcing steel other than ASTM A 706.	—	X	AWS D1.4 or ACI 318: Section 3.5.2	—
2) Reinforcing steel-resisting flexural and axial forces in intermediate and special moment frames, and boundary elements of special reinforced concrete shear walls and shear reinforcement.	X	—		
3) Shear reinforcement.	X	—		
4) Other reinforcing steel.	—	X		

Commenter's Reason: As approved at the Code Development Hearing, S121-09/10 will result in a reduction of the frequency of welding special inspection.

The frequency of special inspections has always been defined in the International Building Code (IBC) by the use of the terms "continuous" and "periodic". Continuous special inspection is invoked for work that cannot be verified when complete, such as concrete placement and multipass welding. Periodic inspection is invoked for work that can be verified adequately by initial inspection of materials and procedures, some in-process inspection, and final inspection of the completed work.

Continuous special inspection has been required by Table 1704.3 for complete and partial penetration groove welds, multipass fillet welds, fillet welds > 5/16", and plug and slot welds.

Proposal S121-09/10 has removed the special inspections for welding and bolting of structural steel from IBC Chapter 17 in favor of the quality assurance provisions of the new Chapter N in AISC 360-10.

Chapter N of AISC 360-10 does not use "continuous" or "periodic" to describe the frequency of welding inspection. Rather, the terms **O**bserve and **P**erform are applied to the welding inspection tasks identified in three tables (for Before, During, and After welding).

Observe and Perform are defined as follows (AISC 360-10, N5.4 Inspection of Welding):

O – Observe these items on a random basis. Operations need not be delayed pending these inspections.

P – Perform these tasks for each welded joint or member.

The Observe level of inspection is applied to all of the Before and During Welding tasks, with the exception of verifying that WPSs are available, and that manufacturer certifications for welding consumables are available. Inspection tasks such as verifying fit-up of groove welds and fillet welds (before welding), verifying that the WPS is followed and that interpass cleaning and quality are adequate (during welding), would thus only be performed on a "random basis".

This would allow welding on any particular joint to be performed without any in-process inspection, once the welding inspector has verified the materials, procedures, and welder skill. In fact, there is no requirement that the welding inspector be on site while welding is performed.

This is not appropriate for complete and partial penetration groove welds, multipass fillet welds, and fillet welds > 5/16" which currently require continuous inspection.

This public comment corrects this deficiency by adding an exception to the language of 1704.3.1 which invokes the quality assurance inspection requirements of AISC 360.

Public Comment 3:

Homer Maiel, PE. CBO, City of San Jose, CA, representing ICC Tri-Chapter (Peninsula, East Bay, Monterey Bay Chapters), requests Disapproval.

Commenter's Reason: As approved at the Code Development Hearing, S121-09/10 permits a significant reduction of the frequency and thoroughness of inspections that must be conducted for multi-pass welds by the special inspector. This reduction was not disclosed in the proponent's reason statement nor was it discussed by the IBC Structural Committee that voted to approve the proposal.

Continuous special inspection has been required by Table 1704.3 since the inception of the IBC for complete and partial penetration groove welds, multipass fillet welds, and single pass fillet welds greater than 5/16". Plug and slot welds were added to that list in the 2009 edition.

Proposal S121-09/10 removes most of Table 1704.3 and replaces that information by referencing the quality assurance (QA) provisions of the new Chapter N in AISC 360-10.

Chapter N of AISC 360-10 does not use the traditional code terminology of "continuous" or "periodic" to describe the frequency of welding inspection. Rather, the terms Observe (O), and Perform (P) are applied to the welding inspection tasks identified in three separate tables that address the inspection tasks to be performed Before, During, and After welding.

Observe and Perform are defined in AISC 360-10, Section N5.4 Inspection of Welding as follows:

O – Observe these items on a random basis. Operations need not be delayed pending these inspections.

P – Perform these tasks for each welded joint or member.

The Observe level of inspection is applied to all of the "Before" and "During" welding inspection tasks, with the exception of verifying that welding procedure specifications (WPSs) are available, and that manufacturer certifications for welding consumables are available. Inspection tasks such as verifying fit-up of groove welds and fillet welds (before welding), and verifying that the WPS is followed and that interpass cleaning and quality (during welding) are adequate, would thus only be performed on a "random basis". AISC 360 Commentary indicates that the inspector would not need to be on site when welding is performed, provided he or she has verified the materials, processes, and the welder's skill level. This is clearly very different than current IBC requirements that specify continuous inspection yet the reason statement provided for S121 did not acknowledge this significant change nor did it provide any insight into why such a reduction might be warranted.

The Tri-Chapter requests that the approval given to S121-09/10 be rescinded so that welding special inspection is not reduced, until such time that this reduction can be fully justified and be openly discussed by the members of ICC that enforce the current provisions of the code.

Final Action: AS AM AMPC____ D

S124-09/10

1704.6, Table 1704.6 (New), 1706.2, 1707.3, 1704.3.5 (New), Table 1704.3, 1706.3, 1707.4

Proposed Change as Submitted

Proponent: D. Kirk Harman, The Harman Group, representing The National Council of Structural Engineers Associations (NCSEA) Code Advisory Committee, Quality Assurance and Special Inspection Subcommittee

1. Revise as follows:

1704.6 Wood construction. ~~Special inspections of the fabrication process of prefabricated wood structural elements and assemblies shall be in accordance with Section 1704.2.Special inspections of site-built assemblies shall be in accordance with this section.~~ Special Inspections for prefabricated and site built wood construction and assemblies including shear walls, braces, diaphragms, collectors (drag struts) and hold-downs shall be as required by this section and Table 1704.6.

Exceptions:

1. *Special inspection* of wood construction for buildings and structures in Occupancy Category I shall not be required.
2. *Special inspection* of wood construction for buildings and structures in Occupancy Category II that are 3 or less stories in height shall not be required.

2. Add new Table as follows:

TABLE 1704.6
REQUIRED VERIFICATION AND INSPECTION OF WOOD CONSTRUCTION

VERIFICATION AND INSPECTION	CONTINUOUS	PERIODIC
1. Verify that grade stamp on framing lumber, plywood and OSB panels conforms to the construction documents.		X
2. Verify that wood connections including nail quantity, size and spacing; bolt size and location anchor bolt size, spacing and location; tie down size location and configuration; beam hangers and framing anchors conform to the approved construction documents.		X
3. Inspect details of wood framing including framing layout, member sizes, blocking, bridging and bearing lengths.		X
4. Inspect diaphragms and shear walls to verify that wood structural panel sheathing is of the grade and thickness indicated on the approved construction documents and the nominal size of framing		X

members at adjoining panel edges, the nail or staple diameter and length, are as indicated on the approved construction documents.		

3. Revise as follows:

1706.2 Structural wood. Continuous special inspection is required during field gluing operations of elements of the main wind-force-resisting system. ~~Periodic special inspection is required for nailing, bolting, anchoring and other fastening of components within the main wind-force-resisting system, including wood shear walls, wood diaphragms, drag struts, braces and hold-downs.~~

> ~~**Exception:** *Special inspection* is not required for wood shearwalls, shear panels and diaphragms, including nailing, bolting, anchoring and other fastening to other components of the main wind-force-resisting system, where the fastener spacing of the sheathing is more than 4 inches (102 mm) on center.~~

1707.3 Structural wood. Continuous special inspection is required during field gluing operations of elements of the seismic-force-resisting system. ~~Periodic special inspection is required for nailing, bolting, anchoring and other fastening of components within the seismic-force-resisting system, including wood shear walls, wood diaphragms, drag struts, braces, shear panels and hold-downs.~~

> ~~**Exception:** Special inspection is not required for wood shearwalls, shear panels and diaphragms, including nailing, bolting, anchoring and other fastening to other components of the seismic-force-resisting system, where the fastener spacing of the sheathing is more than 4 inches (102 mm) on center (o.c.).~~

4. Add new text as follows:

1704.3.5 Cold-formed steel light-frame construction. Special Inspections for prefabricated and site built cold-formed steel light-frame construction and assemblies including shear walls, braces, diaphragms, collectors (drag struts) and hold-downs shall be as required by this section and Table 1704.3.

Exceptions:

1. *Special inspection* of cold-formed steel light-frame construction for buildings and structures in Occupancy Category I shall not be required.
2. *Special inspection* of cold-formed steel light-frame construction for buildings and structures in Occupancy Category II that are 3 or less stories in height shall not be required.

5. Revise as follows:

TABLE 1704.3
REQUIRED VERIFICATION AND INSPECTION OF STEEL CONSTRUCTION

VERIFICATION AND INSPECTION	CONTINUOUS	PERIODIC	REFERENCED STANDARD[a]	IBC REFERENCE
3. Material verification of structural steel, cold-formed steel light-frame construction and cold-formed steel deck:				
a. For structural steel, identification markings to conform to AISC 360	–	X	AISC 360, Section M5.5	
b. For other steel, identification markings to conform to ASTM standards specified in the approved construction documents.	–	X	Applicable ASTM material standards	
c. Manufacturer's certified test reports.	–	X		
5. Inspection of welding:				
a. Structural steel, cold-formed steel light-frame construction and cold-formed steel deck:				
1) Complete and partial joint penetration groove welds.	X	–	AWS D1.1	1704.3.1
2) Multipass fillet welds	X	–		
3) Single-pass fillet welds > 5/16"	X	–		
4) Plug and slot welds	X	–		
5) Single-pass fillet welds 5/16"	–	X		

VERIFICATION AND INSPECTION	CONTINUOUS	PERIODIC	REFERENCED STANDARD[a]	IBC REFERENCE
6) Floor and roof deck welds.	–	X	AWS D1.3	
7) Cold-formed steel light-frame construction welds		X	AWS D1.3	
6. Inspection of steel frame joint details for compliance with approved construction documents:				
a. Details such as bracing, drag struts and stiffening.	–	X	–	1704.3.2
b. Member locations.	–	X		
c. Application of joint details at each connection.	–	X		
d. Mechanical connections for cold-formed steel light-frame construction including screws, powder actuated fasteners, bolts, anchor bolts, tie downs, anchors and other fastening components		X	Applicable ASTM material standards	

(Portions of table not shown remain unchanged)

6. Delete without substitution:

~~**1706.3 Cold-formed steel light-frame construction.** Periodic special inspection is required during welding operations of elements of the main wind-force-resisting system. Periodic special inspection is required for screw attachment, bolting, anchoring and other fastening of components within the main wind-force-resisting system, including shear walls, braces, diaphragms, collectors (drag struts) and hold-downs.~~

> ~~**Exception:** *Special inspection* is not required for cold-formed steel light-frame shear walls, braces, diaphragms, collectors (drag struts) and hold-downs where either of the following apply:~~
>
> ~~1. The sheathing is gypsum board or fiberboard.~~
> ~~2. The sheathing is wood structural panel or steel sheets on only one side of the shear wall, shear panel or diaphragm assembly and the fastener spacing of the sheathing is more than 4 inches (102 mm) on center (o.c.).~~

~~**1707.4 Cold-formed steel light-frame construction.** Periodic special inspection is required during welding operations of elements of the seismic-force-resisting system. Periodic special inspection is required for screw attachment, bolting, anchoring and other fastening of components within the seismic-force-resisting system, including shear walls, braces, diaphragms, collectors (drag struts) and hold-downs.~~

> ~~**Exception:** *Special inspection* is not required for cold-formed steel light-frame shear walls, braces, diaphragms, collectors (drag struts) and hold-downs where either of the following apply:~~
>
> ~~1. The sheathing is gypsum board or fiberboard.~~
> ~~2. The sheathing is wood structural panel or steel sheets on only one side of the shear wall, shear panel or diaphragm assembly and the fastener spacing of the sheathing is more than 4 inches (102 mm) o.c.~~

Reason: NCSEA believes that light frame construction in wood and cold formed steel have become more commonly used for load bearing applications of significant height and in regions with moderate and high seismic and wind concerns. These types of construction should be subject to Special Inspections in a similar manner and to a comparable extent as other systems such as concrete, structural steel and masonry. The Code is vague in the requirements for these systems resulting in confusion as to what special inspections and to what extent special inspection is required. This proposal clarifies requirements to be consistent across both systems and to improve the consistency of special inspections across all the major structural materials.

The emphasis of the existing special inspection requirements for wood framed construction is on shop inspection of fabricated wood assemblies rather than the field assembly of wood framing. Quality control problems with wood construction are most pronounced in the field work rather than in prefabricated components. The proposed provisions focus on the areas of wood construction that would benefit most from more comprehensive inspections. Deletion of the exception under 1707.3 coordinates with this change.

Exceptions are provided to limit the applicability of these provisions to exclude single and two family dwellings, small commercial, agricultural and buildings of lesser occupancies.

Sections 1706.2, 1706.3, 1707.3 and 1707.4 are revised because the provisions deleted from these sections are now covered in the new or revised tables. The exceptions are deleted to be consistent with the proposal.

This proposal contains provisions addressing both wood frame and cold-formed steel light-frame construction together. This is an effort to address both systems in one change therefore avoiding any perception of one system having an advantage over the other regarding special inspection.

There will be some increase in construction cost due to the increased special inspection that will take place. However, the improved field quality assurance will improve safety and reduced field errors resulting in a savings in construction cost and schedule. The improved public safety far outweighs any minor increase there may be in construction cost.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: Harman-S2-1704

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: Based on the historical performance of light-frame construction of wood and cold-formed steel, the proposed changes in special inspections were too substantial to make without better substantiation by the proponent. There was nothing in the way of case studies, calculation or rational analysis offered to the committee. Additionally the proponent's rather extensive floor modification would indicate that this proposal needs work before it can be approved. Clarification of inspection for prefabricated structural assemblies and components may be necessary but these need to be clearer so that it can be implemented both with building inspectors and third party inspectors. Since the proposal is getting into new territory, it would be preferable to treat wood and cold-formed steel separately so they can be discussed and voted on individually.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

D. Kirk Harman, PE, SE, SECB , The Harman Group, Inc, representing The National Council of Structural Engineers Associations (NCSEA) Code Advisory Committee, Quality Assurance and Special Inspection Subcommittee requests Approval as Modified by this Public Comment.

Replace the proposal as follows:

1704.6 Wood construction. ~~Special inspections of the fabrication process of prefabricated wood structural elements and assemblies shall be in accordance with Section 1704.2. Special inspections of site-built assemblies shall be in accordance with this section.~~ Special Inspections for prefabricated and site built wood construction and assemblies including shear walls, braces, diaphragms, collectors (drag struts) and hold-downs shall be as required by this section and Table 1704.6.

Exceptions:

1. *Special inspection* of wood construction for buildings and structures in Occupancy Category I shall not berequired.
2. *Special inspection* of wood construction for buildings and structures in Occupancy Category II that are 3 or less stories in height above grade plane and that are not included in Sections 1706 or 1707, shall not be required.

TABLE 1704.6
REQUIRED VERIFICATION AND INSPECTION OF WOOD CONSTRUCTION

VERIFICATION AND INSPECTION	CONTINUOUS	PERIODIC
1. Verify that grade stamp on framing lumber, plywood and OSB panels conforms to the construction documents.		X
2. Verify that wood connections including nail quantity, size and spacing; bolt size and location anchor bolt size, spacing and location; tie down size location and configuration; beam hangers and framing anchors conform to the approved construction documents.		X
3. Inspect details of wood framing including framing layout, member sizes, blocking, bridging and bearing lengths.		X
4. Inspect diaphragms and shear walls to verify that wood structural panel sheathing is of the grade and thickness indicated on the approved construction documents and the nominal size of framing members at adjoining panel edges, the nail or staple diameter and length, are as indicated on the approved construction documents.		X

1706.2 Structural wood. Continuous special inspection is required during field gluing operations of elements of the main wind-force-resisting system. Periodic special inspection is required for nailing, bolting, anchoring and other fastening of components within the main wind-force-resisting system, including wood shear walls, wood diaphragms, drag struts, braces and hold-downs.

Exception: For buildings and structures in Occupancy Category I, or in Occupancy Category II and 3 or less stories in height above grade plane, s~~S~~*pecial inspection* is not required for wood shearwalls, shear panels and diaphragms, including nailing, bolting, anchoring and other fastening to other components of the main wind-force-resisting system, where the fastener spacing of the sheathing is more than 4 inches (102 mm) on center.

1707.3 Structural wood. Continuous special inspection is required during field gluing operations of elements of the seismic-force-resisting system. Periodic special inspection is required for nailing, bolting, anchoring and other fastening of components within the seismic-force-resisting system, including wood shear walls, wood diaphragms, drag struts, braces, shear panels and hold-downs.

> **Exception:** For buildings and structures in Occupancy Category I, or in Occupancy Category II and 3 or less stories in height above grade plane, s~~S~~pecial inspection is not required for wood shearwalls, shear panels and diaphragms, including nailing, bolting, anchoring and other fastening to other components of the seismic-force-resisting system, where the fastener spacing of the sheathing is more than 4 inches (102 mm) on center (o.c.).

1704.3.5 Cold-formed steel light-frame construction. Special Inspections for prefabricated and site built cold-formed steel light-frame construction and assemblies including shear walls, braces, diaphragms, collectors (drag struts) and hold-downs shall be as required by this section and Table 1704.3.

Exceptions:

1. *Special inspection* of cold-formed steel light-frame construction for buildings and structures in Occupancy Category I shall not be required.
2. *Special inspection* of cold-formed steel light-frame construction for buildings and structures in Occupancy Category II that are 3 or less stories in height above grade plane and that are not included in Sections 1706 or 1707, shall not be required.

TABLE 1704.3
REQUIRED VERIFICATION AND INSPECTION OF STEEL CONSTRUCTION

VERIFICATION AND INSPECTION	CONTINUOUS	PERIODIC	REFERENCED STANDARD[a]	IBC REFERENCE
3. Material verification of structural steel, cold-formed steel light-frame construction and cold-formed steel deck:				
a. For structural steel, identification markings to conform to AISC 360	_	X	AISC 360, Section M5.5	
b. For cold-formed steel light-frame construction, identification markings to conform to AISI S200 as specified in the approved construction documents.	_	X	AISI S200 Section A5.4

d. Mechanical connections for cold-formed steel light-frame construction including screws, powder actuated fasteners, bolts, anchor bolts, tie downs, anchors and other fastening components		X	AISI S200 Section D	

(Portions of table not shown are unchanged).

1706.3 Cold-formed steel light-frame construction. Periodic special inspection is required during welding operations of elements of the main wind-force-resisting system. Periodic special inspection is required for screw attachment, bolting, anchoring and other fastening of components within the main wind-force-resisting system, including shear walls, braces, diaphragms, collectors (drag struts) and hold-downs.

> **Exception:** For buildings and structures in Occupancy Category I, or in Occupancy Category II and 3 or less stories in height above grade plane, s~~S~~*pecial inspection* is not required for cold-formed steel light-frame shear walls, braces, diaphragms, collectors (drag struts) and hold-downs where either of the following apply:
>
> 1. The sheathing is gypsum board or fiberboard.
> 2. The sheathing is wood structural panel or steel sheets on only one side of the shear wall, shear panel or diaphragm assembly and the fastener spacing of the sheathing is more than 4 inches (102 mm) on center (o.c.).

1707.4 Cold-formed steel light-frame construction. Periodic special inspection is required during welding operations of elements of the seismic-force-resisting system. Periodic special inspection is required for screw attachment, bolting, anchoring and other fastening of components within the seismic-force-resisting system, including shear walls, braces, diaphragms, collectors (drag struts) and hold-downs.

Exception: For buildings and structures in Occupancy Category I, or in Occupancy Category II and 3 or less stories in height above grade plane, s~~S~~*pecial inspection* is not required for cold-formed steel light-frame shear walls, braces, diaphragms, collectors (drag struts) and hold-downs where either of the following apply:

1. The sheathing is gypsum board or fiberboard.
2. The sheathing is wood structural panel or steel sheets on only one side of the shear wall, shear panel or diaphragm assembly and the fastener spacing of the sheathing is more than 4 inches (102 mm) o.c.

Commenter's Reason: The above revision to the proposal addresses comments received from various interested parties. This version maintains all Special Inspections for light frame systems in high wind and high seismic situations, (Sections 1706 and 1707). The purpose of the previous floor modification was to address these areas. The above version now reflects these changes.

The above revision also adds reference to AISI S200 for inspection procedures. This document is currently referenced in the IBC for design of cold formed steel light frame construction.

The proposal seeks to capture the buildings constructed with light frame systems that are over 3 stories in height. For this reason buildings in Occupancy Category I, or in Occupancy Category II and 3 or less stories in height above grade plane are excluded from the requirements. This will exclude nearly all single family and two family dwellings, most low-rise multi-family residential buildings and light frame low-rise commercial buildings. Therefore, the vast majority of buildings constructed with light frame wood or cold formed steel systems will not be included in the proposed Special Inspection requirements. It is only those taller buildings, 4 stories or more in height, which would be subject to the proposed Special Inspections.

Each comment by the committee contained in the Public Hearing Results is addressed below individually:

Based on the historical performance of light-frame construction of wood and cold-formed steel, the proposed changes in special inspections were too substantial to make without better substantiation by the proponent.

To date light frame construction has been used predominantly in buildings 3 stories or less in height. These buildings would remain exempt under this proposal; therefore, the historical performance of these buildings has been recognized. It is only recently that light frame construction has been pushed to heights of nine stories and more. These taller buildings are a small number of the total buildings constructed each year with light frame systems therefore the proposed changes are not substantial across all light frame buildings. The proposed Special Inspections are limited to the small number of light frame structures that are at risk under the current IBC. NCSEA represents over 11,000 structural engineers throughout the United States. The structural engineers in our Member Organizations have voiced concern for the safety of these taller buildings as these systems are pushed to the limits of their capacity while not subject to the same level of Special Inspections as other structural systems used in the same height buildings. The only reason that there has not been a failure is that engineers designing these taller buildings have specified a higher level of inspection than the IBC requires. However, this is not a mandated inspection and the situation presents a very high risk to the public.

There was nothing in the way of case studies, calculation or rational analysis offered to the committee.

If the ICC waited for buildings to collapse before making changes to the Code, seismic design requirements would be twenty years out of date. This proposal is based on the observations of numerous structural engineers working in the field and observing these structures on a daily basis. The risk is real. The day that one of these structures collapses due to lack of inspection will be one day too late for the lives lost.

Additionally the proponent's rather extensive floor modification would indicate that this proposal needs work before it can be approved.

The floor modification has been incorporated into the revised proposal represented in this public comment.

Clarification of inspection for prefabricated structural assemblies and components may be necessary but these need to be clearer so that it can be implemented both with building inspectors and third party inspectors.

The proposal addresses both prefabricated assemblies and components as well as field constructed structural systems. The requirements are set forth in the same format as the current requirements for other systems.

Since the proposal is getting into new territory, it would be preferable to treat wood and cold-formed steel separately so they can be discussed and voted on individually.

To avoid any argument that one system (wood or cold formed steel) would have a competitive disadvantage relative to the other as a result of improved inspection of one and not the other, the two materials are covered in one proposal. Both systems of light frame-frame construction are being used in taller buildings previously envisioned by the current Special Inspection requirements.

This is not "new territory" for Special Inspection. Special inspections have been required for decades for all other buildings over three stories in height constructed using structural steel, concrete and masonry. Until recently light frame construction was rarely used for buildings over 3 stories so Special Inspection for these systems were never addressed. These systems are now "getting into new territory" and should be treated in the same manner as any other structural system employed in buildings over 3 stories.

One additional argument against providing Special Inspections for light frame construction is that the Inspections of Chapter 1 of the IBC are sufficient and no special expertise is required for these inspections.

If a four story building is constructed with structural steel, it is subject to the rigorous Special Inspections of Chapter 17. If the same building is constructed using wood frame or cold formed steel, there is no requirement for Special Inspections and the only inspections are those performed by the Building Official. This places an unreasonable burden on the Building Official to inspect at a much higher level than is anticipated by the provisions of Chapter 1. The AWS welding inspection requirements for cold formed steel are well outside the responsibility of the Building Official yet the Code has no requirements for Special Inspection.

If an eight story masonry bearing wall building is constructed with precast concrete floor units, it is subject to the rigorous Special Inspections of Chapter 17. If that same building is constructed using cold formed steel bearing walls and precast concrete floor units, there is no requirement for Special Inspections of the bearing wall system and the only inspections are those performed by the Building Official. This places an even more unreasonable burden on the Building Official to inspect at a much higher level than is anticipated by the provisions of Chapter 1. There is a serious risk to public safety when an eight story building can be constructed and the only inspections are those by a Building Official, in the same manner as a single family home. These are buildings such as senior living facilities, student housing, apartments, and hotels.

This proposal seeks to plug a serious hole in the Special Inspections requirements of the IBC. It seeks to apply the same level of Special Inspection to all structural systems used in buildings over three stories in height.

Final Action: AS AM AMPC____ D

S127-09/10
1704.15 (New), Chapter 35

Proposed Change as Submitted

Proponent: William E. Koffel, Koffel Associates, Inc., representing Firestop Contractors International Association

1. Add new text as follows:

1704.15 Fire-resistant penetrations and joints. In buildings assigned an Occupancy Category of III or IV in accordance with Section 1604.5, special inspections for through penetrations, membrane penetration firestops, fire resistant joint systems, and perimeter fire barrier systems of the types specified in Sections 713.3.1.2, 713.4.1.2, 714.3 and 714.4 shall be in accordance with Sections 1704.15.1 or 1704.15.2.

1704.15.1 Penetration firestops. Inspections of penetration firestop systems of the types specified in Sections 713.3.1.2 and 713.4.1.2 shall be conducted by an approved inspection agency in accordance with ASTM E 2174.

1704.15.2 Fire-resistant joint systems. Inspection of fire resistant joint systems of the types specified in Sections 714.3 and 714.4 shall be conducted by an approved inspection agency in accordance with ASTM E 2393.

2. Add standards to Chapter 35 as follows:

ASTM International

E 2174-09	Standard Practice for On-Site Inspection of Installed Fire Stops
E 2393-09	Standard Practice for On-Site Inspection of Installed Fire Resistive Joint Systems and Perimeter Fire Barrier

Reason: Through penetration and joint firestop systems are critical to maintaining the fire resistance rating of fire resistance rated construction, including fire barriers, smoke barriers, and fire resistance rated horizontal assemblies. Every construction trade has very unique requirements that are specific to that trade, with technical knowledge built through cumulative continued work in the trade. Firestopping is no different. The concept has been proposed in the past and some felt the scope was too broad. Therefore, the scope of the proposed requirement has been limited to those buildings that represent a substantial hazard to human life in the event of a system failure or that are considered to be essential facilities in accordance with Table 1604.5.

In order to meet the requirements of a listed firestop system from the UL Fire Resistance, Intertek, FM Approvals or other testing laboratory directories, a 'zero tolerance' systems installation protocol is needed, or a system can be violated and rendered ineffective. The violation can be as small as a minor annular space size variance, joint width exceeding system requirements, penetrating item size or type not as listed. There are no typical 'construction tolerances' allowed in firestopping for fire and life safety.

Firestop Systems must be selected from the listing directories, then applied in the correct manner, in the right place. With endless variations to penetrating items, hole sizes and shapes, plus the classified systems to restore the fire ratings, firestop systems selection looks easy to the untrained eye.

The UL Fire Resistance Directories have over 8,500 listed firestop systems, each with variations that multiplies possible systems for a building exponentially. Systems selection is not a 'generic process'. Systems selection is an exacting exercise by skilled contractors who submit appropriate systems for approval, then communicate these systems to the educated firestop – containment workers they employ….which becomes the inspection document for a qualified inspector of firestop systems to leading documents such as International Accreditation Services Accreditation Criteria, AC 291, section 6.11, Firestop Systems.

Should a penetration or joint condition in the field vary from the system design listing from the directories, the firestop system may not perform as intended, opening risk to the structure, and the occupants on the other side of the fire. Structurally, the floor, floor-ceiling or wall assemblies are not tested with unprotected holes with penetrating items or joints allowing fire attack to take place from both sides at once. They are tested with fire attack from one side, with all openings and penetrating items and joints firestopped.

On construction projects, there are three ways firestopping is installed currently. First, the 'he or she who pokes the hole fills it with firestopping' takes place, about 1/3 the time. A specialty firestop contractor installs for about another 1/3 of installations. The final 1/3 is a combination of specialty firestop contractors and the 'he or she who pokes the hole fills it' method. In other words, about ½ of the installations are installed by companies who most likely do not understand firestop systems selection nor the zero tolerance installation protocol. And, with the 20+ trades who potentially touch firestopping, many who perform the work as a 'sideline', the potential for a mistake increases exponentially when inexperienced companies install firestopping. However, firestopping is a complex operation, just like any other trade. Mastering more than one trade by attending a 30 minute to 16 hour class is nearly impossible for workers of any trade background.

In simple terms, inadequate firestopping makes the fire resistance rated floor or wall assembly become swiss cheese like, and not representative of testing. The risks of inadequate firestopping are apparent due to the many trades who install firestopping as a sideline…who just don't get the 'zero tolerance' systems oriented approach needed to get firestopping done right. Inspection to ASTM E 2174 and ASTM E 2393 brings a needed check to this important discipline, whether a FCIA Member specialty firestop contractor is installing or not.

Cost Impact: This will increase cost of construction when a contractor installing firestopping does not understand the zero tolerance protocol for firestopping. It will not increase the cost of construction when a contractor knowledgeable in the zero tolerance protocol for firestopping is used.

Analysis: A review of the standard(s) proposed for inclusion in the code, ASTM E2174-09 and ASTME E2393-09, for compliance with ICC criteria for referenced standards given in Section 3.6 of Council Policy #CP 28 will be posted on the ICC website on or before September 24, 2009.

ICCFILENAME: KOFFELL-S3-1704.15 NEW

Public Hearing Results

This code change was contained in the errata posted on the ICC website. Please go to http://www.iccsafe.org/cs/codes/Pages/09-10ProposedChanges.aspx.

Note: The following analysis was not in the Code Change monograph but was published on the ICC website at http://www.iccsafe.org/cs/codes/Documents/2009-10cycle/ProposedChanges/Standards-Analysis.pdf :

Analysis: Review of proposed new standards ASTM E 2174 and ASTM E 2393 indicated that, in the opinion of ICC Staff, the standards comply with ICC standards criteria.

Committee Action: Approved as Modified

Modify the proposal as follows:

1704.15 Fire-resistant penetrations and joints. In buildings assigned an Occupancy Category of III or IV in accordance with Section 1604.5, special inspections for through penetrations, membrane penetration firestops, fire resistant joint systems, and perimeter fire barrier systems ~~of the types specified~~ ~~in~~ tested and listed in accordance with Sections 713.3.1.2, 713.4.1.2, 714.3 and 714.4 shall be in accordance with Sections 1704.15.1 or 1704.15.2.

1704.15.1 Penetration firestops. Inspections of penetration firestop systems ~~of the types specified~~ ~~in~~ tested and listed in accordance with Sections 713.3.1.2 and 713.4.1.2 shall be conducted by an approved inspection agency in accordance with ASTM E 2174.

1704.15.2 Fire-resistant joint systems. Inspection of fire resistant joint systems ~~of the types specified~~ ~~in~~ tested and listed in accordance with Sections 714.3 and 714.4 shall be conducted by an approved inspection agency in accordance with ASTM E 2393.

(Portions of the proposal not shown remain unchanged)

Committee Reason: The committee agreed that these installations were critical and that special inspections should be required for these installations in buildings assigned an Occupancy Category of III or IV. The modification more appropriately identifies the systems as those that are tested and listed.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Dave Frable, U.S. General Services Administration, requests Disapproval.

Commenter's Reason: We do not concur with the action of the Fire Safety Code Committee to require the need for special inspections to be conducted by an approved inspection agency in accordance with ASTM E 2174 for all penetration firestop systems and ASTM E 2393 for all fire-resistant joint systems in all Occupancy Category Class III and IV buildings.

Typically, special inspections are only required for complex engineering systems or systems that are unusual in nature. It is our opinion that penetration firestop systems and fire resistant joint systems typically occur on every new construction project and are currently adequately addressed in Sections 110.3.6 and 110.3.8. Therefore, the need to require special inspections in all Occupancy Category Class III and IV buildings is not warranted.

In addition, the proponent has failed to provide any technical data or life loss data to substantiate that if the penetration firestop systems and fire resistant joint systems fail within any of the Occupancy Category Class III and IV buildings, a substantial hazard to human life would occur (e.g., an office building having an occupancy greater than 5000, a fire station, a police station, etc.).

It should also be pointed out that ASTM E 2174 and ASTM E 2393 do not provide any minimum qualification requirements for an "inspection agency" but does have qualification requirements for the inspector. For example, one acceptable qualification includes having a minimum of two years experience in construction field inspections and have education, credentials, and experience acceptable to the authorizing authority (i.e., architect, engineer, building owner). Therefore, we feel that these requirements should be in the project specification and not the Code.

Lastly, we also disagree with the proponent that the requirement for special inspections will not increase construction costs.

Public Comment 2:

Steve Orlowski, National Association of Home Builders (NAHB), requests Disapproval.

Commenter's Reason: The authority having jurisdiction, under the auspice of section 1704.15 as found in the current 2009 IBC, already has the authority to require certain methods and materials to be certified by a third party. The proponent has provide no technical justification nor any historical data showing that AHJ or their inspectors are unqualified to conduct these inspection or have failed in their duties due to a loss of any magnitude. In the proponent's written testimony, there are numerous examples referencing the misapplication of products by unqualified installers, yet the proposed change takes away the ability for the AHJ to perform inspections on these products unless they are an approved inspection agency in accordance with the two ASTM standards, as referenced. NAHB requests the final assembly to reject this proposal given that the AHJ already has the option to request special inspections be conducted if they are unfamiliar with products and that this needlessly increases the number of special inspection required by the code.

Final Action: AS AM AMPC____ D

S128-09/10
1704.15 (New), Chapter 35

Proposed Change as Submitted

Proponent: William E. Koffel, Koffel Associates, Inc., representing Firestop Contractors International Association

1. Add new text as follows:

1704.15 Fire-resistant penetrations and joints. In buildings having occupied floors located more than 75 feet (22860 mm) above the lowest level of fire department vehicle access, special inspections for through penetrations, membrane penetration firestops, fire resistant joint systems, and perimeter fire barrier systems of the types specified in Sections 713.3.1.2, 713.4.1.2, 714.3 and 714.4 shall be in accordance with Sections 1704.15.1 or 1704.15.2.

1704.15.1 Penetration firestops. Inspections of penetration firestop systems of the types specified in Sections 713.3.1.2 and 713.4.1.2 shall be conducted by an approved inspection agency in accordance with ASTM E 2174.

1704.15.2 Fire-resistant joint systems. Inspection of fire resistant joint systems of the types specified in Sections 714.3 and 714.4 shall be conducted by an approved inspection agency in accordance with ASTM E 2393.

2. Add standards to Chapter 35 as follows:

ASTM International

E 2174-09	Standard Practice for On-Site Inspection of Installed Fire Stops
E 2393-09	Standard Practice for On-Site Inspection of Installed Fire Resistive Joint Systems and Perimeter Fire Barrier

Reason: Through penetration and joint firestop systems are critical to maintaining the fire resistance rating of fire resistance rated construction, including fire barriers, smoke barriers, and fire resistance rated horizontal assemblies. Every construction trade has very unique requirements that are specific to that trade, with technical knowledge built through cumulative continued work in the trade. Firestopping is no different. Final Action: AS AM AMPC____ D

S141-09/10
1715.5.1

Proposed Change as Submitted

Proponent: William E. Koffel, Koffel Associates, Inc., representing Glazing Industry Code Committee

Revise as follows:

1715.5.1 Exterior windows and doors. Exterior windows and sliding doors shall be tested and labeled as conforming to AAMA/WDMA/CSA 101/I.S.2/A440. The label shall state the name of the manufacturer, the approved labeling agency, and the product designation as specified in AAMA/WDMA/CSA101/I.S.2/A440. Exterior side-hinged doors shall be tested and labeled as conforming to AAMA/WDMA/CSA 101/I.S.2/A440 or comply with Section 1715.5.2. Products <u>installed in buildings of Group R not more than three stories above grade plane that are</u> tested and labeled as conforming to AAMA/WDMA/CSA 101/I.S.2/A440 shall not be subject to the requirements of Sections 2403.2 and 2403.3.

Reason: The purpose of this proposal is to restrict the application of the exemption that fenestration products labeled to AAMA/WDMA/CSA 101/I.S.2/A440 do not have to meet the requirements of sections 2403.2 and 2403.3, which ensure safe performance through proper support of glass. Specifically, section 2403.3 requires that the deflection of framing members supporting glass may not exceed 1/175 of the glass edge length (or ¾ inch, whichever is less) when subjected to the design load. Chapter 24 of the IBC relies on glass design curves that are contained in ASTM E 1300. This ASTM standard recognizes the importance of limiting edge deflection of the glass and also recommends a limitation of 1/175 of the glass edge length. Prior to the IBC, the legacy codes required deflection limitations of 1/175 of the span for glass holding members. It was not until the IBC was published that this exemption was allowed.

AAMA/WDMA/CSA 101/I.S.2/A440 does require testing in accordance with ASTM E330 and measurement of deflection. However, AAMA/WDMA/CSA 101/I.S.2/A440 only places a limit on the frame and sash deflection for heavy commercial (HC) and architectural products (AW), and has no requirement on deflection for residential (R), light commercial (LC), and commercial (C) products. Excessive deflection of the frame or sash can have an adverse effect on stress in the glass and could result in glass breakage at or below design loads creating a safety concern. The single ASTM E330 load test required in AAMA/WDMA/CSA 101/I.S.2/A440 is not statistically significant in ensuring that the stress does not increase the probability of breakage beyond the industry standard of eight lites per thousand when the deflection limitation of 1/175 is exceeded. Although the deflection exemption remains in the IRC for residential buildings and as proposed in the IBC for low-rise residential, it is inappropriate to have an exemption for these products when used in more diverse and larger buildings built to the IBC. This proposal would ensure that an appropriate limit on frame deflection is placed on fenestration products from all performance classes. Because the deflection is already being measured for all these products (but not limited for R, LC, and C classes), there is no cost impact except for products which do not comply with this more conservative and appropriate requirement.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: KOFFELL-S1-1714.5.1

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: Disapproved for same reasoning as S140 – 09/10.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Thomas S. Zaremba, Roetzel & Andress, representing Glazing Industry Code Committee (GICC), a committee of the Glass Association of North America (GANA) and Thomas D. Culp, Ph.D, Birch Point Consulting LLC, representing Aluminum Extruders Council, request Approval as Submitted.

Commenter's Reason: The adoption of this proposal will 1- strengthen the structural integrity of exterior window and door assemblies, 2- decrease the likelihood they will break, and, thus, 3- make them safer when subjected to design loads.

Chapter 24 of the IBC and ASTM E1300 both establish maximum deflection limits for glazing in order to ensure that the glazing is firmly supported and does not break when subjected to design loads. However, Section 1715.5.1 provides an exemption from deflection limits for products labeled to the AAMA/WDMA/CSA 101/I.S.2/A440 standard. This exemption applies to all product types and to all occupancies and is, therefore, far too broad. This proposal would correct the overbreadth of Section 1715.5.1 by removing it from most occupancies, thus, restoring an appropriate safety margin of less than an 8 in 1000 probability of glass breakage under design loads.

In disapproving the proposal, the committee questioned why the proposal retained the exemption from deflection limits for low-rise Group R occupancies (ie., those that are not more than three stories above grade) but eliminated it as to other occupancies. The reason for retaining the exemption for low-rise Group R occupancies is, simply, that an exemption for the lighter products used in low-rise residential construction may well be appropriate. However, just because it is appropriate for the very light construction used in those applications, does not make it appropriate to exempt all other occupancies from the deflection limits mandated by Chapter 24 and ASTM E1300. Moreover, retaining the exemption for low-rise Group R occupancies will maintain consistency with the IRC, where detached one- and two-family dwellings and townhouses with a separate means of egress are currently exempt from deflection limit requirements.

Final Action Agenda voters are urged to vote against the standing motion to disapprove this proposal in order to vote in favor of a motion to approve S141 As Submitted.

Final Action: AS AM AMPC____ D

S143-09/10
1715.4.2, Chapter 35

<u>Proposed Change as Submitted</u>

Proponent: John Woestman, The Kellen Company, representing the Door Safety Council (DSC)

1. Add new text as follows:

1715.5.2 Exterior windows and door assemblies not provided for in Section 1715.5.1. Exterior window and door assemblies shall be tested in accordance with ASTM E 330. <u>Structural performance of exterior side-hinged door assemblies shall be determined in accordance with either ASTM E330 or ANSI A250.13.</u> Structural performance of garage doors shall be determined in accordance with either ASTM E 330 or ANSI/DASMA 108, and shall meet the acceptance criteria of ANSI/DASMA 108. Exterior window and door assemblies containing glass shall comply with Section 2403. The design pressure for testing shall be calculated in accordance with Chapter 16. Each assembly shall be tested for <u>a minimum of</u> 10 seconds at a load equal to 1.5 times the design pressure.

2. Add new standard to Chapter 35 as follows:

ANSI
<u>ANSI A250.13-08</u> <u>Testing and Rating of Severe Windstorm Resistant Components for Swinging Door Assemblies</u>

Reason: This proposal helps resolve performance and code compliance issues when exterior side-hinged door openings are comprised of components from multiple sources and include interchangeable elements (ie; doors, frames, hinging and latching hardware, etc.).

Through the ANSI standards development process, stake-holders, comprising most major manufacturing associations, testing and certification organizations, specifiers, code officials and end users, developed a national standard for a component-based approach to testing for windstorm resistance of swinging door openings. The test procedures used in this standard represent the most severe requirements found in the windstorm resistance standards referenced in today's building codes. These procedures are designed to isolate the loads, conditions and critical performance requirements that a particular component is subjected to in full assembly tests and duplicate these specific conditions. Using a combination of worst-case scenario design and safety factors, this standard is designed to provide a component rating that relates directly to the component's ability to withstand the conditions that occur in full assembly tests.

This proposed change allows an alternative method to demonstrate structural performance for side-hinged door openings by requiring components to be tested per ANSI A250.13-2008. A250.13 contains language that prescribes how components are to be selected to create complete swinging door openings expected to perform equivalently to those tested to ASTM E 330. ANSI A250.13 has additional requirements that are more stringent than those in the current 1714.5.2, including testing for a minimum of <u>30</u> seconds at a load equal to 1.5 times the design pressure. Currently 1714.5.2 requires testing for <u>10</u> seconds at a load equal to 1.5 times the design pressure.

Prior to releasing the current revision, validation tests were performed at three design-load levels, using the A250.13 test protocol to establish performance ratings. The study confirmed that at the same design-load level, openings comprised of such components will perform in the same manner as those in assembly based test protocols. The validation tests also showed that where an element was identified as the weakest in an opening during component testing, it would perform similarly when tested as part of an assembly at the same design-load.

Building designers will use the performance based criteria of ANSI A250.13 to select appropriate components to construct swinging door openings by conducting the presently required opening-by-opening design analysis, verify code compliance, and submit the results through the normal plans review process. Code authorities will therefore need only to verify the design load calculations and compliance analysis are correct and that ANSI A250.13 compliant products are utilized and installed in accordance with the manufacturer's instructions during construction.

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: A review of the standard(s) proposed for inclusion in the code, ANSI A250 13-08 for compliance with ICC criteria for referenced standards given in Section 3.6 of Council Policy #CP 28 will be posted on the ICC website on or before September 24, 2009.

ICCFILENAME: WOESTMAN-S2-1714.5.2

Public Hearing Results

Note: The following analysis was not in the Code Change monograph but was published on the ICC website at http://www.iccsafe.org/cs/codes/Documents/2009-10cycle/ProposedChanges/Standards-Analysis.pdf :

Analysis: Review of proposed new standard ANSI A250.13 indicated that, in the opinion of ICC Staff, the standard complies with ICC standards criteria.

Committee Action: Disapproved

Committee Reason: There are concerns on the applicability of the proposed referenced standard to this portion of the IBC. There is also a question of who takes responsibility for the entire door assembly, when only the individual parts are tested by the standard.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

John Woestman, The Kellen Company, representing Builders Hardware Manufacturers Association (BHMA), Bud Bulley, representing the National Association of Architectural Metal Manufacturers (NAAMM) and representing the Hollow Metal Manufacturer's Association (HMMA); Jeff Wherry, representing the Steel Door Institute (SDI); Jerry Heppes, representing the Door and Hardware Institute (DHI), requests Approval as Submitted.

Commenter's Reason: This proposal helps resolve performance and code compliance issues when exterior side-hinged door openings are comprised of components from multiple sources and include interchangeable elements (ie; doors, frames, hinging and latching hardware, etc.).

Through the ANSI standards development process, stake-holders, comprising most major manufacturing associations, testing and certification organizations, specifiers, code officials and end users, developed a national standard for a component-based approach to testing for windstorm resistance of swinging door openings.

The test procedures used in this standard represent the most severe requirements found in the windstorm resistance standards referenced in today's building codes. These procedures are designed to isolate the loads, conditions and critical performance requirements that a particular component is subjected to in full assembly tests and duplicate these specific conditions. Using a combination of worst-case scenario design and engineering safety factors, this standard is designed to provide a component rating that relates directly to the component's ability to withstand the conditions that occur in full assembly tests. The developers of the standard recognized the complexity and variables of door components interacting as an assembly and incorporated stringent test criteria and engineering safety factors in the standard to address these variables.

This proposed change to the IBC allows an alternative method to demonstrate structural performance for side-hinged door openings by requiring components to be tested per ANSI A250.13-2008. A250.13 prescribes how components are to be selected to create complete swinging door assemblies expected to perform equivalently (or better) to those tested to ASTM E 330. ANSI A250.13 has additional requirements that are more stringent than those in the current 1715.5.2, including testing for a minimum of 30 seconds at a load equal to 1.5 times the design pressure. Currently 1715.5.2 requires testing for 10 seconds at a load equal to 1.5 times the design pressure.

Prior to releasing the current revision, validation tests were performed at three design-load levels, using the A250.13 test protocol to establish performance ratings. The study confirmed that at the same design-load level, door assemblies comprised of such components will perform the same (or better) as those in assembly-based test protocols (ASTM E330). The validation tests also showed that where a door component was identified as the weakest in a door assembly during component testing, it would perform similarly when tested as part of an entire door assembly at the same design-load.

Building designers will use the performance based criteria of ANSI A250.13 to select appropriate components to construct swinging door assemblies by conducting the presently required opening-by-opening design analysis, verify code compliance, and submit the results through the normal plans review process. Code authorities will therefore need only to verify the design load calculations and compliance analysis are correct and that ANSI A250.13 compliant products are utilized and installed in accordance with the manufacturer's instructions during construction.

Addressing the committee's question of "who takes responsibility for the entire door assembly, when only individual parts are tested by the standard", Section 1703.4 of the IBC addresses this question by requiring specific and sufficient information be provided to the building official. With the introduction to the IBC of A250.13 for door component selection for side-hinged doors, similar to door component selection for fire-rated doors, each component of the side-hinged door would be selected to meet or exceed the code-required design criteria of the opening.

The committee's other concern of the applicability of ANSI A250.13 to this section of the code, this standard was developed explicitly as an optional alternative to ASTM E330 testing (as required by the code). Door assemblies designed and assembled for hurricane-prone areas generally exceed the design pressure requirements required outside hurricane-prone areas. As a result, doors assembled of components tested and evaluated to A250.13 (i.e. meeting the required design pressure of a specific project in a hurricane-prone area) could be used in a building where the design pressure is considerably lower.

This proposal will not increase the cost of construction – it should decrease the testing costs of complying with the building code resulting in a slight decrease of the cost of door components.

Public Comment 2:

Larry J. Tanner, P.E., Texas Tech University, representing Wind Science & Engineering Research Center, Debris Impact Test Laboratory, requests Disapproval

Commenter's Reason: The ANSI A250 Standard, along with the ASTM 1886/1996 standards, were developed to prevent the proliferation of envelope perforations and the resulting inundation of rainwater from hurricane events. Evidence from hurricane investigations has revealed that indeed buildings designed to these standards performed better than buildings without said protection. However, it should be understood and specifically included in technical specifications by the manufacturers and advertisements to the consumers, that such products are intended only for non-catastrophic property protection from rainwater inundation and not for the protection of building occupants (Life Safety). I was a coauthor of both FEMA 320 and FEMA 361 which utilize Tornado and Hurricane Saferoom Design Wind Speed Maps. Never were the above referenced ANSI and ASTM standards considered suitable for FEMA 320 Saferooms or FEMA 361 Community Shelters. Specifics to the proposed changes to the ANSI A250.13-2008 Standard:

1. From a quantitative standpoint the "stiffness theory" appears reasonable; however laboratory tests have proven otherwise. Texas Tech University has been the leading "storm debris impact researcher" for over 35 years. Tests on door assemblies have proven that success or failure from wind pressures and debris impacts is unique to the door (or window unit) and the hardware components installed. A heavily constructed door absorbs little energy and directs most of the energy to the attaching components and has proven to fail components that previously passed on other less massive doors. Lighter constructed doors can bend excessively and either pull out locking bolts or cause bolting bending and ultimate failure. Doors passing the impact tests must have a unique set of hardware that matches the door performance, thus doors are rated as a complete assembly, inclusive of frame, door(s), hinging, and locking hardware. Window lites in doors compromise the strength of the door and present another set of unique circumstances which require the unit to be rated as a complete assembly. Window unit performance is unique to the opening size, frame type, and the glazing. The elasticity of the glazing is a function of size and type. Based on size, some glazing is so elastic that it bounces out of the frame. Smaller is not always better; some glazing will destroy the framing system and be pushed out. Thus, the only way to predict window behavior under impact is by full scale testing in the laboratory in "as specified and installed" condition.
2. Though these Standards were developed for "envelope" protection to reduce rainwater intrusion, these components that are now rated as "Hurricane Tested" are now being used in hardened "Hurricane Shelters" which are intended to protect lives. This is the result of misleading specification sheets, and uninformed dealers and consumers.
3. The "component rating" system does not consider the size of doors or glazed openings; the stiffness of doors with various sizes of lites, nor the quantity of hinges or latches required per size to carry the loads.
4. The Standard requires the component to be rated by ultimate load, but there is no guidance regarding the "assembly rating" based upon mixture of components with various ratings.
5. The Standard does not require engineering review or oversight.
6. According to the Test Procedure stated in Section 5.2.2, the impact energy should be 350 foot-pounds. However, for hinges, Section 6.1.1.2 and Latching Hardware, Section 7.1.1.3, the impact kinetic energy has been reduced to 125 foot-pounds. I understand the "stiffness" theory of the test fixture and product configuration, but this assumes that every laboratory will have the same fixtures and the same laboratory conditions.
7. The wind speed range has changed from 110-150 mph for the 2003 Standard to 110-170 mph for the 2008 Standard, but the test loads and impact criteria has not changed.
8. The impact location 6" above the floor on Figure 4, page 6 is unrealistic. In researching most all of the severe tornadoes and hurricanes since 1989, I have never seen an impact lower than 2.5 feet on a vertical surface.
9. Although there is not the opportunity at this time, to prevent the misuse of these products as describe above, I would suggest that the title of the standard be changed to: *Testing and Rating of Windstorm Resistant Components for Swinging Doors for Non-Life Safety Uses.*

Final Action: AS AM AMPC____ D

S144-09/10-PART I

1715.6 (New), 202

Proposed Change as Submitted

Proponent: Julie Ruth, PE, JRuth Code Consulting, representing American Architectural Manufacturers Association

PART I – IBC STRUCTURAL

1. Revise as follows:

SECTION 202

SKYLIGHT, UNIT. A factory-assembled, glazed fenestration unit, containing one panel of glazing material that allows for natural lighting through an opening in the roof assembly while preserving the weather-resistant barrier of the roof. Unit skylights include, but are not limited to, tubular daylighting devices (TDDs).

2. Add new text as follows:

1715.6 Skylights and sloped glazing. Unit skylights shall comply with the requirements of Section 2405. All other skylights and sloped glazing shall comply with the requirements of Chapter 24.

(Renumber subsequent sections)

Reason: This proposal clarifies that tubular daylighting devices (TDDs) are unit skylights and therefore subject to the testing and labeling requirements of Section 2405 for these devices. It also points the code user to the appropriate location in the IBC for the structural requirements for unit skylights, TDDs and all other types of sloped glazing.

Cost Impact: The code change will not increase the cost of construction.

ICCFILENAME: RUTH-G1-202

Public Hearing Results

PART I- IBC STRUCTURAL
Committee Action: Disapproved

Committee Reason: There was concern with the proposed Section 1715.6 being located in the section on testing.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Julie Ruth, JRuth Code Consulting, representing American Architectural Manufacturers Association, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

PART I – IBC STRUCTURAL

SECTION 202

SKYLIGHT, UNIT. A factory-assembled, glazed fenestration unit, containing one panel of glazing material that allows for natural lighting through an opening in the roof assembly while preserving the weather-resistant barrier of the roof. Unit skylights include, but are not limited to, tubular daylighting devices (TDDs).

~~**1715.6 Skylights and sloped glazing.** Unit skylights shall comply with the requirements of Section 2405. All other skylights and sloped glazing shall comply with the requirements of Chapter 24.~~

Commenter's Reason: The intent of S144 was to clarify within both the IBC and IRC that tubular daylighting devices are unit skylights, and therefore shall be tested and labeled in accordance with AAMA/WDMA/CSA 101/I.S.2/A440, as required for unit skylights in IBC Section 2405 and IRC Section R308.6.9.

S144, Part I also included a pointer from Section 1715 of the IBC, where AAMA/WDMA/CSA 101/I.S.2/A440 is referenced for windows and sliding doors, to Section 2405, which contains the reference to the same standard for unit skylights. The IBC Structural Committee did not agree with the addition of this pointer in Section 1715 of the IBC, and therefore they disapproved S144, Part I.

S144, Part II, which only added tubular daylight devices to the definition of unit skylights, and did not contain a pointer to another code section for reference to the applicable standard, was approved by the IRC Building and Energy Committee.

This Public Comment removes the proposed pointer, and simply seeks the addition of tubular daylighting devices to the definition of unit skylights in the IBC. Its approval would be consistent with the action taken on S144, Part II.

Public Comment 2:

Gary J. Ehrlich, PE, National Association of Home Builders, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

PART I – IBC STRUCTURAL

SECTION 202

SKYLIGHT, UNIT. A factory-assembled, glazed fenestration unit, containing one panel of glazing material that allows for natural lighting through an opening in the roof assembly while preserving the weather-resistant barrier of the roof. ~~Unit skylights include, but are not limited to, tubular daylighting devices (TDDs)~~.

<u>**TUBULAR DAYLIGHTING DEVICE (TDD).** A non-operable fenestration unit primarily designed to transmit daylight from a roof surface to an interior ceiling via a tubular conduit. The basic unit consists of an exterior glazed weathering surface, a light-transmitting tube with a reflective interior surface, and an interior-sealing device such as a translucent ceiling panel. The unit may be factory assembled, or field-assembled from a manufactured kit.</u>

1715.6 Skylights and sloped glazing. Unit skylights and tubular daylighting devices (TDDs) shall comply with the requirements of Section 2405. All other skylights and sloped glazing shall comply with the requirements of Chapter 24.

Commenter's Reason: The purpose of this public comment is to amend the proposed requirements for tubular daylighting devices. A tubular daylighting device (TDD) is typically field-assembled from a manufactured kit, unlike a unit skylight which is typically shipped as a factory-assembled unit. If the current unit skylight definition is applied to TDDs, some code users will expect that TDDs be entirely assembled in the factory. Also, the dome of a TDD is not necessarily constructed out of a single panel of glazing material. As such, a separate definition from that of a unit skylight is needed. The proposed definition is adapted from the definition in AAMA/WDMA A440. A reference to TDDs is added to Section 1715.6.

Final Action: AS AM AMPC____ D

S144-09/10-PART II
IRC R308.6.1

Proposed Change as Submitted

Proponent: Julie Ruth, PE, JRuth Code Consulting, representing American Architectural Manufacturers Association

PART II – IRC BUILDING/ENERGY

Revise as follows:

R308.6.1 Definitions.

~~UNIT SKYLIGHT~~ SKYLIGHT, UNIT. A factory assembled, glazed fenestration unit, containing one panel of glazing material, that allows for natural daylighting through an opening in the roof assembly while preserving the weather-resistant barrier of the roof. Unit skylights include, but are not limited to, tubular daylighting devices (TDDs).

Reason: This proposal clarifies that tubular daylighting devices (TDDs) are unit skylights and therefore subject to the testing and labeling requirements of the IRC for same.

Cost Impact: The code change will not increase the cost of construction.

ICCFILENAME: RUTH-G1-202

Public Hearing Results

PART II- IRC B/E
Committee Action: **Approved as Submitted**

Committee Reason: This change clarifies that a tubular daylighting devices (TDDs) is a unit skylight. The TDD was added to the energy conservation part of the code.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Gary J. Ehrlich, PE., National Association of Home Builders, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

PART II – IRC BUILDING/ENERGY

R308.6.1 Definitions.

SKYLIGHTS AND SLOPED GLAZING. Glass or other transparent or translucent glazing material installed at a slope of 15 degrees (0.26 rad) or more from vertical. Glazing materials in skylights, including unit skylights, tubular daylighting devices, solariums, sunrooms, roofs and sloped walls are included in this definition.

SKYLIGHT, UNIT. A factory assembled, glazed fenestration unit, containing one panel of glazing material, that allows for natural daylighting through an opening in the roof assembly while preserving the weather resistant barrier of the roof. ~~Unit skylights include, but are not limited to, tubular daylighting devices (TDDs).~~

<u>**TUBULAR DAYLIGHTING DEVICE (TDD).** A non-operable fenestration unit primarily designed to transmit daylight from a roof surface to an interior ceiling via a tubular conduit. The basic unit consists of an exterior glazed weathering surface, a light-transmitting tube with a reflective interior surface, and an interior-sealing device such as a translucent ceiling panel. The unit may be factory assembled, or field-assembled from a manufactured kit.</u>

R308.6.9 Testing and labeling. Unit skylights <u>and tubular daylighting devices</u> shall be tested by an *approved* independent laboratory, and bear a *label* identifying manufacturer, performance *grade* rating and *approved* inspection agency to indicate compliance with the requirements of AAMA/WDMA/CSA 101/I.S.2/A440.

Commenter's Reason: The purpose of this public comment is to amend the proposed requirements for tubular daylighting devices. A tubular daylighting device (TDD) is typically field-assembled from a manufactured kit, unlike a unit skylight which is typically shipped as a factory-assembled unit. If the current unit skylight definition is applied to TDDs, some code users will expect that TDDs be entirely assembled in the factory. Also, the dome of a TDD is not necessarily constructed out of a single panel of glazing material. As such, a separate definition from that of a unit skylight is needed. The proposed definition is adapted from the definition in AAMA/WDMA A440. A reference to TDDs is added to Sections R308.6.1 and R308.6.9.

Final Action: AS AM AMPC____ D

S149-09/10
1803.5.12

<u>Proposed Change as Submitted</u>

Proponent: Ali M. Fattah, City of San Diego, representing SD Area Chapter ICC Code Committee

Revise as follows:

1803.5.12 Seismic Design Categories D through F. For structures assigned to *Seismic Design Category* D, E or F in accordance with Section 1613, the geotechnical investigation required by Section 1803.5.11, shall also include:

1. The determination of lateral <u>earth</u> pressures on foundation walls and retaining walls <u>supporting more than 12 feet (3.66 m) of backfill height,</u> due to earthquake motions.
2. The potential for liquefaction and soil strength loss evaluated for site peak ground accelerations, magnitudes and source characteristics consistent with the design earthquake ground motions. Peak ground acceleration shall be permitted to be determined based on a site-specific study taking into account soil amplification effects, as specified in Chapter 21 of ASCE 7, or, in the absence of such a study, peak ground accelerations shall be assumed equal to $S_{DS}/2.5$, where S_{DS} is determined in accordance with Section 1613.5.4.
3. An assessment of potential consequences of liquefaction and soil strength loss, including estimation of differential settlement, lateral movement, lateral loads on foundations, reduction in foundation soil-bearing capacity, increases in lateral pressures on retaining walls and flotation of buried structures.
4. Discussion of mitigation measures such as, but not limited to, ground stabilization, selection of appropriate foundation type and depths, selection of appropriate structural systems to accommodate anticipated displacements and forces, or any combination of these measures and how they shall be considered in the design of the structure.

Reason: The proposed code change deletes a current requirement. The current requirement is onerous on small structures and light framed structures as well as for retaining walls. The California Building Code has had an amendment that was added in the 1990's that addresses this issue and limits the requirement to retaining walls higher than 12 ft. The amendment only applies to hospitals projects, school projects and State owned buildings (See Section 1806A.1 General, http://www.bsc.ca.gov/default.htm).

Evidence from recent earthquakes and recent experimental research results, including work recently completed at the University of California, Berkeley, CA (Al Atik and Sitar, 2008) have demonstrated that the retaining walls structures would have to move in order to develop the failure wedge postulated in the so-called Mononobe and Okabe method. This method was developed by Okabe (1926) and Mononobe & Matsuo (1929) as an extension of Coulomb's static earth pressure theory to include the inertial forces due to the horizontal and vertical back-fill accelerations. The M-O method was developed for dry cohesionless backfill retained by a gravity wall and is mainly based on the following assumptions (Seed & Whitman 1970):

1. The wall yields sufficiently to produce minimum active pressure and the soil is assumed to satisfy the Mohr-Coulomb failure criterion;
2. When the minimum active pressure is attained, a soil wedge behind the wall is at the point of incipient failure, and the maximum shear strength is mobilized along the potential sliding surface; and
3. The soil wedge behaves as a rigid body, and accelerations are constant throughout the mass.

However, this condition can only occur when the wall has already failed due to other causes and the current body of field evidence does not provide any evidence of existence of this proposed mechanism of failure.

Retaining wall backfill is what imposes the inertial forces and is controlled backfill, usually not cohesionless and is compacted.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME:Fattah-S2-1803.5.1.2

Public Hearing Results

Committee Action: Approved as Submitted

Committee Reason: This code change relieves the geo-technical requirement for determination of lateral earth pressure on small structures as well as retaining walls that support backfill no more than 12 feet in height. It is the height of the backfill that imposes the inertial force. This is based on a California Building Code requirement that recognizes earthquake is not controlling loading on these structures.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Ali M. Fattah, PE., City of San Diego, Development Services Department, representing San Diego Area Chapter of ICC, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

1803.5.12 Seismic Design Category D, E or F.

For structures assigned to Seismic Design Category D, E or F in accordance with Section 1613, the geotechnical investigation required by Section 1803.5.11, shall also include:

1. The determination of lateral earth pressures on foundation walls, and retaining walls supporting more than ~~12~~ 6 feet of backfill height, due to earthquake motions.
2. The potential for liquefaction and soil strength loss evaluated for site peak ground accelerations, magnitudes and source characteristics consistent with the design earthquake ground motions. Peak ground acceleration shall be permitted to be determined based on a site-specific study taking into account soil amplification effects, as specified in Chapter 21 of ASCE 7, or, in the absence of such a study, peak ground accelerations shall be assumed equal to $S_{DS}/2.5$, where S_{DS} is determined in accordance with Section 1613.5.4.
3. An assessment of potential consequences of liquefaction and soil strength loss, including estimation of differential settlement, lateral movement, lateral loads on foundations, reduction in foundation soil-bearing capacity, increases in lateral pressures on retaining walls and flotation of buried structures.
4. Discussion of mitigation measures such as, but not limited to, ground stabilization, selection of appropriate foundation type and depths, selection of appropriate structural systems to accommodate anticipated displacements and forces, or any combination of these measures and how they shall be considered in the design of the structure

Commenter's Reason: This public comment requests that the voting membership support the IBC Structural Committee's assessment of the need for this code change and to support a modification to the height threshold that may allay the concerns of other interested parties that may not be in support of the Committee's action.

The proposed code change was concurrently submitted for adoption into the 2010 California Building Code and the Structural Design - Lateral Forces Committee Code Advisory Committee recommended that the California Building Standard Commission adopt a similar code change that was limited to 6 ft height and not 12 ft as was proposed in the IBC.

The public comment reduces the height exemption to 6 ft to satisfy the concerns of certain stakeholders that disagree with the IBC Structural Committee decision. The SEAOC Code Committee saw the merits of the code change as proposed to both bodies and took a neutral stance. The proponent was not able to attend the meeting but was informed that NCSEA offered support to the IBC proposal.

The Division of the State Architect and the Office of Statewide Health Planning and Development repealed the 12 ft height exemption that has been published in editions of the California Building Code prior to the 2010 edition and decided to defer to Section 11.8 of ASCE 7-05. The proponent acknowledges that the code change will result in a conflict with Section 11.8 of ASCE 7-05 however the building code governs over the referenced standard. Had the requirements been struck from the Building Code as was the case for most of the seismic requirements in Chapter 16 the proponent would have sought to change the ASCE 7-05.

The proponent was not able to attend the Structural Committee meeting to explain that the justification for the code change was not only based on the CBC. The justification included a research study on the issue performed at the University of California as well as post earthquake reconnaissance. The committee action report seems to imply that the basis of approval was because a similar provision existed in the CBC.

The proposed code change is necessary for uniform enforcement and to avoid non-enforcement of the requirement on many miscellaneous structures such as swimming pools, minor earth retaining structures, some of which many not require a building permit. As structured, the code requirement in both ASCE 7-05 and the IBC places an enormous burden on an applicant to investigate a site for a structure that will be located on native undisturbed ground, that does not include fill materials or expansive soils and where ASCE 7-05 and the IBC provide adequate lateral earth design parameters that negate the need for a report. We urge the voting memberships support.

Public Comment 2:

Steven Winkel, FAIA, PE; Susan Dowty, SE; John Gillengerten, SE, representing the Federal Emergency Management Agency/Building Seismic Safety Council Code Resource Support Committee (FEMA/BSSC CRSC), request Disapproval.

Commenter's Reason: The committee reason for support of this proposal, that it "…is based on a California Building Code (CBC) requirement that recognizes earthquake is not controlling on these structures" is not valid. This CBC requirement was repealed in 2009 in favor of the requirements in ASCE 7-05 Section 11.8.3. This ASCE 7 provision requires that determination of lateral pressures on basement and retaining walls due to earthquake motions for structures Seismic Design Categories D, E, and F be included in a geotechnical investigations. Also, it should be noted that ASCE 7 Section 15.6.1, Earth-Retaining Structures, references Section 11.8.3 for determining lateral earth pressures due to earthquake ground motions.

Final Action: AS AM AMPC____ D

S164-09/10
1908.1.2

<u>Proposed Change as Submitted</u>

Proponent: Alan Robinson, SE, representing Structural Engineers Association of California

Revise as follows:

1908.1.2 ACI 318, Section 21.1.1. Modify ACI 318 Sections 21.1.1.3 and 21.1.1.7 to read as follows:

21.1.1.3 – Structures assigned to Seismic Design Category A shall satisfy requirements of Chapters 1 to 19 and 22; Chapter 21 does not apply. Structures assigned to Seismic Design Category B, C, D, E or F also shall satisfy 21.1.1.4 through 21.1.1.8, as applicable. Except for structural elements of plain concrete complying with Section 1908.1.8 of the International Building Code, structural elements of plain concrete are prohibited in structures assigned to Seismic Design Category C, D, E or F.

21.1.1.7 – Structural systems designated as part of the seismic-force-resisting system shall be restricted to those *permitted by ASCE 7*. Except for *Seismic Design Category* A, for which Chapter 21 does not apply, the following provisions shall be satisfied for each structural system designated as part of the seismic-force-resisting system, regardless of the *Seismic Design Category*:

(a) Ordinary moment frames shall satisfy 21.2.
(b) Ordinary reinforced concrete structural walls *and ordinary precast structural walls* need not satisfy any provisions in Chapter 21.
(c) Intermediate moment frames shall satisfy 21.3.
(d) Intermediate precast *structural* walls shall satisfy 21.4.
(e) Special moment frames shall satisfy 21.5 through 21.8.
(f) Special structural walls shall satisfy 21.9.
(g) Special structural walls constructed using precast concrete shall satisfy 21.10.
<u>(h) In Seismic Design Category D, E or F, concrete tilt-up wall panels that exceed the limitations of intermediate precast structural wall system shall satisfy 21.9 in addition to 21.4.2 and 21.4.3.</u>

All special moment frames and special structural walls shall also satisfy 21.1.3 through 21.1.7.

Reason: Concrete tilt-up wall panels is an alternative forming system of site-cast concrete wall panels which are tilted or lifted in place. They do not qualify for special precast structural wall system, which must meet the PRESSS test protocol or ACI ITG-5.2. Unlike earlier construction of box-liked industrial buildings, current practice in commercial buildings constructed using tilt-up panel wall system commonly consists of large window and door openings in consecutive panels. Wall panels varying up to three stories high with openings in consecutive panels tend to resemble wall frame, which is not currently recognized under any of the defined seismic-force resisting systems other than consideration as one of the precast structural wall systems. While special boundary elements are probably not required by calculation if there are a number of panels in one shear line, spandrel panels often should be investigated for requirements of coupling beams.

Large tilt-up buildings with flexible diaphragm also may include isolated interior structural wall panels, either cast-in-place or precast, which are designed to resist high required shear strength demand. These isolated structural wall panels must be investigated for special boundary elements. Based on the current code language, intermediate precast structural wall are exempt from requirements of ACI 318-08 section 21.9 and thus design for boundary element, coupling beam and ductile detailing will be absent. This proposal does not affect the selection of seismic response R-factor given in ASCE 7 Table 12.2-1. This proposal gives requirement under which design and detailing need to conform to special structural wall system provisions in ACI-318 section 21.9. This proposal further enhances minimum life safety building performance under earthquake forces in SDC D, E or F.

Cost Impact: The code change proposal will not increase the cost of construction for typical tilt-up buildings in higher SDC.

ICCFILENAME: ROBINSON-S1-1908.1.2

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The current requirements on intermediate precast structural wall systems are clear, making this proposal unnecessary.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Alan Robinson, SE., Structural Engineers Association of California, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

1908.1.2 ACI 318, Section 21.1.1. Modify ACI 318 Sections 21.1.1.3 and 21.1.1.7 to read as follows:

21.1.1.3 – Structures assigned to Seismic Design Category A shall satisfy requirements of Chapters 1 to 19 and 22; Chapter 21 does not apply. Structures assigned to Seismic Design Category B, C, D, E or F also shall satisfy 21.1.1.4 through 21.1.1.8, as applicable. Except for structural elements of plain concrete complying with Section 1908.1.8 of the International Building Code, structural elements of plain concrete are prohibited in structures assigned to Seismic Design Category C, D, E or F.

21.1.1.7 – Structural systems designated as part of the seismic-force-resisting system shall be restricted to those *permitted by ASCE 7*. Except for *Seismic Design Category* A, for which Chapter 21 does not apply, the following provisions shall be satisfied for each structural system designated as part of the seismic-force-resisting system, regardless of the *Seismic Design Category*:

(a) Ordinary moment frames shall satisfy 21.2.
(b) Ordinary reinforced concrete structural walls *and ordinary precast structural walls* need not satisfy any provisions in Chapter 21.
(c) Intermediate moment frames shall satisfy 21.3.
(d) Intermediate precast *structural* walls shall satisfy 21.4.
(e) Special moment frames shall satisfy 21.5 through 21.8.
(f) Special structural walls shall satisfy 21.9.
(g) Special structural walls constructed using precast concrete shall satisfy 21.10.
~~(h) In Seismic Design Category D, E or F, concrete tilt-up wall panels that exceed the limitations of intermediate precast structural wall system shall satisfy 21.9 in addition to 21.4.2 and 21.4.3.~~

All special moment frames and special structural walls shall also satisfy 21.1.3 through 21.1.7. <u>In Seismic Design Category D, E or F, concrete tilt-up wall panels classified as intermediate precast structural wall system shall satisfy 21.9 in addition to 21.4.2 and 21.4.3.</u>

Commenter's Reason: After further research in ACI 318, it was noted that by virtue of ACI 318 Sec. 21.1.1.7(d), intermediate precast structural walls designed under Sec. 21.4, material requirements intended under provisions 21.1.4, 21.1.5, 21.1.6, and 21.1.7 would be excluded for structures assigned to SDC D, E or F. Since the deliberation at the code development hearing, we have had further discussions with ACI 318-H in their meeting in New Orleans. It was a consensus that clarification of ACI 318 chapter 21 is needed to ensure that structural walls designed under ASCE 7 using the intermediate wall panel category would conform to ductility requirements comparable to special structural wall; and conformance to the long standing practice of ACI 318 to impose special requirements for high seismic design regions. This public comment gives explicit requirement under which design and detailing need to conform to special structural wall system provision in ACI-318 section 21.9, which covers both cast-in-place as well as precast. This public comment further gives building officials the tools to enforce minimum life safety building performance under earthquake forces in SDC D, E or F.

Final Action: AS AM AMPC____ D

S166-09/10
1908.1.8

Proposed Change as Submitted

Proponent: Homer Maiel, PE, CBO, City of San Jose**,** representing ICC Tri-Chapter (Peninsula, East Bay, Monterey Bay)

Revise as follows:

1908.1.8 ACI 318, Section 22.10. Delete ACI 318, Section 22.10, and replace with the following:

22.10 – Plain concrete in structures assigned to Seismic Design Category C, D, E or F.

22.10.1 – Structures assigned to Seismic Design Category C, D, E or F shall not have elements of structural plain concrete, except as follows:

(a) Structural plain concrete basement, foundation or other walls below the base are permitted in detached one- and two-family dwellings three stories or less in height constructed with stud-bearing walls. In dwellings assigned to Seismic Design Category D or E, the height of the wall shall not exceed 8 feet (2438 mm), the thickness shall not be less than 71/2 inches (190 mm), and the wall shall retain no more than 4 feet (1219 mm) of unbalanced fill. Walls shall have reinforcement in accordance with 22.6.6.5.

(b) Isolated footings of plain concrete supporting pedestals or columns are permitted, provided the projection of the footing beyond the face of the supported member does not exceed the footing thickness.

Exception: In detached one- and two-family dwellings three stories or less in height, the projection of the footing beyond the face of the supported member is permitted to exceed the footing thickness.

(c) Plain concrete footings supporting walls are permitted, provided the footings have at least two continuous longitudinal reinforcing bars. Bars shall not be smaller than No. 4 and shall have a total area of not less than 0.002 times the gross cross-sectional area of the footing. For footings that exceed 8 inches (203 mm) in thickness, a minimum of one bar shall be provided at the top and bottom of the footing. Continuity of reinforcement shall be provided at corners and intersections.

Exceptions:

1. In <u>Group U occupancies</u> ~~detached one-and two-family dwellings three stories or less in height and~~ constructed with stud-bearing walls, plain concrete footings without longitudinal reinforcement supporting walls are permitted.
2. <u>In structures assigned to Seismic Design Categories D, E and F,</u> ~~For~~ foundation systems consisting of a plain concrete footing and a plain concrete stemwall, a minimum of one <u>No. 4</u> bar shall be provided at the top of the stemwall and at the bottom of the footing.
3. Where a slab on ground is cast monolithically with the footing, one No. 5 bar is permitted to be located at either the top of the slab or bottom of the footing.

Reason: If any occupancy warrants no reinforcing, it is a U occupancy. A three story dwelling in Seismic Design Category D, E or F should have at least 1 #4 bar at the top and bottom of the footing. Concrete cracks without reinforcing. A minimal amount of reinforcing will limit cracks during a seismic event.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: MAIEL-S5-1908.1.8

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: There are concerns with revising the exemption to now apply to Group U. In addition these proposed changes would be inconsistent with the NEHRP Provisions.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Homer Maiel, PE, CBO, City of San Jose, representing ICC Tri-Chapter (Peninsula, East Bay, Monterey Chapters), requests Approval as Modified by this Public Comment.

Replace the proposal as follows:

1908.1.8 ACI 318, Section 22.10. Delete ACI 318, Section 22.10, and replace with the following:

22.10 – Plain concrete in structures assigned to Seismic Design Category C, D, E or F.

22.10.1 – Structures assigned to Seismic Design Category C, D, E or F shall not have elements of structural plain concrete, except as follows:

(a) Structural plain concrete basement, foundation or other walls below the base are permitted in detached one and two-family dwellings three stories or less in height constructed with stud-bearing walls. In dwellings assigned to Seismic Design Category D or E, the height of the wall shall not exceed 8 feet (2438 mm), the thickness shall not be less than 71/2 inches (190 mm), and the wall shall retain no more than 4 feet (1219 mm) of unbalanced fill. Walls shall have reinforcement in accordance with 22.6.6.5.

(b) Isolated footings of plain concrete supporting pedestals or columns are permitted, provided the projection of the footing beyond the face of the supported member does not exceed the footing thickness.

Exception: In detached one- and two-family dwellings three stories or less in height, the projection of the footing beyond the face of the supported member is permitted to exceed the footing thickness.

(c) Plain concrete footings supporting walls are permitted, provided the footings have at least two continuous longitudinal reinforcing bars. Bars shall not be smaller than No. 4 and shall have a total area of not less than 0.002 times the gross cross-sectional area of the footing. For footings that exceed 8 inches (203 mm) in thickness, a minimum of one bar shall be provided at the top and bottom of the footing. Continuity of reinforcement shall be provided at corners and intersections.

Exceptions:

1. In <u>Seismic Design Categories A, B and C</u>, detached one-and two-family dwellings three stories or less in height ~~and~~ constructed with stud-bearing walls, <u>are permitted to have</u> plain concrete footings without longitudinal reinforcement ~~supporting walls are permitted~~.
2. For foundation systems consisting of a plain concrete footing and a plain concrete stemwall, a minimum of one bar shall be provided at the top of the stemwall and at the bottom of the footing.
3. Where a slab on ground is cast monolithically with the footing, one No. 5 bar is permitted to be located at either the top of the slab or bottom of the footing.

Commenter's Reason: In seismic design categories D, E and F, the flexural demands placed upon footings of stud wall framed detached one- and two-family dwellings make the use of plain concrete footings devoid of any longitudinal reinforcing unacceptable. The footing is an integral part of the seismic force-resisting load path and deserves to be constructed in a manner consistent with the seismic-resisting braced walls or shear wall panels it is supporting. The current specific allowance for absence of any longitudinal reinforcing will also prevent any vertical reinforcing from being placed in the footing, since there is nothing to tie any vertical bar to; consequently the current provision is allowing totally unreinforced footings in dwellings up to three stories in height.

Since the mid-1990's wood light-frame prescriptive provisions (currently in IBC Section 2308.9.3.1) for alternative wall bracing using tie-downs have required that the foundation at these alternative panels utilize one No. 4 bar top and bottom. Also, more recent alternative wall bracing provisions (Section 2308.9.3.2) that use tie-downs similarly specify footings with one No. 4 bar top and bottom. In addition, since the 2003 IBC, provisions for tie-downs at braced walls of buildings having stone or masonry veneer have been specified (Sections 2308.11.2 and 2308.12.2), but without any mention of minimum foundation reinforcing. Each time a tie-down is installed, the footing should be capable of resisting the flexural demands induced by that connection, yet the current 1918.1(c) exception 1 ignores this need.

There are additional reasons that this provision should be revised. The 2006 IBC reduced the number of stories permitted when using conventional construction provisions to two stories in Seismic Design Category C (Section 2308.11.1) and to one story in Seismic Design Categories D and E (Section 2308.12.1), while section 1908.1.8 continues to allow plain concrete footings for stud bearing wall of one- and two-family dwellings up to <u>three stories in height</u>. This implies that plain concrete footings are permitted even in engineered one- and two-family dwelling construction. The IBC also explicitly deems the use of AF&PA Wood frame Construction Manuel (WFCM) as permitted to substitute for the traditional 2308 bracing provisions, but in that document all walls providing lateral resistance are required to use various types of tie-downs.

To address the concern of the ICC Structural Committee in Baltimore regarding the original proposal's application of the exception 2 to U occupancies, that change has been removed in this amended public comment proposal. With regard to any inconsistency of this proposal with the NEHRP Provisions, it must be noted that the applicable NEHRP provision (Sec. 9.4.2.2 Exception 1) has not been updated since its publication in 2004 (FEMA 450-1/2003) while conventional construction limits on number of permitted story levels and the use of tie-downs have progressed in the IBC since that time, as noted above.

While we recognize there is a cost of installing this minimum reinforcing, we believe that most builders of dwellings in Seismic Design Categories D through F are already providing this level of reinforcing, and that the cost of repairing cracks caused to interior and exterior finishes not to mention the foundation itself would far exceed the cost of minimal reinforcement of footings during the original construction.

Final Action: AS AM AMPC____ D

S167-09/10
1908.1.9

Proposed Change as Submitted

Proponent: Kevin Moore, PE, SE, SECB and Edwin Huston, PE, SE, SECB, representing National Council of Structural Engineers Associations

Revise as follows:

1908.1.9 ACI 318, Section D.3.3. Modify ACI 318, Sections D.3.3.1, D3.3.4 and D3.3.5, and add Section D.3.3.7 to read as follows:

D.3.3.1 – The provisions of Appendix D do not apply to the design of anchors in plastic hinge zones of concrete structures under earthquake forces or to anchors that meet the requirements of Section D.3.3.7.

D.3.3.4 – Anchors shall be designed to be governed by the steel strength of a ductile steel element as determined in accordance with D.5.1 and D.6.1, unless either D.3.3.5 or D.3.3.6 is satisfied.

Exceptions:

1. Anchors in concrete designed to support nonstructural components in accordance with ASCE 7 Section 13.4.2 need not satisfy Section D.3.3.4.
2. Anchors designed to resist wall out-of-plane forces with design strengths equal to or greater than the force determined in accordance with ASCE 7 Equation 12.11-1 or 12.14-10 need not satisfy Section D.3.3.4.

D.3.3.5 – Instead of D.3.3.4, the attachment that the anchor is connecting to the structure shall be designed so that the attachment will undergo ductile yielding at a force level corresponding to anchor forces no greater than the design strength of anchors specified in D.3.3.3.

Exceptions:

1. Anchors in concrete designed to support nonstructural components in accordance with ASCE 7 Section 13.4.2 need not satisfy Section D.3.3.5.
2. Anchors designed to resist wall out-of-plane forces with design strengths equal to or greater than the force determined in accordance with ASCE 7 Equation 12.11-1 or 12.14-10 need not satisfy Section D.3.3.5.

D.3.3.7 – For anchors installed in wood sill plates a maximum of 2 ½ inches (38 mm) in net thickness, the allowable lateral design values for shear in the cast-in-place anchor, parallel to the grain of the wood sill plate, are permitted to be determined in accordance with Section 2305 of the *International Building Code*, provided the anchor installation complies with all of the following:

1. Anchor nominal diameter is 5/8 inches (16 mm);
2. Anchors are embedded into concrete a minimum of 7 inches (178 mm);
3. Anchors are located a minimum of 2 ½ anchor diameters from the edge of the concrete parallel to the length of the wood sill plate; and
4. Anchors are located a minimum of 15 anchor diameters from the edge of the concrete perpendicular to the length of the wood sill plate

Reason: Current design provisions require calculation of the capacity of anchor bolt fastening wood sill plates to concrete foundations via methods promulgated in ACI 318, Appendix D. These methods result in significantly reduced capacities for this connection when compared to historical values and legacy code requirements. The state of knowledge regarding this connection is ambiguous and does not support such a large reduction for a common assembly.

Recent experimental testing and analysis indicates that actual capacities of the considered connection far exceed those historically used for design, supporting the use of wood dowel design values for the connection. The experimental data used to support this code change proposal indicates that concrete failure modes do not control the capacity of the connection, so the need to calculate the capacity of the bolt related to concrete strength for proper embedment and edge spacing is superfluous.

Reference: W. Andrew Fennell, et al. *Report on laboratory testing of anchor bolts connecting wood sill plates to concrete with minimum edge distances.* March 29, 2009.

Cost Impact: The code change proposal will decrease the cost of construction.

ICCFILENAME: MOORE-HUSTON-S1-1908.1.9 D.3.3.1

Public Hearing Results

Committee Action: Approved as Modified

Modify the proposal as follows:

1908.1.9 ACI 318, Section D.3.3. Modify ACI 318, Sections ~~D.3.3.1,~~ D3.3.4 and D3.3.5~~, and add Section D.3.3.7~~ to read as follows:

~~D.3.3.1 The provisions of Appendix D do not apply to the design of anchors in plastic hinge zones of concrete structures under earthquake forces or to anchors that meet the requirements of Section D.3.3.7.~~

D.3.3.4 – Anchors shall be designed to be governed by the steel strength of a ductile steel element as determined in accordance with D.5.1 and D.6.1, unless either D.3.3.5 or D.3.3.6 is satisfied.

Exceptions:

~~1.~~ ~~Anchors in concrete designed to support nonstructural components in accordance with ASCE 7 Section 13.4.2 need not satisfy Section D.3.3.4.~~

~~2~~ 1. Anchors designed to resist wall out-of-plane forces with design strengths equal to or greater than the force determined in accordance with ASCE 7 Equation 12.11-1 or 12.14-10 need not satisfy Section D.3.3.4.

2. In light-frame wood structure bearing or non-bearing walls, for the design of anchors used to attach wood sill plates to foundations or foundation stem walls, it shall be permitted to take the allowable in-plane shear strength of the anchors in accordance with Section 2305.1.2 of the International Building Code.

D.3.3.5 – Instead of D.3.3.4, the attachment that the anchor is connecting to the structure shall be designed so that the attachment will undergo ductile yielding at a force level corresponding to anchor forces no greater than the design strength of anchors specified in D.3.3.3.

Exceptions:

1. Anchors in concrete designed to support nonstructural components in accordance with ASCE 7 Section 13.4.2 need not satisfy Section D.3.3.5.
2. Anchors designed to resist wall out-of-plane forces with design strengths equal to or greater than the force determined in accordance with ASCE 7 Equation 12.11-1 or 12.14-10 need not satisfy Section D.3.3.5.

~~D.3.3.7 – For anchors installed in wood sill plates a maximum of 2 ½ inches (38 mm) in net thickness, the allowable lateral design values for shear in the cast-in-place anchor, parallel to the grain of the wood sill plate, are permitted to be determined in accordance with Section 2305 of the *International Building Code*, provided the anchor installation complies with all of the following:~~

2305.1.2 Sill plate anchor bolts. For sill plates of 2x or 3x nominal thickness, the allowable lateral design for shear parallel to the grain of sill plate anchor bolts is permitted to be determined using the lateral design value for a bolt attaching a wood sill plate to concrete, as specified in AF&PA NDS Table 11E, provide the anchor bolts comply with all of the following:

1. The maximum anchor nominal diameter is 5/8 inches (16 mm);
2. Anchors are embedded into concrete a minimum of 7 inches (178 mm);
3. Anchors are located a minimum of ~~2 ½ anchor diameters~~ 1-3/4 inches (45 mm) from the edge of the concrete parallel to the length of the wood sill plate; and
4. Anchors are located a minimum of 15 anchor diameters from the edge of the concrete perpendicular to the length of the wood sill plate.

Committee Reason: This proposal revises the determination of anchor bolt capacity under Appendix D of ACI 318, in recognition that both lab tests and field experience show that failure of the wood sill plate controls the capacity. In these instances there is no need for laborious concrete strength calculations. The modification removes an exception that is no longer needed with the updates in the next edition of the ASCE 7 Standard. It also reformats the proposal as new Exception 3 and places the sill plate anchor details in new Section 2305.1.2. This also combines and addresses issues raised by code changes S170- 09/10 and S209 – 09/10.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Don Allen, Steel Framing Alliance, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

1908.1.9 ACI 318, Section D.3.3. Modify ACI 318, Sections D3.3.4 and D3.3.5 to read as follows:

D.3.3.4 – Anchors shall be designed to be governed by the steel strength of a ductile steel element as determined in accordance with D.5.1 and D.6.1, unless either D.3.3.5 or D.3.3.6 is satisfied.

Exceptions:

1. Anchors designed to resist wall out-of-plane forces with design strengths equal to or greater than the force determined in accordance with ASCE 7 Equation 12.11-1 or 12.14-10 need not satisfy Section D.3.3.4.
2. In light-frame wood structure bearing or non-bearing walls, for the design of anchors used to attach wood sill plates to foundations or foundation stem walls, it shall be permitted to take the allowable in-plane shear strength of the anchors in accordance with Section 2305.1.2 of the International Building Code.
3. <u>In cold-formed steel light-frame construction, for the design of anchors used to attach cold-formed steel track to foundations or foundation stem walls, it shall be permitted to take the allowable in-plane shear strength of the anchors in accordance with Section 2210.8 of the International Building Code.</u>

D.3.3.5 – Instead of D.3.3.4, the attachment that the anchor is connecting to the structure shall be designed so that the attachment will undergo ductile yielding at a force level corresponding to anchor forces no greater than the design strength of anchors specified in D.3.3.3.

Exceptions:

1. Anchors in concrete designed to support nonstructural components in accordance with ASCE 7 Section 13.4.2 need not satisfy Section D.3.3.5.
2. Anchors designed to resist wall out-of-plane forces with design strengths equal to or greater than the force determined in accordance with ASCE 7 Equation 12.11-1 or 12.14-10 need not satisfy Section D.3.3.5.

Add new text as follows:

<u>**2210.8 Sill plate anchor bolts.** For cold-formed steel light-frame tracks of 33 to 68 mil designation thickness, the allowable lateral design for shear parallel to the track with anchor bolts is permitted to be determined using the lateral design value for a bolt attaching a cold-formed steel light-frame track to concrete, as specified in AISI S100, Section E.3.3.1, provided the anchor bolts comply with all of the following:</u>

1. <u>The maximum anchor nominal diameter is 5/8 inches (16 mm);</u>
2. <u>Anchors are embedded into concrete a minimum of 7 inches (178 mm);</u>
3. <u>Anchors are located a minimum of 1-3/4 inches (45 mm) from the edge of the concrete parallel to the length of the track; and</u>
4. <u>Anchors are located a minimum of 15 anchor diameters from the edge of the concrete perpendicular to the length of the track.</u>

(Portions of proposal not shown remain unchanged)

Commenter's Reason: ACI 318 Appendix D design provisions are required for calculation of the capacity of anchor bolt fastening cold-formed steel (CFS) bottom track sill plates to concrete foundations. These methods result in significantly reduced capacities for this connection when compared to historical values and legacy code requirements. The state of knowledge regarding this connection is ambiguous and does not support such a large reduction for a common assembly.

Recent experimental testing and analysis indicates that actual capacities of the track-to-concrete anchor bolt connection far exceed those historically used for design, supporting the use of AISI bolt-bearing design values for the connection. The experimental data used to support this code change proposal indicates that ductile steel failure rather than concrete failure modes control the capacity of the connection, so the need to calculate the capacity of the bolt related to concrete strength for proper embedment and edge spacing is superfluous.

Please note that testing results will be posted at www.steel.org by April 15, 2010.

Public Comment 2:

Bonnie Manley, American Iron and Steel Institute, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

1908.1.9 ACI 318, Section D.3.3. Modify ACI 318, Sections D3.3.4 and D3.3.5 to read as follows:

D.3.3.4 – Anchors shall be designed to be governed by the steel strength of a ductile steel element as determined in accordance with D.5.1 and D.6.1, unless either D.3.3.5 or D.3.3.6 is satisfied.

Exceptions:

1. Anchors designed to resist wall out-of-plane forces with design strengths equal to or greater than the force determined in accordance with ASCE 7 Equation 12.11-1 or 12.14-10 need not satisfy Section D.3.3.4.
2. In light-frame wood structure bearing or non-bearing walls, for the design of anchors used to attach wood sill plates to foundations or foundation stem walls, it shall be permitted to take the allowable in-plane shear strength of the anchors in accordance with Section 2305.1.2 of the International Building Code.
3. Section D.3.3.4 need not apply and the design shear strength in accordance with Section D.6.2.1(c) need not be computed for anchor bolts attaching cold-formed steel track of bearing or non-bearing walls of light-frame construction to foundations or foundation stem walls provided all of the following are satisfied:

    1. The maximum anchor nominal diameter is 5/8 inches (16 mm).
    2. Anchors are embedded into concrete a minimum of 7 inches (178 mm).
    3. Anchors are located a minimum of 1-3/4 inches (45 mm) from the edge of the concrete parallel to the length of the track.
    4. Anchors are located a minimum of 15 anchor diameters from the edge of the concrete perpendicular to the length of the track.
    5. The track is 33 to 68 mil designation thickness.

    Allowable in-plane shear strength of exempt anchors, parallel to the edge of concrete shall be permitted to be determined in accordance with AISI S100 Section E3.3.1.

D.3.3.5 – Instead of D.3.3.4, the attachment that the anchor is connecting to the structure shall be designed so that the attachment will undergo ductile yielding at a force level corresponding to anchor forces no greater than the design strength of anchors specified in D.3.3.3.

Exceptions:

1. Anchors in concrete designed to support nonstructural components in accordance with ASCE 7 Section 13.4.2 need not satisfy Section D.3.3.5.
2. Anchors designed to resist wall out-of-plane forces with design strengths equal to or greater than the force determined in accordance with ASCE 7 Equation 12.11-1 or 12.14-10 need not satisfy Section D.3.3.5.

(Portions of proposal not shown remain unchanged)

Commenter's Reason: ACI 318 Appendix D design provisions are required for calculation of the capacity of anchor bolt fastening cold-formed steel (CFS) bottom track sill plates to concrete foundations. These methods result in significantly reduced capacities for this connection when compared to historical values and legacy code requirements. The state of knowledge regarding this connection is ambiguous and does not support such a large reduction for a common assembly.

Recent experimental testing and analysis indicates that actual capacities of the track-to-concrete anchor bolt connection far exceed those historically used for design, supporting the use of AISI bolt-bearing design values for the connection. The experimental data used to support this code change proposal indicates that ductile steel failure rather than concrete failure modes control the capacity of the connection, so the need to calculate the capacity of the bolt related to concrete strength for proper embedment and edge spacing is superfluous.

Please note that testing results will be posted at www.steel.org by April 15, 2010.

Public Comment 3:

James E. Russell, Building Codes Consultant and Brad Douglas AF&PA and American Wood Council, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

1908.1.9 ACI 318, Section D.3.3. Modify ACI 318, Sections D3.3.4 and D3.3.5 to read as follows:

D.3.3.4 – Anchors shall be designed to be governed by the steel strength of a ductile steel element as determined in accordance with D.5.1 and D.6.1, unless either D.3.3.5 or D.3.3.6 is satisfied.

Exceptions:

1. Anchors designed to resist wall out-of-plane forces with design strengths equal to or greater than the force determined in accordance with ASCE 7 Equation 12.11-1 or 12.14-10 need not satisfy Section D.3.3.4.

~~2. In light-frame wood structure bearing or non-bearing walls, for the design of anchors used to attach wood sill plates to foundations or foundation stem walls, it shall be permitted to take the allowable in-plane shear strength of the anchors in accordance with Section 2305.1.2 of the International Building Code.~~

2. D.3.3.4 need not apply and the design shear strength in accordance with D.6.2.1(c) need not be computed for anchor bolts attaching wood sill plates of bearing or non-bearing walls of light-frame wood structures to foundations or foundation stem walls provided all of the following are satisfied:

    1. The allowable in-plane shear strength of the anchor is determined in accordance with AF&PA NDS Table 11E for lateral design values parallel to grain.
    2. The maximum anchor nominal diameter is 5/8 inches (16 mm).
    3. Anchor bolts are embedded into concrete a minimum of 7 inches (178 mm).
    4. Anchor bolts are located a minimum of 1-3/4 inches (45 mm) from the edge of the concrete parallel to the length of the wood sill plate.

5. <u>Anchor bolts are located a minimum of 15 anchor diameters from the edge of the concrete perpendicular to the length of the wood sill plate.</u>
6. <u>The sill plate is 2-inch or 3-inch nominal thickness.</u>

D.3.3.5 – Instead of D.3.3.4, the attachment that the anchor is connecting to the structure shall be designed so that the attachment will undergo ductile yielding at a force level corresponding to anchor forces no greater than the design strength of anchors specified in D.3.3.3.

Exceptions:

1. Anchors in concrete designed to support nonstructural components in accordance with ASCE 7 Section 13.4.2 need not satisfy Section D.3.3.5.
2. Anchors designed to resist wall out-of-plane forces with design strengths equal to or greater than the force determined in accordance with ASCE 7 Equation 12.11-1 or 12.14-10 need not satisfy Section D.3.3.5.

~~**2305.1.2 Sill plate anchor bolts.** For sill plates of 2x or 3x nominal thickness, the allowable lateral design for shear parallel to the grain of sill plate anchor bolts is permitted to be determined using the lateral design value for a bolt attaching a wood sill plate to concrete, as specified in AF&PA NDS Table 11E, provide the anchor bolts comply with all of the following:~~

1. ~~The maximum anchor nominal diameter is 5/8 inches (16 mm);~~
2. ~~Anchors are embedded into concrete a minimum of 7 inches (178 mm);~~
3. ~~Anchors are located a minimum of 1-3/4 inches (45 mm) from the edge of the concrete parallel to the length of the wood sill plate; and~~
4. ~~Anchors are located a minimum of 15 anchor diameters from the edge of the concrete perpendicular to the length of the wood sill plate.~~

Commenter's Reason: The addition of 2305.1.2 in the "As Modified" approval of S167 as currently worded limits the use of NDS provisions for sill anchor bolts to applications with 2x or 3x sill plates, parallel to grain applications, and anchor diameters of 5/8" or less for <u>all lateral and shear loads</u> including those from wind and low seismic areas. Anchor bolt limitations were originally intended to define a specific range of sill plate anchor conditions for which relief from specific concrete anchor strength provisions for <u>seismic design</u> was warranted, based on results of cyclic testing. Concrete anchor strength provisions for which relief is provided are (i) ductility requirements of D.3.3.4, and (ii) required concrete breakout strength in shear parallel to the edge in accordance with D.6.2.1(c). To restore the original intent of the proposal, provisions of the proposed new section 2305.1.2 , that specify exactly what size sill plates, anchor bolts and bolt locations in concrete were tested, are relocated by this public comment to the section from which they are referenced (e.g. 1908.1.9 Exception 2).

This revision is necessary to accomplish two purposes: First it avoids the unintended interpretation that new section 2305.1.2 limits the use of the NDS as it applies to anchor bolt installations, and second it clarifies that in lieu of computing the concrete breakout strength in shear parallel to the edge for the anchor, it is the intent to allow the allowable load parallel to the edge of the foundation to be based on AF&PA NDS Table 11E for a limited range of sill plate anchor conditions.

Final Action: AS AM AMPC____ D

S168-09/10
1908.1.9

<u>Proposed Change as Submitted</u>

Proponent: Alan Robinson, SE, representing Structural Engineers Association of California

Revise as follows:

1908.1.9 ACI 318, Section D.3.3. Modify ACI 318, Sections D.3.3.4 and D.3.3.5 <u>delete and replace D.3.3.6 and add D.3.3.7</u> to read as follows:

D.3.3.4 - Anchors shall be designed to be governed by the steel strength of a ductile steel element as determined in accordance with D.5.1 and D.6.1, unless either D.3.3.5 or D.3.3.6 is satisfied.

Exceptions:

1. Anchors in concrete designed to support nonstructural components in accordance with ASCE 7 Section 13.4.2 need not satisfy Section D.3.3.4.
2. Anchors designed to resist wall out-of-plane forces with design strengths equal to or greater than the force determined in accordance with ASCE 7 Equation 12.11-1 or 12.14-10 need not satisfy Section D.3.3.4.
3. <u>In light-frame wood construction, design of anchors in concrete shall be permitted to satisfy D.3.3.7.</u>

D.3.3.5 - Instead of D.3.3.4, the attachment that the anchor is connecting to the structure shall be designed so that the attachment will undergo ductile yielding at a force level corresponding to anchor forces no greater than the design strength of anchors specified in D.3.3.3.

Exceptions:

1. Anchors in concrete designed to support nonstructural components in accordance with ASCE 7 Section 13.4.2 need not satisfy Section D.3.3.5.
2. Anchors designed to resist wall out-of-plane forces with design strengths equal to or greater than the force determined in accordance with ASCE 7 Equation 12.11-1 or 12.14-10 need not satisfy Section D.3.3.5.

<u>D.3.3.6 - As an alternative to D.3.3.4 and D.3.3.5, it shall be permitted to take the design strength of the anchors as 0.4 times the design strength determined in accordance with D.3.3.3.</u>

<u>D.3.3.7 – In light-frame wood structures, bearing or non-bearing walls, concrete anchors of sill plate to foundation or foundation stem wall need not satisfy D.3.3.5 and D.3.3.6 when the design strength of the anchors is determined in accordance with D.3.3.3.</u>

Reason: Development of Appendix D was based primarily on tests of concrete anchor using steel plates with substantially larger edge distance than common practice in light-frame construction. There are insufficient tests of concrete anchors with wood sill plate at minimum side cover distance to justify the arbitrary assignment of 50 per cent reduction of the design strength stated in D.3.3.6. Additional limitation for anchorage of wood stud wall is removed from current ACI 318-08 D.3.3.6 (i.e. D.3.3.6 - As an alternative to D.3.3.4 and D.3.3.5, it shall be permitted to take the design strength of the anchors as 0.4 times the design strength determined in accordance with D.3.3.3. A new section D.3.3.7 is introduced under this proposal to further modify ACI code for concrete anchors used in light-framed wood construction.

In common construction practice of light-frame construction, bolts are centered on sill plates giving an side edge distance of $1^3/_4$ inches. Current code requirements under ACI 318 Appendix D lead to substantial reduction of design capacity based on breakout strength of a single anchor under Section D.6.2.1(c) or D.6.2.2. As an example, the design strength for 5/8 inch diameter anchor bolt strength under D.3.3.3 is 1116 lbs. Requirement under D.3.3.6 will further reduce the design strength to 558 lbs. for use in sill bolts. The ASD value would be 398 lbs. This is a substantial reduction from prior codes leading to impractical bolt spacing for most wood shear panel nail spacing range. A comparison between ACI Appendix D to IBC Table 1911.2, Allowable Service Loads on Embedded Bolts, shows the disparity of concrete anchor value.

The primary mode of failure of plywood sheathed panels attached to wood sill plate has been through nail slippage and yielding. This mode of failure together with bending of bolt offers the ductility and toughness of wood wall panels. Over-strength factor does not apply in the transfer of seismic forces from wood shear panel to concrete. Additional reduction factor is not warranted based on recent laboratory test conducted under SEAOC Seismology Committee purview. Result of the test is summarized below.

Attachment:

Excerpt from Report on laboratory testing of anchor bolts connecting wood sill plates to concrete with minimum edge distances

IBC-06 references ACI 318-05 Appendix D for the determination of anchor bolt capacity (in single-shear) when attaching wood sill plates to concrete foundations. Engineers have historically anticipated the controlling failure of this connection to occur between the anchor bolts and the wood sill plate. Under the IBC, the wind resistance values of anchor bolts are about the same as in historical practice. However, design capacities seismic forces based on break-out strength in shear determined in accordance with ACI 318-05 Appendix D are greatly reduced and less than the wood to concrete connection design capacity for small side edge distances. Many practicing engineers and building officials are mystified by the substantial reduction of anchor bolt capacities obtained from the application of Appendix D equations for wood framed construction in seismic design categories D, E and F. In the absence of available test data, members of SEAOC Seismology Committee undertook a study of typical anchor bolted connections to establish a basis for evaluating design capacities while better understanding the behavior of this traditional connection.

Test parameters and procedures were established. The testing consisted of typical anchor bolt connections found in wood framed shear walls using pressure treated wood 2x4, 3x4, 2x6 and 3x6 sill plates and 5/8 inch diameter by seven inches embedment anchor bolts with code prescribed washers. Side edge distance of 1-3/4 inches for 2x4 and 3x4 and 2-3/4 inches for 3x4 and 3x6 sill plates. This Testing Program was completed in December 2008 and the results can be downloaded on the SEAOC website: http://www.SEAOC.org/bluebook.

The load protocol adopted for the tests was a displacement-controlled load protocol. Peak loads from monotonic tests were used to establish the reference force, which was used to prescribe the load steps in the pseudo-cyclic testing. Monotonic tests were run at a sufficiently slow rate to pick up the internal flaws forming within the concrete by using impact-echo testing. The Pseudo-cyclic tests were based on the CUREE load protocol but with cycles added at low load levels. All tests were conducted without intentionally pre-cracked concrete.

Impact-echo method was used to detect concrete side break-out, if any, during the tests. When concrete deterioration was detected, the corresponding load and displacement were recorded for each specimen. It was observed that the first stage of deterioration is a series of cracks that form within the concrete propagated from the centerline of the anchor bolt and angling out towards the outer free face of the concrete. The cracks ultimately reach the outer face and became shallow spall shapes. It is important to note that the early stages of concrete deterioration are not always visually apparent. A strong correlation between the "peak" envelope values with the onset of concrete side break-out was, however, observed. Peak values were in the range of 7,200 lb to 8,500 lb.

All cyclic test data was analyzed in accordance with ASTM E 2126 Standard Test Methods for Cyclic (Reversed) Load Test for Shear Resistance of Walls for Buildings. Result of cycle test of specimen 296/ 302 is shown in Figure A-1. The positive and negative envelop curves for each specimens were combined to produce an average envelope curve used to establish peak load, displacement at peak load, ultimate load, and displacement at ultimate load and summarized in Figures A-2 and A-3.

Findings of the anchor bolt test program were as follows:

1. The results of the Anchor Bolt Testing Program has shown that wood components attached to concrete with minimum edge distances exhibited ductile behavior. The wood "yield" is the first material limit state.
2. The tests indicated that concrete cracks were not produced at service level loads. In the non-linear range of performance, delamination generally produced a decline in capacity corresponding to a wood displacement of about 0.60 inches, with the bolt experiencing considerable deformation.
3. Further excursion of the wood plate in some cases produced a complete concrete spall, however the bolt head remained intact and considerable residual strength was provided as the bolt remained in tension.
4. Cracking through the section did not occur at any point. For these reason, cracked section reduction appears overly conservative. It should also be noted that according to the available literature reductions are generally not required for shear anchorage applied perpendicular to a crack.
5. Test support design bolt values based on ACI 318 section D.3.3.3 using $0.75\Phi V_n$.

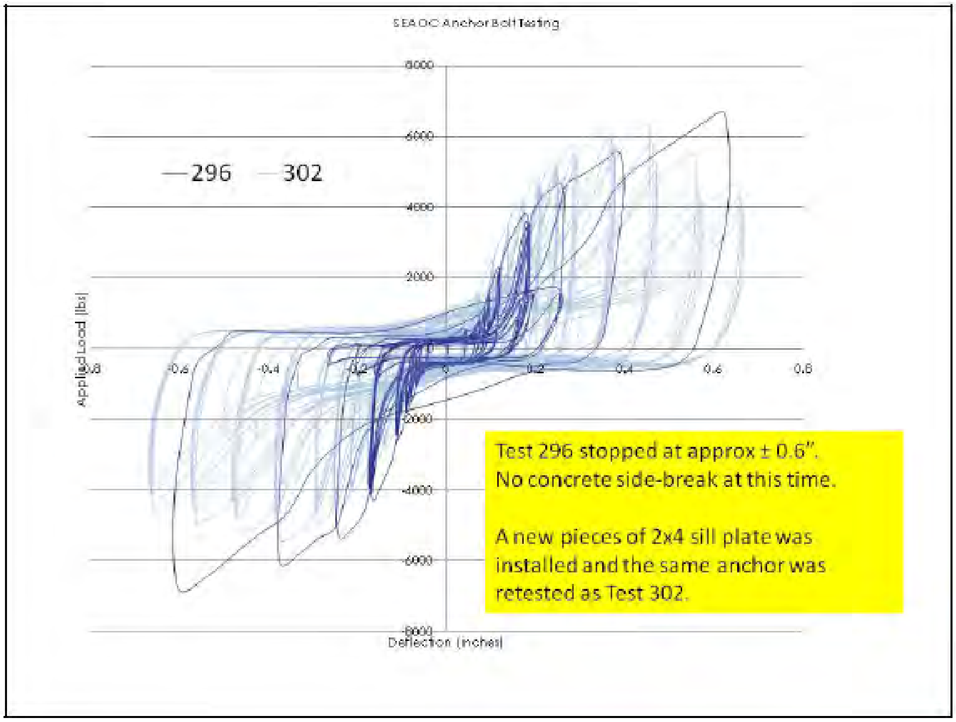

Figure A1 - Result of cycle test specimen 296 and 302

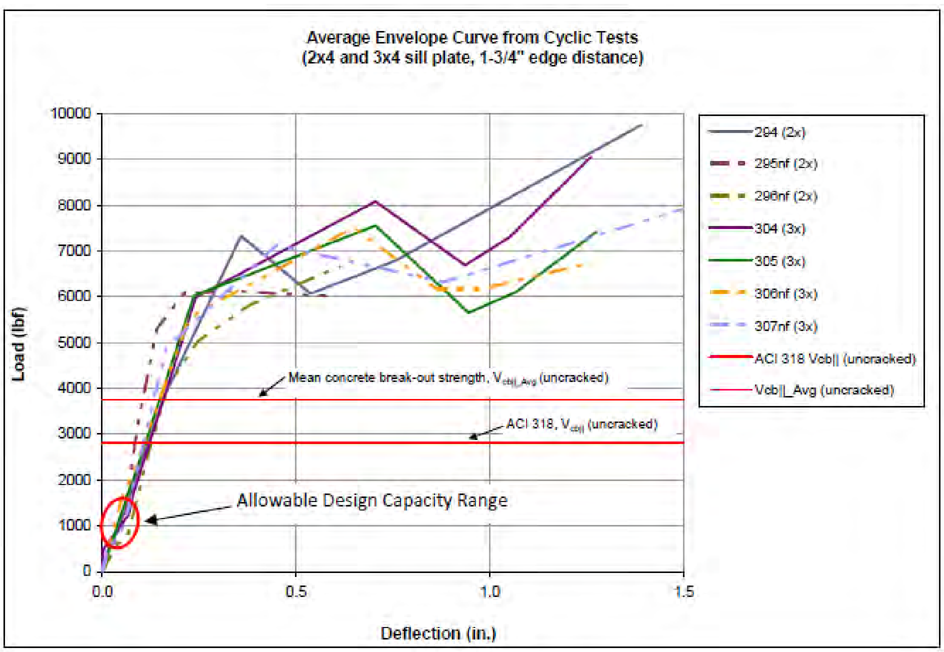

Fig. A2 – Average envelope curve of cyclic tests for concrete anchor of 2x4 and 3x4 sill plate

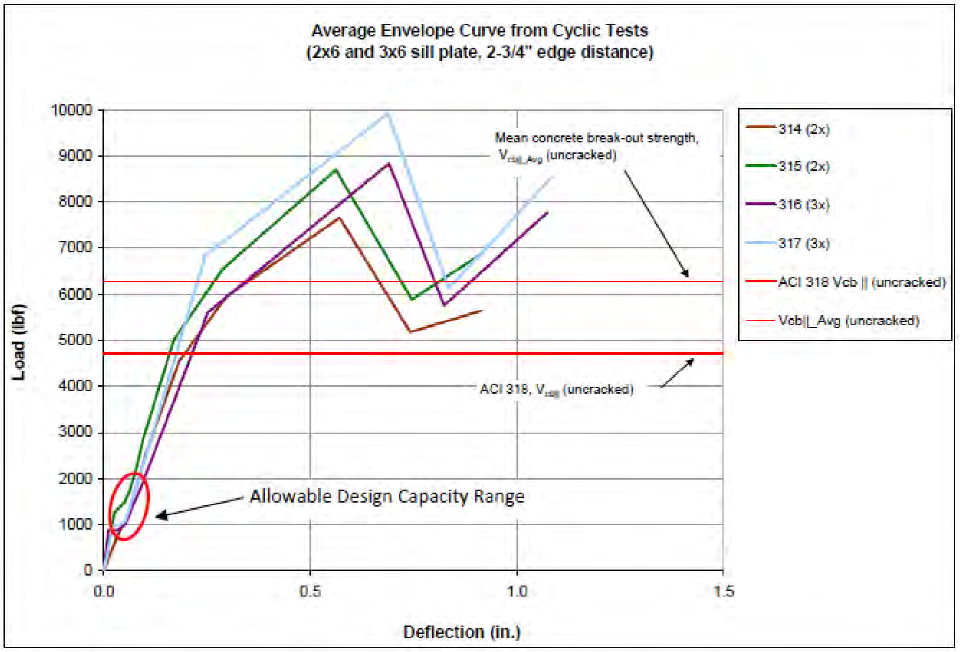

Fig. A3 – Average envelope curve of cyclic tests for concrete anchor of 2x6 and 3x6 sill plate

Ref. Fennel, Mochizuki, Moore (2008) "Report on laboratory testing of anchor bolts connection wood sill plates to concrete with minimum edge distances" SEAONC, San Francisco, CA

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: ROBINSON-S3-1908.1.9

Public Hearing Results

Committee Action: Disapproved

Committee Reason: With the liberalization of concrete anchorage approved in S167–09/10 a significant portion of problems posed in light-frame construction has been addressed. There is concern about the proposed extrapolation of data from testing that is ongoing. When dealing with an edge distance of only a little over an inch and considering typical construction tolerances, some anchor bolts could be installed awfully close to the edge of the concrete. Approval could possibly conflict with some portions of S167-09/10. The proponent is encouraged to provide better justification in the public comment phase.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Alan Robinson, SE, representing Structural Engineers Association of California, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

1908.1.9 ACI 318, Section D.3.3. Modify ACI 318, Sections D.3.3.4 and D.3.3.5 delete and replace D.3.3.6 and add D.3.3.7 to read as follows:

D.3.3.4 - Anchors shall be designed to be governed by the steel strength of a ductile steel element as determined in accordance with D.5.1 and D.6.1, unless either D.3.3.5 or D.3.3.6 is satisfied.

Exceptions:

1. Anchors in concrete designed to support nonstructural components in accordance with ASCE 7 Section 13.4.2 need not satisfy Section D.3.3.4.

2. Anchors designed to resist wall out-of-plane forces with design strengths equal to or greater than the force determined in accordance with ASCE 7 Equation 12.11-1 or 12.14-10 need not satisfy Section D.3.3.4.

3. In light-frame ~~wood~~ construction, design of anchors in concrete shall be permitted to satisfy D.3.3.7.

D.3.3.5 - Instead of D.3.3.4, the attachment that the anchor is connecting to the structure shall be designed so that the attachment will undergo ductile yielding at a force level corresponding to anchor forces no greater than the design strength of anchors specified in D.3.3.3.

Exceptions:

1. Anchors in concrete designed to support nonstructural components in accordance with ASCE 7 Section 13.4.2 need not satisfy Section D.3.3.5.
2. Anchors designed to resist wall out-of-plane forces with design strengths equal to or greater than the force determined in accordance with ASCE 7 Equation 12.11-1 or 12.14-10 need not satisfy Section D.3.3.5.

D.3.3.6 - As an alternative to D.3.3.4 and D.3.3.5, it shall be permitted to take the design strength of the anchors as 0.4 times the design strength determined in accordance with D.3.3.3.

D.3.3.7 – In light-frame ~~wood structures~~ construction, bearing or non-bearing walls, shear strength of concrete anchors less than or equal to 1 inch [25 mm] in diameter of sill plate or track to foundation or foundation stem wall need not satisfy ~~D.3.3.5 and~~ D.3.3.6 when the design strength of the anchors is determined in accordance with ~~D.3.3.3~~ D.6.2.1(c).

Commenter's Reason: As presented in a companion change proposal S167, which was approved in the Code Development Hearing, based on results of Anchor Bolt Testing Program. The results of the bolt test, summarized under the original submittal of S168, showed the wood components attached to concrete exhibited ductile behavior. The wood "yield" being the first material limit state demonstrated that the reduction factor in ACI 318-08 Section D.3.3.6 need not be satisfied for bolts anchored to footings provided minimum concrete cover under ACI 318 sec. 7.7 is met. ACI 318 is currently considering changes to section 3.3 with various arbitrary reduction factors removed. ACI 318-08 sec. D.6.2.1(c) is specific for the design of concrete anchors parallel to a free edge.

A series of tests are planned by AISI for spring 2010, following closely with the test protocols used in the SEAOC wood sill concrete anchor tests. It is expected that results of the tests will be available prior to the Final Action Hearing. It is anticipated that similar ductile behavior of light gauge metal track as for wood sill plate with yielding of the steel track occurred prior to spalling of concrete. This public comment is amended to apply to light frame construction.

Final Action: AS AM AMPC____ D

S179-09/10
2109.1.1, 2308.2, 2308.2.1

Proposed Change as Submitted

Proponent: T. Eric Stafford, PE, representing Institute for Business and Home Safety

Revise as follows:

2109.1.1 Limitations. The use of empirical design of masonry shall be limited as noted in Section 5.1.2 of TMS 402/ACI 530/ASCE 5. Section 5.1.2.2 of TMS 402/ACI 530/ASCE 5 shall be modified as follows:

5.1.2.2 *Wind* – Empirical requirements shall not apply to the design or construction of masonry for buildings, parts of buildings, or other structures to be located in areas where the basic wind speed exceeds 130 mph (58 m/s) as given in ASCE 7.

The use of dry-stacked, surface-bonded masonry shall be prohibited in *Occupancy Category* IV structures. In buildings that exceed one or more of the limitations of Section 5.1.2 of TMS 402/ACI 530/ASCE 5, masonry shall be designed in accordance with the engineered design provisions of Section 2101.2.1, 2101.2.2 or 2101.2.3 or the foundation wall provisions of Section 1807.1.5.

2308.2 Limitations. Buildings are permitted to be constructed in accordance with the provisions of *conventional light-frame construction*, subject to the following limitations, and to further limitations of Sections 2308.11 and 2308.12.

1. Buildings shall be limited to a maximum of three *stories above grade plane*. For the purposes of this section, for buildings in *Seismic Design Category* D or E as determined in Section 1613, cripple stud walls shall be considered to be a *story*.

   Exception: Solid blocked cripplewalls not exceeding 14 inches (356 mm)in height need not be considered a *story*.

2. Maximum floor-to-floor height shall not exceed 11 feet, 7 inches (3531 mm). Bearing wall height shall not exceed a stud height of 10 feet (3048 mm).
3. Loads as determined in Chapter 16 shall not exceed the following:
   3.1. Average dead loads shall not exceed 15 psf (718 N/m2) for combined roof and ceiling, exterior walls, floors and partitions.

   Exceptions:

   1. Subject to the limitations of Sections 2308.11.2 and 2308.12.2, stone or masonry veneer up to the lesser of 5 inches (127 mm) thick or 50 psf (2395 N/m2) and installed in accordance with Chapter 14 is permitted to a height of 30 feet (9144 mm) above a noncombustible foundation, with an additional 8 feet (2438 mm) permitted for gable ends.
   2. Concrete or masonry fireplaces, heaters and chimneys shall be permitted in accordance with the provisions of this code.

   3.2. Live loads shall not exceed 40 psf (1916 N/m2) for floors.
   3.3. Ground snow loads shall not exceed 50 psf (2395 N/m2).

4. Wind speeds shall not exceed 130 ~~100~~ miles per hour (mph) (~~44~~ 58 m/s) (3-second gust).

   Exception: Wind speeds shall not exceed 140 ~~110~~ mph (~~48.4~~ 63 m/s) (3-second gust) for buildings in Exposure Category B that are not located in a *hurricane-prone region*.

5. Roof trusses and rafters shall not span more than 40 feet (12 192 mm) between points of vertical support.
6. The use of the provisions for *conventional light-frame construction* in this section shall not be permitted for *Occupancy Category* IV buildings assigned to *Seismic Design Category* B, C, D, E or F, as determined in Section 1613.
7. *Conventional light-frame construction* is limited in irregular structures in *Seismic Design Category* D or E, as specified in Section 2308.12.6.

2308.2.1 Basic wind speed greater than ~~100~~ 130 mph (3-second gust). Where the basic wind speed exceeds 130 ~~100~~ mph (58 m/s) (3-second gust), the provisions of either AF&PAWFCM, or the ICC 600 are permitted to be used. Wind speeds in Figure 1609A, 1609B, and 1609C shall be converted in accordance with Section 1609.3.1 for use with AF&PA WFCM or ICC 600.

Reason: The purpose of this code change is to correlate the prescriptive limits for empirical design of masonry and conventional wood frame construction with other proposals that are updating the wind speed maps in the IBC and the IRC. The wind speed maps in ASCE 7 are being updated to ultimate wind speeds as opposed to the ASD level wind speed maps that currently exist in ASCE 7 and in the IBC and IRC. See IBC code change for information on why the wind speed maps are being updated. While a way to convert the ultimate wind speeds to ASD level wind speeds is proposed in the IBC, the converted wind speeds do not match, from a geographic standpoint, the limitations the code previously imposed. Since the empirical provisions and conventional methods for wood frame construction, typically can't be calculated to equate to the lower level wind speeds at the current limit, including the fact that these provisions are missing some of the key wind resistant construction design methods (e.g. gable end wall bracing, bond beam reinforcement, vertical wall reinforcement, etc.), the proposed limitations will roughly, maintain the current limitations on empirical and conventional methods that currently exist in terms of geographic location on the wind speed map. While some areas of the country will see a reduction in areas where empirical design of masonry or conventional construction would be allowed, other areas will see in increase in areas where these methods would be allowed.

Cost Impact: The code change proposal will increase the cost of construction.

ICCFILENAME: Stafford-S1-2109

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The proposed correlation of wind speed triggers with the updated provisions approved in code change S84-09/10 need to be consistent with the wind terminology.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

T. Eric Stafford, representing Institute for Business and Home Safety, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

2308.2 Limitations. Buildings are permitted to be constructed in accordance with the provisions of *conventional light-frame construction*, subject to the following limitations, and to further limitations of Sections 2308.11 and 2308.12.

1. Buildings shall be limited to a maximum of three *stories above grade plane*. For the purposes of this section, for buildings in *Seismic Design Category* D or E as determined in Section 1613, cripple stud walls shall be considered to be a *story*.

   Exception: Solid blocked cripplewalls not exceeding 14 inches (356 mm)in height need not be considered a *story*.

2. Maximum floor-to-floor height shall not exceed 11 feet, 7 inches (3531 mm). Bearing wall height shall not exceed a stud height of 10 feet (3048 mm).
3. Loads as determined in Chapter 16 shall not exceed the following:
   3.1. Average dead loads shall not exceed 15 psf (718 N/m2) for combined roof and ceiling, exterior walls, floors and partitions.

   Exceptions:

   1. Subject to the limitations of Sections 2308.11.2 and 2308.12.2, stone or masonry veneer up to the lesser of 5 inches (127 mm) thick or 50 psf (2395 N/m2) and installed in accordance with Chapter 14 is permitted to a height of 30 feet (9144 mm) above a noncombustible foundation, with an additional 8 feet (2438 mm) permitted for gable ends.
   2. Concrete or masonry fireplaces, heaters and chimneys shall be permitted in accordance with the provisions of this code.

   3.2. Live loads shall not exceed 40 psf (1916 N/m2) for floors.
   3.3. Ground snow loads shall not exceed 50 psf (2395 N/m2).

4. Ultimate Design Wind ~~s~~Speeds, V_{ult} shall not exceed 130 miles per hour (mph) (44 m/s) (3-second gust).

   Exception: Wind speeds shall not exceed 140 mph (48.4 m/s) (3-second gust) for buildings in Exposure Category B that are not located in a *hurricane-prone region*.

5. Roof trusses and rafters shall not span more than 40 feet (12 192 mm) between points of vertical support.
6. The use of the provisions for *conventional light-frame construction* in this section shall not be permitted for *Occupancy Category* IV buildings assigned to *Seismic Design Category* B, C, D, E or F, as determined in Section 1613.
7. *Conventional light-frame construction* is limited in irregular structures in *Seismic Design Category* D or E, as specified in Section 2308.12.6.

2308.2.1 Ultimate Design ~~Basic~~ w Wind ~~s~~Speed, V_{ult} greater than 130 ~~100~~ mph (3-second gust). Where the Ultimate Design ~~basic~~ ~~w~~Wind ~~s~~Speed, V_{ult} exceeds 130 mph (3-second gust), the provisions of either AF&PA WFCM, or the ICC 600 are permitted to be used. Wind speeds in Figure 1609A, 1609B, and 1609C shall be converted in accordance with Section 1609.3.1 for use with AF&PA WFCM or ICC 600.

Add new text as follows:

1405.6.3 Wind requirements. Sections 6.2.2.1 and 6.2.2.11 of TMS 402/ACI 530/ASCE 5 shall be modified as follows:

6.2.2.1 Except as provided in Section 6.2.2.11, prescriptive requirements for anchored masonry veneer shall not be used in areas where the basic wind speed exceeds 130 mph (177 km/hr) as given in ASCE 7.

6.2.2.11 *Requirements in areas of high winds* — The following requirements apply in areas where the basic wind speed exceeds 130 mph (177 km/hr) but does not exceed 150 mph (209 km/hr) and the building's mean roof height is less than or equal to 60 ft (18.3 m):

(a) Reduce the maximum wall area supported by each anchor to 70 percent of that required in Sections 6.2.2.5.6.1 and 6.2.2.5.6.2.
(b) Space anchors at a maximum 18 in. (457 mm) horizontally and vertically.
(c) Provide additional anchors around openings larger than 16 in. (406 mm) in either direction. Space anchors around perimeter of opening at a maximum of 24 in. (610 mm) on center. Place anchors within 12 in. (305 mm) of openings.

(Portions of the proposal not shown remain unchanged)

Commenter's Reason: The purpose of this code change is to correlate the prescriptive limits for empirical design of masonry and conventional wood frame construction with other proposals that are updating the wind speed maps in the IBC and the IRC. The wind speed maps in ASCE 7 are being updated to ultimate wind speeds as opposed to the ASD level wind speed maps that currently exist in ASCE 7 and in the IBC and IRC. See IBC code change for information on why the wind speed maps are being updated. While a way to convert the ultimate wind speeds to ASD level wind speeds is proposed in the IBC, the converted wind speeds do not match, from a geographic standpoint, the limitations the code previously imposed. Since the empirical provisions and conventional methods for wood frame construction, typically can't be calculated to equate to the lower level wind speeds at the current limit, including the fact that these provisions are missing some of the key wind resistant construction design methods (e.g. gable endwall bracing, bond beam reinforcement, vertical wall reinforcement, etc.), the proposed limitations will roughly, maintain the current limitations on empirical and conventional methods that currently exist in terms of geographic location on the wind speed map. While some areas of the country will see a reduction in areas where empirical design of masonry or conventional construction would be allowed, other areas will see in increase in areas where these methods would be allowed.

The modification proposed by this public comment simply makes some editorial corrections and provides a similar correlation for brick veneer as described above.

Final Action: AS AM AMPC____ D

S186-09/10
2208.1

Proposed Change as Submitted

Proponent: Bonnie Manley, representing American Iron and Steel Institute

Revise as follows:

2208.1 Storage racks. The design, testing and utilization of industrial steel storage racks made of cold-formed or hot-rolled steel structural members, shall be in accordance with RMI/ANSI MH 16.1. Where required by ASCE 7, the seismic design of storage racks shall be in accordance with the <u>additional</u> provisions of Section 15.5.3 of ASCE 7~~, except that items (1), (2)and (3) of Section 15.5.3 of ASCE 7 do not apply when the rack design satisfies RMI/ANSI MH 16.1~~.

Reason: The exception recommended for deletion was inserted last cycle in Proposal S205-07/08 in order to coordinate the 2008 edition of RMI's ANSI/MH 16.1, *Specification for Design, Testing and Utilization of Industrial Steel Storage Racks,* with ASCE 7-05, which had originally adopted the 2002 edition of the RMI standard. The 2010 edition of ASCE 7 adopts and modifies the 2008 edition of ANSI/MH16.1. Consequently, the list of exceptions is no longer needed. Also, the word "additional" is added to emphasize that, for seismic design, steel storage racks must also be designed in accordance with the modifications contained in ASCE 7, Section 15.5.3.

Cost Impact: There is no anticipated impact on the cost of construction.

ICCFILENAME: Manley-S4-2208.1

Public Hearing Results

Committee Action: **Approved as Modified**

Modify the proposal as follows:

2208.1 Storage racks. The design, testing and utilization of industrial steel storage racks made of cold-formed or hot-rolled steel structural members, shall be in accordance with the RMI/ANSI MH 16.1. Where required by ASCE 7, the seismic design of storage racks shall be in accordance with the ~~additional~~ provisions of Section 15.5.3 of ASCE 7.

Committee Reason: This proposal will correlate the reference to the RMI rack standard with the earthquake load requirements of ASCE 7. The modification removes a word that would cause confusion.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Steven Winkel, FAIA, PE, and Robert E. Bachman, SE, representing the Federal Emergency Management Agency/Building Seismic Safety Council Code Resource Support Committee (FEMA/BSSC CRSC), requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

2208.1 Storage racks. The design, testing and utilization of industrial steel storage racks made of cold-formed or hot-rolled steel structural members, shall be in accordance with the RMI/ANSI MH 16.1. Where required by ASCE 7, the seismic design of storage racks shall be in accordance with the provisions of Section 15.5.3 of ASCE 7 except that the mapped acceleration parameters S_s and S_1 shall be determined in accordance in Section 1613.5.1.

Commenter's Reason: The modification is proposed so that storage racks will be designed to the latest seismic maps that have been adopted in the 2012 IBC and ASCE 7-10. MH16.1 currently is a self-contained document that includes seismic maps that are same as the 2009 IBC and ASCE 7-05 seismic maps.

Public Comment 2:

Bonnie Manley, American Iron and Steel Institute, representing RMI, requests Disapproval.

Commenter's Reason: The 2010 edition of the RMI standard has been completed and is recommended for adoption in Proposal S187-09/10. A comment has been submitted to Proposal S187-09/10 requesting approval as modified. If that comment is successful, then this proposal (Proposal S186-09/10) is not needed and the action on this proposal should be disapproved.

Final Action: AS AM AMPC____ D

S187-09/10
2208.1, Chapter 35

Proposed Change as Submitted

Proponent: Bonnie Manley, American Iron and Steel Institute representing Rack Manufacturers Institute

1. Revise as follows:

2208.1 Storage racks. The design, testing and utilization of industrial steel storage racks made of cold-formed or hot-rolled steel structural members, shall be in accordance with the RMI/ANSI MH 16.1. Where required by ASCE 7, the seismic design of storage racks shall be in accordance with the additional provisions of Section 15.5.3 of ASCE 7~~,~~ except that items ~~(1),~~ (2) and (3) of Section 15.5.3 of ASCE 7 do not apply when the rack design satisfies RMI/ANSI MH 16.1.

2. Revise Chapter 35 standard as follows:

RMI
ANSI/MH 16.1-~~08~~ 11 Specification for Design, Testing and Utilization of Industrial Steel Storage Rack, 2011

Reason: This proposal updates the edition year of RMI's ANSI/MH 16.1, *Specification for Design, Testing and Utilization of Industrial Steel Storage Racks,* from 2008 to 2011. The document is expected to be completed in early 2010. The modification to the last sentence of Section 2208.1 coordinates the 2011 edition of the RMI standard with ASCE 7-10, which adopts the 2008 edition of the RMI standard. Also, the word "additional" is added to emphasize that, for seismic design, steel storage racks must also be designed in accordance with the applicable modifications contained in ASCE 7, Section 15.5.3.

Cost Impact: There is no anticipated impact on the cost of construction..

ICCFILENAME: Manley-S5-2208.1

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The proposal was disapproved at the request of the proponent while work continues on the next edition of the RMI Steel Rack Standard.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Bonnie Manley, American Iron and Steel Institute, representing RMI, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

SECTION 2208
STEEL STORAGE RACKS

2208.1 Storage racks. The design, testing and utilization of industrial steel storage racks made of cold-formed or hot-rolled steel structural members, shall be in accordance with the RMI/ANSI MH 16.1. Where required by ASCE 7, the seismic design of storage racks shall be in accordance with the ~~additional~~ provisions of Section 15.5.3 of ASCE 7~~ except that items (2) and (3) of Section 15.5.3 of ASCE 7 do not apply when the rack design satisfies RMI/ANSI MH 16.1~~.

RMI
ANSI/MH16.1-~~11~~ 10*Specification for Design, Testing and Utilization of Industrial Steel Storage Racks,* 2010~~2011~~

Commenter's Reason: The 2010 edition of the RMI standard has been completed (instead of the 2011 year as originally thought) and is recommended for adoption in this comment. Also, the exception in the last sentence of Section 2208.1 has been deleted. This language is not needed for coordination between the 2010 edition of MH16.1-10 and ASCE 7-10.

If this comment is approved, then the coordinating comment on Proposal S186-09/10, which requests disapproval, needs to be approved to ensure full coordination.

Final Action: AS AM AMPC____ D

S188-09/10
1604.3.3, 2209.2.1

Proposed Change as Submitted

Proponent: Edwin Huston, representing National Council of Structural Engineers Associations- Code Advisory Committee - General Requirements Subcommittee

1. Delete without substitution:

~~**2209.2.1 Composite slabs on steel decks.** Composite slabs of concrete and steel deck shall be designed and constructed in accordance with ASCE 3.~~

(Renumber subsequent sections)

2. Revise as follows:

1604.3.3 Steel. The deflection of steel structural members shall not exceed that permitted by AISC 360, AISI S100, ~~ASCE 3,~~ ASCE 8, SJI CJ-1.0, SJI JG-1.1, SJI K-1.1 or SJI LH/DLH-1.1, as applicable.

Reason: The referenced standard will be 21 years old by the time the 2012 IBC is available for use. We found no evidence of recent updates. We understand that the standard development organization, ASCE/SEI is beginning the process to update the standard. Until it is updated, it should be removed as a reference standard.

Cost Impact: This code change proposal will increase the cost of construction.

ICCFILENAME: HUSTON-S8-2209.2

Public Hearing Results

Committee Action: **Approved as Submitted**

Committee Reason: This code removes the ASCE 3 standard for composite slab construction. The standard is out of print and availability is a problem. There are also some concerns such as not addressing serviceability.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Todd Hawkinson, Hawkinson Associates, LLC, requests Disapproval.

Commenter's Reason: 1. The Section 2209.2.1 should remain requiring the engineer to follow an accepted standard, ASCE 3, for the design of composite slabs on steel deck. The standard, ASCE 3 as well as ASCE 9, "Standard for the Structural Design of Composite Slabs (ANSI/ASCE 3-91)" and "Standard Practice for Construction and Inspection of Composite Slabs (ANSI / ASCE 9-91)", respectively, are available and copies can be purchased from the Linda Hall Library, located at 5109 Cherry Street, Kansas City, MO 64110-2498, Phone: (816) 363-4600 or (800) 662-1545. permission for Reuse can be obtained from the American Society of Civil Engineers, ASCE.

2. Though the standard ASCE 3, as well ASCE 9, while technically do not meet the ICC criteria, the requirements are still valid, the standards are industry accepted and have been proven over time. Given that ASCE/SEI intends to update this standard in the future, maintaining the standard in this code, the International Building Code, requires engineers designing composite slabs on steel deck to adhere to the design requirements for the construction of such slabs and provides code officials design requirements that engineers must adhere to.

Final Action: AS AM AMPC____ D

S189-09/10
2209.1 through 2209.1.1.3, 2209.2 through 2209.3.6 (New)

Proposed Change as Submitted

Proponent: Bonnie Manley, American Iron and Steel Institute representing American Iron and Steel Institute

1. Revise as follows:

2209.1 General. The design of cold-formed carbon and low-alloy steel structural members shall be in accordance with AISI S100. The design of cold-formed stainless-steel structural members shall be in accordance with ASCE 8. Cold-formed steel light-frame construction shall also comply with Section 2210. Where required, the seismic design of cold-formed steel structures shall be in accordance with the additional provisions of Section 2209.2.

~~2209.2~~ 2209.1.1 Steel decks. The design and construction of cold-formed steel decks shall be in accordance with this section.

~~2209.2.1~~ 2209.1.1.1 Composite slabs on steel decks. Composite slabs of concrete and steel deck shall be designed and constructed in accordance with ASCE 3.

~~2209.2.2~~ 2209.1.1.2 Noncomposite steel floor decks. Noncomposite steel floor decks shall be permitted to be designed and constructed in accordance with ANSI/SDI-NC1.0, as modified in Section ~~2209.2.2.1~~ 2209.1.1.2.1.

~~2209.2.2.1~~ 2209.1.1.2.1 ANSI/SDI-NC1.0 Section 2.4B1. Replace Section 2.4B1 of ANSI/SDI-NC1.0 with the following:

1. General: The design of the concrete slabs shall be done in accordance with the ACI *Building Code Requirements for Reinforced Concrete*. The minimum concrete thickness above the top of the deck shall be 11/2 inches (38 mm).

~~2209.2.3~~ 2209.1.1.3 Steel roof deck. Steel roof decks shall be permitted to be designed and constructed in accordance with ANSI/SDI-RD1.0.

2. Add new text as follows:

2209.2 Seismic requirements for cold-formed steel structures. Where a response modification coefficient, R, in accordance with ASCE 7, Table 12.2-1 is used for the design of cold-formed steel structures, the structures shall be designed and detailed in accordance with the requirements of AISI S100, ASCE 8, or AISI S110 as modified in Section 2209.3.

2209.3 Modifications to AISI S110. The text of AISI S110 shall be modified as indicated in Sections 2209.3.1 through 2209.3.6.

2209.3.1 AISI S110, Section D1. Modify AISI S110, Section D1 to read as follows:

D1 Cold-Formed Steel Special Bolted Moment Frames (CFS-SBMF). Cold-formed steel–special bolted moment frames (CFS-SBMF) systems shall withstand significant inelastic deformations through friction and bearing at their bolted connections. Beams, columns, and connections shall satisfy the requirements in this section. CFS-SBMF systems shall be limited to one-story structures, no greater than 35 feet in height, without column splices and satisfying the requirements in this section. The CFS-SBMF shall engage all columns supporting the roof or floor above. The single size beam and single size column with the same bolted moment connection detail shall be used for each frame. The frame is to be supported on a level floor or foundation.

2209.3.2 AISI S110, Section D1.1.1. Modify AISI S110, Section D1.1.1 to read as follows:

D1.1.1 Connection Limitations. Beam-to-column connections .in CFS-SBMF systems shall be bolted connections with snug-tight high-strength bolts. The bolt spacing and edge distance shall be in accordance with the limits of AISI S100, Section E3. The 8-bolt configuration shown in Table D1-1 shall be used. The faying surfaces of the beam and column in the bolted moment connection region shall be free of lubricants or debris.

2209.3.3 AISI S110, Section D1.2.1. Modify AISI S110, Section D1.2.1 to read as follows:

D1.2.1 Beam Limitations. In addition to the requirements of Section D1.2.3, beams in CFS-SBMF systems shall be ASTM A 653 galvanized 55 ksi (374 MPa) yield stress cold-formed steel C-sections members with lips, and designed in accordance with Chapter C of AISI S100. The beams shall have a minimum design thickness of 0.105 inches (2.67 mm). The beam depth shall be not less than 12 in (305 mm) or greater than 20 in (508 mm). The flat depth-to-thickness ratio of the web shall not exceed 6.18 $\sqrt{E/F_y}$.

2209.3.4 AISI S110, Section D1.2.2. Modify AISI S110, Section D1.2.2 to read as follows:

D1.2.2 Column Limitations. In addition to the requirements of D1.2.3, columns in CFS-SBMF systems shall be ASTM A 500 Grade B cold-formed steel hollow structural section (HSS) members painted with a standard industrial finished surface, and designed in accordance with Chapter C of AISI S100. The column depth shall be not less than 8 in (203 mm) or greater than 12 in (305 mm). The flat depth-to-thickness ratio shall not exceed 1.40 $\sqrt{E/F_y}$.

2209.3.5 AISI S110, Section D1.3. Modify AISI S110, Section D1.3 to read as follows:

D1.3 Design Story Drift. Where the applicable building code does not contain design coefficients for CSF-SBMF systems, the provisions of Appendix 1 shall apply. For structures having a period less than T_S, as defined in the applicable building code, alternate methods of computing Δ shall be permitted, provided such alternate methods are acceptable to the authority having jurisdiction.

2209.3.6 AISI S110, Section D1.5. Add a new Section D1.5 to read as follows:

D1.5 Period Determination. The fundamental period of the structure, T, in the direction under consideration shall be established in accordance with the applicable building code using the structural properties and deformational characteristics of the resisting elements in a properly substantiated analysis. Use of the approximate building period, T_a, as an alternative fundamental period shall not be permitted.

3. Add standard to Chapter 35 as follows:

AISI

S110-07 Standard for Seismic Design Of Cold-Formed Steel Structural Systems – Special Bolted Moment Frames.

Reason: This proposal introduces a reference to the first edition of AISI S110, *Standard For Seismic Design Of Cold-Formed Steel Structural Systems – Special Bolted Moment Frames*, which is based upon research conducted by Drs. Uang and Sato at UCSD (2007). Specifically, the standard focuses on providing design provisions for a newly defined seismic force resisting system entitled “Cold-formed Steel – Special Bolted Moment Frame” or CFS-SBMFs. This type of system is expected to experience substantial inelastic deformation during significant seismic events. It is intended that most of the inelastic deformation will take place at the bolted connections, due to slip and bearing. In order to develop the designated mechanism, requirements based on the capacity design principles are provided for the design of the beams, columns and associated connections. Additionally, AISI S110 has specific requirements for the application of quality assurance and quality control procedures.

This system has been vetted through the BSSC process (Proposal 6-4R) and will be included in Part I of the 2009 NEHRP Provisions. Additionally, it has been introduced for consideration in the 2010 edition of ASCE 7 (Proposal TC-6-CH12-102-R3). As a first pass, Appendix 1 of AISI S110 makes recommendations on the seismic design coefficients of the CFS-SBMF system. These parameters have been introduced for consideration in the ASCE 7-10 proposal. The Response Modification Coefficient, R, is set at 3.5. Cyclic testing has shown that CFS-SBMFs have very large ductility capacity and significant hardening. This justifies the use of a value of 3.5 for the R-factor. The derivation of the deflection amplification factor, C_d, can be found in the AISI S110 Commentary, Section D1.3. Furthermore, a capacity design procedure has been provided in Section D1.5 of AISI S110 Commentary so that the designer can explicitly calculate the seismic load effect with overstrength, E_{mh},. at the design story drift level. Alternatively, a conservative system overstrength factor, , is also provided to be compatible with the conventional approach to compute E_{mh} in ASCE 7. Finally the height limitation of 35 feet for all SDCs is based on practical use only and not from any limits on the CFS-SBMF system strength.

Modifications to AISI S110 (2007 edition) were developed primarily in the BSSC's NEHRP process and adopted by ASCE 7 in Chapter 14. Since ASCE 7, Chapter 14 is not adopted in the IBC, these modifications need to be included within this proposal. The reasons for the modifications are as follows:

In Section 2209.3.1, the language was modified to reflect that CFS-SBMF needs to use the same-size beams and same-size columns throughout. In addition, the system needs to engage all primary columns, which support the roof or floor above, and those columns need to be supported on a level floor or foundation.

In Section 2209.3.2, the modifications were made for consistency with the test database.

In Section 2209.3.3, the modifications were made to be consistent with the test database (Uang and Sato, 2007), and limitations on the beam depth, steel grade, and surface treatment are added in Section D1.2.1 of AISI S110.

In Section 2209.3.4 the language was modified to be consistent with the test database (Uang and Sato, 2007), and limitations on column depth, steel grade, and surface treatment are added in Section D1.2.2 of AISI S110. The width-thickness ratio was reduced based upon further review of the test specimens.

In Section 2209.3.5, AISI S110 is intended primarily for industrial platforms; however, the standard is not limited to these non-building structures and does not prohibit architectural attachments (such as partition walls). As approved by the BSSC PUC, Proposal 6-4R reduced the 0.05*h* drift limit in Section D1.3 of AISI S110 to 0.03*h* in order to more closely align with the 0.025*h* drift limit of ASCE 7. Also, the BSSC PUC inserted the sentence, "In no case shall the design story drift exceed 0.05h." to ensure an absolute upper bound on the drift limit. However, the ASCE 7 Seismic Subcommittee did not agree with the BSSC PUC and, instead, requested that ASCE 7, Section 12.12 not be overwritten by AISI S110. Therefore, the 0.05*h* drift limit in Section D1.3 of AISI S110 has been eliminated in deference to the design story drift limits found in ASCE 7, Section 12.12. In addition, the first sentence of the AISI S110, Section D1.3 was deleted because it was considered commentary.

Two additional modifications are presented in this proposal which are not being considered for inclusion in ASCE 7-10, Chapter 14, but were deemed important enough to be included in the IBC. These two items resulted from discussions with SEAOC. First in Section 2209.3.3, a minimum thickness for the beams was added to reflect the test database. Secondly, Section 2209.3.6 clarifies that the approximate fundamental period, T_a, in accordance with ASCE 7 Section 12.8.2.1, should not be used in the design of CFS-SBMF systems. Instead, the fundamental period of the structure, T, needs to be based upon the structural properties and deformational characteristics of the resisting elements. The approximate fundamental period in ASCE 7, Section 12.8.1 simply does not predict the period as accurately as needed for the variety of uses of this framing system.

Cost Impact: There is no anticipated impact on the cost of construction.

Analysis: A review of the standard(s) proposed for inclusion in the code, AISI S110-07, for compliance with ICC criteria for referenced standards given in Section 3.6 of Council Policy #CP 28 will be posted on the ICC website on or before September 24, 2009.

ICCFILENAME: Manley-S3-2209

Public Hearing Results

Note: The following analysis was not in the Code Change monograph but was published on the ICC website at http://www.iccsafe.org/cs/codes/Documents/2009-10cycle/ProposedChanges/Standards-Analysis.pdf :

Analysis: Review of proposed new standard AISI S110 indicated that, in the opinion of ICC Staff, the standard complies with ICC standards criteria.

Committee Action: Approved as Modified

Modify the proposal as follows:

2209.3.1 AISI S110, Section D1. Modify Section D1 by revising to read as follows.

D1 Cold-Formed Steel Special Bolted Moment Frames (CFS-SBMF)
Cold-formed steel–special bolted moment frames (CFS-SBMF) systems shall withstand significant inelastic deformations through friction and bearing at their bolted connections. Beams, columns, and connections shall satisfy the requirements in this section. CFS-SBMF systems shall be limited to one-story structures, no greater than 35 feet in height, without column splices and satisfying the requirements in this section. The CFS-SBMF shall engage all columns supporting the roof or floor above. The single size beam and single size column with the same bolted moment connection detail shall be used for each frame. The frame ~~is to~~ shall be supported on a level floor or foundation.

…

2209.3.3 AISI S110, Section D1.2.1. Modify Section D1.2.1 by revising to read as follows.

D1.2.1 Beam Limitations
In addition to the requirements of Section D1.2.3, beams in CFS-SBMF systems shall be ASTM A653 galvanized 55 ksi (374 MPa) yield stress cold-formed steel C-sections members with lips, and designed in accordance with Chapter C of AISI S100. The beams

shall have a minimum design thickness of 0.105 inches (2.67 mm). The beam depth shall be not less than 12 in (305 mm) or greater than 20 in (508 mm). The flat depth-to-thickness ratio of the web shall not exceed 6.18 $\sqrt{E/F_y}$.

D1.2.1.1 Single C-Section Beam Limitations
In addition to the requirements of Section D1.2.1, when single C-section beams are used, torsional effects shall be accounted for in the design.

…

~~**2209.3.6 AISI S110, Section D1.5.** Add a new Section D1.5 as follows.~~

~~**D1.5 Period Determination**~~
~~The fundamental period of the structure, T, in the direction under consideration shall be established in accordance with the applicable building code using the structural properties and deformational characteristics of the resisting elements in a properly substantiated analysis. Use of the approximate building period, T_a, as an alternative fundamental period shall not be permitted.~~

(Portions of proposal not shown are unchanged)

Committee Reason: This proposal adds requirements for cold-formed steel special bolted moment frames by reference to AISI S110. The modification coordinates the AISI S110 modifications for consistency with the updated earthquake load provisions in ASCE 7.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Bonnie Manley, American Iron and Steel Institute, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

2209.1 General. The design of cold-formed carbon and low-alloy steel structural members shall be in accordance with AISI S100. The design of cold-formed stainless-steel structural members shall be in accordance with ASCE 8. Cold-formed steel light-frame construction shall also comply with Section 2210. Where required, the seismic design of cold-formed steel structures shall be in accordance with the additional provisions of Section 2209.2.

2209.1.1 Steel decks. The design and construction of cold-formed steel decks shall be in accordance with this section.

2209.1.1.1 Composite slabs on steel decks. Composite slabs of concrete and steel deck shall be designed and constructed in accordance with ASCE 3.

2209.1.1.2 Noncomposite steel floor decks. Noncomposite steel floor decks shall be permitted to be designed and constructed in accordance with ANSI/SDI-NC1.0, as modified in Section 2209.1.1.2.1.

2209.1.1.2.1 ANSI/SDI-NC1.0 Section 2.4B1. Replace Section 2.4B1 of ANSI/SDI-NC1.0 with the following:

1. General: The design of the concrete slabs shall be done in accordance with the ACI *Building Code Requirements for Reinforced Concrete*. The minimum concrete thickness above the top of the deck shall be 11/2 inches (38 mm).

2209.1.1.3 Steel roof deck. Steel roof decks shall be permitted to be designed and constructed in accordance with ANSI/SBI-RD1.0.

2209.2 Seismic Requirements for Cold-Formed Steel Structures. Where a response modification coefficient, R, in accordance with ASCE 7, Table 12.2-1 is used for the design of cold-formed steel structures, the structures shall be designed and detailed in accordance with the requirements of AISI S100, ASCE 8, ~~or~~ <u>and, for cold-formed steel special bolted moment frames,</u> AISI S110 ~~as modified in Section 2209.3~~.

~~**2209.3 Modifications to AISI S110.** The text of AISI S110 shall be modified as indicated in Sections 2209.3.1 through 2209.3.5.~~

~~**2209.3.1 AISI S110, Section D1.** Modify AISI S110, Section D1 to read as follows:~~

~~**D1 Cold-Formed Steel Special Bolted Moment Frames (CFS-SBMF).** Cold-formed steel special bolted moment frames (CFS-SBMF) systems shall withstand significant inelastic deformations through friction and bearing at their bolted connections. Beams, columns, and connections shall satisfy the requirements in this section. CFS-SBMF systems shall be limited to one-story structures, no greater than 35 feet in height, without column splices and satisfying the requirements in this section. The CFS-SBMF shall engage all columns supporting the roof or floor above. The single size beam and single size column with the same bolted moment connection detail shall be used for each frame. The frame shall be supported on a level floor or foundation.~~

~~**2209.3.2 AISI S110, Section D1.1.1.** Modify AISI S110, Section D1.1.1 to read as follows.~~

~~**D1.1.1 Connection Limitations.** Beam-to-column connections in CFS-SBMF systems shall be bolted connections with snug-tight high-strength bolts. The bolt spacing and edge distance shall be in accordance with the limits of AISI S100, Section E3. The 8-bolt configuration shown in Table D1-1 shall be used. The faying surfaces of the beam and column in the bolted moment connection region shall be free of lubricants or debris.~~

~~**2209.3.3 AISI S110, Section D1.2.1.** Modify AISI S110, Section D1.2.1 to read as follows.~~

> ~~**D1.2.1 Beam Limitations.** In addition to the requirements of Section D1.2.3, beams in CFS-SBMF systems shall be ASTM A653 galvanized 55 ksi (374 MPa) yield stress cold-formed steel C-sections members with lips, and designed in accordance with Chapter C of AISI S100. The beams shall have a minimum design thickness of 0.105 inches (2.67 mm). The beam depth shall be not less than 12 in (305 mm) or greater than 20 in (508 mm). The flat depth-to-thickness ratio of the web shall not exceed 6.18~~ $\cancel{\sqrt{E/F_y}}$.
>
> ~~**D1.2.1.1 Single C-Section Beam Limitations.** In addition to the requirements of Section D1.2.1, when single C-section beams are used, torsional effects shall be accounted for in the design.~~

~~**2209.3.4 AISI S110, Section D1.2.2.** Modify AISI S110, Section D1.2.2 to read as follows.~~

> ~~**D1.2.2 Column Limitations.** In addition to the requirements of D1.2.3, columns in CFS-SBMF systems shall be ASTM A500 Grade B cold-formed steel hollow structural section (HSS) members painted with a standard industrial finished surface, and designed in accordance with Chapter C of AISI S100. The column depth shall be not less than 8 in (203 mm) or greater than 12 in (305 mm). The flat depth-to-thickness ratio shall not exceed 1.40~~ $\cancel{\sqrt{E/F_y}}$.

~~**2209.3.5 AISI S110, Section D1.3.** Modify AISI S110, Section D1.3 to read as follows.~~

> ~~**D1.3 Design Story Drift.** Where the applicable building code does not contain design coefficients for CSF-SBMF systems, the provisions of Appendix 1 shall apply. For structures having a period less than~~ $\cancel{T_s}$~~, as defined in the applicable building code, alternate methods of computing Δ shall be permitted, provided such alternate methods are acceptable to the authority having jurisdiction~~

AISI
AISI S110-07 Standard for Seismic Design Of Cold-Formed Steel Structural Systems – Special Bolted Moment Frames, with Supplement 1, dated 2009.

Commenter's Reason: The modifications made to AISI S110-07 in Proposal S189-09/10 resulted from the review of the document in the development of the 2009 NEHRP Recommended Provisions (FEMA P-750) and ASCE 7-10. To improve the usability of the IBC, AISI's Committee on Specification recently completed AISI S110-07 Supplement 1-09, which adopts all of the technical changes presented in IBC Section 2209.3 of Proposal S121-09/10. Consequently, this Public Comment recommends the deletion of these modifications to AISI S110-07 from the IBC.
Please note this supplement has been issued by AISI and is available for review at www.steel.org or http://www.steel.org//AM/TemplateRedirect.cfm?Template=/CM/ContentDisplay.cfm&ContentID=36728.

Final Action: AS AM AMPC____ D

S191-09/10
2209.2.1, 2209.2.1.1 (New) Chapter 35

Proposed Change as Submitted

Proponent: Thomas Sputo, Ph.D., PE, SE, Steel Deck Institute, representing Steel Deck Institute

1. Revise as follows:

2209.2.1 Composite slabs on steel decks. Composite slabs of concrete and steel deck shall be permitted to be designed and constructed in accordance with ~~ASCE 3~~ ANSI/SDI-C1.0, as modified in Section 2209.2.1.1.

2. Add new text as follows:

2209.2.1.1 ANSI/SDI-C1.0 Section 2.4B6a. Replace Section 2.4B6a of ANSI/SDI-C1.0 with the following:

a. Temperature and shrinkage reinforcement, consisting of welded wire fabric or reinforcing bars, shall have a minimum area of 0.00075 times the area of the concrete above the deck (per foot or meter of width), but shall not be less than the area provided by 6 x 6 – W1.4 x W1.4 welded wire fabric.

3. Add standard to Chapter 35 as follows:

SDI
C1.0-06 Standard for Composite Steel Floor Deck

Reason: ASCE 3-91 is proposed for deletion because it does not meet the criteria set forth in CP#28-05, revised 2/27/09 for referenced standards. Section 3.6.3.2 requires a reference standard to be maintained. This standard has not been reaffirmed since its approval by ANSI in 1992. The ASCE committee responsible for this standard has been inactive since approximately 1997 and has taken no action on this standard since then. "ASCE Rules for Standards Committees" (2006) require standards to be reaffirmed at intervals not to exceed 5 years (Section 5.8). Additionally, this standard is out-of-print and is therefore not readily available to code officials, designers, or users of the code.

ANSI/SDI C1.0 is proposed for inclusion because it is the current standard for the design of composite steel deck. This standard is readily available to code officials, designers, and other users of the code, both in print form and as a free download from the Steel Deck Institute website. Section 2.4B6a is modified to delete the option for the use of fibers because of lack of complete consensus among all interested parties on proper specification of fibers for the purpose of control of shrinkage and temperature fluctuation effects in concrete on composite steel deck.

Section 2.4B6a – Text as it appears in SDI-C1.0:

a. Temperature and shrinkage reinforcement, consisting of welded wire fabric or reinforcing bars, shall have a minimum area of 0.00075 times the area of the concrete above the deck (per foot or meter of width), but shall not be less than the area provided by 6 x 6 – W1.4 x W1.4 welded wire fabric.

Fibers shall be permitted as a suitable alternative to the welded wire fabric specified for temperature and shrinkage reinforcement. Cold-drawn steel fibers meeting the criteria of ASTM A820, at a minimum addition rate of 25 lb/cu yd (14.8 kg/cu meter), or macro synthetic fibers "Coarse fibers" (per ASTM Subcommittee C09.42), made from virgin polyolefin, shall have an equivalent diameter between 0.4 mm (0.016 in.) and 1.25 mm (0.05 in.), having a minimum aspect ratio (length/equivalent diameter) of 50, at a minimum addition rate of 4 lb./cu yd (2.4 kg/m^3) are suitable to be used as minimum temperature and shrinkage reinforcement.

Cost Impact: The code change proposal will not increase the cost of construction

Analysis: A review of the standard(s) proposed for inclusion in the code, SDI C1.0-06, for compliance with ICC criteria for referenced standards given in Section 3.6 of Council Policy #CP 28 will be posted on the ICC website on or before September 24, 2009.

ICCFILENAME: Sputo-S1-2209.2.1

Public Hearing Results

Note: The following analysis was not in the Code Change monograph but was published on the ICC website at http://www.iccsafe.org/cs/codes/Documents/2009-10cycle/ProposedChanges/Standards-Analysis.pdf :

Analysis: Review of proposed new standard SDI-C1.0 indicated that, in the opinion of ICC Staff, the standard complies with ICC standards criteria.

Committee Action: Disapproved

Committee Reason: The proposed reference standard, SDI-C1.0 is still in need of work. Questions have been raised on its treatment of serviceability and wheel loads. The need to exclude fiber reinforcement should be clarified.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Thomas Sputo, Ph.D., PE, SE representing Steel Deck Institute, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

2209.2.1 Composite slabs on steel decks. Composite slabs of concrete and steel deck shall be permitted to be designed and constructed to resist loads other than wheel loads in accordance with ANSI/SDI-C1.0, Standard for Composite Steel Floor Deck, as modified in Section 2209.2.1.1.

2209.2.1.1 ANSI/SDI-C1.0 Section 2.4B6a. Replace Section 2.4B6a of ANSI/SDI-C1.0 with the following:

a. Temperature and shrinkage reinforcement, consisting of welded wire fabric or reinforcing bars, shall have a minimum area of 0.00075 times the area of the concrete above the deck (per foot or meter of width), but shall not be less than the area provided by 6 x 6 – W1.4 x W1.4 welded wire fabric.

(Portions of proposal not shown remain unchanged)

Commenter's Reason: ASCE 3-91 was approved for deletion under Proposals S-188 and S-193. The fact that it has not been revised or reaffirmed since 1991 is sufficient reason for this action.

ASCE 3-91 should have been replaced with ANSI/SDI C1.0-2006, which is current, actively supported and today used almost exclusively by designers of composite floor slabs. The ANSI/SDI C1.0-2006 standard is also readily available as a free download by any building official or design professional at the SDI website. However, reasons were cited for not taking this action including serviceability, wheel loads and fibers. These reasons are not sufficient justification to create a void in the building code for the design of composite floor slabs.

SDI C1.0-2006 addresses serviceability of floor slabs in the same empirical manner as does other standards included in the IBC, such as ACI-318. It requires empirically based minimum amounts of reinforcement to control the effects of temperature and shrinkage. No consensus based analytical method exists to further address this issue for any type of temperature and shrinkage reinforcement. It is not a safety issue, and should not have been considered as a valid reason to not include ANSI/SDI C1.0-2006 in the IBC.

Designing for wheel loads is an analytical procedure that is outside the scope of ANSI/SDI C1.0-2006, which is intended to cover typical static loads. A designer following good engineering practice would use rational analysis combined with the requirements of a standard such as ANSI/SDI C1.0-2006 to properly address this rare, atypical condition. However, for clarification, we are proposing to modify S-191 to specifically exclude wheel loads.

Fibers are included in ANSI/SDI C1.0-2006 as an optional means to control the effects of temperature and shrinkage. However, inclusion of fibers in the building code has been controversial. Since this option is not essential to the function of ANSI/SDI C1.0-2006, SDI has most recently proposed to not include it in order to gain incorporation of the remaining parts of a standard that is already accepted by the design community into the IBC. However, S-191 may be modified to include the fiber option by deleting section 2209.2.1.1 from the proposal.

Final Action: AS AM AMPC____ D

S196-09/10
2302.1

<u>Proposed Change as Submitted</u>

Proponent: Edward L. Keith, PE, APA - The Engineered Wood Association

Revise as follows:

STRUCTURAL COMPOSITE LUMBER. Structural members manufactured using wood elements bonded together with exterior adhesives. Examples of structural composite lumber are:

> **Laminated veneer lumber (LVL).** A composite of wood veneer elements with wood fibers primarily oriented along the length of the member. <u>Veneer thickness shall not exceed 0.25 inches (6.4 mm).</u>
>
> **Parallel strand lumber (PSL).** A composite of wood strand elements with wood fibers primarily oriented along the length of the member. <u>The least dimension of the strands shall not exceed 0.25 inches (6.4 mm) and the average length shall be a minimum of 300 times the least dimension.</u>
>
> <u>**Laminated strand lumber (LSL).** A composite of wood strand elements with wood fibers primarily oriented along the length of the member. The least dimension of the strands shall not exceed 0.10 inches (2.54 mm) and the average length shall be a minimum of 150 times the least dimension.</u>
>
> <u>**Oriented strand lumber (OSL).** A composite of wood strand elements with wood fibers primarily oriented along the length of the member. The least dimension of the strands shall not exceed 0.10 inches (2.54 mm) and the average length shall be a minimum of 75 times the least dimension.</u>

Reason: ASTM Standard D5456 recognizes 4 types of structural composite lumber. This proposal adds the two types missing from the existing definition and makes them consistent with ASTM D5456

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: KEITH-S2-2302.1 Definitions

<u>Public Hearing Results</u>

Committee Action: **Approved as Submitted**

Committee Reason: The added definitions of structural composite lumber types will clear up some confusion with their use. The definitions include some requirements and this should be corrected in the public comment phase.

Assembly Action: **None**

<u>Individual Consideration Agenda</u>

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Edward L. Keith, The Engineered Wood Association, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

> **STRUCTURAL COMPOSITE LUMBER.** Structural members manufactured using wood elements bonded together with exterior adhesives. Examples of structural composite lumber are:
>
> **Laminated veneer lumber (LVL).** A composite of wood veneer elements with wood fibers primarily oriented along the length of the member~~.~~<u>, where the veneer element</u> ~~Veneer~~ thickness<u>es are</u> 0.25 inches (6.4 mm)<u> or less</u>.
>
> **Parallel strand lumber (PSL).** A composite of wood strand elements with wood fibers primarily oriented along the length of the member~~. The~~<u>, where the</u> least dimension of the <u>wood</u> strand~~s shall not exceed~~ <u>elements is</u> 0.25 in. (6.4 mm)<u> or less</u> and ~~the~~ <u>their</u> average length<u>s</u> ~~shall be a minimum~~ <u>are a minimum</u> of 300 times the least dimension<u> of the wood strand elements.</u>
>
> **Laminated strand lumber (LSL).** A composite of wood strand elements with wood fibers primarily oriented along the length of the member~~. The~~<u>, where the</u> least dimension of the <u>wood</u> strand~~s shall not exceed~~ <u>elements is</u> 0.10 in. (2.54 mm) <u>or less</u> and ~~the~~ <u>their</u> average length<u>s</u> ~~shall be a minimum~~ <u>are a minimum</u> of 150 times the least dimension <u>of the wood strand elements</u>.

Oriented strand lumber (OSL). A composite of wood strand elements with wood fibers primarily oriented along the length of the member~~. The~~, where the least dimension of the wood strand~~s shall not exceed~~ elements is 0.10 in. (2.54 mm) or less and ~~the~~ their average lengths ~~shall be a minimum~~ are a minimum of 75 times and less than 150 times the least dimension ~~or more~~ of the wood strand elements.

Commenter's Reason: While the provisions were approved by the Committee as proposed, it was suggested by the Committee that the Public Comment process be used to eliminate mandatory language from the definitions for consistency with the format of other definitions in the code. The above modification does so. With one exception the changes above in this Public Comment are non-technical. In the definition for OSL the further limitation "and less than 150 times" was returned to the definition. It was inadvertently left out of the original proposal but is a part of the definition in the standard. It is a necessary part of the definition to distinguish OSL from LSL.

Final Action: AS AM AMPC____ D

S200-09/10-PART I
2303.1.4

Proposed Change as Submitted

Proponent: Edward L. Keith, PE, APA - The Engineered Wood Association

PART I – IBC STRUCTURAL

Revise as follows:

2303.1.4 Wood structural panels. Wood structural panels, when used structurally (including those used for siding, roof and wall sheathing, subflooring, diaphragms and built-up members), shall conform to the requirements for their type in DOC PS 1 or PS 2. Each panel or member shall be identified for grade, ~~and glue type~~ bond classification, and Performance Class by the trademarks of an *approved* testing and grading agency. The Performance Class value shall be used as the "nominal panel thickness" or "panel thickness" whenever referenced in this code. Wood structural panel components shall be designed and fabricated in accordance with the applicable standards listed in Section 2306.1 and identified by the trademarks of an *approved* testing and inspection agency indicating conformance with the applicable standard. In addition, wood structural panels when permanently exposed in outdoor applications shall be of ~~exterior~~ Exterior type, except that wood structural panel roof sheathing exposed to the outdoors on the underside is permitted to be ~~interior type bonded with exterior glue,~~ Exposure 1 type.

Reason: (IBC & IRC) This is a nomenclature change that reflects the newest versions of National Standards PS 1 and PS 2. Wood structural panels are required to be in conformance to DOC PS 1 and PS 2 in the code. The PS 1 and PS 2 consensus standard committees have revised both standards to include the terminologies of "bond classification" to reference glue type and "Performance Classes" to reference the thicknesses tolerance consistent with the nominal panel thicknesses in the IBC. This change proposal updates the code to the nomenclature that appears on the trademark of wood structural panels in the field in accordance with DOC PS 1 and PS 2. This is not a technical change.

Cost Impact: This will **not** impact the cost of construction.

ICCFILENAME: Keith-S4-2303.1.4

Public Hearing Results

PART I- IBC STRUCTURAL
Committee Action: **Approved as Submitted**

Committee Reason: This proposal adds terminology that coordinates the IBC with the wood structure panel product standards. A public comment is in order to include a definition of the new term "Performance Class".

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Edward L. Keith, APA, The Engineered Wood Association, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

2303.1.4 Wood structural panels. Wood structural panels, when used structurally (including those used for siding, roof and wall sheathing, subflooring, diaphragms and built-up members), shall conform to the requirements for their type in DOC PS 1 or PS 2. Each panel or member shall be identified for grade, bond classification, and Performance ~~Class~~ Category by the trademarks of an *approved* testing and grading agency. The Performance ~~Class~~ Category value shall be used as the "nominal panel thickness" or "panel thickness" whenever referenced in this code. Wood structural panel components shall be designed and fabricated in accordance with the applicable standards listed in Section 2306.1 and identified by the trademarks of an *approved* testing and inspection agency indicating conformance with the applicable standard. In addition, wood structural panels when permanently exposed in outdoor applications shall be of Exterior type, except that wood structural panel roof sheathing exposed to the outdoors on the underside is permitted to be Exposure 1 type.

PERFORMANCE CATEGORY. A designation of wood structural panels as related to the panel performance used in Chapter 23.

Commenter's Reason: At the final ballot process, the PS1 and PS2 update committees changed editorially the term "Performance Class" to "Performance Category" in the standards. Item 1 of Part I and Item 1 of Part II above in this Public Comment make this editorial change to the proposed code change text.

Along with the recommendation for approval by the IBC and IRC Committees, a recommendation was made by one of the committee members at the Code Development Hearing that a definition for the term "Performance Class" (now "Performance Category") be added to the IBC and IRC as the term was new to the building codes. The above definition is proposed for the IBC and IRC in accordance with that committee member's recommendation.

Final Action: AS AM AMPC____ D

S200-09/10-PART II
IRC R503.2.1, R503.2.1.1, R602.3, R803.2.1

Proposed Change as Submitted

Proponent: Edward L. Keith, PE, APA - The Engineered Wood Association

PART II – IRC BUILDING/ENERGY

Revise as follows:

R503.2.1 Identification and grade. Wood structural panel sheathing used for structural purposes shall conform to DOC PS 1, DOC PS 2 or, when manufactured in Canada, CSA O437 or CSA O325. All panels shall be identified for grade, bond classification, and Performance Class by a grade mark of certificate or inspection issued by an approved agency. The Performance Class value shall be used as the "nominal panel thickness" or "panel thickness" whenever referenced in this code.

R503.2.1.1 Subfloor and combined subfloor underlayment. Where used as subflooring or combination subfloor underlayment, wood structural panels shall be of one of the grades specified in Table R503.2.1.1(1). When sanded plywood is used as combination subfloor underlayment, the grade, bond classification, and Performance Class shall be as specified in Table R503.2.1.1(2).

R602.3 Design and construction. Exterior walls of wood-frame construction shall be designed and constructed in accordance with the provisions of this chapter and Figures R602.3(1) and R602.3.(2) or in accordance with AF&PA's NDS. Components of exterior walls shall be fastened in accordance with Tables R602.3(1) through R602.3(4). Structural wall sheathing shall be fastened directly to structural framing members. Exterior wall coverings shall be capable of resisting the wind pressures listed in Table R301.2(2) adjusted for height and exposure using Table R301.2(3). Wood structural panel sheathing used for exterior walls shall conform to DOC PS 1, DOC PS 2 or, when manufactured in Canada, CSA O437 or CSA O325. All panels shall be identified for grade, bond classification, and

Performance Class by a grade mark or certificate of inspection issued by an approved agency and shall conform to the requirements of Table R602.3(3).

R803.2.1 Identification and grade. Wood structural panels shall conform to DOC PS 1, DOC PS 2 or, when manufactured in Canada, CSA O437 or CSA O325, and shall be identified for grade, bond classification, and Performance Class by a grade mark or certificate of inspection issued by an approved agency. Wood structural panels shall comply with the grades specified in Table R503.2.1.1(1).

Reason: (IBC & IRC) This is a nomenclature change that reflects the newest versions of National Standards PS 1 and PS 2. Wood structural panels are required to be in conformance to DOC PS 1 and PS 2 in the code. The PS 1 and PS 2 consensus standard committees have revised both standards to include the terminologies of "bond classification" to reference glue type and "Performance Classes" to reference the thicknesses tolerance consistent with the nominal panel thicknesses in the IBC. This change proposal updates the code to the nomenclature that appears on the trademark of wood structural panels in the field in accordance with DOC PS 1 and PS 2. This is not a technical change.

(IRC)In Section R602.3, the description of wood structural panel was added as it shows up in Chapters 5 and 8 where wood structural panels are also specified. This was done to make the code read consistently between similar sections.

Cost Impact: This will **not** impact the cost of construction.

ICCFILENAME: Keith-S4-2303.1.4

Public Hearing Results

PART II- IRC B/E

Committee Action: **Approved as Submitted**

Committee Reason: This change updates the code for identification requirements for wood structural panels to be consistent with the latest versions of DOC PS1 and DOC PS2. This change is consistent with the IBC.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Edward L. Keith, APA, The Engineered Wood Association, requests Approval as Modified by this Public Comment.

Modify the proposal as follows

Part II – IRC BUILDING/ENERGY

R503.2.1 Identification and grade. Wood structural panel sheathing used for structural purposes shall conform to DOC PS 1, DOC PS 2 or, when manufactured in Canada, CSA O437 or CSA O325. All panels shall be identified for grade, bond classification, and Performance ~~Class~~ Category by a grade mark of certificate or inspection issued by an approved agency. The Performance ~~Class~~ Category value shall be used as the "nominal panel thickness" or "panel thickness" whenever referenced in this code.

R503.2.1.1 Subfloor and combined subfloor underlayment. Where used as subflooring or combination subfloor underlayment, wood structural panels shall be of one of the grades specified in Table R503.2.1.1(1). When sanded plywood is used as combination subfloor underlayment, the grade, bond classification, and Performance ~~Class~~ Category shall be as specified in Table R503.2.1.1(2).

R602.3 Design and construction. Exterior walls of wood-frame construction shall be designed and constructed in accordance with the provisions of this chapter and Figures R602.3(1) and R602.3.(2) or in accordance with AF&PA's NDS. Components of exterior walls shall be fastened in accordance with Tables R602.3(1) through R602.3(4). Structural wall sheathing shall be fastened directly to structural framing members. Exterior wall coverings shall be capable of resisting the wind pressures listed in Table R301.2(2) adjusted for height and exposure using Table R301.2(3). Wood structural panel sheathing used for exterior walls shall conform to DOC PS 1, DOC PS 2 or, when manufactured in Canada, CSA O437 or CSA O325. All panels shall be identified for grade, bond classification, and Performance ~~Class~~ Category by a grade mark or certificate of inspection issued by an approved agency and shall conform to the requirements of Table R602.3(3).

R803.2.1 Identification and grade. Wood structural panels shall conform to DOC PS 1, DOC PS 2 or, when manufactured in Canada, CSA O437 or CSA O325, and shall be identified for grade, bond classification, and Performance ~~Class~~ Category by a grade mark or certificate of inspection issued by an approved agency. Wood structural panels shall comply with the grades specified in Table R503.2.1.1(1).

Add definition to Section R202 as follows:

PERFORMANCE CATEGORY. A designation of wood structural panels as related to the panel performance used in Chapters 4, 5, 6, and 8.

Commenter's Reason: At the final ballot process, the PS1 and PS2 update committees changed editorially the term "Performance Class" to "Performance Category" in the standards. Item 1 of Part I and Item 1 of Part II above in this Public Comment make this editorial change to the proposed code change text.

Along with the recommendation for approval by the IBC and IRC Committees, a recommendation was made by one of the committee members at the Code Development Hearing that a definition for the term "Performance Class" (now "Performance Category") be added to the IBC and IRC as the term was new to the building codes. The above definition is proposed for the IBC and IRC in accordance with that committee member's recommendation.

Final Action: AS AM AMPC____ D

S201-09/10, Part I
2303.2, 2303.2.1, 2303.2.2, 2303.2.3

Proposed Change as Submitted

Proponent: Joe Holland and Dave Bueche, representing Hoover Treated Wood Products

PART I- IBC STRUCTURAL

1. Revise as follows:

2303.2 Fire-retardant-treated wood. *Fire-retardant-treated wood* (FRTW) is a pressure treated ~~any~~ wood product ~~which, when impregnated with chemicals by a pressure process or other means during manufacture, shall have, when~~ tested in accordance with ASTME 84 or UL723~~,~~.FRTW shall have a *listed* flame spread index of 25 or less and show no evidence of significant progressive combustion when the test is continued for an additional 20-minute period. ~~Additionally, t~~The flame front shall not progress more than 101/2 feet (3200 mm) beyond the centerline of the burners at any time during the test.

2. Delete without substitution:

~~**2303.2.1 Pressure process.** For wood products impregnated with chemicals by a pressure process, the process shall be performed in closed vessels under pressures not less than 50 pounds per square inch gauge (psig) (345 kPa).~~

~~**2303.2.2 Other means during manufacture.** For wood products produced by other means during manufacture, the treatment shall be an integral part of the manufacturing process of the wood product. The treatment shall provide permanent protection to all surfaces of the wood product.~~

~~**2303.2.3 Testing.** For wood products produced by other means during manufacture, other than a pressure process, all sides of the wood product shall be tested in accordance with and produce the results required in Section 2303.2. Wood structural panels shall be permitted to test only the front and back faces.~~

(Renumber remaining sections)

Reason: Revision is more concise. Present section is wordy. In the fifty years of recognition of FRTW in the code there is no wood product meeting the requirement of FRTW where adding the fire retardant to the wood is done during manufacture. This provision creates interpretation problems in the field. Revision will improve enforcement of section. "Pressure process" and "other means during manufacturer" are no longer used; delete Sections 2303.2.1 through 2303.2.3.

Cost Impact: The code change proposal will not increase the cost of construction.

FILENAME: Holland-Bueche-S1-2303.2-RB-2-R802.1.3

Public Hearing Results

PART I- IBC STRUCTURAL

Committee Action: **Disapproved**

Committee Reason: The proposal is not editorial as the reason suggests. If accepted, it would no longer allow fire-retardant treated wood products that currently comply with the code. If there are problems, they would appear to accent the need for education. Acceptability should be defined by the products performance not the means or method of manufacture.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Final Action: AS AM AMPC____ D

S205-09/10
2304.11.6

Proposed Change as Submitted

Proponent: Homer Maiel, PE, CBO, City of San Jose**,** representing ICC Tri-Chapter (Peninsula, East Bay, Monterey Bay)

Revise as follows:

Section 2304.11.6 Termite protection. In geographical areas where hazard of termite damage is known to be very heavy, wood floor framing <u>exposed to the ground in crawl spaces or unexcavated areas located within the periphery of the building foundation and exposed framing of exterior decks or balconies,</u> shall be of durable species (termite resistant) or preservative treated in accordance with AWPA U1 for the species, product preservative and end use or provided with approved methods of termite protection.

Reason: This change intends to clarify that the wood floor framing that needs to be durable species or preservative treated wood are limited to those interior floors with exposure to soil instead of all floors in the building. In addition exposed exterior decks or balcony framing are specifically added. Other provisions address wood in contact with concrete or close to grade for all termite hazard regions.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: MAIEL-S1-2304.11.6

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The need for this requirement for termite protection is unclear, since Section 2304.11.2.1 already covers wood within 18 inches of exposed earth.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Gary J. Ehrlich, PE., National Association of Home Builders (NAHB), requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

Section 2304.11.6 Termite protection. In geographical areas where hazard of termite damage is known to be very heavy, wood floor framing in the locations specified in Section 2304.11.2.1 ~~exposed to the ground in crawl spaces or unexcavated areas located within the periphery of the building foundation~~ and exposed framing of exterior decks or balconies, shall be of durable species (termite resistant) or preservative treated in accordance with AWPA U1 for the species, product preservative and end use or provided with approved methods of termite protection.

Commenter's Reason: The purpose of this public comment is to further clarify the requirements for termite protection of floor framing. We agree with the proponents' intent that only those interior floors with direct exposure to soil need termite protection. The Structural Committee, in disapproving the proposal, believed that Section 2304.11.2.1 already covered the proponent's intent. However, the charging language of Section 2304.11.2 does not explicitly mention termite resistance. Thus, to clearly make the connection between Section 2304.11.6 and the specific requirements for exposure to ground, a direct reference to Section 2304.11.2.1 needs to be provided in Section 2304.11.6.

Final Action: AS AM AMPC____ D

S207-09/10-PART I
2302.1, 2303.1, 2303.1.12 (New), 2304.13 (New), CHAPTER 35;

Proposed Change as Submitted

Proponent: John Woestman, The Kellen Company representing the Composite Lumber Manufacturers Association (CLMA)

PART I – IBC STRUCTURAL

1. Add new definition as follows:

WOOD PLASTIC COMPOSITE. A composite material made primarily from wood or cellulose-based materials, and plastic.

2. Revise as follows:

2303.1 General. Structural sawn lumber; end-jointed lumber; prefabricated wood I-joists; structural glued laminated timber; wood structural panels, fiberboard sheathing (when used structurally); hardboard siding (when used structurally); particleboard; preservative-treated wood; structural log members; structural composite lumber; round timber poles and piles; fire-retardant-treated wood; hardwood plywood; wood trusses; wood plastic composite exterior deck components; joist hangers; nails; and staples shall conform to the applicable provisions of this section.

3. Add new text as follows:

2303.1.12 Wood plastic composite exterior deck, railing, and stairway components. Structural capacities for exterior wood plastic composite deck boards, stair treads, handrails and guardrail systems shall be determined in accordance with ASTM D 7032.

2304.13 Wood plastic composite exterior deck, railing, and stairway components. Exterior wood plastic composite deck boards, deck boards used as stair treads, handrails and guardrail systems shall meet the applicable requirements of ASTM D 7032, and bear a label indicating the required performance levels and demonstrating compliance with ASTM D 7032,

4. Add new standard to Chapter 35 as follows:

ASTM

<u>D 7032-08</u> <u>Standard Specification for Establishing Performance Ratings For Wood-Plastic Composite Deck Boards and Guardrail Systems (Guards or Handrails)</u>

5. Add new text as follows:

<u>**2304.13.1 Labeling.** Labels for deck boards and stair treads shall include the allowable maximum load and span. Labels for handrails and guardrail systems shall indicate the allowable maximum span.</u>

6. Add new text as follows:

<u>**2304.13.2 Installation.** Wood plastic composite deck components shall be installed in accordance with the manufacturer's instructions.</u>

Reason:
(Part I, items 1-4) The IBC is currently silent regarding requirements for wood plastic composite exterior deck components. The Composite Lumber Manufacturers Association (CLMA) seeks to make it easier for code officials to enforce the IBC and to make it easier for deck builders to comply with the code by incorporating requirements for wood plastic composite decking into the IBC.

This code change proposes to include requirements for wood plastic composite exterior deck components in Chapter 23 of the IBC, which is the most appropriate chapter of the IBC for these products. Section 2301.2 refers to elements or systems "constructed partially or wholly of wood or wood-based products". No other IBC chapter incorporates wood-based products of this type.

Wood plastic composite exterior deck components are constructed partially of wood-based material (as are particleboard and composite panels; included in Chapter 23), and partially of resin bonded by heat and pressure (as are several materials included in Chapter 23, such as particleboard). CLMA reviewed Chapter 26, Plastic, but concluded that wood plastic composite exterior deck components are much more closely aligned with the methods of distribution and application to the materials included in Chapter 23 than those in Chapter 26. Moreover, the ASTM standard governing wood plastic composite decking (ASTM D 7032) has been developed by and continues to be maintained by the ASTM D7 committee on wood. For these reasons, this proposal includes revisions to Chapter 23.

This CLMA proposal complements language in the 2009 IRC which defines "wood plastic composite" and requires wood plastic composite deck boards, stair treads, handrails and guardrail systems to bear a label indicating the required performance levels and demonstrating compliance to ASTM D 7032. This labeling requirement, by definition of "label" in the IBC, includes 3rd-party certification and ongoing quality assurance and will help to assure the code official that wood-plastic composite decking will meet the performance provisions in the IBC.

Complying with ASTM D 7032 verifies the wood plastic composite materials are appropriate for use as deck components and includes deck-related performance evaluations such as flexural tests, ultraviolet resistance tests, freeze-thaw resistance tests, bio-deterioration tests, fire performance tests, creep recovery tests, mechanical fastener holding tests, and slip resistance tests. The standard also includes consideration of the effects of temperature and moisture, concentrated loads, and fire propagation tests.

This code change for the IBC will make it faster and easier to verify that a deck constructed of wood plastic composite material complies with the code.

(Part I, item 5) This item adds a new subject matter in 2304.13.1. This new requirement specifies that the load and span information is required on the labels.

This item will make it faster and easier to verify that a deck constructed of wood plastic composite material complies with the code. The wood plastic composite deck boards and stair treads are to have a label indicating the span rating (i.e. 100 lbs/ft^2 at 16" O.C.). Handrails and guardrail systems will be similarly labeled. The load and span information will improve the ability to verify compliance to the code.

(Part I, item 6) This item adds a new subject matter in 2304.13.2 which requires that wood plastic composite deck components be installed per the manufacturer's instructions.

As with most engineered building components, wood plastic composite deck components should be required to be installed per the manufacturer's instructions. It's important that wood plastic composite deck components be installed as intended by the manufacturer.

Cost Impact: The code change proposal will not increase the cost of construction.

Analysis: A review of the standard(s) proposed for inclusion in the code, ASTM D7032-08, for compliance with ICC criteria for referenced standards given in Section 3.6 of Council Policy #CP 28 will be posted on the ICC website on or before September 24, 2009.

ICCFILENAME: WOESTMAN-S7-2304.13.2

Public Hearing Results

Note: The following analysis was not in the Code Change monograph but was published on the ICC website at http://www.iccsafe.org/cs/codes/Documents/2009-10cycle/ProposedChanges/Standards-Analysis.pdf :

Analysis: Review of proposed new standard ASTM D 7032 indicated that, in the opinion of ICC Staff, the standard complies with ICC standards criteria.

PART I- IBC STRUCTURAL
Committee Action: **Disapproved**

Committee Reason: Wood plastic composite materials are currently qualified by evaluation reports and including them in the code is not appropriate at this time. It is important to be able to verify design capacities. The proposed term, structural capacities, may not correlate with the proposed reference standard.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

John Woestman, Kellen Company, representing Composite Lumber Manufacturer's Association, requests Approval as Modified by this Public Comment.

Replace proposal as follows:

CHAPTER 35
COMPOSITES

SECTION 3501
GENERAL

3501.1 Scope. These provisions shall govern the materials, design, application, construction and installation of composite materials and products.

SECTION 3502
DEFINITIONS

3502.1 General. The following words and terms shall, for the purposes of this chapter have the meanings shown herein.

WOOD PLASTIC COMPOSITE. A composite material made primarily from wood or cellulose-based materials, and plastic.

SECTION 3503
WOOD PLASTIC COMPOSITE EXTERIOR MATERIALS AND PRODUCTS

3503.1 General. The provisions of this section shall govern the requirements and uses of wood plastic composite materials and products for exterior decks, balconies, and porches of buildings and structures.

3503.1.1 Wood plastic composite exterior deck boards, stair treads, handrails, and guardrail systems. Exterior deck boards, stair treads, handrails, and guardrail systems of wood plastic composite shall comply with this section.

3503.1.1.1 Minimum standards and quality. Exterior wood plastic composite deck boards, stair treads, and handrails and guardrail systems shall comply with ASTM D 7032.

3503.1.1.2 Structural. The allowable load and maximum allowable span for exterior wood plastic composite deck boards and stair treads shall be determined in accordance with ASTM D 7032. Testing of handrails and guardrail systems to demonstrate compliance to the structural performance requirements of this code shall be in accordance with ASTM D7032.

3503.1.1.3 Labeling. Deck boards and stair treads shall bear a label that indicates compliance to ASTM D 7032 and includes the allowable load and maximum allowable span. Handrails and guardrail systems or their packaging shall bear a label that indicates compliance to ASTM D 7032 and includes the maximum allowable span.

3503.1.1.4 Installation. Wood plastic composite deck components shall be installed in accordance with the manufacturer's instructions.

Add standard to Chapter 3~~5~~6 as follows:

ASTM

D 7032-08 Standard Specification for Establishing Performance Ratings For Wood-Plastic Composite Deck Boards and Guardrail Systems (Guards or Handrails)

(Renumber existing Chapter 35 Reference Standards)

Commenter's Reason: The proponent, the Composite Lumber Manufacturers Association (CLMA), proposed creating a new chapter in the IBC for composite building products as a floor amendment at the Baltimore committee hearings in Oct. 2009. The committee chair ruled the floor amendment "in order." This public comment follows that ruling and proposes to create a new chapter in the IBC for composite building products. This public comment also addresses testimony and committee concerns in the text of the proposal or in the Reason statements. This public comment replaces the original S207 Part 1 proposal.

Currently, the IBC is silent regarding specific requirements for certain composite building materials. Proposals S207 Part 1 (this proposal) and FS189 (by AF&PA) both sought to introduce into the IBC requirements for a specific type of composite building material, wood plastic composite (WPC), used as exterior deck boards, stair treads, handrails and guardrail systems.

Discussion and debate before and during the committee hearings in Baltimore resulted in the conclusion that, rather than place WPCs in the wood chapter of the IBC (Chapter 23) or in the plastics chapter (Chapter 26), a logical location for this material is in a new chapter titled "Composites." Looking to the future, this new chapter creates a logical location in the IBC for other composites that may be utilized in building construction but fall outside the scopes of Chapter 23 and Chapter 26.

This proposal introduces a definition of wood plastic composite and creates a section for exterior materials and products made from this specific material. Then the proposal limits the scope of the requirements to materials and products for exterior decks, balconies, and porches. Finally, the proposal introduces specific requirements for exterior wood plastic composite deck boards, stair treads, handrails, and guardrail systems.

With this proposal, CLMA seeks to introduce mandatory requirements in the IBC for exterior wood plastic composite deck components while making it easier for builders to comply with the code and for building officials to enforce their code.

Including the labeling requirement in this proposal brings WPCs within the requirements of the definition of "label" in Chapter 2 of the IBC, thus requiring 3rd party certification of these WPCs and ongoing quality assurance. This requirement helps to assure building officials that wood plastic composite decking and guards will meet the performance requirements of the IBC.

As with most engineered building components, wood plastic composite deck components should be required to be installed per the manufacturer's instructions.

Addressing the published committee reasons for disapproval:

Committee reason for disapproval: "Wood plastic composite deck boards and guardrail systems are currently qualified by evaluation reports and including them into the Code is not appropriate at this time."

Proponent response: This proposal adds into the IBC sufficient explicit requirements for these specific products; therefore, no longer requiring them to be qualified by evaluation reports. The mandatory requirements of this proposal – testing and compliance to ASTM D7032, labeling, and installation – are based on and compliment existing requirements in the code.

Committee reason for disapproval: "It is important to be able to verify design capabilities."

Proponent response: WPC deck boards, stair treads, and handrail and guardrail systems are engineered products.

This proposal requires wood plastic composite deck boards, stair treads, handrails and guardrail systems to meet the requirements of ASTM D7032, a standard developed specifically for demonstrating code compliance of WPC exterior deck components. Meeting the requirements of ASTM D7032 verifies the engineered WPC products are appropriate for use as exterior deck components. ASTM D7032 includes deck-related performance evaluations and performance requirements such as flexural tests, bio-degradation tests, fire performance tests, creep recovery tests, mechanical fastener holding tests, and slip resistance tests. The standard also includes consideration of the effects of temperature, moisture, concentrated loads, freeze-thaw resistance tests, UV resistance, and duration of load on WPC deck boards, stair treads, and handrail and guardrail systems.

The design capacity of each WPC deck board, stair tread, handrail, and guardrail system is tested and evaluated according to product specification ASTM D7032. The testing required in D7032 addresses IBC requirements for deck boards, stair treads, handrails, and guardrail systems.

The result of these tests determines an allowable load and span rating for deck boards and a stringer spacing for stair treads. Product labels will show verification of compliance with ASTM D 7032 and provide the appropriate performance information. For example, deck board labels would identify the allowable load and span (e.g., 100 psf load on a 16" span would be expressed as "16/100"). For stair treads, ASTM D7032 requires load and span testing at higher loads (300 psf and 750 lb concentrated load). This concentrated load test for WPC stair treads is 2.5 times what's required in the IBC in Table 1607.1, Footnote f.

Guardrail systems, per ASTM D7032, are required to be subjected to and pass the in-fill load test, the uniform load test, and the concentrated load test at 2.5 times the loads required by the IBC (in Sections 1607.7.1.2; 1607.7.1; and 1607.7.1.1 respectively) with the guardrail system constructed according to the manufacturer's instructions. These tests evaluate the strength and stiffness of all components and their connections.

For designers, specifiers, builders, and for code enforcement, the maximum post spacing (span) for guardrail systems is required to be on the label, as is verifying compliance to ASTM D7032. And, of course, guardrail systems for projects constructed under the IBC must meet the requirements of Section 1012 and 1013.

Assuming WPC deck boards, stair treads, and guardrail systems are selected, specified, and installed according to the manufacturer's instructions – and the manufacturer confirms compliance to ASTM D7032 in their literature and on the product label – designing exterior deck projects which use WPC components is quite straightforward: 1) Select WPC deck boards that meet or exceed the required load (per IBC Table 1607.1) at the desired span of the deck's joists. 2) Plan for stair stringers no farther apart than the maximum allowable span for the desired WPC stair treads. 3) Select a WPC guardrail system that meets the minimum height requirements for the project (i.e. 42" for the IBC) and plan for guardrail supports (posts) no further apart than the maximum spacing (span) allowed by the guardrail system's manufacturer.

CLMA recommends approval of S207 Part 1, as modified by this public comment.

Final Action: AS AM AMPC____ D

S207-09/10-PART II
IRC R317.4.1 (New)

Proposed Change as Submitted

Proponent: John Woestman, The Kellen Company representing the Composite Lumber Manufacturers Association

PART II – IRC BUILDING/ENERGY

1. Add new text as follows:

R317.4.1 Labeling. Labels for deck boards and stair treads shall include the allowable maximum load and span. Labels for handrails and guardrail systems shall indicate the allowable maximum span.

2. Revise as follows:

~~**R317.4.1**~~ **R317.4.2 Installation.** Wood/plastic composites shall be installed in accordance with the manufacturer's instructions.

Reason: **(Part II, IRC)** This CLMA proposal complements language proposed for IBC (see Part I, item 5).

This code change for the IRC will make it faster and easier to verify that a deck constructed of wood plastic composite material complies with the code. The wood plastic composite deck boards and stair treads are to have a label indicating the span rating (i.e. 100 lbs/ft^2 at 16” O.C.) in addition to confirming compliance to ASTM D7032. Handrails and guardrail systems will be similarly labeled with their span rating (distance between support posts).

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: WOESTMAN-S7-2304.13.2

Public Hearing Results

PART II- IRC B/E
Committee Action: Disapproved

Committee Reason: The labeling requirements are unclear and present a problem for inspectors after installation. There are no directions for how to label and the location of the label. The labeling should be similar to sheathing that allows the inspector to visibly, easily and readily verify that the proper material is installed.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Rick Davidson, representing self, requests Approval as Submitted.

Commenter’s Reason: Because of the different installation requirements for composite decking, especially when used for stair treads, having this information on the label may eliminate the need for field inspection staff to read through research reports (that may not always be available in the field) in order to approve an installation. It seems that having this additional information would make life easier for both the installer and the field inspector and it should be approved.

Public Comment 2:

John Woestman, Kellen Company, representing Composite Lumber Manufacturer’s Association (CLMA), requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R317.4.1 Labeling. ~~Labels for deck boards and stair treads shall include the allowable maximum load and span. Labels for handrails and guardrail systems shall indicate the allowable maximum span.~~ <u>Deck boards and stair treads shall bear a label that indicates compliance to ASTM D 7032 and includes the allowable load and maximum allowable span. Handrails and guardrail systems or their packaging shall bear a label that indicates compliance to ASTM D 7032 and includes the maximum allowable span.</u>

R317.4.2 Installation. Wood/plastic composites shall be installed in accordance with the manufacturer’s instructions.

Commenter’s Reason: This proposal clarifies mandatory labeling requirements for wood/plastic composites currently in this section of the IRC.

Each deck board and stair tread, similar to pressure-preservative treated wood, is required to have a label. The required label would be applied on an end or on a face (side) of each board. Product labels will show verification of compliance with ASTM D 7032 and provide the appropriate performance information. For example, deck board labels would identify the allowable load and span (e.g., 40 psf load on a 16” span would be expressed as “16/40”).

Handrails and guardrail systems, which are more often supplied as “kits” in packages, require labels on the items or on the packaging. For ease of code enforcement, the maximum span (maximum vertical post spacing) is required to be on the label, as is verifying compliance to ASTM D7032.

In summary, for ease of code enforcement, this code change clarifies / adds items required on the labels to be placed on wood/plastic composite deck boards, stair treads, handrails, and guardrail systems. CLMA recommends approval of S207 Part 2, as modified by this public comment.

Final Action: AS AM AMPC____ D

S211-09/10
2308.3.2, 2308.3.2.1 (New), 2308.3.2.2 (New), 2308.12.6

Proposed Change as Submitted

Proponent: Robert Rice, Grants Pass, representing Josephine County Building Safety and Southern Oregon Chapter International Code Council.

Revise as follows:

2308.3.2 Braced wall line connections. Wind and seismic lateral forces shall be transferred from the roof ~~roofs~~ and floor ~~floors~~ diaphragms to braced wall lines and from the braced wall lines in upper stories to the braced wall lines in the story below in accordance with ~~this section~~ Sections 2308.3.2.1 and 2308.3.2.2.

2308.3.2.1 Bottom plate connection. Braced wall line bottom plates shall be connected to joists or full-depth blocking below in accordance with Table 2304.9.1, Item 6, or to foundations in accordance with Section 2308.3.3.

2308.3.2.2 Top plate connection. Where joists or rafters are used, braced wall line top plates shall be fastened to joists, rafters or full-depth blocking above in accordance with Table 2304.9.1, Items 11, 12, 15 or 19 as applicable based on the orientation of the joists or rafters to the braced wall line. ~~Braced wall line bottom plates shall be connected to joists or blocking below in accordance with Table 2304.9.1, Item 6, or to foundations in accordance with Section 2308.3.3.~~ Blocking shall be a minimum of 2 inches (51 mm) nominal in thickness and equal to the depth of the joist or rafter at the wall line and shall be fastened to the braced wall line top plate as specified in Table 2304.9.1, Item 11.

> **Exception:** Blocking at rafters need not be full depth when there are no braced wall lines above but shall extend to within 2 inches (51 mm) from the sheathing above.

At exterior gable end walls braced wall panel sheathing in the top *story* shall be extended and fastened to roof framing where the spacing between parallel exterior braced wall lines is greater than 50 feet (15240 mm).

> ~~**Exception:**~~ Where roof trusses are used and are installed perpendicular to an exterior braced wall line, lateral forces shall be transferred from the roof diaphragm to the braced wall by blocking of the ends of the trusses or by other *approved* methods providing equivalent lateral force transfer. Blocking shall be minimum 2 inch (51 mm) nominal thickness and equal to the depth of the truss at the wall line and shall be fastened to the braced wall line top plate as specified in Table 2304.9.1, Item 11

2308.12.6 Irregular structures. *Conventional light-frame construction* shall not be used in irregular portions of structures in *Seismic Design Category* D or E. Such irregular portions of structures shall be designed to resist the forces specified in Chapter 16 to the extent such irregular features affect the performance of the conventional framing system. A portion of a structure shall be considered to be irregular where one or more of the conditions described in Items 1 through 6 below are present.

1. Where exterior braced wall panels are not in one plane vertically from the foundation to the uppermost *story* in which they are required, the structure shall be considered to be irregular [see Figure 2308.12.6(1)].

   Exception: Floors with cantilevers or setbacks not exceeding four times the nominal depth of the floor joists [see Figure 2308.12.6(2)] are permitted to support braced wall panels provided:

   1. Floor joists are 2 inches by 10 inches (51mm by 254 mm) or larger and spaced not more than 16 inches (406 mm) o.c.
   2. The ratio of the back span to the cantilever is at least 2:1.
   3. Floor joists at ends of braced wall panels are doubled.
   4. A continuous rim joist is connected to the ends of cantilevered joists. The rim joist is less than 0.058 inch (1.47 mm) (16 galvanized gage) and 11/2 inches (38 mm) wide fastened with six 16d common nails on each side. The metal tie shall have a minimum yield of 33,000 psi (227 MPa).
   5. Joists at setbacks or the end of cantilevered joists shall not carry gravity loads from more than a single *story* having uniform wall and roof loads, nor carry the reactions from headers having a span of 8 feet (2438 mm) or more.

2. Where a section of floor or roof is not laterally supported by braced wall lines on all edges <u>and connected in accordance with Section 2308.3.2,</u> the structure shall be considered to be irregular [see Figure 2308.12.6(3)].

    Exception: Portions of roofs or floors that do not support braced wall panels above are permitted to extend up to 6 feet (1829 mm) beyond a braced wall line [see Figure 2308.12.6(4)] <u>provided that the framing members are connected to the braced wall line below in accordance with Section 2308.3.2.</u>

3. Where the end of a required braced wall panel extends more than 1 foot (305 mm)over an opening in the wall below, the structure shall be considered to be irregular. This requirement is applicable to braced wall panels offset in plane and to braced wall panels offset out of plane as permitted by the exception to Item 1 above in this section [see Figure 2308.12.6(5)].

    Exception: Braced wall panels are permitted to extend over an opening not more than 8 feet (2438 mm) in width where the header is a 4-inch by 12-inch (102 mm by 305 mm) or larger member.

4. Where portions of a floor level are vertically offset such that the framing members on either side of the offset cannot be lapped or tied together in an *approved* manner, the structure shall be considered to be irregular [see Figure 2308.12.6(6)].

    Exception: Framing supported directly by foundations need not be lapped or tied directly together.

5. Where braced wall lines are not perpendicular to each other, the structure shall be considered to be irregular [see Figure 2308.12.6(7)].

6. Where openings in floor and roof diaphragms having a maximum dimension greater than 50 percent of the distance between lines of bracing or an area greater than 25 percent of the area between orthogonal pairs of braced wall lines are present, the structure shall be considered to be irregular [see Figure 2308.12.6(8)].

Reason: This code section addresses the connection of braced wall lines to framing above and below to transfer lateral (wind and seismic) forces into the roof and floor diaphragms. This proposal does not add any new requirements. First, in Section 2308.3.2, this proposal separates the top plate connection requirements from the bottom plate connections for clarity. Secondly, in section 2308.12.6, a reference is added to point to the connection requirements in 2308.3.2.

Purpose: As currently written, the text of the code combines top plate and bottom plate connections in the same paragraph. Top plate connection requirements at roofs and ceilings are typically different than connections to floors above. At roofs, rafters or trusses are used and pose different challenges as opposed to flat floor joists. This proposal is intended to make the section read more clearly as well as arrange it to work with another proposal revising this section that will provide prescriptive solutions for connections at the top plate to the roof diaphragm when full-depth, solid blocking will not work or is impractical.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: RICE-S1-2308.3.2

<u>Public Hearing Results</u>

Committee Action: **Approved as Modified**

Modify the proposal as follows:

2308.3.2.2 Top plate connection. Where joists <u>and/</u>or rafters are used, braced wall line top plates shall be fastened to joists, rafters<u>, rimboards</u> or ~~full-depth~~ blocking above in accordance with Table 2304.9.1, Items 11, 12, 15 or 19 as applicable based on the orientation of the joists or rafters to the braced wall line. Blocking <u>at joists with walls above</u> ~~shall be a minimum of 2 inches (51 mm) nominal in thickness and~~ <u>shall be</u> equal to the depth of the joist ~~or rafter~~ at the <u>braced</u> wall line ~~and shall be fastened to the braced wall line top plate as specified in Table 2304.9.1, Item 11~~. ~~**Exception:**~~ Blocking at rafters need not be full depth ~~when there are no braced wall lines above~~ but shall extend to within 2 inches (51 mm) from the <u>roof</u> sheathing above. <u>Blocking shall be a minimum of 2 inches (51 mm) nominal in thickness and shall be fastened to the braced wall line top plate as specified in Table 2304.9.1, Item 11.</u>

At exterior gable end walls braced wall panel sheathing in the top *story* shall be extended and fastened to roof framing where the spacing between parallel exterior braced wall lines is greater than 50 feet (15240 mm).

Where roof trusses are used and are installed perpendicular to an exterior braced wall line, lateral forces shall be transferred from the roof diaphragm to the braced wall by blocking of the ends of the trusses or by other *approved* methods providing equivalent lateral force transfer. Blocking shall be minimum 2 inch (51 mm) nominal thickness and equal to the depth of the truss at the wall line and shall be fastened to the braced wall line top plate as specified in Table 2304.9.1, Item 11

(Portions of proposal not shown are unchanged)

Committee Reason: This code change clarifies what's required for braced wall line connections by breaking out the requirements for top plate and bottom plate. This is often difficult to accommodate while addressing energy code and ventilation issues. There are unresolved issues with the 2 inch gap allowed at rafters, but it is considered acceptable. The modification cleans up the proposed wording and provides an acceptable starting point for getting these clarifications into the code.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Gary J. Ehrlich, PE National Association of Home Builders, requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

2308.3.2.2 Top plate connection. Where joists and/or rafters are used, braced wall line top plates shall be fastened to joists, rafters, rimboards or blocking above in accordance with Table 2304.9.1, Items 11, 12, 15 or 19 as applicable based on the orientation of the joists or rafters to the braced wall line. Blocking at joists with walls above shall be equal to the depth of the joist at the braced wall line. Blocking at rafters need not be full depth but shall extend to within 2 inches (51 mm) from the roof sheathing above. Blocking shall be a minimum of 2 inches (51 mm) nominal in thickness and shall be fastened to the braced wall line top plate as specified in Table 2304.9.1, Item 11. <u>Notching or drilling of holes in blocking in accordance with the requirements of Section 2308.8.2 or Section 2308.10.4.2 shall be permitted.</u>

At exterior gable end walls braced wall panel sheathing in the top *story* shall be extended and fastened to roof framing where the spacing between parallel exterior braced wall lines is greater than 50 feet (15240 mm).

Where roof trusses are used and are installed perpendicular to an exterior braced wall line, lateral forces shall be transferred from the roof diaphragm to the braced wall by blocking of the ends of the trusses or by other *approved* methods providing equivalent lateral force transfer. Blocking shall be minimum 2 inch (51 mm) nominal thickness and equal to the depth of the truss at the wall line and shall be fastened to the braced wall line top plate as specified in Table 2304.9.1, Item 11. <u>Notching or drilling of holes in blocking in accordance with the requirements of Section 2308.8.2 or Section 2308.10.4.2 shall be permitted.</u>

(Portions of proposal not shown are unchanged)

Commenter's Reason: The purpose of this public comment is to amend the blocking provisions approved at the Public Hearings in Baltimore. Increased requirements for ventilation of attic and roof spaces are being introduced in the energy codes. These provisions conflict with requirements for solid full-depth blocking, necessitating engineered solutions. Some of these engineered details are quite complex, often involving double rows of blocking. Often, "pre-engineered" blocking with pre-drilled holes is provided. The language proposed here would permit the application of the prescriptive drilling and notching requirements currently allowed for joists and rafters to be used for blocking. A similar change was approved last cycle for Section R802.7.1 of the IRC.

Public Comment 2:

Larry Wainright, Qualtim, Inc, representing Structural Building Components Association, (SBCA), requests Approval as Modified by this Public Comment.

Further modify the proposal as follows:

2308.3.2.2 Top plate connection. Where joists and/or rafters are used, braced wall line top plates shall be fastened to joists, rafters, rimboards or blocking above in accordance with Table 2304.9.1, Items 11, 12, 15 or 19 as applicable based on the orientation of the joists or rafters to the braced wall line. Blocking at joists with walls above shall be equal to the depth of the joist at the braced wall line. Blocking at rafters need not be full depth but shall extend to within 2 inches (51 mm) from the roof sheathing above. Blocking shall be a minimum of 2 inches (51 mm) nominal in thickness and shall be fastened to the braced wall line top plate as specified in Table 2304.9.1, Item 11.

At exterior gable end walls braced wall panel sheathing in the top *story* shall be extended and fastened to roof framing where the spacing between parallel exterior braced wall lines is greater than 50 feet (15240 mm).

Where roof trusses are used and are installed perpendicular to an exterior braced wall line, lateral forces shall be transferred from the roof diaphragm to the braced wall by blocking of the ends of the trusses or by other *approved* methods providing equivalent lateral force transfer. Blocking shall be minimum 2 inch (51 mm) nominal thickness and ~~equal to the depth of the truss at the wall line~~ <u>shall extend to within 2 inches (51 mm) from the roof sheathing above</u> and shall be fastened to the braced wall line top plate as specified in Table 2304.9.1, Item 11.

(Portions of proposal not shown are unchanged)

Commenter's Reason: The purpose of this change is to maintain consistency between differing products used in the same application. The modification that was approved at the code development hearings allow the blocking between rafters to extend to within 2" of the roof sheathing to allow for proper ventilation. This provision was inadvertently left out of the same provision for roof trusses.

Public Comment 3:

Steven Winkel, FAIA, PE, and Kelly Cobeen, PE, SE, representing the Federal Emergency Management Agency/Building Seismic Safety Council Code Resource Support Committee (FEMA/BSSC CRSC); Alan Robinson, representing the Structural Engineers Association of California, request Approval as Modified by this Public Comment.

Further modify the proposal as follows:

2308.3.2.2 Top plate connection. Where joists and/or rafters are used, braced wall line top plates shall be fastened <u>over the full length of the braced wall line</u> to joists, rafters, rimboards or blocking above in accordance with Table 2304.9.1, Items 11, 12, 15 or 19 as applicable based on the orientation of the joists or rafters to the braced wall line. Blocking at joists with walls above shall be equal to the depth of the joist at the braced wall line. Blocking at rafters need not be full depth but shall extend to within 2 inches (51 mm) from the roof sheathing above. Blocking shall be a minimum of 2 inches (51 mm) nominal in thickness and shall be fastened to the braced wall line top plate as specified in Table 2304.9.1, Item 11.

At exterior gable end walls braced wall panel sheathing in the top *story* shall be extended and fastened to roof framing where the spacing between parallel exterior braced wall lines is greater than 50 feet (15240 mm).

Where roof trusses are used and are installed perpendicular to an exterior braced wall line, lateral forces shall be transferred from the roof diaphragm to the braced wall <u>over the full length of the braced wall line</u> by blocking of the ends of the trusses or by other *approved* methods providing equivalent lateral force transfer. Blocking shall be minimum 2 inch (51 mm) nominal thickness and equal to the depth of the truss at the wall line and shall be fastened to the braced wall line top plate as specified in Table 2304.9.1, Item 11.

(Portions of proposal not shown are unchanged)

Commenter's' Reason: This public comment clarifies the required extent of shear transfer connections for braced wall panels. A related public comment to RB 109 clarifies similar construction in the IRC. The purpose of these connections is to transfer seismic and wind loads from the roof to the wall below or from wall above to wall below. This code change as approved by the IBC structural committee permits the addition of a 2-inch gap between the top of blocking and the roof sheathing, which reduces the strength and capacity of the roof system and the shear transfer connection. There is not adequate research available to demonstrate that the reduced strength and stiffness are sufficient when blocking is limited to the length of the braced wall panel. Extension of the blocking over the full braced wall line length replicates common existing construction that has a history of adequate performance.

S212-09/10

2308.3.2, Figure 2308.3.2(1) (New), Figure 2308.3.2(2) (New)

<u>Proposed Change as Submitted</u>

Proponent: Robert Rice, Grants Pass, OR, representing Josephine County Building Safety and Southern Oregon Chapter International Code Council.

Revise as follows:

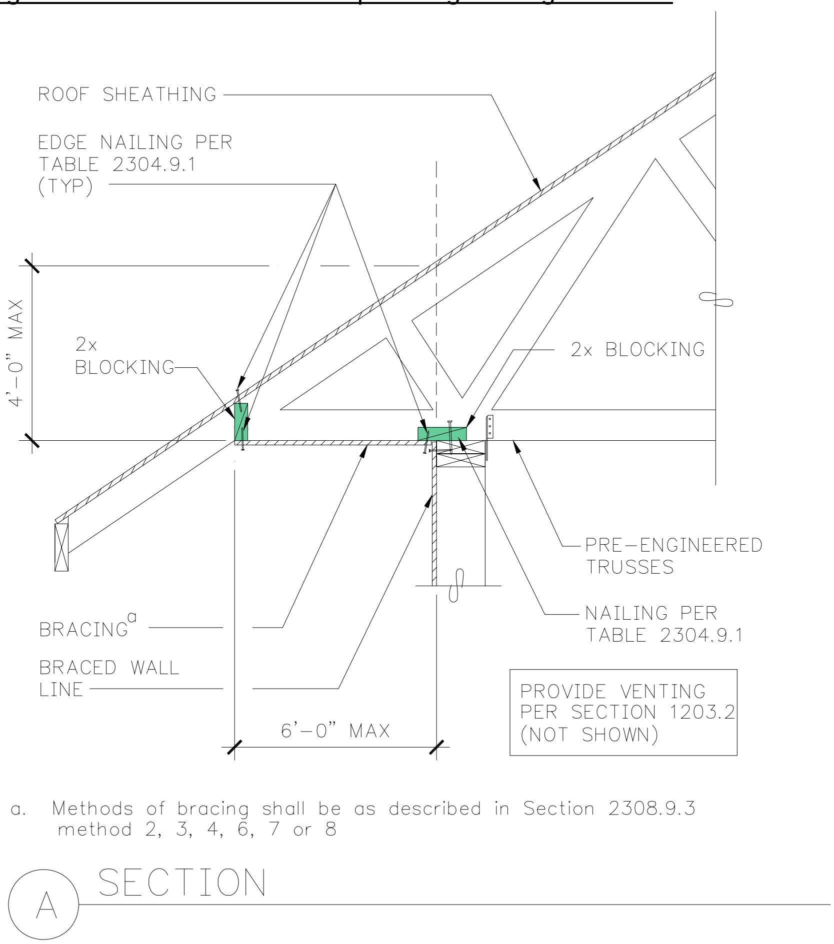
2308.3.2 Braced wall line connections. Wind and seismic lateral forces shall be transferred from the roofs and floors to braced wall lines and from the braced wall lines in upper stories to the braced wall lines in the story below in accordance with is section.

Braced wall line top plates shall be fastened to joists, rafters or full-depth blocking above in accordance with Table 2304.9.1, Items 11, 12, 15 or 19 as applicable based on the orientation of the joists or rafters to the braced wall line. Braced wall line bottom plates shall be connected to joists or blocking below in accordance with Table 2304.9.1, Item 6, or to foundations in accordance with Section 2308.3.3. At exterior gable end walls, braced wall panel sheathing in the top story shall be extended and fastened to roof framing where the spacing between parallel exterior braced wall lines is greater than 50 feet (15 240 mm).

~~**Exception:**~~ Where roof trusses are used and are installed perpendicular to an exterior braced wall line, lateral forces shall be transferred from the roof diaphragm to the braced wall by blocking of the ends of the trusses or by other approved methods providing equivalent lateral force transfer. Blocking shall be a minimum of 2 inches (51 mm) nominal in thickness and equal to the depth of the truss at the wall line and shall be fastened to the braced wall line top plate as specified in Table 2304.9.1, Item 11.

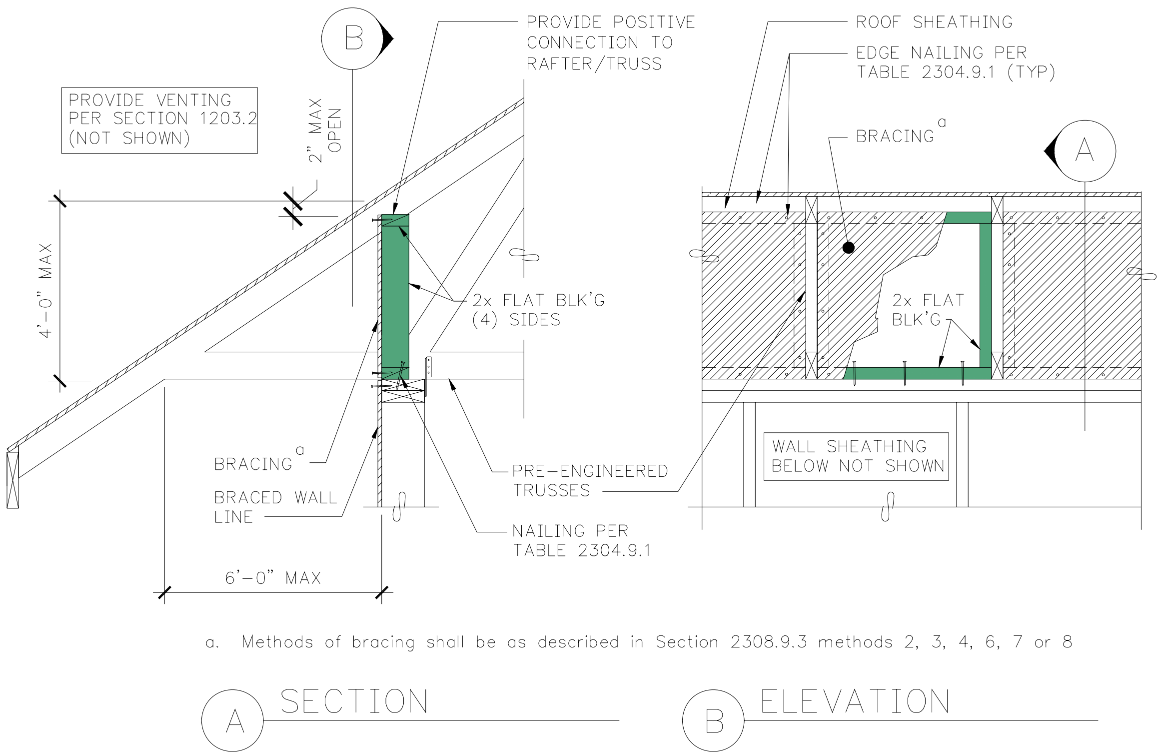
Exceptions:

1. For buildings that are classified as Seismic Design Category A, B or C and the basic wind speed is less than 100 mph (45 m/s) where the framing members are perpendicular to the wall line below and the distance from the top plate to the sheathing above is less than 9 1/4 inches (235 mm) solid blocking need not be provided when the perpendicular framing members or a parallel member such as a continuous rim joist or header is attached to the wall line in accordance with Table 2304.9.1.
2. Where the roof sheathing is greater than 9-1/4 inches (235 mm) above the top plate solid blocking is not required when the framing members are connected in accordance with one of the following methods:
   - 2.1 In accordance with Figure 2308.3.2 (1)
   - 2.2 In accordance with Figure 2308.3.2 (2)
   - 2.3 With full height engineered blocking panels designed for values listed in AF&PA WFCM.
   - 2.4 Designed in accordance with accepted engineering methods.



For SI: 1 inch = 25.4 mm

FIGURE 2308.3.2 (1)
BRACED WALL PANEL TOP PLATE CONNECTION



For SI: 1 inch = 25.4 mm

FIGURE 2308.3.2 (2) BRACED WALL PANEL TOP PLATE CONNECTION

Reason: The 2006 IBC had fairly clear wording that the diaphragms need to be connected to the braced wall lines. With the approval of proposal 2008/2009 S224 the 2009 language was modified to make the purpose even more clear in that the connection is required to resist wind and seismic (lateral) forces. This proposal merely provides prescriptive methods to accomplish the connection whether with solid blocking or when solid blocking doesn't work.

In addition, another proposal that I have submitted rearranges the existing section to separate top plate connections from bottom plate connections since roof connections at the top plate differ from conditions where there is floor framing above. The two proposals are intended to work together and are shown at the end of the purpose statement combined as one.

Purpose: The current text of the IBC states the intention of connecting the braced wall line to the roof or floor diaphragm above in section 2308.3.2. A similar version of this proposal was adopted as an Oregon amendment for the adoption of the 2006 IBC (and the recent adoption of the 2009 IBC) and has worked well. Since then, countless hours have gone into developing proposals for both the IRC and the IBC in the 2009 code development process. The proposal for the IRC (which was the main focus) was successful and was approved for the 2009 IRC. The details for that proposal are the same ones submitted for this proposal. During the process of resolving opposition and developing a consensus two main changes were made to the proposals. First, based on engineering reports and historical data, an exception was made for low heel connections (9 ¼") in lower wind and seismic zones to not require the blocking. Second, the details for the high-heel blocking was modified to allow a 2" gap at the top to allow for venting (again, backed up by engineering data). Following the approval for the 2009 IRC an article was published in the Spring 2009 issue of *Wood Design Focus* addressing the issue. The article, "*When is Roof Eave Blocking Required?", states, Because the 2006 IRC lacks clarity on when roof eave blocking is required for lateral force transfer, IRC users and code officials are forced to interpret its intent on a case by case basis, often with varied results." "Fortunately, Section R602.10.6.2 of the 2009 IRC provides a reasonable solution that addresses the above concerns, places reasonable limits on past successful practices, and avoids the pitfalls of the 2006 IRC…..".*

This proposal does not add additional requirements to the code. This proposal clarifies that the connection needs to occur and provides prescriptive solutions when solid blocking in not possible or is impractical.

Per accepted engineering practice for lateral design loads, the floor and roof diaphragms transmit wind and seismic loads into the braced walls (engineered shearwalls or prescriptive braced panels). The fact that the diaphragm needs to be connected to the braced wall line is often not fully understood by plans examiners, inspectors and contractors. The typical requirement that is intended by the code is that solid blocking occur at this connection with the blocking connected to the top plate of the wall to transfer the diaphragm (plf) force to the wall top plates. This is evidenced in the IBC by the exception to irregular structures stating, *"..lateral forces shall be transferred from the roof diaphragm to the braced wall by blocking of the ends of the trusses.."*. In order for the forces to be transferred there has to be a connection capable of transferring the diaphragm shear evenly to the top plates.

The condition that occurs at an increasing rate that brings this issue up is with cantilevered or high stub-heel trusses. In that construction method solid blocking (either with 2x or engineered wood products) is often not possible due to the height of the diaphragm above the top plate of the wall.

Without this clarification of the text it is a connection that may or may not occur based on what I have seen in the field and have discussed with code officials. The blocking that is called for in the code serves three functions. It provides closure to prevent animals, birds, etc. from entering the attic space, it prevents the trusses or rafters from "rolling over" and it transfers the diaphragm forces to the wall. Most code officials, inspectors and contractors understand the first two objectives. However, the latter is a concept that is often not fully understood. This needs to be perceived, understood and implemented in a uniform way.

In addition, rather than identify a problem without providing a solution, my proposal includes two details to accomplish this connection simply. The solutions are, in principle, fundamentally extending the braced wall sheathing to the roof diaphragm either vertically in the truss bays or horizontally through the soffit. No engineering or testing is required since it is just completing the load path with the already defined sheathing and nailing.

Without prescriptive provisions in the current code this condition would require engineering or, as stated in 2308.3.2, Exception to item 1 "..by other approved methods." would be left up to the Authority Having Jurisdiction to determine what is acceptable without any guidance or uniformity between jurisdictions.

Typically, the engineering solution would provide details similar to those included in this proposal. Therefore, the solution and construction costs would not change. Costs would be reduced by eliminating additional costs for engineering where these prescriptive solutions work.

If approved, the two proposals I have submitted for section 2308.3.2 would read as shown below when combined:

2308.3.2 Braced wall line connections. Wind and seismic lateral forces shall be transferred from the roof and floor diaphragms to braced wall lines and from the braced wall lines in upper stories to the braced wall lines in the story below in accordance with this sections 2308.3.2.1 and 2308.3.2.2.
2308.3.2.1 Bottom plate connection. Braced wall line bottom plates shall be connected to joists or full depth blocking below in accordance with Table 2304.9.1, Item 6, or to foundations in accordance with Section 2308.3.3.
2308.3.2.2 Top plate connection. Where joists or rafters are used, braced wall line top plates shall be fastened to joists, rafters or full-depth blocking above in accordance with Table 2304.9.1, Items 11, 12, 15 or 19 as applicable based on the orientation of the joists or rafters to the braced wall line. Blocking shall be a minimum of 2 inches (51 mm) nominal in thickness and equal to the depth of the truss at the wall line and shall be fastened to the braced wall line top plate as specified in Table 2304.9.1, Item 11.

Exception: Blocking at rafters need not be full depth when there are no braced wall lines above but shall extend to within 2 inches (51mm) from the sheathing above.

At exterior gable end walls, braced wall panel sheathing in the top story shall be extended and fastened to roof framing where the spacing between parallel exterior braced wall lines is greater than 50 feet (15 240 mm).

Where roof trusses are used and are installed perpendicular to an exterior braced wall line, lateral forces shall be transferred from the roof diaphragm to the braced wall by blocking of the ends of the trusses or by other approved methods providing equivalent lateral force transfer. Blocking shall be a minimum of 2 inches (51 mm) nominal in thickness and equal to the depth of the truss at the wall line and shall be fastened to the braced wall line top plate as specified in Table 2304.9.1, Item 11.

Exceptions:

1. For Seismic Design Categories C and less and wind speed zones less than 100 mph where the rafters, joists or trusses are perpendicular to the wall line below and the distance from the top plate is less than 9 ¼ inches (235 mm) solid blocking need not be provided when the perpendicular framing members or a parallel member such as a continuous rim joist or header is attached to the wall line per Table 2304.9.1
2. Where the roof sheathing is greater than 9-1/4 inches (235 mm) above the top plate solid blocking is not required when the rafters, joists or trusses are connected in accordance with one of the following methods:

    1. In accordance with Figure 2308.3.2 (1)
    2. In accordance with Figure 2308.3.2 (2)
    3. With full height engineered blocking panels designed for values listed in American Forest and Paper Association (AF&PA) Wood Frame Construction Manual for One- and Two-Family Dwellings (WFCM).
    4. Designed in accordance with accepted engineering methods.

Bibliography: "When is Roof Eave Blocking Required*", by Jay H. Crandell, P.E., Robert Rice, Brian Foley, P.E., and Frank Woeste, PhD, P.E Volume 19, Number 1, Spring 2009 Wood Design Focus, a quarterly publication of Forest Products Society, Madison WI..*

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: RICE-S2-2308.3.2

Public Hearing Results

Committee Action: Disapproved

Committee Reason: The proposed prescriptive requirements for braced wall panel top plate connections are not exactly like those in the IRC and there are different triggers. There were concerns expressed with the stability of the remote blocking option.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Robert Rice, Josephine County, OR, representing Southern Oregon Chapter of ICC requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

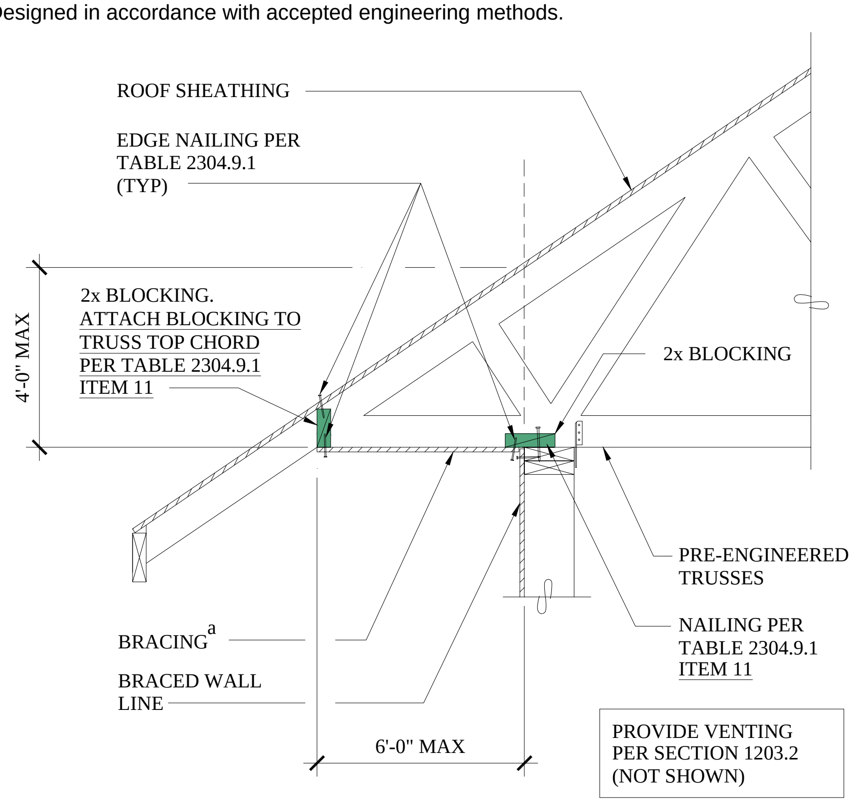
2308.3.2 Braced wall line connections. Wind and seismic lateral forces shall be transferred from the roofs and floors to braced wall lines and from the braced wall lines in upper stories to the braced wall lines in the story below in accordance with is section.

Braced wall line top plates shall be fastened to joists, rafters or full-depth blocking above in accordance with Table 2304.9.1, Items 11, 12, 15 or 19 as applicable based on the orientation of the joists or rafters to the braced wall line. Braced wall line bottom plates shall be connected to joists or blocking below in accordance with Table 2304.9.1, Item 6, or to foundations in accordance with Section 2308.3.3. At exterior gable end walls, braced wall panel sheathing in the top story shall be extended and fastened to roof framing where the spacing between parallel exterior braced wall lines is greater than 50 feet (15 240 mm).

Where roof trusses are used and are installed perpendicular to an exterior braced wall line, lateral forces shall be transferred from the roof diaphragm to the braced wall by blocking of the ends of the trusses or by other approved methods providing equivalent lateral force transfer. Blocking shall be a minimum of 2 inches (51 mm) nominal in thickness and equal to the depth of the truss at the wall line and shall be fastened to the braced wall line top plate as specified in Table 2304.9.1, Item 11.

Exceptions:

1. For Seismic Design Categories C and less and wind speed zones less than 100 mph ~~For buildings that are classified as Seismic Design Category A, B or C and the basic wind speed is less than 100 mph (45 m/s)~~ where the framing members are perpendicular to the wall line below and the distance from the top plate to the sheathing above is less than 9 1/4 inches (235 mm) full-height ~~solid~~ blocking need not be provided when the perpendicular framing members or a parallel member such as a continuous rim joist or header is attached to the wall line in accordance with Table 2304.9.1.
2. Where the roof sheathing is greater than 9-1/4 inches (235 mm) above the top plate solid full-height blocking is not required when the framing members are connected in accordance with one of the following methods:
   ~~2.1~~ 1. In accordance with Figure 2308.3.2 (1)
   ~~2.2~~ 2. In accordance with Figure 2308.3.2 (2)
   ~~2.3~~ 3. With full height engineered blocking panels designed for values listed in AF&PA WFCM.
   ~~2.4~~ 4. Designed in accordance with accepted engineering methods.



a. Methods of bracing shall be as described in Section 2308.9.3 method 2, 3, 4, 6, 7 or 8

For SI: 1 inch = 25.4 mm

FASTENING SCHEDULE

CONNECTION	FASTENING[a],	LOCATION
1. Joist to sill or girder	3 - 8d common (21/2" x 0.131") 3 – 3" x 0.131" nails 3 – 3" 14 gage staples	toenail
2. Bridging to joist	2 - 8d common (21/2" x 0.131") 2 – 3" x 0.131" nails 2 – 3" 14 gage staples	toenail each end
11. Blocking between joists, ~~or~~ rafters or trusses to top plate	3 - 8d common (21/2" x 0.131") 3 – 3" x 0.131" nails 3 – 3" 14 gage staples	toenail
Blocking between rafters or truss chords, not at the wall top plate, to rafter or truss	2 - 8d common (21/2" x 0.131") 2 – 3" x 0.131" nails 2 – 3" 14 gage staples	toenail each end
	2 - 16d common (31/2" x 0.162") 3 – 3" x 0.131" nails 3 – 3" 14 gage staples	endnail

(Portions of table not shown are unchanged)

Commenter's Reason: The 2006 IBC had fairly clear wording that the diaphragms need to be connected to the braced wall line. With the approval of proposal 2008/2009 S224 the 2009 language was changed to make the purpose even more clear in that the connection is required to resist wind and seismic (lateral) forces. In addition, I submitted S211 09/10 and it was approved by committee in Baltimore. S211 09/10 rearranges the existing section 2308.3.2 to separate top plate connections from bottom plate connections since roof connections at the top plate differ from conditions where there is floor framing above. It also allows the blocking at the roof to have a maximum 2 inch gap from the roof sheathing to the blocking to allow venting. S211 09/10 and S212 09/10 are intended to work together and are shown combined at the end of this public comment.

At the code development hearings the committee expressed concern the details provided could be used on large buildings of five, six or more stories and were reluctant to not stay with the “solid full-height” blocking. In reality, the prescriptive provisions of “conventional light-frame construction” as provided for in section 2308 are very limited in scope. In section 2308.2 they are limited to:

1. Three stories max (two stories max in SDC C, one story in SDC D and above)
2. Max floor to floor height of 11’-7”
3. Max dead loads of 15 psf
4. Floor live load of 40 psf max
5. Ground snow 50 psf max
6. Wind speeds 100 max (w/ exception)
7. Roof truss span of 40 feet max between support
8. Occupancy Category IV buildings not allowed in SDC B,C,D,E or F
9. Limited by “irregular structures” definitions in 2308.12.6
10. More restrictive requirements for SDC B and above defined in 2308.11.
11. Braced wall line spacing 35 feet max each direction, each floor. In SDC D and E max spacing is 25 feet. (IRC allow exception up to 50 feet)

In other words, due to the limitations listed above as well as the other limitations in the code not listed here, the structures that are built with the provisions of section 2308 are small, light-framed buildings that do not have the significant lateral loading that other buildings do.

There was item that was raised by the committee regarding figure 2308.3.2(2). It was not specified in the detail how the top blocking is to attach to the truss or rafter. The note, “Nailing per table 2304.9.1” only pointed to the bottom blocking nailing to the top plate. At the hearings I pointed out that the significant load that this detail addresses is in the plane of the wall and that the blocking would be nailed in place by typical construction methods and was not a significant factor. This blocking is similar to 2x bridging that is often installed at the mid-span of joists. Table 2304.9.1 specifies fasteners for bridging in item 2. Item 11 of the table addresses the fasteners for the blocking between joists and rafters to the wall top plate. This public comment adds the same fasteners as bridging in item 2 to item 11 of the table where blocking between joists or rafters is not at the wall top plate. (Note: “trusses” was added to the existing table item but is merely editorial and has no bearing or impact on this proposal)

This proposal merely provides direction to accomplish the connection. It provides three prescriptive options when solid blocking doesn’t work.

Purpose: The current code text (IBC) states the intention of connecting the braced wall line to the roof or floor diaphragm above in section 2308.3.2. A similar version of this proposal was adopted as an Oregon amendment for the adoption of the 2006 IBC and has worked well. Since then, countless hours have gone into developing proposals for both the IRC and the IBC in the 2009 code development process. The IRC proposal was approved in Minneapolis. During the process of resolving concerns and developing a consensus changes were made to the proposal. Based on engineering reports and historical data, an exception was made for low heel connections (9 ¼”) in lower wind and seismic zones to not require the blocking.

This proposal does not add additional requirements to the code. This proposal clarifies that the connection needs to occur and provides prescriptive solutions when solid blocking, per the current text, is not possible or is impractical..

Per accepted engineering practice for lateral design loads, the floor and roof diaphragms transmit wind and seismic loads into the braced walls (engineered shearwalls or prescriptive braced panels). The fact that the diaphragm needs to be connected to the braced wall line to complete the load path is often not fully understood by plans examiners, inspectors and contractors. The typical requirement that is intended by the code is that full height solid blocking occur at this connection with edge nailing to the blocking and the blocking connected to the top plate of the wall to transfer the diaphragm (plf) force to the wall top plates. This is evidenced in the IBC by the exception to irregular structures stating, *“..lateral forces shall be transferred from the roof diaphragm to the braced wall by blocking of the ends of the trusses..”*. In order for the forces to be transferred there has to be a connection capable of transferring the diaphragm shear evenly to the top plates.

The condition that occurs at an increasing rate that brings this issue up is with cantilevered or stub-heel trusses. In that construction method solid blocking (either with 2x or engineered wood products) is often not possible due to the height of the diaphragm above the top plate of the wall.

Without this clarification of the text it is a connection that may or may not occur based on what I have seen in the field and have discussed with code officials. The blocking that is called for in the code serves three functions. It provides closure to prevent animals, birds, etc. from entering the attic space, it prevents the trusses or rafters from “rolling over” and it transfers the diaphragm forces to the wall. Most code officials, inspectors and contractors understand the first two objectives. However, the latter is a concept that is often not fully understood. This needs to be perceived, understood and implemented in a uniform way.

In addition, rather than identify a problem without providing a solution, my proposal includes two details to accomplish this connection simply. The solutions are, in principle, fundamentally extending the roof diaphragm sheathing to the wall top plates either vertically in the truss bays or horizontally through the soffit. No engineering or testing is required since it is just completing the load path with the already defined sheathing and nailing.

Without prescriptive provisions in the current code this condition would require engineering or, as stated in 2308.3.2, Exception to item 1 “..by other approved methods.” would be left up to the Authority Having Jurisdiction to determine what is acceptable without any guidance or uniformity between jurisdictions.

Typically, the engineering solution would provide details similar to those included in this proposal. Therefore, the solution and construction costs would not change. Costs would be reduced by eliminating additional costs for engineering where these prescriptive solutions work.

I had also submitted proposal S211 09/10 for this same code section and it was approved by committee in Baltimore. S211 09/10 reorganizes section 2308.3.2. If this public comment to S212 is approved, section 2308.3.2 would read as shown below when the two are combined:

2308.3.2 Braced wall line connections. *Wind and seismic lateral forces shall be transferred from the roof~~s~~ and floor diaphragms to braced wall lines and from the braced wall lines in upper stories to the braced wall lines in the story below in accordance with this section.*

2308.3.2.1 Bottom plate connection. *Braced wall line bottom plates shall be connected to joists or full-depth blocking below in accordance with Table 2304.9.1, Item 6, or to foundations in accordance with Section 2308.3.3.*

2308.3.2.2 Top plate connection. *Where joists and/or rafters are used, braced wall line top plates shall be fastened to joists, rafters, rimboard or blocking above in accordance with Table 2304.9.1, Items 11, 12, 15 or 19 as applicable based on the orientation of the joists or rafters to the braced wall line. Blocking at joists with walls above shall be equal to the depth of the joist at the braced wall line. Blocking at rafters need not be full depth but shall extend to within 2 inches (51 mm) from the roof sheathing above. Blocking shall be shall be a minimum of 2 inches (51 mm) nominal in thickness and shall be fastened to the braced wall line top plate as specified in Table 2304.9.1, Item 11.*

At exterior gable end walls, braced wall panel sheathing in the top story shall be extended and fastened to roof framing where the spacing between parallel exterior braced wall lines is greater than 50 feet (15 240 mm).

Where roof trusses are used and are installed perpendicular to an exterior braced wall line, lateral forces shall be transferred from the roof diaphragm to the braced wall by blocking of the ends of the trusses or by other approved methods providing equivalent lateral force transfer. Blocking shall be a minimum of 2 inches (51 mm) nominal in thickness and equal to the depth of the truss at the wall line and shall be fastened to the braced wall line top plate as specified in Table 2304.9.1, Item 11.

Exceptions:

1. For Seismic Design Categories C and less and wind speed zones less than 100 mph where the framing members are perpendicular to the wall line below and the distance from the top plate to the sheathing above is less than 9 1/4 inches (235 mm) solid, full-height blocking need not be provided when the perpendicular framing members or a parallel member such as a continuous rim joist or header is attached to the wall line per Table 2304.9.1
2. Where the roof sheathing is greater than 9-1/4 inches (235 mm) above the top plate solid full-height blocking is not required when the framing members are connected in accordance with one of the following methods:
   1. In accordance with Figure 2308.3.2 (1)
   2. In accordance with Figure 2308.3.2 (2)
   3. With full height engineered blocking panels designed for values listed in American Forest and Paper Association (AF&PA) Wood Frame Construction Manual for One- and Two-Family Dwellings (WFCM).
   4. Designed in accordance with accepted engineering methods.

Final Action: AS AM AMPC____ D

S213-09/10
2308.9.2.3

Proposed Change as Submitted

Proponent: Edwin Huston, National Council of Structural Engineers Associations- Code Advisory Committee - General Requirements Subcommittee

Revise as follows:

2308.9.2.3 Nonbearing walls and partitions. In nonbearing walls and partitions, studs shall be spaced not more than ~~28~~ 24 inches (~~711~~ 609 mm) o.c. and in interior nonbearing walls and partitions, are permitted to be set with the long dimension parallel to the wall. Interior nonbearing partitions shall be capped with no less than a single top plate installed to provide overlapping at corners and at intersections with other walls and partitions. The plate shall be continuously tied at joints by solid blocking at least 16 inches (406 mm) in length and equal in size to the plate or by 1/2-inch by 11/2-inch (12.7 mm by 38 mm) metal ties with spliced sections fastened with two 16d nails on each side of the joint.

Reason: The ICC Structural Committee liked the idea of Code Change Proposal S228-07/08 but thought it was unclear. NCSEA was not the author of S228-07/08, but is now proposing a change to this section to address what we see as a potential safety concern for wind loading. Section 2308.9.2.3 allows 2x studs to be placed flat wise in a wall and be spaced at up to 28" oc. Table 2308.9.1 limits the height of edge wise studs in such a wall to 14 feet for 2x4 nonbearing walls, for example. Our Code Change Proposal is aimed at limiting this construction to interior walls. Tall flat wise stud construction is not appropriate for exterior walls which are subject to wind loads.

We are also recommending that the 28" spacing in Section 2308.9.2.3 should be changed to 24" oc. Table 2308.9.1 limits the maximum spacing of edge wise studs in all non-bearing walls to 24". Turning the stud and using it flat wise in the wall, should not let the stud spacing increase. We also note that in modern construction almost all wall framing is based on modules which fit within dimensions of 48" or 96". A spacing of 24" oc is a module of 48" and 96" but a spacing of 28" oc is not.

Cost Impact: This code change proposal will not increase the cost of construction.

ICCFILENAME: HUSTON-S1-2308.9.2.3

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The proposal did not adequately justify reducing stud spacing from 28 to 24 inches. There may be some 28 inch applications currently that would be affected. The remainder of the proposal is acceptable but the proponent should consider an adjustment in a public comment.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Edwin Huston, National Council of Structural Engineers Associations (NCSEA), representing NCSEA Code Advisory Subcommittee – General Requirements Subcommittee, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

2308.9.2.3 Nonbearing walls and partitions. In nonbearing walls and partitions, studs shall be spaced not more than ~~24~~ 28 inches (711 ~~609~~ mm) oc. and in interior nonbearing walls and partitions, are permitted to be set with the long dimension parallel to the wall. Interior nonbearing partitions shall be capped with no less than a single top plate installed to provide overlapping at corners and at intersections with other walls and partitions. The plate shall be continuously tied at joints by solid blocking at least 16 inches (406 mm) in length and equal in size to the plate or by 1/2-inch by 11/2-inch (12.7 mm by 38 mm) metal ties with spliced sections fastened with two 16d nails on each side of the joint

Commenter's Reason: The ICC Structural Committee liked the idea of Code Change Proposal S213-09/10 but there was testimony in opposition to the change from 28" oc. to 24" oc. The ICC Structural Committee urged NCSEA to provide a Public Comment. NCSEA is providing this Public Comment to address what we see as a potential safety concern for wind loading. Section 2308.9.2.3 allows 2x studs to be placed flat wise in a wall and be spaced at up to 28" oc. Table 2308.9.1 limits the height of edge wise studs in such a wall to 14 feet for 2x4 nonbearing walls, for example. S213-09/10 is aimed at limiting this construction to interior walls. Tall flat wise stud construction is not appropriate for exterior walls which are subject to wind loads. Using tall, flat wise studs in an exterior wall, could lead to failure under wind loading.

Due to the testimony about the change in the maximum spacing to 28" this change is not being proposed.

Final Action: AS AM AMPC____ D

S214-09/10-PART I
2308.9.4

Proposed Change as Submitted

Proponent: Robert Rice, Grants Pass, representing Josephine County Building Safety and Southern Oregon Chapter International Code Council.

PART I – IBC STRUCTURAL

Revise as follows:

2308.9.4 Cripple walls. Foundation cripple walls shall ~~be framed of studs~~ not be less in size than the required width of the studding above with a minimum length of 14 inches (356 mm), or the wall shall be framed of solid blocking or other approved method to prevent the studs from splitting. Where exceeding 4 feet (1219 mm) in height, such walls shall be framed of studs having the size required for an additional story.

Reason: There are situations where the wall above is of studs larger than what would be required for structural reasons. In some cases it is to accommodate increased insulation or for tall walls. Typically, a 2x4 cripple wall is structurally sufficient even though the wall above may be 2x 6 for insulation reasons or 2x 8 for tall studs. The words "..required width…" would clear this up.

Regarding the 14" studs, this code section has been modified in the past by Oregon amendment and perhaps been misunderstood by others. The purpose for "Cripple walls with a stud height less than 14 inches…", to be sheathed does not relate to lateral bracing as the Oregon amendment implies,

For example, the Oregon amendment reads as follows:

> *Cripple walls with a stud height less than 14 inches (356 mm)* ***supporting exterior walls or an interior braced wall line which is supported by a continuous foundation as required by Section 602.10.9*** *shall be sheathed on at least one side with a wood structural panel that is fastened to both the top and bottom plates in accordance with Table R602.3(1), or the cripple walls shall be constructed of solid blocking.*

The intention of this code requirement is to ensure structural stability of walls with studs that are short enough to be susceptible to splitting. The 14" limit is due to the fact that, historically, up to 14" dimensional lumber was available to be used as solid blocking in lieu of the short studs. In addition, the proposal states, "or other approved method" since mechanical anchors are currently available that would allow the studs to be attached to the top and bottom plate without damaging the studs.

With the provision contained in R602.9, studs shorter than 14" can be used as long as sheathing is placed on one side of the wall to maintain the integrity of the studs and plates. The text continues, "...or the cripple walls shall be constructed of solid blocking." which would allow a number of products, now available, to be used such as glue-laminated beams (GLB), laminated veneer lumber beams (LVL) or dimensional lumber such as 4x's and 6x's.

The IRC commentary states, "The minimum length of 14 inches for cripple wall studs provides sufficient clear space for required nailing of the framing". The IBC commentary states, "The minimum stud length of 14 inches is based on the length necessary to properly fasten the studs to the foundation wall plate and the double plate above."

In addition, "Section R602.9 Cripple Walls" appears in the wall "framing" portion of the code. Wall "bracing" begins to be addressed in section R602.10. In Section R602.10.2 "Cripple wall bracing" is addressed specifically.

In summary, section "R602.9 Cripple Walls" has nothing to do with lateral bracing.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: RICE-S-2308.9.4

Public Hearing Results

PART I- IBC STRUCTURAL
Committee Action: Disapproved

Committee Reason: The proposed revisions to cripple wall are poorly worded and would not make the code any clearer.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Robert Rice, Josephine County Oregon, representing Southern Oregon Chapter of ICC, requests Approval as Modified by this Public Comment.

Replace proposal as follows:

PART I –IBC STRUCTURAL

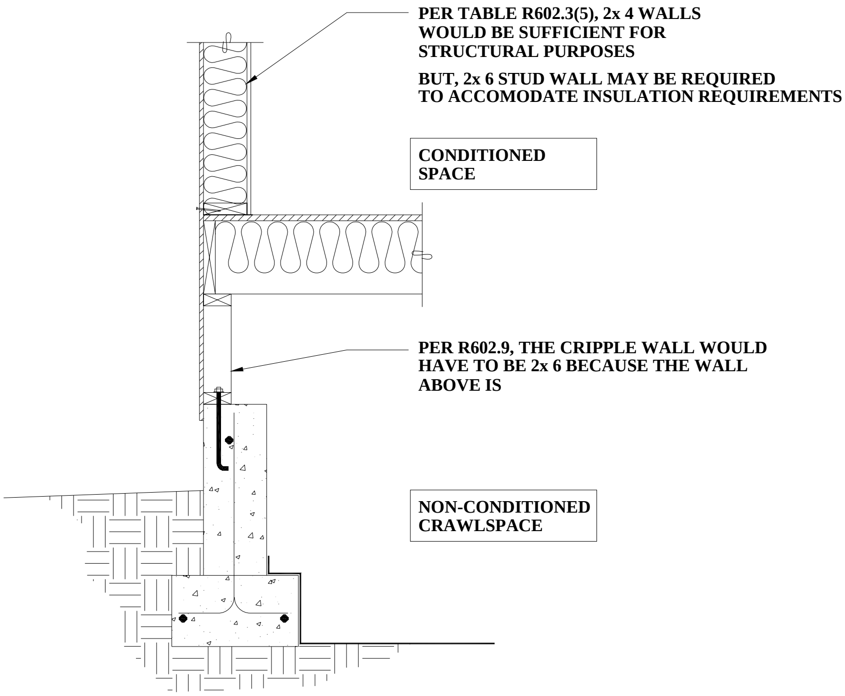
2308.9.4 Cripple walls. Foundation cripple walls shall be framed of studs not less in size than the studding above. ~~with a minimum length of 14 inches (356 mm), or shall be framed of solid blocking.~~

> **Exception:** Cripple wall studs are permitted to be smaller in size than the studding above when the wall above is separated by a floor system that is supported by the cripple wall and the studding in the wall above is larger than required per Table 2308.9.1 provided the cripple wall studs comply with Table 2308.9.1.

Where exceeding 4 feet (1219 mm) in height, such walls shall be framed of studs having the size required for an additional story. Cripple walls shall be framed with studs not less than 14 inches (356 mm) in height or the wall shall be framed of solid blocking.

> **Exception:** Cripple walls with studs less than 14 inches (356 mm) in height shall be permitted when the cripple wall is continuously sheathed on at least one side with wood structural panels fastened to both the top and bottom plates in accordance with Table 2304.9.1,

Commenter's Reason: The original S214 proposal attempted to address two concerns with cripples walls. First, the existing text has the un-intended consequence of being overly restrictive in certain construction methods. In the case of crawlspace construction it is common to have cripple walls where the site is not level. Tables R602.3(5) and R602.3.1 in the IRC and Table 2308.9.1 in the IBC establish the stud size, height and spacing for vertical gravity, wind and seismic loads. However, there are cases where the studs are larger than necessary per the tables. For instance, to accommodate required wall insulation 2x 6 studs may be used where 2 x 4 would work per the tables. In crawlspace construction when a cripple wall is used to support the floor system the current text would require that the cripple wall be framed of 2x6 as well (see the IRC example below).



Also, the original proposal attempted to clarify that the requirement for sheathing when studs are less than 14 inches had nothing to do with wall bracing requirements. Some code officials, contractors and code adoption committees have misunderstood the intent of this section and apply it only when the cripple wall supports braced wall lines above. The intent is that wall studs less than 14 inches can be difficult to nail to plates without splitting and applying sheathing to one side adds stability to the studs in the wall.

This replacement of the original proposal would make the text more easily understood. The committee had concern about wording in the original proposal where it stated *"…or other approved method to prevent studs form splitting"* That language has been removed Also, the committee noted that RB106 that had been approved just prior to this proposal modified some language in this section. So, to ensure that there is no conflict, this amendment incorporates the approved language from RB106 from the Ad Hoc Wall Bracing Committee which stated, *"….Cripple walls with studs less than 14 inches (356 mm) in height shall be permitted when the cripple wall is <u>continuously</u> sheathed on ~~at least~~ one side with ~~a~~ wood structural panel<u>s</u> fastened to….".* No major changes are made to the current code text. In addition, the language has been rearranged to make the IRC and IBC sections more consistent. This proposal would reduce the cost of construction

Final Action: AS AM AMPC____ D

S214-09/10-PART II
IRC R602.9

<u>*Proposed Change as Submitted*</u>

Proponent: Robert Rice, Grants Pass, representing Josephine County Building Safety and Southern Oregon Chapter International Code Council.

PART II – IRC BUILDING/ENERGY

Revise as follows:

R602.9 Cripple Walls. Foundation cripple walls shall be framed of studs not smaller than <u>required size of</u> the studding above. When exceeding 4 feet (1219 mm) in height, such walls shall be framed of studs having the size required for an additional story.

Cripple walls with a stud height less than 14 inches (356 mm) shall be sheathed on at least one side with a wood structural panel that is fastened to both the top and bottom plates in accordance with Table R602.3(1) <u>or other approved method to prevent studs from splitting</u> or the cripple walls shall be constructed of solid blocking. Cripple walls shall be braced as required for lateral loads per section R602.10.2 and R602.10.11.4 and supported on continuous foundations~~.~~

Reason: There are situations where the wall above is of studs larger than what would be required for structural reasons. In some cases it is to accommodate increased insulation or for tall walls. Typically, a 2x4 cripple wall is structurally sufficient even though the wall above may be 2x 6 for insulation reasons or 2x 8 for tall studs. The words "..required width…" would clear this up.

Regarding the 14" studs, this code section has been modified in the past by Oregon amendment and perhaps been misunderstood by others. The purpose for "Cripple walls with a stud height less than 14 inches…", to be sheathed does not relate to lateral bracing as the Oregon amendment implies,

For example, the Oregon amendment reads as follows:

> *Cripple walls with a stud height less than 14 inches (356 mm)* ***supporting exterior walls or an interior braced wall line which is supported by a continuous foundation as required by Section 602.10.9*** *shall be sheathed on at least one side with a wood structural panel that is fastened to both the top and bottom plates in accordance with Table R602.3(1), or the cripple walls shall be constructed of solid blocking.*

The intention of this code requirement is to ensure structural stability of walls with studs that are short enough to be susceptible to splitting. The 14" limit is due to the fact that, historically, up to 14" dimensional lumber was available to be used as solid blocking in lieu of the short studs. In addition, the proposal states, "or other approved method" since mechanical anchors are currently available that would allow the studs to be attached to the top and bottom plate without damaging the studs.

With the provision contained in R602.9, studs shorter than 14" can be used as long as sheathing is placed on one side of the wall to maintain the integrity of the studs and plates. The text continues, "...or the cripple walls shall be constructed of solid blocking." which would allow a number of products, now available, to be used such as glue-laminated beams (GLB), laminated veneer lumber beams (LVL) or dimensional lumber such as 4x's and 6x's.

The IRC commentary states, "The minimum length of 14 inches for cripple wall studs provides sufficient clear space for required nailing of the framing". The IBC commentary states, "The minimum stud length of 14 inches is based on the length necessary to properly fasten the studs to the foundation wall plate and the double plate above."

In addition, "Section R602.9 Cripple Walls" appears in the wall "framing" portion of the code. Wall "bracing" begins to be addressed in section R602.10. In Section R602.10.2 "Cripple wall bracing" is addressed specifically.

In summary, section "R602.9 Cripple Walls" has nothing to do with lateral bracing.

Cost Impact: The code change proposal will not increase the cost of construction.

ICCFILENAME: RICE-S-2308.9.4

Public Hearing Results

PART II- IRC B/E
Committee Action: Disapproved

Committee Reason: This proposal needs additional information to define "method to prevent studs from splitting". The added reference sections may create potential problems with other sections of the code in the previously approved RB105-09/10 and RB106-09/10.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Robert Rice, Josephine County Oregon, representing Southern Oregon Chapter of ICC, requests Approval as Modified by this Public Comment.

Replace proposal as follows:

PART II –IRC BUILDING/ENERGY

R602.9 Cripple walls. Foundation cripple walls shall be framed of studs not smaller than the studding above.

> **Exception:** Cripple wall studs are permitted to be smaller in size than the studding above when the wall above is separated by a floor system that is supported by the cripple wall and the studding in the wall above is larger than required per Tables R602.3(5) and R602.3.1 provided the cripple wall studs comply with Tables R602.3(5) and R602.3.1.

When exceeding 4 feet (1219 mm) in height, such walls shall be framed of studs having the size required for an additional story. ~~Cripple walls with a stud height less than 14 inches (356 mm) shall be sheathed on at least one side with a wood structural panel that is fastened to both the top and bottom plates in accordance with Table R602.3(1) or the cripple walls shall be constructed of solid blocking.~~ Cripple walls shall be framed with studs not less than 14 inches (356 mm) in height or the wall shall be constructed of solid blocking.

> **Exception:** Cripple walls with studs less than 14 inches (356 mm) in height shall be permitted when the cripple wall is continuously sheathed on one side with ~~a~~ wood structural panels fastened to both the top and bottom plates in accordance with Table R602.3(1).

All cripple walls shall be supported on continuous foundations and braced as required for lateral loads in accordance with Section R602.10.9.

Commenter's Reason: See S214-09/10-Part I

Final Action: AS AM AMPC____ D

S223-09/10
2509.2

Proposed Change as Submitted

Proponent: Jose M. Estrada, representing USG Corporation

1. Revise as follows:

2509.2 Base for Tile. Glass mat water-resistant gypsum backing panel, discrete nonasbestos fiber-cement interior substrate sheets, water-resistant fiber-reinforced gypsum backers or nonasbestos fiber-mat reinforced cement substrate sheets in compliance with ASTM C 1178, C 1288, C 1278 or C 1325 and installed in accordance with manufacturer recommendations shall be used as a base for the wall tile in tub and shower areas and wall and ceiling panels in shower areas. Water-resistant gypsum backing board shall be used as a base for tile in water closet compartment walls when installed in accordance with GA -216 or ASTM C 840 and manufacturers recommendations. Regular gypsum wallboard is permitted under tile or wall panels in other wall and ceiling areas when installed in accordance with GA-216 or ASTM C 840.

Reason: The purpose of this proposal is to include an ASTM material standard for current provisions of the IBC. ASTM C 1278 products are engineered and manufactured specifically for interior water-resistant backing. The proposed ASTM material standard has been recognized by the International Residential Code (IRC) since the 2007 Supplement. The water-resistant products complying with this ASTM standard have a demonstrated track record, which has been documented substantially and historically, in consensus industry publications such as the TCA Handbook for Ceramic Tile Installation, published by the Tile Council of North America, where the ASTM C1278 products have been recognized for use in wet areas, including their use as a base for the wall tile in tub and shower surrounds since 2007. The wall and floor designs for the ASTM C1278 products listed in the TCA Handbook for wet area application are equivalent to those of ASTM C 1178, C 1288 and C 1325 products. The products covered under ASTM C 1278 for use as a base for tile have a proven track record in the field, where hundreds of millions of feet have been installed since its release to the market. The inclusion of this standard will allow for more competitive product bidding in turn reducing overall construction costs.

Bibliography:
The Tile Council of North America. 2009 TCA Handbook for Ceramic Tile Installation. Anderson, SC: TCNA, 2009.

Cost Impact: This code proposal will not increase the cost of construction.

ICCFILENAME: ESTRADA-S1-2509.2

Public Hearing Results

Committee Action: **Disapproved**

Committee Reason: The documentation provided in the proponent's reason indicated these gypsum backers are not appropriate in the IBC for shower areas.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Richard P. Goldberg, AIA, CSI, NCARB, Professional Consultants International, LLC, representing United States Gypsum Company, requests Approval as Submitted.

Commenter's Reason: This public comment is written in objection to the disapproval of Code Change Proposal # S223-09/10 at the 09/10 Public Hearing, and in support of Final Action Hearing approval of same Code Change Proposal # S223-09/10 as submitted for the ICC Public Hearing consideration. The # S223-09/10 proposal requested the modification of §2509.2 and Chapter 35 Referenced Standards to include a water-resistant fiber-reinforced gypsum backer board complying with ASTM C1278 as an additional alternative to similar products previously approved for use by that section of the IBC Code in the 2004-05 code cycle.

As an architect and tile industry consultant, it is my opinion that the committee's disapproval action summarily dismissed consideration of the technical merits of the proposal, and was simply based on a misinterpretation of the proprietary product literature documentation provided in the proposal. The reason given for disapproval was that the proponent's documentation indicated that fiber-reinforced gypsum backers were not appropriate for shower areas under the IBC.

Product literature documentation did in fact indicate that the product was not intended for use as a tile backer panel in commercial gang shower areas. However, this situation is a "red herring", as the literature was simply consistent with IBC requirements current at the time of the proposal, and was not intended as an actual physical limitation of an ASTM C1278 compliant product for the purposes of the code change proposal. In other words, the proposal failed to recognize and explain the formality that the literature would be revised if the ASTM C1278 compliant product was approved for use as a tile backer under the IBC.

Our firm, PROCON, has conducted extensive independent laboratory testing comparing ASTM C 1178, ASTM C 1288, and ASTM C1325 compliant tile backers (currently approved for use in IBC §2509.2) with ASTM 1278 compliant water-resistant fiber-reinforced gypsum tile backers. This testing has determined that all four tile backer material standards provide equivalent performance under commercial wet-area conditions. These test results were an important factor in approval of water-resistant fiber-reinforced gypsum as a tile backer in wet areas, as recognized by both the IRC International Residential Code 2007 Supplement, as well as tile industry consensus publication Tile Council of North America (TCNA) 2007 Handbook for Ceramic Tile Installation.

Most important, the water resistance properties of the proposed ASTM C 1278 compliant product and the approved ASTM C1178 products (both gypsum-based) are comparable, including < 5% water absorption after 2 hours water immersion, no water percolation or wicking after 48 hrs., and mold resistance in accordance with ASTM D3273 (see attached supporting document # 1 & 2).

It is important to note that the TCNA tile industry consensus standard has recognized ASTM C 1278 compliant water-resistant fiber-reinforced gypsum as a backer for tile in wet areas, without discrimination as to residential or commercial construction applications (see attached supporting document # 3 & 4). The reason is that comparison of respective product category physical properties, as well as laboratory testing, has proven that ASTM C1278 compliant products meet or exceed the physical properties of ASTM C 1178, ASTM C 1288, and ASTM C1325 compliant tile backers currently approved for use in IBC § 2509.2.

I also call attention to the February 2005 ICC Public Hearing proposal and subsequent approval of proposal # S218-04/05 requiring the use of cement, fiber-cement, and glass mat gypsum backers in compliance with ASTM C1288, C 1325 & C 1178 respectively, to replace previously allowed water-resistant gypsum board ("green board") as a substrate for tile in tubs, showers and water closet compartments. Among other considerations, the premise of that approved code modification was "intended to bring the IBC in line with IRC in this respect", based on IRC approval in the 2003-04 code change cycle.

The modification sought by proposal # S223-09/10 is similar in spirit and in fact. Both IRC and TCNA tile industry consensus standards recognize ASTM C1288, C 1325, C 1178 *and* C 1278 compliant water-resistant fiber-reinforced gypsum as suitable tile backers in wet areas, yet there is no basis in fact for exclusion from the IBC, other than the misinterpretation of the proponent's documentation. The literature is simply a commercial reflection of current IBC requirements, but not reflective of the proponent's technical position.

The fact is that physical properties, testing and a proven history of ASTM C1278 compliant water-resistant fiber-reinforced gypsum as a tile backer in wet areas since release to the market in 2003 indicate that the material is suitable for use as a tile backer in commercial / institutional showers and tub surrounds. Most important (and the sole reason for Public Hearing disapproval), the proponent will revise literature by not limiting such use once that use is recognized by the IBC.

Therefore, I offer this public comment and reasoning in support of Final Action Hearing approval of the code change proposal # S223-09/10, as originally submitted, to modify IBC § 2509.2 and Chapter 35 Referenced Standards to include ASTM 1278 compliant water-resistant fiber-reinforced gypsum tile backer. This action will offer less restrictive, equivalent tile backer material standards, not change the cost of construction, with potential to reduce construction costs through increased competition.

TCA TEST REPORT NUMBER: TCA-308-05 **PAGE: 1 OF 1**

TEST REQUESTED BY:

USG Corporation
Research and Technology Center
Attn: John Ellicson
700 N. Highway 45
Libertyville, IL 60048

TEST SUBJECT MATERIAL: Identified by client as: ½-inch Denshield and Fiberock

TEST DATE: 1/13/06-1/14/06

TEST PROCEDURE:

One two inch diameter tube, twelve inches long, with a square base was bonded to each sample with a silicone sealant. The silicone was allowed to cure for 48 hours before introducing the water. The tubes were filled with water to a height of twelve inches and then covered to minimize evaporation. The samples were placed on a stable surface in the laboratory and held at 74 degrees Fahrenheit and 45-55% R.H. After 48 hours the amount of water percolation (drop in water level) was recorded. The results are detailed below.

TEST RESULTS:

Both samples (one Denshield and one Fiberock) exhibited a **¼-inch** drop in the water level after 48 hours of the above detailed percolation test. The amount of loss that is due to evaporation is not known.

WALLS, INTERIOR

Wood or Metal Studs

Continued from previous page.

07 **Materials:**
- coated glass mat, water-resistant gypsum backer board—ASTM C1178.
- 2" alkali-resistant glass fiber mesh tape.
- fasteners—noncorrosive and nonoxidizing.
- dry-set mortar—ANSI A118.1.
- latex-portland cement mortar—ANSI A118.4.
- organic adhesive—ANSI A136.1. Type I for residential wet areas and Type I or Type II for dry areas.
- grout—ANSI A118.3, A118.6, or A118.7

07 **Preparation by Other Trades:**
- maximum variation in the wood or metal studs—not to exceed 1/4" in 10'-0" and 1/16" in 1'-0" from the required plane.

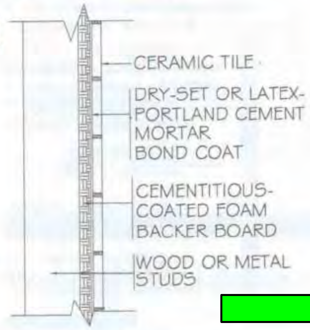
07 **Preparation by Backer Board Installers:**
- 2" alkali-resistant glass fiber mesh tape—embed in a skim coat of dry-set or latex-portland cement mortar over joints and corners.
- caulk or seal penetrations and abutments to dissimilar materials.

Movement Joint (architect must specify type of joint and show location and details on drawings):
- movement joints—mandatory according to Method EJ171, page 79.

Installation Specifications:
- follow manufacturer's instructions.
- tile—ANSI A108.4 or A108.5.
- grout—ANSI A108.6 or A108.10.

07 Cementitious-Coated Foam Backer Board W246-07

07



Recommended Uses:
- in wet or dry areas.
- over dry, well-braced wood studs or furring.
- over well-braced metal studs.
- where waterproof properties are required.

07 **Requirements:**
- set tile in dry-set or latex-portland cement mortar.
- stud spacing—maximum 16" o.c.
- minimum recommended stud depth—3-1/2".
- metal studs—20 gauge (0.039") or heavier.
- Fasten units to studs per manufacturer's recommendations.

Materials:
- cementitious-coated extruded foam backer board.
- waterproofing for seams and fastener heads—ANSI A118.10.
- fasteners—noncorrosive and nonoxidizing.
- dry-set mortar—ANSI A118.1.
- latex-portland cement mortar—ANSI A118.4.
- grout—ANSI A118.3, A118.6, or A118.7.
- metal studs—ASTM C645.

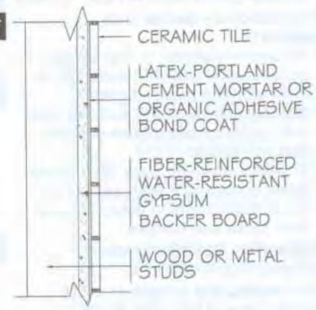
07 **Preparation by Backer Board Installers:**
- maximum variation in the backing surface—1/4" in 10'-0" and 1/16" in 1'-0" from the required plane.
- horizontal and vertical joints and corners—butt tightly together, a exible caul fing) in joints and

Movement Joint (architect must specify type of joint and show location and details on drawings):
- movement joints—mandatory according to Method EJ171, page 79.

Installation Specifications:
- cementitious-coated extruded foam backer board—install according to manufacturer's instructions.
- tile—ANSI A108.5.
- grout—ANSI A108.6 or A108.10.

Fiber-Reinforced Water-Resistant Gypsum Backer Board W247-07

07



07 **Recommended Uses:**
- in wet or dry areas.
- over dry, well-braced wood studs or furring.
- over well-braced metal studs.

07 **Requirements:**
- set tile in latex-portland cement mortar or organic adhesive.
- stud spacing—maximum 16" o.c. or 24" o.c. with blocking at all joints, ends, and edges.
- minimum recommended stud depth—3-1/2".
- metal studs—20 gauge (0.039") or heavier for tile applications.

07 **Materials:**
- fiber-reinforced water-resistant gypsum backer board 1/2" or thicker—ASTM C1278 (Paragraph 6.1).
- 2" alkali-resistant glass fiber mesh tape.
- fasteners—noncorrosive and non-oxidizing.
- latex-portland cement mortar—ANSI A118.4.

Continued on next page.

All specifications for ceramic tile installations must conform to local building codes, ordinances, trade practices, and climatic conditions.

Not all methods are suitable for glass tile installations. Consult glass tile manufacturer for specific recommendations.

Web Site: www.tileusa.com

shadows are created from side lighting interior walls and floors when light shines at that angle through windows and doors.

Exterior:

When natural or artificial light shines on exterior walls and floors at a flat angle almost parallel to tile surfaces, normal and acceptable inconsistencies in the tilework are highlighted by shadows that exaggerate these conditions.

07 Wet Area Definition:

Tile surfaces that are either soaked, saturated, or regularly and frequently subjected to moisture or liquids (usually water), such as gang showers, tub enclosures, showers, laundries, saunas, steam rooms, swimming pools, hot tubs, commercial kitchens, and exterior areas.

Limited Water Exposure Area:

Tile surfaces that are subjected to moisture or liquids but do not become soaked or saturated due to the system design or the time exposure.

Examples include: residential bathroom floors and foyers, residential bathroom vertical surfaces including tub surrounds without a shower head, and kitchen countertops.

Mortar Bed Weight:

Typically, a 1" thick mortar bed will weigh 12 lbs. per square foot. A thin-bed typically weighs 0.5 lbs. to 1.5 lbs. per square foot.

Bonding Large-Format Tile for Coverage and Support:

The following installation techniques are required to ensure proper coverage of the bonding surface of larger tiles and provide full support of edges and corners. Large tiles are generally considered to be 8" x 8" and greater. Select a notched trowel sized to facilitate the proper coverage. Key the mortar into the substrate with the flat side of the trowel. Comb with the notched side of the trowel in ONE DIRECTION. Firmly press tiles into the mortar and move them perpendicularly ACROSS the ridges, forward and back approximately 1/8" to 1/4", to flatten the ridges and fill the valleys. This method can produce maximum coverage, with the corners and edges fully supported, without backbuttering or beat-in. Periodically remove and check a tile to assure proper coverage is being attained.

07 Coefficient of Friction:

When coefficient of friction (COF) data are required for a specific project, testing shall conform to ASTM C1028. However, because **area of use and maintenance by the owner of installed tile directly affect coefficient of friction**, the COF of the manufactured product shall be as agreed upon by manufacturer and purchaser.

Water (especially standing water), oil, grease, etc., create slippery conditions. Floor applications with exposure to these elements require extra maintenance and caution in product selection.

Lippage:

Lippage is a condition where one edge of a tile is higher than an adjacent tile, giving the finished surface an uneven appearance. This condition is inherent in all installation methods and may also be unavoidable due to the tile tolerances, in accordance with ANSI A137.1.

Protecting New Tile Work:

To avoid damage to finished tilework, schedule floor installations to begin only after all structural work, building enclosure, and overhead finishing work, such as ceilings, painting, mechanical, and electrical work, are completed. Keep all traffic off finished tile floors until they have fully cured. Builder shall provide up to 3/4"-thick plywood or OSB protection over non-staining kraft paper to protect floors after installation materials have cured. Covering the floor with polyethylene or plywood in direct contact with the floor may adversely affect the curing process of grout and latex/polymer modified portland cement mortar.

07 Maintenance:

All tile installations (especially exterior installations, which include the movement joint sealant) require periodic inspection and maintenance by the owner. Consult material manufacturers and maintenance product manufacturers for recommended procedures.

CAUTION – Wood-based panels such as particle board, composite panels (veneer faces bonded to reconstituted wood cores), non-veneer panels (wafer board, oriented strand board, and other similar boards), lauan plywood, and softwood plywood expand and contract with changes in moisture content and are not recommended as backing materials for direct bonding of ceramic tile. Plywood, however, manufactured with fully waterproof adhesive and with an exposure durability rating of Exposure 1 or Exterior may be used on residential horizontal surfaces when installed in accordance to ANSI Specifications for the Installation of Ceramic Tile (A108.01-3.4).

Submittal Sheet

Fiberock® Aqua-Tough™ Tile Backerboard

Finishing flexibility, strength, and superior water resistance in a single panel

– Superior tile bond for ceramic tile
– Uniform composition provides both strength and water resistance
– Suitable for ceramic tile wall and tub surround applications in intermittently wet and dry areas

Description

FIBEROCK® brand AQUA-TOUGH™ tile backerboard is a unique fiber-reinforced gypsum product that represents a new era in substrate performance for wet or dry areas. This durable panel offers superior performance and tile bond because of its integral water-resistant core.

Unlike traditional water-resistant gypsum board, FIBEROCK tile backerboard derives both strength and water-resistance from its uniform composition. Made of a uniquely engineered gypsum/cellulose-fiber combination, FIBEROCK tile backerboard is strong and water resistant all the way through. With no paper to delaminate, FIBEROCK tile backerboard maintains its integrity even when wet.

Advantages

Abuse Resistant Engineered to provide increased resistance to abrasion, indentation and penetration. Outperforms paper-faced or glass mat faced panels. FIBEROCK tile backerboard has no paper face to tear or scratch.
Water Resistant FIBEROCK tile backerboard is water resistant through the core and intended for use in ~~intermittently~~ wet areas including tub surrounds.
Mold Resistant In independent lab tests per ASTM D3273-00 "Standard Test Method for Resistance to Growth of Mold on the Surface of Interior Coatings in an Environmental Chamber," the score for FIBEROCK tile backerboard was 10 (highest score).
Fire Resistant These panels offer superior fire resistance and demonstrate exceptional surface burning characteristics.
Finishing Flexibility FIBEROCK tile backerboard can be finished with ceramic tile or painted.
Environmentally Friendly Made from 95% recycled materials. Awarded Green Cross Certification from Scientific Certification Systems.

Limitations

1. Maximum stud spacing:

Wall Panel	Frame Spacing	Nails	Screws
1/2″	16″ o.c.	8″ o.c.	12″ o.c

2. For marble and stone applications, consult current TCA guidelines for recommendations.
3. Do not use in areas subject to prolonged exposure to standing water— for instance, in gang showers, saunas, or hot-tub decks.
4. FIBEROCK Tile Backerboard must be tiled or painted, not used as a finish surface.
5. Panels should not be exposed to sustained temperatures above 125 °F (51.6 °C).
6. For fire-resistant or abuse-resistant construction over steel framing, a minimum of 20 gauge steel framing is required.
7. Do not use in areas subject to standing water, such as ~~gang showers, saunas~~ or hot-tub decks.

Product Data

Dimensions: 1/2″ FIBEROCK tile backerboard, 3′ x 5′, 4′ x 4′, 4′ x 5′ and 4′ x 8′, with square-edge configuration
Compliance with standards: Meets ASTM standard C1278

Installation Practices

Environmental Conditions

In cold weather and during FIBEROCK tile backboard installation, joint finishing, and tile application, temperatures within the building shall be maintained within the range of 55-70 ºF. Adequate ventilation shall be provided to carry off excess moisture. Wood framing shall approximate the moisture content it will reach in service prior to the application of the panels. FIBEROCK tile backerboard should be stored in an enclosed shelter providing protection from damage and exposure to the elements. Allow FIBEROCK backerboard to acclimate to the temperature and humidity conditions at the jobsite prior to installation.

Framing

Steel or wood wall framing to receive FIBEROCK tile backerboard shall be structurally sound and in general compliance with local building code requirements. Damaged and excessively bowed studs shall be replaced before installation of FIBEROCK tile backerboard.

Space wood and steel framing a maximum of 24″ o.c. Framing shall be designed to meet L/360 deflection for tile and L/240 for flexible finishes such as paint. For floor applications, framing shall be designed to meet L/360 deflection.

S226-09/10, Part II
IRC: R902.1

NOTE: PART I DID NOT RECEIVE A PUBLIC COMMENT AND IS ON THE CONSENT AGENDA. PART I IS REPRODUCED ONLY FOR INFORMATIONAL PURPOSES ONLY FOLLOWING ALL OF PART II.

Proposed Change as Submitted

Proponent: Craig Thompson, representing Copper Development Assn.

PART II – IRC BUILDING/ENERGY

R902.1 Roofing covering materials. Roofs shall be covered with materials as set forth in Sections R904 and R905. Class A, B or C roofing shall be installed in areas designated by law as requiring their use or when the edge of the roof is less than 3 feet (914 mm) from a property line. Classes A, B and C roofing required by this section to be listed shall be tested in accordance with UL 790 or ASTM E 108.

Exceptions:

1. Class A roof assemblies include those with coverings of brick, masonry and exposed concrete roof deck.
2. Class A roof assemblies also include ferrous or copper shingles or sheets, metal sheets and shingles, clay or concrete roof tile, or slate installed on non-combustible decks.
3. <u>Class A roof assemblies include copper sheets installed over combustible decks.</u>

Reason: : The reason the exceptions clause was modified in the last code cycle was primarily due to a test report submitted by the National Association of State Fire Marshalls from Underwriters Laboratories Inc., (UL), dated January 17, 2007. The report references the findings of a fact finding report done by UL to show that the exceptions to the Class A rating are not valid because, as the fact finding report shows, 30 gauge sheet steel, 24 gauge sheet steel, 0.040 aluminum sheet & 14" X 10" wide , 6" exposure slate installed over A-C plywood do not pass fire test requirements under Standards E108 & UL970 for roof coverings used over combustible roof deck. However this same report states that 16 oz. copper sheet does conform to fire test requirements under Standards E108 & UL 970. The report affirms that the copper roof assembly does pass. Therefore there is no viable reason why copper shingles or sheets should not retain their exception as a Class A roof material. In addition, for the UL test to be valid each assembly must pass four consecutive burning brand tests, two consecutive flame spread tests and two consecutive intermittent flame tests as spelled out in ASTM E108 & UL970. Each assembly was tested only once in the Fire Marshall's report, not as per the standard, thus nullifying the report's conclusions.

In addition, as per the attached report from the Southwest Research Institute, (SwRI), a typical standing seam copper roof assembly, over a combustible deck, was tested and passed as per ASTM E108 for Class A roof assemblies. ASTM E108 is the recognized standard by which all Class A roof assemblies are measured. Therefore the typical copper standing seam roof assembly, on a combustible deck, should rightfully be listed as a Class A roof assembly exception as per the SwRI report dated 1/7/09.

2. Underwriters Laboratories; *Fact –Finding Investigation of Metal and Slate Prepared Roof Coverings;* National Association of State Fire Marshals, Washington, DC; Northbrook, IL, January 17, 2007

Cost Impact: None given.

ICCFILENAME: THOMPSON, C-S1-1505.2

Public Hearing Results

PART II- IRC B/E
Committee Action: **Approved as Submitted**

Committee Reason: Copper sheets installed on a combustible deck are Class A and was inadvertently omitted last code change cycle as stated in the proponent's published reason. This change brings this roof covering back into the code as Class A and exempt from testing.

Assembly Action: **None**

Individual Consideration Agenda

This item is on the agenda for individual consideration because public comments were submitted.

Public Comment 1:

Bob Eugene, Underwriters Laboratories Inc, requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R902.1 Roofing covering materials. Roofs shall be covered with materials as set forth in Sections R904 and R905. Class A, B or C roofing shall be installed in areas designated by law as requiring their use or when the edge of the roof is less than 3 feet (914 mm) from a property line. Classes A, B and C roofing required by this section to be listed shall be tested in accordance with UL 790 or ASTM E 108.

Exceptions:

1. Class A roof assemblies include those with coverings of brick, masonry and exposed concrete roof deck.
2. Class A roof assemblies also include ferrous or copper shingles or sheets, metal sheets and shingles, clay or concrete roof tile, or slate installed on non-combustible decks.
3. Class A roof assemblies include minimum 16 oz/ft^2 copper sheets installed over combustible decks.

Commenter's Reason: Added text is consistent with the action of the IBC Fire Safety Committee.

Public Comment 2:

John Woestman, Kellen Company, and Craig Thompson, representing Copper Development Assn., requests Approval as Modified by this Public Comment.

Modify the proposal as follows:

R902.1 Roofing covering materials. Roofs shall be covered with materials as set forth in Sections R904 and R905. Class A, B or C roofing shall be installed in areas designated by law as requiring their use or when the edge of the roof is less than 3 feet (914 mm) from a property line. Classes A, B and C roofing required by this section to be listed shall be tested in accordance with UL 790 or ASTM E 108.

Exceptions:

1. Class A roof assemblies include those with coverings of brick, masonry and exposed concrete roof deck.
2. Class A roof assemblies also include ferrous or copper shingles or sheets, metal sheets and shingles, clay or concrete roof tile, or slate installed on non-combustible decks.
3. Class A roof assemblies include minimum 16 oz/ft^2 copper sheets installed over combustible decks.

Commenter's Reason: This proposed modification sets minimum copper sheet specifications consistent with the testing performed, as referenced in the original proposal, and is consistent with the language recommended for approval for the IBC in S226 Part I

Final Action: AS AM AMPC____ D

NOTE: PART I REPRODUCED FOR INFORMATIONAL PURPOSES ONLY –SEE ABOVE

S226-09/10-PART I – IBC FIRE SAFETY

Revise as follows:

1505.2 Class A roof assemblies. Class A roof assemblies are those that are effective against severe fire test exposure. Class A roof assemblies and roof coverings shall be listed and identified as Class A by any approved testing agency. Class A roof assemblies shall be permitted for use in buildings or structures of all types of construction.

Exceptions:

1. Class A roof assemblies include those with coverings of brick, masonry and exposed concrete roof deck.
2. Class A roof assemblies also include ferrous or copper shingles or sheets, metal sheets and shingles, clay or concrete roof tile, or slate installed on non-combustible decks or ferrous, copper or metal sheets installed without a roof deck on noncombustible framing.
3. Class A roof assemblies include copper sheets installed over combustible decks.

Reason: : The reason the exceptions clause was modified in the last code cycle was primarily due to a test report submitted by the National Association of State Fire Marshalls from Underwriters Laboratories Inc., (UL), dated January 17, 2007. The report references the findings of a fact finding report done by UL to show that the exceptions to the Class A rating are not valid because, as the fact finding report shows, 30 gauge sheet steel, 24 gauge sheet steel, 0.040 aluminum sheet & 14" X 10" wide , 6" exposure slate installed over A-C plywood do not pass fire test requirements under Standards E108 & UL970 for roof coverings used over combustible roof deck. However this same report states that

16 oz. copper sheet does conform to fire test requirements under Standards E108 & UL 970. The report affirms that the copper roof assembly does pass. Therefore there is no viable reason why copper shingles or sheets should not retain their exception as a Class A roof material. In addition, for the UL test to be valid each assembly must pass four consecutive burning brand tests, two consecutive flame spread tests and two consecutive intermittent flame tests as spelled out in ASTM E108 & UL970. Each assembly was tested only once in the Fire Marshall's report, not as per the standard, thus nullifying the report's conclusions.

In addition, as per the attached report from the Southwest Research Institute, (SwRI), a typical standing seam copper roof assembly, over a combustible deck, was tested and passed as per ASTM E108 for Class A roof assemblies. ASTM E108 is the recognized standard by which all Class A roof assemblies are measured. Therefore the typical copper standing seam roof assembly, on a combustible deck, should rightfully be listed as a Class A roof assembly exception as per the SwRI report dated 1/7/09.

Bibliography:

1. Southwest Research Institute; *Evaluation of the External Fire Resistance Characteristics of Roof Covering Systems in Accordance with ASTM E 108-07a, Standard Test Methods for Fire Tests of Roof Coverings: Class A Testing;* San Antonio, TX, January 7, 2009
2. Underwriters Laboratories; *Fact –Finding Investigation of Metal and Slate Prepared Roof Coverings;* National Association of State Fire Marshals, Washington, DC; Northbrook, IL, January 17, 2007

Cost Impact: None given

PART I- IBC FIRE SAFETY
Committee Action: **Approved as Modified**

Modify the proposal as follows:

1505.2 Class A roof assemblies. Class A roof assemblies are those that are effective against severe fire test exposure. Class A roof assemblies and roof coverings shall be listed and identified as Class A by any approved testing agency. Class A roof assemblies shall be permitted for use in buildings or structures of all types of construction.

Exceptions:

1. Class A roof assemblies include those with coverings of brick, masonry and exposed concrete roof deck.
2. Class A roof assemblies also include ferrous or copper shingles or sheets, metal sheets and shingles, clay or concrete roof tile, or slate installed on non-combustible decks or ferrous, copper or metal sheets installed without a roof deck on noncombustible framing.
3. Class A roof assemblies include minimum 16 oz/ft^2 copper sheets installed over combustible decks.

Committee Reason: The committee agreed that copper sheets over combustible decking was appropriate for a prescribed class A roof assembly based on the testing submitted with the proposal. The modification includes the necessary minimum copper sheet specifications that are tied to the testing performed.

Assembly Action: **None**

S229-09/10

2211.1 (New), 2211.2 (New), Chapter 35

Proposed Change as Submitted

Proponent: Victor D. Azzi, PhD, PE, Consulting Structural Engineer, representing the Storage Equipment Manufacturers Association (SMA), a division of the Material Handling Industry of America (MHIA).

1. Add new text as follows:

SECTION 2211
INDUSTRIAL STEEL WORK PLATFORMS

2211.1 General. The design, testing, utilization, application, and maintenance of industrial steel work platforms shall be in accordance with the provisions of ANSI/SMA MH28.3. An industrial steel work platform is herein defined as a pre-engineered, prefabricated, elevated platform, employing a steel framing system, located in an industrial environment. Other structural or nonstructural elements shall be permitted for flooring including but not limited to, concrete, steel, and engineered wood products. Personnel working on such platforms are trained employees, accustomed to a manufacturing environment and dressed accordingly.

2211.2 Materials. Steel shall be in accordance with the ASTM specifications listed in AISI S100 and AISC 360. Steels not listed in the above specifications are not excluded, provided that they conform to the chemical and mechanical properties of one or more of the listed specifications, or of other specifications which establish their properties and structural suitability, and provided that they are subjected by either the producer or the purchaser to analyses, tests, and other controls to the extent and in the manner prescribed by one of the listed specifications, as applicable.

Materials used in the decking structure and surfaces for these work platforms shall be concrete, engineered wood products, plywood or other wood products, steel sheet, steel plate or grating, supported by the steel framing system. Such decking materials shall conform to the applicable provisions of this code and referenced standards appropriate to their use in this application and work environment.

2. Add standard to Chapter 35 as follows:

SMA
MH28.3-08 Specification for the Design, Manufacture and Installation of Industrial Steel Work-Platforms.

Reason: The Engineering committees of the Storage Equipment Manufacturers Association (SMA), have worked to develop standard engineering practices for the design, testing, and utilization of Industrial Steel Work Platforms. The use of this standard permits loading capacities and performance ratings, as well as functional requirements, to be determined and verified by designers and users of these products. The SMA, a Product Section of the Material Handling Industry of America (MHIA), comprises the substantial portion of the companies that design and manufacture the preponderance of industrial steel work platforms as defined by the scope of this standard. The SMA has recognized the need to establish rigorous industry standards, and have supported the development and promulgation of the ANSI/SMA standard for the benefit of the work-platform industry as well as the users of its products. This SMA/ANSI Standard has been developed using the canvassing processes of the MHIA and the ANSI. The ANSI canvass process for this new ANSI MH28.3 Standard was recently completed and the SMA Engineering Committee has resolved several items involving small editorial changes and corrections.

Cost Impact: This addition to the IBC will not increase the cost of construction.

ICCFILENAME: AZZI-S1-2211 (New)

Public Hearing Results

This code change was contained in the errata posted on the ICC website. Please go to http://www.iccsafe.org/cs/codes/Pages/09-10ProposedChanges.aspx.

Note: The following analysis was not in the Code Change monograph but was published on the ICC website at http://www.iccsafe.org/cs/codes/Documents/2009-10cycle/ProposedChanges/Standards-Analysis.pdf :

Analysis: Review of proposed new standard SMA MH28.3 indicated that, in the opinion of ICC Staff, the standard did not comply with ICC standards criteria, Section 3.6.3(1) Readily available.

Committee Action: Disapproved

Committee Reason: The code change includes a definition of the term "industrial steel work platform" which is unclear and is more of a description. It also is included within a provision rather than being listed separately in a definitions section. The proposed reference standard does not appear to allow anything that's not already in the code.

Assembly Action: None

Individual Consideration Agenda

This item is on the agenda for individual consideration because a public comment was submitted.

Public Comment:

Victor D. Azzi, representing Storage Equipment Manufacturers Association (SMA), requests Approval as Modified by this Public Comment.

Modify proposal as follows:

SECTION 2211
INDUSTRIAL STEEL WORK PLATFORMS

2211.1 General. The design, testing, utilization, application, and maintenance of industrial steel work platforms shall be in accordance with the provisions of ANSI/SMA MH28.3. An industrial steel work platform shall be~~is herein~~ defined as a pre-engineered, prefabricated, elevated platform, employing a steel framing system, located in an industrial environment. ~~Other structural or nonstructural elements shall be permitted for flooring including but not limited to, concrete, steel, and engineered wood products. Personnel working on such platforms are trained employees, accustomed to a manufacturing environment and dressed accordingly.~~

~~**2211.2 Materials.** Steel shall be in accordance with the ASTM specifications listed in AISI S100 and AISC 360. Steels not listed in the above specifications are not excluded, provided that they conform to the chemical and mechanical properties of one or more of the listed specifications, or of other specifications which establish their properties and structural suitability, and provided that they are subjected by either the producer or the purchaser to analyses, tests, and other controls to the extent and in the manner prescribed by one of the listed specifications, as applicable.~~

~~Materials used in the decking structure and surfaces for these work platforms shall be concrete, engineered wood products, plywood or other wood products, steel sheet, steel plate or grating, supported by the steel framing system. Such decking materials shall conform to the applicable provisions of this code and referenced standards appropriate to their use in this application and work environment.~~

SMA
ANSI MH28.3-09~~8~~ *Specification for the Design, Manufacture and Installation of Industrial Steel Work-Platforms*

Commenter's Reason: This comment simply eliminates unnecessary language, which was in the original proposal. Please note that the standard is now readily available and, as such, is compliant with ICC rules. Also, the date is corrected from 2008 to 2009; the new edition of this Standard was approved by ANSI on October 27, 2009.

Final Action: AS AM AMPC____ D
